Intracellular acidosis is an important modulator of cardiac excitation and contraction, and a potent trigger of electrical arrhythmia, partly through its ability to stimulate acid extruders, which indirectly raises sarcoplasmic reticulum (SR) Ca^{2+}. When this effect is large (a condition known as Ca^{2+}-overload), cardiac myocytes engage in a mode of Ca^{2+} signaling in which Ca^{2+} release from the SR to myoplasm occurs in self-propagating succession along the length of the cell. This event is called a Ca^{2+} wave and is fundamentally a diffusion-reaction phenomenon that is best described with a mathematical model. Wave properties, e.g. frequency, velocity, amplitude and relaxation time are useful parameters to infer how acidic pH affects Ca^{2+}-related components inside the cell, such as the sarco/endoplasmic reticulum Ca^{2+} ATPase (SERCA), myoplasmic Ca^{2+} buffers and the ryanodine receptor (RyR).

We present a new, continuum mathematical model, based on previous work (1), that simulates spontaneous Ca^{2+} waves generated during intracellular acidosis and Ca^{2+}-overload. The model, developed with a user-friendly interface in Matlab, is capable of reproducing Ca^{2+} sparks and wave failure, collision and annihilation. In particular, Ca^{2+} sparks are modeled by a random function that regulates the opening and closing probability of RyRs, which in turn controls the likelihood of wave generation.

Numerical simulations predict that, during Ca^{2+}-overloading conditions, spontaneous Ca^{2+} wave generation significantly helps the cell to control and maintain at a constant level the myoplasmic and luminal Ca^{2+} concentration, as suggested in (2). Increasing Ca^{2+} wave frequency and speed enhances this mechanism, thus giving a simple explanation of what observed experimentally in rat isolated ventricular myocytes, where reducing pH_i increased to 360% (by 60 s) wave frequency, together with increasing wave velocity up to 140%. Inhibiting the sarcolemmal Na^+/H^+ exchanger (NHE) suppressed wave frequency but not the increased velocity. In the model, this behaviour can be reproduced by decreasing K_{ON} of the lumped Ca^{2+} buffers, which is experimentally expected being independent of NHE activity. Wave frequency reduction during NHE inhibition can be explained by a fall in SR Ca^{2+} content mediated by H^+-reduced SERCA activity no longer supported by NHE-driven Ca^{2+} import on NCX. The model shows that reducing SERCA maximum flux instead of its affinity best accounts for the observed experimental change in wave amplitude and relaxation time.

Our model successfully reproduces Ca^{2+} waves using experimentally-derived variables and highlights the importance of SR Ca^{2+} load on wave propagation. At present, we are developing a model to describe a cardiac multicellular system connected by gap junctions, providing Ca^{2+} and H^+ intercellular diffusion.

Heart rate variability responses to different intensities of musical auditory stimulation in healthy men

J.A. do Amaral[1], H.L. Guida[2], L. de Abreu[3] and V.E. Valenti[2]

[1]Departamento de Fonoaudiologia, Faculdade de Filosofia e Ciências, UNESP, Marília, Brazil, [2]Departamento de Fisioterapia e Terapia Ocupacional, Faculdade de Filosofia e Ciências de Marília – Universidade Estadual Paulista, UNESP, Marília, Brazil and [3]Departamento de Morfologia e Fisiologia, Faculdade de Medicina do ABC, Santo Andre, Brazil

Introduction: The literature has briefly described the association between auditory stimulation and the cardiovascular system. In this context, it is known that exposure to auditory stimulus of the classic musical for eight weeks improved cardiac autonomic regulation, by analysis of heart rate variability (HRV). Moreover, heavy metal music style is related to stress responses. Thus, it is thought that exposure to this style of music can contribute to the development of cardiovascular disease. Our object is to investigate the association between the intensity of the music and HRV. Method: Eight healthy male subjects aged between 18 and 30 years were analyzed. All procedures were approved by the Ethical Committee in research of our Institution. It was excluded subjects who had disorders of hearing sensitivity, cardiorespiratory, neurological and other impairments known that avoided the subject performing the procedures, treatment with drugs that influence cardiac autonomic control and people involved with music (dancing, singing or musical instruments). We evaluated the linear HRV indices in the time domain and the frequency and low frequency. The subjects were exposed to musical auditory stimulation musical of classical baroque and heavy metal styles. Initially HRV was recorded at rest for 10 minutes. Subsequently the subjects were exposed to auditory stimuli musical equivalence of the following levels: 60-70 dB, 70-80 dB and 80-90 dB. Each exposure lasted five minutes and there was an interval of five minutes between each exposure. Results: In relation to the time-domain index, we did not observe significant changes during exposure to classical and heavy metal musical auditory stimulation. The SDNN index tended to be reduced during heavy metal music style exposure at 80-90 dB (59.6+33 ms) compared to the control condition (73.5+41 ms), however, there was no statistical significance (p=0.4). Similar responses were observed during classical baroque musical auditory stimulation at 80-90 dB (50.6+23 ms) compared to control (60.9+32 ms) (p=0.6) We found no significant changes regarding the RMSSD and pNN50 indices related to the time-domain analysis. With respect to the frequency-domain analysis, we found no significant changes regarding the LF and HF in absolute and normalized units (p>0.05). Conclusion: There was no significant influence of musical auditory stimulation in different equivalent sound levels on the HRV. We believe this is due to the small population evaluated

Effect of high glycaemic index diet on heart rate variability in Thai Brugada syndrome survivors

R. Chanavirut[1,2], P. Makarawate[3] and N. Leelayuwat[1,2]

[1]Department of Physiology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand, [2]Exercise and sport sciences development and research group, Khon Kaen University, Khon Kaen, Thailand and [3]Department of Medicine, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand

Brugada syndrome is one of the major causes of sudden death among male younger population in Southeast Asian countries including Thailand1. The syndrome manifestation occurs most frequently at night time1. It has been reported that a number of predisposing factors such as exercise, glucose, insulin or meal could modulate the syndrome2-3. In addition, previous studies suggested that an abnormality of autonomic modulation may be related to the syndrome4-5. However, there is no report regarding autonomic response to these factors. Objective of this study was to assess and compare responses of autonomic nervous system to exercise after the ingestion of high glycaemic index (HGI) meal between Thai Brugada syndrome survivors and age-match healthy subjects.

Fifteen patients (age between 40 and 60 years) were randomly assigned to perform exercise on electromagnetic cycle ergometer with and without pre-exercise (an hour) ingestion of 97 g of glutinous rice as a HGI meal. Fifteen age-match healthy subjects also underwent the same protocol. After overnight fasting, an hour before and immediately after the exercise blood samples were collected to analyze glucose and insulin concentrations. Electrocardiogram was recorded and analyzed for heart rate variability (HRV) and heart rate recovery (HRR) throughout the experiment. Data were compared by paired and unpaired-t test and presented in mean ± SE. Our procedure was approved by ethic committee of Khon Kaen University under the Declaration of Helsinki in 1964.

The results revealed that blood glucose (Brugada = 87.67 ± 1.53 and 108.67 ± 5.62 mg/dL and healthy = 93.33 ± 3.70 and 110.93 ± 7.20 mg/dL) and insulin concentration (Brugada = 16.52 ± 3.10 and 25.28 ± 3.00 uIU/ml and healthy = 9.98 ± 1.43 and 24.35 ± 4.46 uIU/ml) significantly increased ($p<0.05$) in both groups with HGI meal. Meanwhile blood parameters were not significantly different between groups without HGI meal.

Having HGI meal did not affect HRR (Brugada with- and without HGI = 22 ± 2, 24 ± 2 beats and healthy = 27 ± 3, 24 ± 3 beats). In addition, both groups did not show any difference in resting HRV. However, Brugada survivor showed a significantly lower sympathetic activity ($p<0.05$) indicated by LF(nu) after exercise without HGI diet. LF(nu) with and without HGI diet during a final stage of exercise testing of Brugada and control were 42.88 ± 6.65, 30.23 ± 5.67 nu and 51.56 ± 3.60, 47.77 ± 3.54 nu, at 1 min of HRR were 47.64 ± 5.83, 34.75 ± 4.32 nu and 44.25 ± 4.01, 49.87 ± 4.40 nu and cool down periods were 43.78 ± 5.92, 32.64 ± 4.59 and 47.24 ± 3.86, 45.51 ± 4.13 nu. Our results suggest that HGI meal stimulated insulin secretion and sympathetic nervous activity in Brugada syndrome survivors whereas without any effect on healthy subjects.

Redox-sensitive inactivation of the phosphatase and tensin homolog deleted on chromosome 10 contribute to enhanced activation of phosphoinositide 3-kinase/serine/threonine protein kinase signaling in rostral ventrolateral medulla and neurogenic hypertension in spontaneously hypertensive rats

J.Y. Chan and S.H. Chan

Center for Translational Research in Biomedical Sciences, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan

The activity of phosphoinositide 3-kinase (PI3K)/serine/threonine protein kinase (Akt) is enhanced under hypertension. The phosphatase and tensin homolog deleted on chromosome 10 (PTEN) is a negative regulator of PI3K signaling, and its activity is redox-sensitive. In rostral ventrolateral medulla (RVLM), which is responsible for the maintenance of blood pressure, oxidative stress plays a pivotal role in neurogenic hypertension. The present study evaluated the hypothesis that redox-sensitive inactivation of PTEN results in enhanced PI3K/Akt signaling in RVLM, leading to neurogenic hypertension. Compared to age-matched normotensive Wistar Kyoto (WKY) rats, PTEN inactivation in the form of oxidation and phosphorylation were greater in RVLM of spontaneously hypertensive rats (SHR). PTEN inactivation was accompanied by augmented PI3K activity and PI3K/Akt signaling. Intracisternal infusion of tempol or microinjection into the bilateral RVLM of adenovirus encoding superoxide dismutase significantly antagonized the PTEN inactivation and blunted the enhanced PI3K/Akt signaling in the anesthetized SHR. Gene transfer of PTEN to RVLM in the anesthetized SHR also abrogated the enhanced Akt activation and promoted antihypertension. Silencing PTEN expression in RVLM with small interfering RNA, on the other hand, augmented PI3K/Akt signaling and promoted long-term pressor response in normotensive WKY rats. The present study demonstrated for the first time that the redox-sensitive check-and-balance process between PTEN and PI3K/Akt signaling is engaged in the pathogenesis of hypertension, and an aberrant interplay between the redox-sensitive PTEN and PI3k/Akt signaling in RVLM underpins neural mechanism of hypertension.

High blood pressure increases brain neuronal nitric oxide synthase activity to buffer salt-sensitive hypertension in Dahl rats

M. Tandai-Hiruma[1], K. Kato[2], T. Kemuriyama[1], H. Ohta[1], A. Tashiro[1], K. Hagisawa[1] and Y. Nishida[1]

[1]Physiology, National Defense Medical College, Tokorozawa, Japan and [2]Psychiatry, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan

We have demonstrated that activity of central neuronal nitric oxide synthase (nNOS) containing neurons and its mediated sympathoinhibition are enhanced in hypertensive Dahl salt-sensitive (DSS) rats (Tandai-Hiruma et al, 2005). However, it is not clear what enhances nNOS activity in these neurons in this rat strain (high salt intake, increased blood pressure or something else) or how these neurons are enhanced in salt-induced hypertension. Are the increases in activity compensatory to buffer the hypertension even though hypertension is not relieved? The aims of the present study were to identify the mechanism underlying enhanced nNOS activity in the brain of hypertensive DSS rats and the consequences of enhanced nNOS activity. Male 8-week-old rats (Dahl/J Seac, n=5 for each group) were fed either a regular (0.4% NaCl) or high-salt (8% NaCl) diet with or without 0.25% nifedipine, for 4 weeks. The effects of nifedipine, which lowers blood pressure peripherally, on central nNOS were determined by measuring nNOS activity, as well as the number of nNOS-positive neurons in the brain stem and diencephalon. The effects of chronic (12 days) intracerebroventricular (i.c.v.) infusion of 7 μg (0.5 μL/h) *S*-methyl-L-thiocitrulline (SMTC, nNOS inhibitor) on mean arterial pressure (MAP) were assessed in conscious freely moving DSS rats using a radiotelemetry system. Rats were anaesthetized with pentobarbital (50 mg/kg, i.p.) and telemetry transmitters installed. Continuous recordings of arterial pressure were made for 20 days (6 days on a regular diet followed by 14 days on a high-salt diet) prior to, and 12 days during, osmotic minipump driven i.c.v. infusion of SMTC. In addition, the number of central nNOS-positive neurons was compared between DSS and salt-insensitive Sprague-Dawley rats (n=5 for each group). Values are means ± S.E.M., compared by ANOVA. Normalization of blood pressure by nifedipine attenuated the increase in nNOS activity in the brain stem of DSS rats. Chronic i.c.v. infusion of SMTC further enhanced hypertension in DSS rats. Differences in average MAP from Day12 to Day 26 were significantly greater ($p<0.05$) in SMTC-infused DSS rats compared with aCSF-infused DSS rats in both the day (31.9 ± 4.7 vs. 17.2 ± 2.1 mmHg) and night (26.1 ± 3.3 vs.12.2 ± 2.2 mmHg) phases (Figure 1). Feeding of a high-salt diet increased nNOS-positive neurons in the lateral parabrachial nucleus, rostral ventrolateral medulla, and nucleus tractus solitarius of DSS compared with Sprague-Dawley rats, whereas nNOS-positive neurons in the paraventricular nucleus remained downregulated in DSS rats. These results suggest that hypertension, rather than a high-salt diet, increases central nNOS activity in hypertensive DSS rats to buffer high blood pressure. However, this compensatory response may be insufficient to relieve salt-induced hypertension.

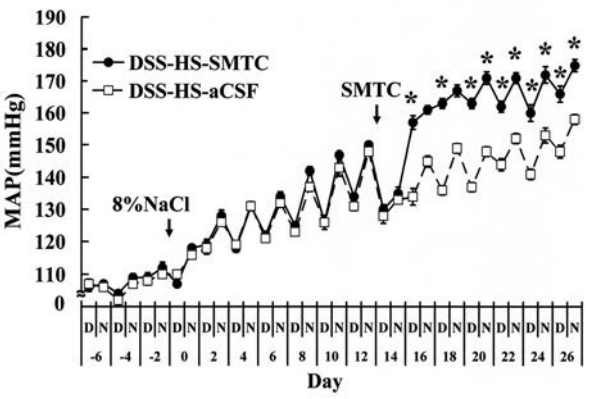

Fig. 1 Changes in mean arterial pressure (MAP) during the day–night (D) and night–day (N) phases in Dahl salt-sensitive (DSS) rats fed a regular diet for 6 days followed by a high-salt diet for 14 days. After 14 days, one group of rats was infused i.c.v. with *S*-methyl-L-thiocitrulline (SMTC; a stereoselective competitive nNOS inhibitor), whereas the other was infused with artificial cerebrospinal fluid (aCSF). Both groups continued on the high-salt diet for a further 12 days. The MAP values in each phase (D or N) of the day are the average of 1440 sampled values obtained by radiotelemetry over 12 h for each group. Data are the mean ± SEM (n = 5 rats per group). $^{*}P<0.05$ compared with average MAP in the corresponding phase on Day 12 in aCSF-infused DSS rats (one-way repeated-measures ANOVA followed by the Tukey–Kramer post hoc test). All night values are significantly larger than the day values, except for the first 4 days of i.c.v. SMTC.

Blood pressure responses to L-cysteine injected into the rostral ventrolateral medulla of the anesthetized rat

Y. Takemoto and Y. Matsumoto

Basic Life Sciences, Hiroshima University Institute of Biomedical and Health Sciences, Hiroshima, Japan

The sulfur containing non-essential amino acid L-cysteine known as neurotoxin is suggested to play a physiological role (ref. 1). When injected into the cisterna magna of conscious rats, L-cysteine produces an increase in blood pressure, equivalent to a neurotransmitter of L-glutamate (ref. 2). The present study examined if the rostral ventrolateral medulla (RVLM), which has cardiovascular sympathetic premotor neurons, responds to microinjected L-cysteine in anesthetized rats. The RVLM was directly accessed by the ventral surface of the medulla under urethane anesthesia (1.3 g/kg, i.p.) and catheters were inserted into the terminal aorta for arterial blood pressure measurement and the femoral vein for drug injections (refs. 3-5). The rat was immobilized by i.v. injection of pancuronium bromide (1 mg/kg, additional 0.5 mg/kg) and ventilated by a respirator. An adequacy of anesthesia was assessed by arterial blood pressure stability and/or the absence of a withdrawal response to a firm tow pinch. In the RVLM identified with pressor response to L-glutamate (0.01 M, 46 nl), seven times repeated injections of L-cysteine (0.1 M, 46 nl) produced stable pressor responses without fading (21.4 ± 1.5 mmHg, mean ± SD, for 62.7 ± 3.9 mmHg), suggesting no neurotoxic action for acute repetitive stimulation with L-cysteine less than this dose in the RVLM. Microinjections of L-cysteine increased blood pressure in a dose-dependent manner (0.003 M to 0.1 M), while L-glutamate did from 0.001 M. An equivalent increase of 15 mmHg was obtained with 0.03 M of L-cysteine and 0.01 M of L-glutamate. Preliminary examinations showed that there were no detectable changes in blood pressure for microinjection of each structurally related amino acid: D-cysteine, N-acetyl-L-cysteine, DL-homocysteine with ranging from 0.003 M to 0.03 M, except a pressor response to L-homocysteine at 0.03 M. The pressor response to L-cysteine (0.03 M, 21.3 ± 6.2 mmHg, n=8) was significantly blocked (2.4 ± 3.4 mmHg, $p<0.01$ by t-test) after prior injections of both types of ionotropic excitatory amino acid receptor antagonists MK801 (20 mM, 68 nl) and 6-cyano-7-nitroquinoxaline- 2,3-dione (CNQX, 2 mM, 68 nl), suggesting involvement of NMDA receptors and non-NMDA receptors in the pressor action of L-cysteine in the RVLM of the rat. The findings indicate that 1) neurons in the RVLM of anesthetized rats produce dose-dependently the pressor response to L-cysteine possibly in a molecular structural specific manner, and 2) the pressor response is mediated by ionotropic excitatory amino acids NMDA and non-NMDA receptors.

Changes in cardiovascular function and electrolyte balance following chronic exposure of rats to gasoline fumes

C.N. Anigbogu and S.E. Adewale

Department of Physiology, University of Lagos, Lagos, Lagos, Nigeria

Increased exposure to gasoline and petroleum products is inevitable due to increased use for transport, power generation and even as substance of abuse. The effects of gasoline vapour on various body functions and electrolyte metabolism have not been fully understood. The present study was designed to investigate the effect of gasoline vapour on blood pressure, heart rate and cardiovascular reflexes and to determine plasma Na+ and K+ concentrations in rats. The Sprague Dawley rats used in this experiment were exposed to 27.8±1.7ml of wholly vaporized Premium Motor Spirit (PMS) blend unleaded gasoline (UG) for 6hr/day, 5 days/week, for 4 weeks in glass exposure chambers. The control rats were not exposed to gasoline vapour but were placed in the chambers. All rats were fed with standard rat chow and tap water ad libitum throughout the experimental period. The control and experimental rats were anaesthetized with sodium pentobarbitone (65mg/kg bodyweight) and dissected. The femoral artery was cannulated for blood pressure recording. The carotid arteries were isolated for test of cardiovascular reflexes by bilateral carotid occlusion (BCO) of 30 seconds duration. Heart rate was computed from the blood pressure pulse. Blood samples were thereafter collected by cardiac puncture for measurement of plasma Na+ and K+ concentrations. The results from the experiments revealed that chronic exposure to gasoline vapour induced a significant reduction in systolic pressure (from 131.70±4.6 to 95.40±4.3mmHg)($p< 0.05$), diastolic pressure (from 100.00±6.1 to 62.00±5.1mmHg), mean

arterial pressure (MAP) (from 110.57±5.4 to 73.13±4.7mmHg) and heart rate (from 419.20±14.8 to 363.30±6.4 beats/min). Baroreflex sensitivity tested by carotid occlusion was lower in the treated rats when compared with the control group. The plasma concentration of Na+ ions showed an insignificant increase (from 137.7±1.1 to 140.0±1.7 mmol/L; P>0.05) while K+ ions were significantly higher in treated rats compared with the control rats (from 4.7±0.4 to 6.5±0.3 mmol/L; P<0.05). This may be an indication of interference with membrane functions. These results obtained in this study indicate that exposure to gasoline vapour cause a reduction in cardiovascular functions and increase in plasma Na+ and K+ concentrations which may imply an alteration of metabolic processes.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC009

The influence of nutrition, smoking and alcohol intake on head blood perfusions in the medical students

T. Zaporozhets, L. Korovina and O. Sanyk

Department of Physiology, Ukrainian medical stomatological academy, Poltava, Ukraine

Health state in the young people is a serious problem in Ukraine. Many of them have abundant weight, use fats and take alcohol as well as they have got low physical activities. We have assessed interconnections between nutrition, smoking and alcohol intake on head blood perfusion in the medical students to gain such a goal as feeding and life style correcting. Using rheoencephalography (REG), anthropometric data has been gathered on 97 medical university students with regard to nutrition, smoking and alcohol intake. Average student age was 19,1, ±0,2 years, body mass was 65,8, ±1,4 kg, height was 173,4, ±1,0 cm, Body Mass Index (BMI) was 24,9 ±1,4 kg/m.

REG data showed that blood perfusion in the front part of the head is reduced in 29,9 % of subjects surveyed, is normal in 37,7 %, and is increased in 32,5 % of cases. Rear head blood perfusions are reduced in 45,5%, are normal in 24,7%, and are increased in 29,9 % of those surveyed. The blood perfusion in the front part of the head was correlated inversely with body mass (τ =-0,39, p <0,001), height (τ =-0,42, p <0,001), body surface area (τ =-0,45, p <0,001), BMI (τ =-0,30, p <0,001), and coefficient of hand force (τ =-0,29, p <0,001). Also a negative relationship was observed with the use of lard (τ =-0,21, p <0,05), intensity of smoking (τ =-0,30, p <0,005 and τ =-0,27, p <0,02 accordingly), incidence of alcohol intake (τ =-0,25, p <0,02 and τ =-0,21, p <0,05 accordingly). The blood perfusion level of the back part of the head had a negative correlation with body mass (τ =-0,30, p <0,001), body surface area (τ =-0,27, p <0,001), BMI (τ =-0,31, p <0,001), coefficient of hand force (τ =-0,21, p <0,02) and level of emotional stress during the previous year (τ =-0,23, p <0,05).

A positive correlation of blood perfusion of the front part was observed with the level of consumption of fresh fruit (τ =0,33, p <0,02), vegetables (τ = 0,34, p <0,001), and fish (τ = 0,24, p <0,001). Similarly, the blood perfusion of the back part of the head also had a positive correlation with the level of consumption of fresh fruit (τ = 0,26, p <0,001), vegetables (τ = 0,23, p <0,001), and quantity of fish (τ = 0,37, p <0,001).

The blood perfusion level of the back part of the head had a positive correlation with the training success of the students (τ = 0,27, p <0,005). Thus, the use of fresh fruit, vegetables and fish may increase the level of blood perfusion of the head. Smoking and the frequent use of alcohol may decrease the level of blood perfusion of the head.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Projections from nucleus raphe obscurus to the caudal pressor area in the rat

H.A. Futuro Neto[1,3], J.G. Pires[2,4] and N.F. Silva[1]

[1]Morphology, UFES, Vitoria, E S, Brazil, [2]UNIVIX, Vitoria, E S, Brazil, [3]EMESCAM, Vitoria, E S, Brazil and [4]UNESC, Colatina, E S, Brazil

Previous studies have shown different cardiorespiratory effects induced by stimulation of nucleus raphe obscurus (NRO). The present study demonstrates the existence of c-Fos activation in the caudal pressor area (CPA) after NRO stimulation in barodenervated rats and projections from the NRO to the CPA with HRP. Male Wistar rats (300-350 g, N = 24) were used. The animals in the c-Fos group were barodenervated (chloral hydrate, 0.4 g/kg, ip). One day later the animals were instrumented for cardiorespiratory recordings (urethane 1.2 g/kg, iv, after Fluothane induction). After electrical stimulation of NRO (SNRO, 70μA, for 10s; 11.8 mm caudal to the Bregma and 7.8 mm depth) done every minute for 1 hr, the animals were killed by urethane overdose and the brains were processed for c-Fos. Control rats had the electrode only positioned. The HRP group, under anesthesia (chloral hydrate, 0.4 g/kg, ip), received unilateral HRP microinjection (50 nL, 20% saline) into the CPA (1.0 mm caudal and 1.7 mm lateral to the obex; 2.0 mm depth) and the animals were kept alive for 2-3 days. Following, they were killed by urethane overdose and the brains were processed for HRP. The experimental protocol was approved by CEUA EMESCAM (No. 021/2007). The results are presented as means ± SEM and statistical significance was assessed with t-test. SNRO caused increase in MBP (control 90 ± 5, SNRO: 156.8 ± 6 mmHg, P<0.01), bradycardia (control 416 ± 16, SNRO: 356 ± 16 bpm, P<0.01) and hypopnea (control 26.6 ± 0.9, SNRO: 16.4 ± 0.3 AU, P<0.01). C-Fos-expression was observed into the CPA ~1.0 mm caudal to the calamus scriptorius, ~2.0 mm lateral to the midline, and ~1.7 mm ventral to the medullary surface, respectively. In a total of 6 rats used for the HRP study, 5 showed markings in the NRO. This study provides additional support to the idea that NRO influences upon autonomic functions are partially mediated through projections to the CPA.

Neurones in the PVN, which project to the intermediolateral cell column, express subunits of the $GABA_A$ and NMDA receptors known to be altered in hypertension and pregnancy

S.C. Cork, P.L. Chazot and S. Pyner

School of Biological and Biomedical Sciences, University of Durham, Durham, UK

Studies suggest that both hypertension and pregnancy are conditions associated with increased activity of the sympathetic nervous system. This increased activity is due, in part, to changes in the neurochemistry of the hypothalamic paraventricular nucleus (PVN).

Work previously presented to the Physiological Society showed that the PVN of both spontaneously hypertensive (SHR) and late-term pregnant rats were associated with a significant decrease in the expression of the α1 and α5 subunits of the $GABA_A$ receptor. In the SHR, α5 expression was 97 ± 2% lower than Wistar controls. Furthermore, the SHR was also associated with a significant increase in expression of the GluN2A subunit of the NMDA receptor. These molecular changes could underpin the sympathoexcitation observed in these two states. We therefore aimed to assess whether these subunits were associated with presympathetic neurones (PSN) targeting the spinal cord.

All experiments were performed in accordance with the Animals (Scientific Procedures) Act, 1986. Female Wistar rats (n=5) were anaesthetised with medetomindine (0.6mg/kg) and ketamine (30mg/kg) and secured into a stereotaxic frame. The T2 region of the spinal cord was exposed and 2μl of 2% Fluorogold (FG) was injected into the IML region. Animals were left to recover for 7 days before being perfused via the descending aorta with 4% paraformaldehyde. Brains were sectioned to 40μm and sections were stained for either the α1 or α5 subunit of the $GABA_A$ receptor or the GluN2A subunit of the NMDA receptor. This was visualised using a fluorescently-conjugating secondary antibody and viewed under epifluorescence.

Quantitative analysis of the number of double labelled neurones show that 55.15 ± 2.5% of PSN express the α1 subunit and 73.29 ± 3.2% express the α5 subunit of the $GABA_A$ receptor. Furthermore, 54.95 ± 2.8% of PSNs express the GluN2A subunit of the NMDA receptor. Of those PSNs which did not express either the α1 or GluN2A subunits, many were found in close apposition to neurones which did express these subunits. Furthermore, a number of neurones were found to be positive for the either of the subunits in the absence of FG expression.

These results suggest that a significant proportion of PSNs emanating from the PVN have the potential to be influenced by the changes in $GABA_A$ and NMDA receptor subunit expression presented previously. The changes observed are likely to significantly increase the level of neuronal activity of these neurones and thus sympathetic activity. Furthermore, it is likely that a number of other neuronal populations within the PVN are also likely to be influenced by these changes.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC013

Superoxide anions in paraventricular nucleus mediate the pressor effects of salusin-β and arginine vasopressin release via PKC signal way in hypertensive rat

H. Sun, L. Zhang, Z. Fan, L. Zhang, X. Xiong, L. Ding, X. Gao and G. Zhu

Department of Physiology, Nanjing Medical University, Nanjing, Jiang Su, China

Salusin-β is a bioactive peptide with peripheral hypotensive, mitogenic, pro-atherosclerotic effects, and stimulates the arginine vasopressin (AVP) release from perifused rat pituitary (Shichiri et al, 2003). Salusin-β was found in paraventricular nucleus (PVN) and posterior pituitary (Suzuki et al, 2007). We recently found that microinjection of salusin-β into the PVN increased blood pressure and sympathetic outflow in renovascular hypertensive rats but not in sham-operated rats, which was mediated by both circulating AVP and AVP in rostral ventrolateral medulla (Chen et al. 2013). However, the downstream pathway in mediating the effects of salusin-β is unkown. The present study was designed to determine whether superoxide anions in the PVN were involved in the effects of salusin-β, and whether the production of superoxide anions was dependent on protein kinase C (PKC) and NAD(P)H oxidase in 2K1C rats. Renovascular hypertension was induced by two-kidney, one-clip (2K1C) in male Sprague–Dawley rats weighing 160-180 g under anaesthesia (pentobarbital sodium, 60 mg/kg, ip). Acute experiments were carried out 4 weeks after the 2K1C or sham operation under urethane (800 mg/kg) and alpha-chloralose (40 mg/kg) anesthesia intraperitoneally. Renal sympathetic nerve activity (RSNA), mean arterial pressure (MAP) and heart rate (HR) were recorded. Superoxide anion levels and NAD(P)H oxidase activity were measured with chemiluminescence method. Plasma AVP levels were determined with commercial Elisa kits. Values were expressed as mean±SE, compared by T-test or ANOVA (n=6 for each group). PVN microinjection of superoxide anion scavenger PEG-SOD (4 IU) almost abolished the RSNA and MAP responses to salusin-β compared with saline (RSNA change: 1.4±1.9 vs. 10.2±2.7 %, $P<0.05$; MAP change: 1.1±1.3 vs. 9.7±2.1 mm Hg, $P<0.05$). Similarly, NAD(P)H oxidase inhibitor apocynin (1 nmol) or PKC inhibitor chelerythrine chloride (CLC, 3 nmol) almostly abolished the effects of salusin-β . Salusin-β in the PVN increased superoxide anion level and NAD(P)H oxidase activity compared with vehicle (26.6±1.6 vs. 13.7±1.5, $P<0.01$, and 20.8±2.9 vs. 8.6±1.9 mean light units/min/mg protein, $P<0.05$, respectively), which was abolished by CLC pretreatment. Pretreatment with either PEG-SOD or CLC abolished the increased plasma AVP levels caused by salusin-β (6.7±0.4 and 7.6±0.2 vs. 12.7±0.9 pg/ml, $P<0.05$ and $P<0.01$, respectively). These results indicate that superoxide anions in the PVN mediate the effects of salusin-β in the PVN on the RSNA, MAP and AVP release, and that the production of superoxide anions in the PVN was dependent on PKC and NAD(P)H oxidase in 2K1C rats.

Further evidence demonstrating the significant role of juxtapulmonary capillary receptors in exertional breathlessness of cardiac disease patients

A. Anand[1], P. Barwad[2], N. Srivastava[1] and S. Ramakrishnan[2]

[1]Exertional Breathlessness Studies Laboratory, Vallabhbhai Patel Chest Institute, Delhi, India and [2]Department of Cardiology, All India Institute of Medical Sciences, New Delhi, India

We established that an increase in dysponea-free duration of exercise in mitral stenosis patients after percutaneous mitral valvulotomy which lowers their raised left atrial pressures and pulmonary congestion, was the reduction of juxtapulmonary capillary (J) receptor stimulus and so of their reflex effects (Anand et. al., 2009) which are to accelerate breathing and limit physical activity (Paintal, 1969). In humans they can be also stimulated chemically by lobeline (Raj,et.al., 1995; Anand et al.,2010). With a view to substantiating this conclusion we studied patients with Eisenmenger syndrome (ES). ES is characterized by both a high pulmonary artery pressure and raised pulmonary vascular resistance index due to a ventricular septal defect which also leads to a fall in arterial oxygen saturation (SaO2). The studies conformed to the Helsinki Declaration and were approved by the ethical committee of All India Institute of Medical Sciences. The protocols involved (i) distance covered in a 6-min walk test (6MWT) (ii) duration of exercise according to a modified Bruce Protocol limited by discomfort or a 20%fall in SaO2 (iii) threshold dose of lobeline for eliciting respiratory sensations. Responses were restudied after 6 weeks of medication with sildenafil (3mg TDS), a phosphodiesterase type-5 inhibitor and a preferential pulmonary vasodilator. After medication the mean (estimated) pulmonary artery systolic pressure fell from 104.5±4.18 to 90.6±2.8 mmHg (P= 0.0001);resting SaO2 which was 89.8± 1.2 mmHg remained unchanged at 89.8± 0.86 mmHg;distance covered in 6MWT increased from 487.5± 44.9 to 551.25±39.0 meters (P=0.0001) and the mean duration of exercise increased from 8.26±0.9 to 10.47±1.06 min (P=0.002), demonstrating a significant improvement in their symptomatic status. Threshold dose of lobeline i.v. gave rise to exercise-related respiratory sensations and decreased significantly from 37.5±3.4 to 20.3±1.8μg/kg (P=0.001).

A fall in lobeline-sensation dose indicates a fall in pulmonary vascular resistance; the latter having been reported with oral tadalafil, also a phosphodiesterase type-5 inhibitor (Mukhopadhyay et al.,2006). Since a reduction in pulmonary vascular resistance with these drugs constitutes a reduction in stimulus to J receptors, their reflexes which are the patients symptoms, will also be attenuated.SaO2 remained unchanged with sildenafil medication for up to 6 weeks and appears to play an insignificant role in the patient's clinical improvement.

The effects of aortic depressor and lingual-trigeminal nerve stimulations on the neurons in the rostral nucleus tractus solitarius

K. Ishizuka and Y. Satoh

Physiology, Nippon Dental University at Niigata, Niigata, Japan

The rostral part of the nucleus tractus solitarius (NTS) is well known as first order gustatory relay center. However, neurons in the rostral NTS also receive afferent inputs from a lot of different structures and respond to various kinds of peripheral stimuli. For example, somatosensory fibers from oral cavity and baroreceptor afferent fibers have shown to project to the rostral NTS. Therefore, we examined the effects of the aortic depressor nerve (AND) and lingual-trigeminal nerve (LTN) stimulations on the activity of the rostral NTS neurons, and also investigated whether these neurons exhibit a pulse-related activity. The experiments were carried out on 7 male SD rats (300-400 g) under urethane-chloralose anesthesia (500 mg/kg and 50 mg/kg, respectively, i.p.). The arterial blood pressure and an ECG were recorded. The right ADN and LTN were dissected and prepared for stimulation. Animals were artificially ventilated with room air containing 20-35% O2 following neuromuscular blockade with pancronium bromide (1 mg/kg, i.v.). The depth of anesthesia was assessed by monitoring the stability of the arterial pressure and heart rate to noxious pinching of the hind paw at regular intervals and if necessary anesthesia was supplemented by injections of urethane-chloralose (50 and 5 mg/kg/h; i.v.). Single unit activity of the rostral NTS neurons were extracellularly recorded using a single microelectrode, and test stimuli (0.1-0.3mA, 1 pulse with 0.2 ms duration at 10Hz for 10 seconds) were applied to the AND and LTN. In the ECG/ABP-triggered correlation histogram, a neuron was classified as having a pulse-related activity if the cardiac coefficient exceeds 2.0. All data are presented as mean ± S.D., and compared using Student's t test. The recording sites were marked and histologically verified. A total of 36 rostral NTS neurons with spontaneous activity were recorded. Among them, 28 neurons (78%) exhibited a pulse-related activity, whereas 8 neurons (22%) did not exhibit it. The ADN stimulation significantly altered ($p<0.05$) their firing rates in 12 (33%) neurons, and did not ($p>0.05$) in 24 (67%) neurons. Out of 12, 11 neurons decreased their firing rate (3.6± 3.5 spikes/sec vs 8.1± 6.1 spikes/sec for pre-stimuli; $p<0.05$), and 1 neuron increased their firing rate (4.7 spikes/sec vs 2.2 spikes/sec for pre-stimuli; $p<0.05$). On the other hand, the LTN stimulation significantly altered ($p<0.05$) their firing rates in 17 (47%) neurons, and did not ($p>0.05$) in 19 (53%) neurons. Out of 17, 11 neurons decreased their firing rate (4.8± 3.6 spikes/sec vs 10.9 ± 6.9 spikes/sec for pre-stimuli; $p<0.05$), and 6 neurons increased their firing rate (11.1 ± 7.1 spikes/sec vs 5.0 ± 3.6 spikes/sec for pre-stimulus, $p<0.05$). We conclude that ADN and LTN stimulations exert inhibitory/excitatory effects on less than half of the rostral NTS neurons, and these neuronal activities may be involved in the reflex cardiovascular responses in part.

Cymbopogon citratus prevents fructose-induced hypertension in rats

A. Thaeomor[1] and S. Roysommuti[2]

[1]School of Physiology, Institute of Science, Suranaree University of Technology, Muang Nakorn Ratchasima, Nakorn Ratchasima, Thailand and [2]Department of Physiology, Faculty of Medicine, Khon Kaen University, Muang Khon Kaen, Khon Kaen, Thailand

In vitro experiments indicate that Cymbopogon citratus possesses cytoprotective, antioxidant and hypotensive activity. This study tests the hypothesis that Cymbopogon citratus prevents fructose-induced hypertension in adult rats. Male Sprague-Dawley rats were fed normal rat chow and drank water alone (C), 10% fructose in water (F), 20% Cymbopogon citratus extract in water (CC) or 10% fructose plus 20% Cymbopogon citratus extract in water (FC) for 8 weeks. At 14 weeks of age, rats were anesthetized with thiopenthal (50 mg/kg body weight, i.p.), and were tracheostomized, and their femoral artery and vein were inserted polyethylene tube (PE-50 fused to PE-10) for the measuring of arterial blood pressure and infusion of phenylephrine and sodium nitroprusside, respectively. All data were expressed means ± S.E.M., compared by ANOVA, body weight, heart rate, baroreflex sensitivity, blood urea nitrogen, plasma creatinine, plasma sodium, plasma potassium and plasma chloride were not significantly different among the four groups. Compared to C group, high fructose intake (F group) significantly increased mean arterial pressure (C, 104±3 mm Hg versus F, 116±4 mm Hg; $p < 0.05$), decreased fasting blood sugar (C, 91±3 mg/dl versus F, 77±5 mg/dl; $p < 0.05$) and displayed glucose intolerance. These fructose effects were all abolished by Cymbopogon citratus extract treatment (FC group). In addition, the Cymbopogon citratus extract treatment alone had no any significant effect on measured parameters. The present data indicate that Cymbopogon citratus extract prevents fructose-induced hypertension in adult rats, likely by increasing insulin sensitivity.

Concerted regulation of respiratory activities via central chemoreceptors

Q. Du, N. Song, R. Guan, G. Wu, D. Zhu and L. Shen

Department of Physiology and Pathophysiology, Fudan University, Shanghai, China

There are possibly multiple pH sensitive chemoreceptors in the central nervous system. Recent findings showed that a fall of pH activates a distinct class of cation channels, the acid-sensing ion channels (ASICs) in peripheral and central nervous system (Akaike and Ueno 1994). On the other hand, the two-pore domain weakly inward rectifying K+ channel (TWIK)-related acid-sensitive potassium (TASK) is pH sensitive channel (Talley et al. 2000) too. Respiratory chemosensitivity seems to arise from interactions of multiple mechanisms, rather than a single unique channel, it has been documented that above mentioned pH sensitive channels may express in a single neuron (Chernov et al. 2010). ASIC1 in lateral hypothalamus contributes to breathing control (Song et al, 2012). But little is known about the composed influences of ASICs and TASK on respiratory regulation. This study investigated the cooperation of ASICs and TASK-1 in central respiratory regulation; they are both acid-sensing ion channels, the former for Na+, and the latter for K+. Sprague-Dawley rats (250-350g, n=8) of either sex were performed in the experiment. Rats were anaesthetized by intraperitoneal administration of 20% urethane (7ml/kg). Artificial cerebrospinal fluid (ACSF) with different pH values (pH = 5.5, 6.5, 7.4, 8.0 respectively, 0.1ul), Amiloride (1.0mM, 0.1ul, the blockade of ASICs), and Arachidonylethanolamide (AEA, 0.92g/mL, 0.1ul, the blockade of TASK-1), were respectively or jointly administered into lateral ventricle (LV) to observe the changes of respiratory activities via phrenic nerve discharge (PND) and its integration (PNDI). The respiratory excitability was increased as pH of ACSF decreased, significantly by pH 5.5 ACSF ($P<0.05$, ANOVAs). A convex concentration-effect curve of AEA was achieved within the concentration range from 10% to 100% at pH7.4. The AEA (50%) excited respiration significantly at pH 7.4 ($P<0.05$, ANOVAs), whereas Amiloride (1mM) inhibited it, though insignificantly. In contrast, the AEA didn't significantly excite the activated respiration at pH 5.5, while Amiloride inhibited it significantly ($P<0.05$, ANOVAs). The joint blockings of ASICs and TASK-1 resulted in the effect in-between that of respective blocking of these channels at both pH 7.4 and pH 5.5. The combined effect of Amiloride and AEA suggest that, medications targeted on ASICs and TASK-1 have opposite effects on phrenic nerve output. These two pH sensitive channels play a concerted role in central chemosensitivity during physiological and pathophysiological changes.

Ionotropic glutamate receptors in paraventricular nucleus mediate adipose afferent reflex in rats

B. Cui, P. Li, H. Sun, L. Ding, Y. Zhou, J. Wang, Y. Han, F. Zhang and G. Zhu

Department of Physiology, Nanjing Medical University, Nanjing, Jiang Su, China

Injection of leptin into white adipose tissue (WAT) increased sympathetic outflow to the epididymal WAT (Niijima, 1998) and kidney (Tanida et al, 2000) in rats. The sensory and efferent sympathetic innervations of WAT were well documented (Bartness & Song, 2007). We recently found that the sympatho-excitatory reflex, adipose afferent reflex (AAR), was caused not only by leptin, but also by capsaicin, bradykinin or adenosine in WAT, and chemical lesion of paraventricular nucleus (PVN) neurons with kainic acid abolished the AAR induced by WAT injection of capsaicin in normal rats (Shi et al, 2012). More recently, we found that the AAR was enhanced in obesity and obesity-related hypertension rats, and the enhanced AAR contributes to sympathetic activation in obesity hypertension (Xiong et al. 2012). It is unknown whether ionotropic glutamate receptors including N-methyl-D-aspartate (NMDA) and non-N-methyl-D-aspartate (non-NMDA) receptors in the PVN are involved in mediating the AAR. Experiments were carried out in male Sprague–Dawley rats weighing between 300 and 400 g. Each rat was anesthetized by intraperitoneal injection of urethane (800 mg/kg) and α-chloralose (40 mg/kg). Renal sympathetic nerve activity (RSNA) and mean arterial pressure (MAP) were recorded. AAR was evaluated by the the RSNA and MAP responses to the injections of capsaicin (1.0 nmol/μl) into four sites of the right inguinal WAT at a rate of 4.0 μl min-1 for 2 min for each site. Values are means ± SE, compared by ANOVA. Compared with the bilateral PVN microinjection of saline, either NMDA receptor (NMADR) antagonist AP5 (1, 3, 9 or 27 nmol) or non-NMDA receptor (non-NMDAR) antagonist CNQX (1, 3, 9 or 27 nmol) attenuated the AAR in a dose-related manner. AP5 plus CNQX completely abolished the AAR Compared with saline treated rats, the RSNA responses to capsaicin in AP5 (9 nmol), CNQX (9 nmol) and AP5 plus CNQX treated rats were 3.6±0.8, 5.9±1.4 and 0.2±1.1 % vs. 17.0±2.5 %, respectively (n=6 for each group, P<0.01); the RSNA responses to capsaicin in NR2A antagonist NVP-AAM077, NR2B antagonist CP-101,606 and NVP-AAM077 plus CP-101,606 treated rats were 10.0±2.2, 11.1±2.1 and 4.2±1.5 % vs. 17.0±2.5, respectively (n=6 for each group, P<0.05). The results indicate that both NMDAR and non-NMDAR in the PVN mediate the AAR. Both NR2A and NR2B subunits of NMDAR in the PVN are involved in the NMDAR-mediated AAR.

Altered expression profile of neurotrophin transcripts and proteins in the NTS of spontaneously hypertensive rats

S. Gouraud[1], H. Waki[1], M. Takagishi[1], A. Kohsaka[1], J.F. Paton[2] and M. Maeda[1]

[1]Physiology, Wakayama Medical University, School of Medicine, Wakayama, Japan and [2]Physiology and Pharmacology, School of medical sciences, University of Bristol, Bristol, UK

Since the nucleus tractus solitarii (NTS) is a pivotal region for regulating the set-point of arterial pressure, we proposed a role for it in the development of neurogenic hypertension. Our previous findings suggest that the NTS of pre-hypertensive and hypertensive rats (SHR) exhibits abnormal inflammatory condition with elevated anti-apoptotic factors, compared to the normotensive rats WKY (1,2). Whether this chronic condition affects the neuronal growth and plasticity in the NTS remains unknown. To unveil the characteristics of the neurodevelopmental environment in the NTS of SHR, we investigated the expression of neurotrophin transcripts and proteins in SHR. Male animals were humanely killed by cervical dislocation and the NTS was dissected out. To screen for differentially expressed neurotrophin transcripts between the NTS of adult SHR and WKY, total RNAs were extracted from the NTS (SHR & WKY, 10 weeks old, n=6) and submitted to the RT2 Profiler PCR Array system targeting rat neurotrophins and their receptors. Genes showing more than 1.5 fold differences in their expression levels between two groups were targeted for further validation using quantitative real-time RT-PCR (SHR & WKY, 3 & 10 weeks old, n=6 each). Their protein expression levels were also assessed in NTS protein extracts from adult animals (SHR & WKY, 10 weeks old, n=12) by using semi-quantitative western-blotting. The data (means ± S.E.M.) were shown as relative fold differences in SHR compared to WKY and unpaired t-test was used. Gene expression of Gfrα3 (Glial cell line-derived neurotrophic factor family receptor alpha-3), which is known to be involved in neuronal survival and migration, was up-regulated (SHR vs WKY: 2.48±0.31 vs 1.08±0.23 p<0.01) in the NTS of adult SHR, while gene expression of Crhbp (Corticotropin releasing hormone binding protein), a potential neurogenesis modulator, was down-regulated (0.131±0.03 vs 1.15±0.27 p<0.001). In parallel, Gfrα3 protein expression was up-regulated (1.36±0.08 vs 1.00±0.08 p<0.01), whereas Crhbp protein expression was down-regulated (0.79±0.04 vs 1.00±0.08 p<0.05) in the NTS of adult SHR. In pre-hypertensive young animals, the Gfrα3 transcript was found increased (1.37±0.08 vs 1.05±0.12 p<0.05) in the NTS of SHR, while Crhbp transcript did not show any differential expression. Together with our previous results showing that the transcript level of Tnfrsf6 (Tumor necrosis factor receptor superfamily, member 6, Fas), known to be involved in neuronal death and branching, was down-regulated in the NTS of both pre-hypertensive and hypertensive SHR (2), these profiles may affect the development of neuronal circuitry regulating cardiovascular autonomic activity and hence result in the development of neurogenic hypertension in the SHR.

Sympathetic nerve activity during the development of hypertension in Dahl salt-sensitive rats

M. Yoshimoto[1], N. Mineyama[2], M. Shirai[1] and K. Miki[2]

[1]Cardiac Physiology, National Cerebral and Cardiovascular Center Research Institute, Osaka, Japan and [2]Integrative Physiology, Nara Women's University, Nara, Japan

It has been thought that sympathoexcitation is involved in the pathogenesis of salt-sensitive hypertension. However, only a few attempts have been made to directly measure sympathetic nerve activity during the development of salt-induced hypertension. In the present study, we tried to elucidate how sympathetic nerve activity was involved in the development of hypertension in Dahl salt-sensitive (DS) rats, by directly and continuously measuring renal (RSNA) and lumbar sympathetic nerve activity (LSNA) in the same animals during the development of salt-induced hypertension. Instruments were attached to the subject male DS and Dahl salt-resistant (DR) rats in order to record RSNA, LSNA and arterial pressure via telemetry. The experiment consisted of 3 time periods, a 3-day control, a 14-day 8% salt-diet loading, and a 7-day recovery period. Mean arterial pressure (MAP), RSNA, LSNA and heart rate (HR) were measured continuously and simultaneously throughout the experimental period. MAP increased sharply during the first 3 days after the onset of 8% salt loading, from 100 ± 1 mmHg to 126 ± 1 mmHg, then continued to increase gradually from the 4th to the 14th day of salt loading, reaching 141 ± 1 mmHg in the DS rats. RSNA and LSNA decreased slightly, but significantly ($P<0.05$), during the salt loading period, relative to the pre-salt loading level. HR decreased gradually throughout the experimental period. These data suggest that the progressive increases in MAP induced by the 8% salt loading may not be attributed to the changes in the RSNA, LSNA or HR.

After cessation of the 8% salt loading, MAP decreased exponentially over the 7-day recovery period. RSNA increased significantly in a sustained fashion in DS rats after cessation of the salt loading, while it remained unchanged during the corresponding period in the DR rats. No differences were shown in the responses of LSNA and HR to the cessation of the salt loading in DS rats, compared with the DR rats. It is therefore likely that RSNA may sensitively response to the decrease in salt intake, while it is insensitive to the increase in salt intake.

In summary, the present observations suggest that neither RSNA and LSNA may be critically involved in the early phase of hypertension development induced by 8% salt loading in Dahl salt-sensitive rats.

PCC022

Phenylbiguanide and capsaicin evoke cardio-respiratory reflexes in anesthetized rats involving different vagal afferent pathways

S.B. Deshpande and A. Dutta

Department of Physiology, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India

The pulmonary artery pressure and pulmonary congestion are regulated by the reflexes originating from the pulmonary C fibre receptors (J receptors) (Paintal 1973; Roberts et al, 1986). Activation of these receptors reflexly diminishes the accumulation of fluid in the pulmonary interstitium (Paintal, 1973). These reflexes can be elicited by phenyldiguanide (PDG), phenylbiguanide (PBG), 5-hydroxytryptamine (5-HT), capsaicin and lobeline in experimental animals. The reflexes evoked manifest as bradycardia, hypotension and apnoea/tachypnoea. These chemicals involve different types of membrane receptors to produce reflex responses. For example, PBG, PDG and 5-HT mediate their actions via 5-HT3 receptors while capsaicin mediates via TRPV1 receptors. Therefore, this study was undertaken to compare the effects of PBG and capsaicin on cardio-respiratory reflexes. In addition, it was aimed to explore the underlying mechanisms. All the experiments were performed after obtaining the approval from the Institute Ethical Committee for conducting animal experiments. Trachea, jugular vein and femoral artery were cannulated in urethane anaesthetized adult rats. Blood pressure, respiratory excursions and ECG were recorded. In some experiments, vagal afferent activity was also recorded. Jugular venous injection of PBG produced concentration-dependent (0.1-100 μg/kg) hypotensive and bradycardiac responses but in case of respiration, there was tachypnoea at lower concentrations (0.1-3 μg/kg) and apnoea at higher concentrations (10-100 μg/kg). After vagotomy, both tachypnoeic and apnoeic responses induced by PBG were abolished along with cardiovascular responses. Ondansetron (5-HT3 receptor antagonist, 10 μg/kg) abolished the PBG-induced reflex responses at all concentrations but capsazepine (TRPV1 receptor antagonist; 3 mg/kg) failed to antagonize the PBG responses. Bolus injection of capsaicin (0.1-10 μg/kg) also produced concentration-dependent apnoea, hypotension and bradycardia but no tachypnoea was observed at any concentrations of capsaicin. Ondansetron failed to block the capsaicin-induced reflex response while bilateral vagotomy abolished the hypotensive and bradycardiac response and attenuated the apnoeic response. In separate series of experiments, PBG produced a burst of activity in afferents along with cardio-respiratory alterations. However, the afferents which evoked activity with PBG failed to evoke any activity with capsaicin even though bradycardia, hypotension and respiratory changes were observed. The present observations indicate that PBG-induced cardio-respiratory responses involve 5-HT3 receptors on vagal afferents where as capsaicin involve different set of afferents.

Expression of small conductance Ca^{2+}-activated K^+ channels SK2 and SK4 in venous atrial junctions

F.C. Shenton and S. Pyner

School of Biological & Biomedical Sciences, Durham University, Durham, UK

A characteristic of hypertension and cardiovascular disease is an over-activation of the sympathetic nervous system [1]. The aetiology underlying the development and maintenance of this excitation is still not fully understood. An aspect of the regulatory process that has largely been ignored is the key role played by the sensory input from cardiac mechanoreceptors in sustaining appropriate cardiac output. One component of this input is the atrial volume reflex arc, initiated by receptors at the venous atrial junction of the heart which respond to changes in blood volume.

Although atrial volume receptors have been reported to be primarily within the endocardium [2], details of the receptor location and mode of function have not been previously described. We have shown that Transient Receptor Potential (TRP) channels TRPC1 and TRPV4 are expressed within the endocardial layer of this region [3] and are therefore candidates as the mechanosensitive channel(s) which respond to mechanical deformations of the atrial wall. TRP proteins are nonselective cation channels, most of which allow the passage of Ca^{2+}, the output from other stretch sensitive endings has been shown to be Ca^{2+} dependent [4] and small conductance Ca^{2+}-activated K^+ (SK) channels influence excitability in these endings [5]. We have used immunolabelling to test for the presence of the SK1-4 isoforms in this region.

Three male Hooded Lister rats were killed under Schedule 1 of the Animals (Scientific Procedures) Act 1986. The atria, including entrances of the major vessels, were removed and fixed overnight in 4% formaldehyde. Following cryoprotection in sucrose/PBS, venous atrial regions were dissected out, frozen and 16μm cryosections collected. Double labelling was carried out with anti-SK antibodies together with the sensory nerve ending vesicle marker anti-synaptophysin (SYN). Appropriate secondary antibodies were applied to distinguish between anti-SK reactivity and the anti-SYN marker. Slides were viewed using a Zeiss Fluorescent microscope.

Strong SK2-immunoreactivity (IR) was evident in nerve fibres within the epicardium. SK2-IR did not coincide with SYN-IR in this layer. SK2-IR was occasionally present within the myocardium and endocardium and here it did coincide with SYN-IR. SK4-IR was found in the endocardium giving small patches of diffuse labelling which appeared to be over epithelial cells, but did not coincide with SYN-IR. No evidence of SK1 or SK3 IR was found throughout this region.

Since there was very little SK2 in the endocardium itself, and the SK4 expressed in this layer did not coincide with SYN-IR, these channels are unlikely to directly regulate afferent sensitivity in this instance. Nevertheless, their presence in this general area suggests they could influence responses to atrial stretch by other mechanisms.

Anti-oxidant strategies to prevent necrotic, mitochondrial and cardiovascular damage in inflammatory shock

A. Cauwels[1], B. Vandendriessche[1], E. Rogge[1], M. Murphy[2] and P. Brouckaert[1]

[1]Department for Molecular Biomedical Research, Ghent University, Ghent, Belgium and [2]2MRC Mitochondrial Biology Unit, Cambridge, UK

Septic shock is caused by a systemic inflammatory response resulting in hypotension, myocardial depression, multiple organ failure and death. Nitric Oxide (NO) is a potent vasodilator, and inhibition of NO synthases (NOS) increases systemic vascular resistance and blood pressure in shock1. Nevertheless, NO also exerts protective roles, as NOS inhibitors worsen and certain NO donors ameliorate shock.1-3

We study inflammatory shock using I.V. Tumor Necrosis Factor (TNF), lipopolysaccharide (LPS), or other TLR agonists in female C57BL/6 mice. Expression of inducible iNOS, as well as systemic NO accumulation, were not correlated with cardiovascular failure, morbidity or mortality, indicating that inflammation-induced NO is not sufficient to cause shock. In contrast, cardiovascular collapse (hypotension, bradycardia, loss of cardiac contractility) and mortality were completely reversed by tempol, a cell-permeable radical scavenger (100% survival vs. 0%, $p<0.001$, Log-Rank test), indicating a decisive role for ROS rather than NO. Protection by tempol was dose dependent (100-300 mg/kg I.P.) and could be achieved by pre- or post-treatment (-45 to +15 min). For cardiovascular analysis, we used PA-C10 or HD-X11 radio-transmitters (Data Sciences International) implanted under isoflurane anesthesia. Mitochondria may be important sources and targets of ROS. Following TNF or LPS, we found evidence for ROS-mediated damage to mitochondrial complexes. Nevertheless, although the mitochondria-targeted antioxidant mitoQ (5-10 mg/kg, I.P. or I.V.) could partially protect against early morbidity (hypothermia), it did not prevent mitochondrial and necrotic damage (measured via complex I activity in homogenized livers and lactate dehydrogenase activity in plasma, respectively), or cardiovascular failure. Our results thus indicate that ROS radicals are critically involved in the induction and progression of inflammatory cardiovascular collapse, and mitochondrial and necrotic damage. However, using a hyperacute shock model associated with excessive oxidative stress4, we also found evidence for a protective role of certain ROS, presumably H2O2, as catalase treatment both aggravated the hyperacute shock and reduced the long-term protective capacity of tempol.5

In conclusion, our results change the current paradigms on NO and ROS in inflammatory cardiovascular dysfunction. While NO seems predominantly protective, we found evidence for both detrimental and protective ROS effects. Hence, selective antioxidants may be a promising therapy to protect against inflammation-associated cardiovascular, mitochondrial and necrotic damage. Since mitoQ cannot reproduce the protective effects of tempol, we hypothesize that other sources of ROS (e.g. NADPH oxidases) may be involved in the detrimental effects, or that mitochondrial ROS is involved in protective pathways.

BT venom induced vasosensory reflexes involving cardiovascular parameters are mediated through B1-kinin receptor in anaesthetised rats

S.K. Singh and S.B. Deshpande

Department of Physiology, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India

Intra-arterial (i.a.) injection of Mesobuthus tamulus (BT; 1 mg/kg) venom produces optimal vasosensory reflex responses altering cardiorespiratory parameters in albino rats [1,2]. Since, bradykinin is a constituent of venom therefore, this study was planned to understand the role of kinin receptors in modulating the cardiorespiratory parameters evoked by venom. All the experiments were performed after obtaining the approval from the Institute Ethical Committee for animal experiments. Adult albino rats (200-300g) were anaesthetised with an intraperitoneal injection of urethane (1.5 g/kg). Tracheostomy was performed to keep the airway patent. Femoral artery was cannulated proximally as well as distally to record the blood pressure and to inject the chemicals, respectively. Blood pressure (BP), electrocardiogram (ECG) and respiration (RR) was recorded in presence or absence of antagonists. After i.a. injection of venom there was immediate (within 2 s) increase in RR which reached to 40% within 30 s, followed by a decrease of 40% from initial. Further, there was sustained increase in RR (50%) up to 60 min. The BP began to increase at 40 s, peaking at 5 min (50%) and remained above the initial level up to 60 min. The bradycardiac response started after 5 min which peaked (50%) at 25 min and remained at that level up to 60 min. In des-Arg (B1 receptor antagonist; 10 ng/kg) pre-treated animals, the venom induced respiratory changes were similar to the venom only group but venom induced cardiovascular responses attenuated (20-25% in MAP and HR) significantly ($P < 0.05$, Two way ANOVA). In Hoe-140 (B2 receptor antagonist; 10 ng/kg) pre-treated group, the venom induced respiratory changes were similar to the venom only group but venom induced BP responses attenuated (~25%) from 30-60 min ($P < 0.05$, Two way ANOVA) and HR responses accentuated (25-50%) up to 15 min significantly ($P < 0.05$). Thus, i.a. injection of venom produces immediate hyperventilatory, intermediate hypertensive and delayed bradycardiac responses. BT venom contains serotonin, histamine, bradykinin potentiating factor, peptide toxins, etc which is a potential nociceptive agents [3]. Bradykinin (BK) is an inflammatory mediator and produces the actions involving B1 and B2 receptors [4]. Involvement of kinin and prostaglandin (PG) to noxious stimulation has been shown [5]. In the present study, the B1 antagonist pre-treatment attenuated the venom induced BP and heart rate changes indicating the B1 receptors involvement in producing the responses. These observations are consistent for the B1 receptor involvement in the nociception. However, the involvements of B2 receptor on venom induced cardiorespiratory parameters are less evident in this study.

Mental stress associated changes in heart rate and blood pressure: Relation to body composition, physical fitness and autonomic status

S. Ghosh

Physiology, MAHSA University College, Kuala Lumpur, Selangor, Malaysia

Influence of mental stress on cardiovascular function differs from individual to individual, based on a variety of inherent factors (1). . Some people show characteristically greater cardiovascular reactivity than others to behaviourally stressful situations. Cardiovascular reactivity reflects the functional status of autonomic nervous system (2). The first year medical students are stressed by emotional factors and also have less physical activity The current study was undertaken to establish a basal autonomic status of adolescent south east Asian students and to find out the changes in cardiovascular parameters and their correlation with physical fitness and body composition. 50 healthy medical students of the age group of 17-19 years were recruited for the study. Cardiorespiratory fitness was assessed by Harvard Step Test and Body Mass Index and

body fat% were measured by Body composition analyzer. Basal autonomic status was studied by calculating changes in heart rate under orthostatic stress from electrocardiographic records and measurement of blood pressure by sphygmomanometer (3). All cardiovascular parameters were recorded before and after application of mental stress by means of public speaking in front of peer group. All data were analysed statistically by using SPSS version 19.0. Informed consent was taken from all subjects and permission of the institutional review board was obtained. Results showed that students with low BMI had a 30:15 ratio of 1.2[0.16] while those with high BMI had a ratio of 1.3[0.28]. Upon application of mental stress, the rate of change of heart rate also varied according to the BMI and Body fat%. Rate of change of heart rate was higher [39.5 +/- 1.7; 32.8+/-6.05] in both the high fat group and low fat group as compared to the normal, high fat group showing a bigger change. Rate of change of systolic pressure showed a similar trend while diastolic pressure change was lower in the high fat group. Subjects with low physical fitness had a poor parasympathetic control which may indicate that they are more vulnerable to break down under mental stress. The data suggested that autonomic reactivity to mental stress is correlated with basal physical fitness level of subjects and is also dependent on their body composition. Basal fitness level did not show any relationship with body composition but both low fitness level and high body fat % were found to show poor autonomic regulation of cardiovascular system. In such individuals, mental stress can cause higher alteration of heart rate and systolic blood pressure due to altered autonomic regulation.

Chronic intracerebroventricular infusion of hyperosmotic saline affects arterial baroreflex via brain angiotensin type 1 receptors in Sprague-Dawley rats

T. Zera and A. Nowinski

Dept.Experimental and Clinical Physiology, The Medical University of Warsaw, Warsaw, Poland

Introduction: Increasing evidence points to the key role of neurogenic component in cardiovascular diseases (1). High load of salt in diet contributes to the development of essential hypertension. One of the possible mechanisms linking salt intake with hypertension is an increased concentration of sodium ions in the cerebrospinal fluid (CSF), which rearranges central control of the cardiovascular system (2). Renin-angiotensin-aldosterone system is a key regulator of sodium balance and plays a culprit role in triggering and maintaining elevated arterial pressure (3). In the present study we aimed at finding out if increased CSF sodium ions alter the control of circulatory system and whether it may be mediated by brain angiotensin type 1 receptors (AT1Rs) for angiotenin II in normotensive rats. Methods: The study was performed on adult Sprague-Dawley male rats. The animals were implanted with L-shaped cannulae connected to osmotic mini-pumps for 2-week intracerebroventricular (ICV) infusions of either isoosmotic saline (0.9% NaCl, 5 μl/hr), hyperosmotic saline (5% NaCl, 5 μl/hr) or AT1Rs blocker losartan together with 5% NaCl (12.5 μg/5 μl/hr). After 14 days catheters were inserted into femoral artery and femoral vein for measurement of blood pressure (BP) and heart rate (HR) and for intravenous infusions respectively. All surgical procedures were performed under ketamine (100 mg/kg i.p.) and xylazine (10 mg/kg i.p.) anesthesia. After the implantation of catheters baroreflex was pharmacologically evaluated in conscious freely moving animals by administration of phenylephrine (i.v. from 20 up to 200 μg/kg/min) and sodium nitroprusside (i.v. from 20 up to 200 μg/kg/min) to induce a ramp increase and decrease of BP respectively. Subsequently autonomic ganglia were blocked with hexamethonium i.v. (20 mg/kg) and measurements of BP and HR continued. CSF was collected from cisterna magna before euthanasia of animals. Results: Infusions of 5% NaCl solutions resulted in higher concentration of sodium ions in CSF than in the plasma, while isoosmotic saline did not elevate CSF sodium concentration. The blockade of autonomic ganglia resulted in decrease of BP and increase in HR, which were similar in all groups. Baroreflex was blunted in rats receiving ICV infusion of hyperosmotic saline in comparison to control group. Intracerebroventricular administration of losartan restored sensitivity of baroreflex.

Conclusions: Present results indicate that chronic ICV infusion of hyperosmotic saline desensitizes arterial baroreflex and this is partially mediated by AT1 receptors for angiotensin II.

Increased expression of angiotensin type 2 receptors in the nucleus of the solitary tract improves baroreflex function and angiotensin converting enzyme 2 levels in renovascular hypertensive rats

G.T. Blanch[1], A.H. Freiria-Oliveira[1], K. Rigatto[2], H. Li[3], E. Colombari[1], C. Sumners[4] and D.S. Colombari[1]

[1]Physiology and Pathology, School of Dentistry - Sao Paulo State University, Araraquara, Sao Paulo, Brazil, [2]Basic Science and Health, UFCSPA, Porto Alegre, Sao Paulo, Brazil, [3]Southern Medical University, Guangzhou, China and [4]Physiology and Functional Genomics, University of Florida, Gainsville, FL, USA

Renovascular hypertensive (2K1C) rats exhibit impaired baroreflexes. Here we studied the effects of increased angiotensin type 2 receptor (AT2R) expression in the nucleus of the solitary tract (NTS) on baroreflex function of 2K1C rats and on selected gene levels at this site. Male Holtzman rats (150-180g) were anaesthetized with a mixture of ketamine (80 mg kg-1) and xylazine (7 mg kg-1, both i.p.) and the left renal artery was partially obstructed with a silver clip (0.2 mm width) or sham surgery. Three weeks later, 2K1C and sham rats were anaesthetized as above and microinjected in the NTS with either AAV2-CBA-AT2R (1.2×10^{12} genomic copies (gc)/ml; n = 6-8/group) or AAV2-CBA-eGFP (1.8×10^{12} gc/ml; n = 4-6/group) to elicit chronic increases in AT2R or GFP (control) expression respectively. Thirty days later, 2K1C and sham rats were anaesthetized as above and femoral artery and vein were cannulated to measure mean arterial pressure (MAP) and heart rate (HR) and perform drug infusions, respectively. The next day, phenylephrine (5 μg/kg, iv) and sodium nitroprusside (30 μg/kg, iv) were used to elicit respective pressor and depressor responses in conscious rats. Reflex HR responses were analyzed to each 10 mmHg change in MAP. Values are means ± S.E.M., compared by ANOVA. Baseline MAP in 2K1C-AT2R rats (173 ± 7 mmHg) was lower than in 2K1C-GFP rats (199 ± 9 mmHg; $p < 0.05$). 2K1C-GFP rats exhibited a significant impairment of the baroreflex (slope: -0.95 ± 0.05, vs. sham-GFP -1.37 ± 0.06, $p<0.05$), which was improved in the 2K1C-AT2R rats (slope: -1.44 ± 0.07). Baroreflex in 2K1C-AT2R was similar to sham-AT2R rats (slope: -1.56 ± 0.06) or sham-GFP. Real time RT-PCR revealed that the lower angiotensin converting enzyme 2 (ACE 2) mRNA levels in 2K1C-GFP rats were normalized in the 2K1C-AT2R rats (sham-GFP: 0.23 ± 0.03; sham-AT2R: 0.18 ± 0.03; 2K1C-GFP: 0.03 ± 0.01; 2K1C-AT2R: 0.31 ± 0.07, $p<0.05$). The results suggest that increased AT2R expression in the NTS of 2K1C rats improves baroreflexes and increases ACE 2 levels and these factors may contribute to the reduction in blood pressure observed in these animals.

NF-kB and Nrf2 compete for CREB binding protein in the RVLM of rats with chronic heart failure: the effects of exercise training

K. Haack, A.M. Harlow and I.H. Zucker

Cellular and Integrative Physiology, University of Nebraska Medical Center, Omaha, NE, USA

Chronic Heart Failure (CHF) is a disease characterized by overactivation of the renin-angiotensin system, increased sympathetic outflow, and high oxidative stress. In conditions of high oxidant stress, Nuclear factor erythroid 2 related factor 2 (Nrf2) is dissociated from Kelch-like ECH associated protein 1 (Keap1) to activate antioxidant response element (ARE) genes such as heme oxygenase 1 (HO1) and NQO1 as a compensatory mechanism. p65 nuclear factor kappa B (NF-kB) is one of the primary transcription factors that contributes to the etiology of CHF, recruiting creb binding protein (CBP) to both increase transcription of pro-inflammatory proteins and inhibit transcription of AREs. Exercise training (ExT) has been shown to decrease sympathetic outflow and oxidative stress and improve quality of life in patients with cardiovascular disease, however the mechanism(s) by which ExT is protective remain unclear. The purpose of this study was to investigate the convergence of the Nrf2/Keap1 and NF-kB pathways on CBP in the rostral ventrolateral medulla (RVLM) of the rat brain following CHF and ExT. Animals were anesthetized with isoflourane (0.5-2% in oxygen), intubated and mechanically ventilated. Animals were then infarcted using coronary artery ligation. Following confirmation of CHF by a decrease in ejection fraction using echocardiography, some animals were exercised four weeks post-surgery on a treadmill at a final speed of 25 m/min for 60 minutes, 5 days a week for 6 weeks. Western blot analysis of RVLM micropunches demonstrated that in CHF, there was a significant upregulation in NF-kB and Keap1 proteins compared to sham and a decrease in Nrf2 (n=4-5 per group, $p=0.003$ for Nrf2 and Keap1, $p=0.0016$ for NF-kB by unpaired t-test). ExT significantly increased Nrf2 and Keap1 expression compared to both sham and CHF groups but normalized NF-kB expression in CHF animals (n=4-5 per group). Co-immunoprecipitation experiments were then performed to examine the interaction of NF-kB and Nrf2 with CBP. In CHF, there was an increase in NF-kB/CBP interaction and a decrease in Nrf2/CBP association compared to sham ($p=0.01$ for NF-kB/CBP and Nrf2/CBP by unpaired t-test, n=2). However, during ExT in both sham and CHF groups, there was an increase in Nrf2/CBP interaction and a compensatory decrease in NF-kB/CBP interaction (n=2). Taken together, these data suggest that central Nrf2 is downregulated in CHF and that NF-kB and Nrf2 compete for CBP during CHF and following ExT.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Lack of hormonal regulation of hypercapnia-induced c-Fos expression in norepinephrine neurons of the male rat locus coeruleus

D. de Carvalho[1,4], D. Marques[1,4], R.A. Lopes[3], J.A. Anselmo-Franci[2], K.C. Bícego[1], R.E. Szawka[3] and L.H. Gargaglioni[1]

[1]São Paulo State University, Jaboticabal, SP, Brazil, [2]Dental School of Ribeirão Preto, University of São Paulo, Ribeirão Preto, SP, Brazil, [3]Biological Science Institute, Federal University of Minas Gerais, Belo Horizonte, MG, Brazil and [4]PIPGCF, Federal University of São Carlos, São Carlos, SP, Brazil

Sex hormones have a significant impact on ventilation in mammals. The effects of menstrual cycle, pregnancy, testosterone, estradiol and progesterone on resting ventilation have been well documented. The noradrenergic neurons of locus coeruleus (LC) contain estrogen and androgen receptors and have been reported to regulate the CO2-drive to breathe. We therefore evaluated the role played by sex hormones in the activation of LC noradrenergic neurones in response to CO2 in male rats. We assessed neuronal activity by c-Fos immunoreactivity in gonad-intact (INT) rats and orchidectomized rats treated with oil (ORX), testosterone (ORX+T), or estradiol (ORX + E2). Hypercapnia (7% CO2, 21% O2 and N2 for balance) or normocapnia (control animals) was administered for 2 hrs. The number of c-Fos/tyrosine hydroxylase (TH)-immunoreactive (ir) neurons was counted bilaterally in the LC (c-Fos/TH-ir neurons per section). The results showed that the number of c-Fos/TH-ir neurons in the LC was significantly increased by hypercapnia in INT (9.7 ± 5.7), ORX (7.6 ± 8.9), ORX + E2 (11.3 ± 9.9) and ORX + T (8.1 ± 7.2) male rats compared to normocapnia (3.9 ± 2.4; 2.3 ± 1.4; 2.1 ± 1; 4 ± 4.1, respectively). However, there was no significant effect of hormonal treatments on the response of LC to hypercapnia. These findings suggest that sex hormones seem to play no role in the LC response to hypercapnia in male rats.

Computational model of cardiovascular dynamics for assessment of cardiac energetic efficiency

T. Shimayoshi[1], Y. Himeno[2], A. Amano[2], T. Matsuda[1] and A. Noma[2]

[1]Graduate School of Informatics, Kyoto University, Kyoto, Kyoto, Japan and [2]Department of Bioinformatics, Ritsumeikan University, Kusatsu, Shiga, Japan

Cardiac energetic efficiency is a ratio of cardiac workload to cardiac energy consumption, and cardiac workload is subject to vascular system. Although a number of computational circulation models have been developed, most of them represent the left ventricle as a time-varying elastance and so cannot compute cardiac energetic efficiency. In the present study, a cardiovascular dynamics model is introduced to assess cardiac energetic efficiency, by integrating a detailed ventricular cell model into a vasculature closed-loop circuit. The vasculature circuit is based on a vascular system model proposed by Heldt et al. (2004). Left ventricular pressure is converted, according to Laplace's law, from the contractile force of ventricular myocyte which is calculated in a cell model by Kuzumoto et al. (2008). Despite combination of highly nonlinear sub-models, the present model successfully reproduce cardiac properties relating to energetic efficiency; response to variation of cardiac afterload, linearity of end-systolic pressure-volume relationship, and linear relationship between left ventricular oxygen consumption and pressure-volume area, which represents the total mechanical energy generated by ventricular contraction.

Introduction
Subcutaneous reserpine has been used for chemical sympathectomy. Its effect to deplete catecholamines in rats has been particularly characterized. Here we report some effects of subcutaneous reserpine that have not previously been described, namely to induce dehydration in rats, and to increase in vivo nitric oxide production in septic rats.
Methods
Male Wistar rats (~300g) received three subcutaneous injections of reserpine (4.5 mg/kg body weight dissolved in dimethyl sulfoxide) 48h and 24h prior to and during cannulations of carotid artery and jugular vein under inhalational anesthesia with 2% isoflurane. Fecal peritonitis was induced 24h after instrumentation, and Fluid resuscitation (1:1 solution of 6% hydroxyethyl starch 130/0.4 and 5% glucose) was given 2h later at 10 ml/kg/h via the jugular venous catheter. The body weight, blood pressure, and arterial base excess, plasma lactate and nitrate/nitrite levels at 6h post-peritonitis were compared with non-reserpinized rats.
Results
A total of 22 rats (mean weight, 306 ± 5 g) were pre-treated with reserpine. Of these animals, eight were used as sham-operated controls, and 14 had peritonitis induced. Prior to induction of sepsis, these animals showed marked weight loss (56 ± 2 g; equivalent to 18.3% body weight loss) within 48h. Sham rats presented with metabolic alkalosis and an elevated plasma lactate level, whereas septic rats presented with a more severe metabolic acidosis and higher in vivo nitric oxide production (Table 1). All rats presented with a lower blood pressure at the time of faecal slurry injection. At the 6h timepoint, sham rats responded to fluid resuscitation and their blood pressure was elevated, whereas septic rats remained hypotensive

(Table 1). Reserpinized septic rats had a higher 6h mortality rate (28.6% vs. 6.1%, p <0.01), whereas none of the sham died at this timepoint.

Conclusion

Subcutaneous reserpine induced dehydration in rats within 48h, which resulted in fluid-responsive hypotension and hyperlactatemia. Septic reserpinized rats also developed increased nitric oxide production. Subcutaneous reserpine may as the means of chemical sympathectomy may generate confound results.

Table 1. Differences in mean arterial pressures, arterial base excess, lactate and plasma nitrate/nitrite levels between non-reserpinized and reserpinized Wistar rats.

	Sham				p	Septic				p
	Non-reserpinized		Reserpinized			Non-reserpinized		Reserpinized

A role of glutamate co-released from orexin neurons in methamphetamine-induced autonomic physiological response

Y. Ikoma[1], K. Miyata[1], T. Kuwaki[1] and Y.Y. Ootsuka[1,2]

[1]Physiology, Kagoshima University, Kagoshima, Kagoshima, Japan and [2]Human Physiology, Flinders University, Bedford Park, SA, Australia

Methamphetamine has a central nervous system stimulant action and causes hyperactivity and elevation of body temperature. Recently, it has been shown that orexin system in the brain plays a key role of stress-related autonomic physiological response such as tachycardia and hyperthermia. In a orexin neuron, various neurotransmitters are co-localized with orexin. Among them, glutamate is focused on since its importance in autonomic physiological response to stress has been suggested. The aim of this study is to explore the role of glutamate as a co-transmitter from orexin neurons in methamphetamine-induced autonomic physiological response. We used a genetically-modified mouse (vGLUT2-KO) in which vGLUT2 is deficient only in orexin neurons and thus glutamate cannot be released from the orexin neurons and a wild type mouse (WT) as a control group. We implanted a telemetry probes to measure heart rate, body temperature and locomotor activity under isoflurance anesthesia (2%, inhalation). After at least one-week recovery period, we examined the effect of methamphetamine (0.5, 2, 5mg/kg, i.p.) on these parameters in conscious free-moving condition. In both groups of vGLUT2-KO and WT mice, methamphetamine caused an increase in body temperature as well as locomotor activity dose-dependently (P<0.05, n=7, Pearson). The amplitude of increases in body temperature as well as activity was significantly greater in vGLUT-KO than in WT mice (by 2.2±0.7 vs by 0.5±0.5 degree Celsius, 0.5mg/kg, n=7, P<0.05, Bonferroni). These results suggest a possible suppressive action of glutamate co-localized in orexin neurons on hyperthermia and hyperactivity induced by methamphetamine.

Fluoxetine reduces the lung injury induced by infrarenal abdominal aortic ischemia-reperfusion in rats

G. Sahin[1], I. Guner[1], M. Yaman[1], D. Uzun[2], H. Erman[4], N. Yelmen[1], M. Inceli[3], U. Aksu[3], R. Gelisgen[4] and H. Uzun[4]

[1]Istanbul University, Cerrahpasa Faculty of Medicine, Department of Physiology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [3]Istanbul University, Science Faculty, Biology, Istanbul, Turkey and [4]Istanbul University, Cerrahpasa Faculty, Department of Biochemistry, Istanbul, Turkey

Lung injury induced by acute aortic occlusion with subsequent aortic ischemia-reperfusion is an important factor in the development of postoperative acute lung injury following abdominal aortic surgery (Gelman,1995). Overproduction and/or insufficient removal of reactive oxygen species during ischemia-reperfusion (IR) result in significant damage to cell structure and organ functions. Fluoxetine, a selective serotonin reuptake inhibitor, has been shown to exert neuroprotective effect against the oxidative stress in animal models but no studies have yet been conducted to test the protective effects of fluoxetine against the lung injury. The present study aimed to examine whether the fluoxetine would be able to prevent the oxidative damage in lung induced by the occlusion and reperfusion of infrarenal abdominal aorta (IAA). Adult male Wistar rats (300-400g, n=24) anaesthetized with pentobarbital sodium (60 mg kg-1,i.p.) were randomized to 3 groups (n=8). Control (Sham), IR, and Fluoxetine+ IR (F+IR) groups. Control group, underwent laparotomy and dissection of IAA without occlusion. The IR group underwent laparotomy and clamping of the IAA for 60 min followed by 120 min of reperfusion. The rats in the F+IR groups received fluoxetine (20 mg kg-1, i.p. Sigma) once daily for 3 days before ischemic surgery. Thirty minutes after the last injection, the same IR procedure was performed. After withdrawn of blood samples, experiment was terminated by deep anesthesia (Pentobarbital sodium; 150 mg kg-1,i.p.). Bronchoalveolar lavage fluid (BALF) and lung tissue specimens were obtained for biochemical evaluations. Lung tissue oxidative stress was investigated by means of lipid hydroperoxide (LHPO), superoxide dismutase (SOD), pro-oxidant antioxidant balance (PAB), ferric reducing/antioxidant power (FRAP) and malondialdehyde (MDA) levels in lung tissue and BALF. Histological evaluation of the rat lung tissues was also performed. Presented values are means + S.E. compared by ANOVA as post-hoc Tukey. Except SOD and FRAP activities, all markers related to lung oxidative stress (PAB, LHPO and MDA) were significantly increased in the lung tissue (p<0.01, p<0.05, p<0.05 vs control; respectively) and likewise BALF samples of IR group (p<0.05vs control). Pretreatment with fluoxetine prevented the increase in PAB, LHPO activities and MDA levels (p>0.05 vs control). SOD and FRAP activities were significantly reduced in the lung tissue and BALF of IR group (p<0.01, p<0.05 vs control), but fluoxetine pretreatment abolished the effect of IR on SOD and FRAP activities (p>0.05 vs control). Fluoxetine also attenuated IR-induced total histo-

logical injury in lung tissue architecture. In conclusion, fluoxetine confers protection against lung IR injury and protective effects seem to be related to the inhibition of oxidative stress and prevention of cellular integrity of lung.

The effects of peripheral NMDA-type glutamate receptors on cardiorespiratory responses in acute hypoxic exposure in rabbits

N. Yelmen, I. Guner, O.M. Yaman and G. Sahin

Physiology, Istanbul University, Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Glutamate is one of the most common excitatory neurotransmitter in the central nerve system. It has been shown that central glutamate N-methyl-D-aspartate (NMDA) receptors are important components of the cardiorespiratory regulation. On the other hand, the presence of NMDA-type glutamate receptors has been demonstrated in many peripheral tissue as lungs, airways and carotid bodies. However the effect of those NMDA receptors on cardiorespiratory parameters is not completely considered. The purpose of this study was to investigate the effect of systemic glutamate NMDA receptors on cardiorespiratory parameters during both normoxia and acute hypoxia in rabbits. In this study 8 adult albino rabbits weighing avarege 2.7 ± 0.4 kg were used. The rabbits were anesthetized with urethane (400mg kg-1, i.v) and alpha-chloralose (40 mg kg-1, i.v). Tracheotomy was performed and the tracheal cannula connected to an inspiratory-expiratory valve was inserted into the trachea. The right femoral arterial catheter was used to collect arterial blood samples. Experiments were terminated by i.v injection of an overdose (500 mg kg-1) of sodyum pentobarbitone. Tidal volume (VT), respiratory frequency (f/min), ventilation minute volume (VE), mean arterial pressure (BP) and heart rate (HR) were recorded during the breathing of the normoxic and hypoxic (8% O2 - 92% N2) gas mixtures, before and after the administration of the i.v MK-801 (glutamate NMDA receptor antagonist) in anaesthetized rabbits. At the end of each experimental phase, PaO2, PaCO2, and pHa were measured. Values are presented as means ±S.E.M., compared by Wilcoxon-Matched Paired t- test. The injection of MK-801 (0.9 mg kg-1, i.v) during normoxia caused a decrease in BP ($p<0.01$), HR ($p<0.001$), VT ($p< 0.01$) and VE ($p<0.01$) values, whereas it caused an increase in f/min ($p<0.001$). After MK-801 administration, when hypoxic gas mixture was breathed to rabbits significant decreases in f/min ($p<0.01$), VE ($p<0.05$) and HR ($p<0.01$) were observed. The elevation response in BP seen during acute hypoxia was completely abolished by MK- 801 administration.

Our findings suggested that glutamate has a excitatory effect on both blood pressure and ventilatory activity via NMDA-type peripheral glutamate receptors during normoxic and acute hypoxic gas breathing. In line, when MK-801 was used to lower blood pressure, its depressor effect on ventilation should be taken into consideration in hypoxic conditions.

Recurrences in cardiovascular dynamics: supine vs. orthostasis

Z. Turianikova[1], M. Javorka[1], K. Javorka[1] and M. Baumert[2]

[1]Department of Physiology, Comenius University, Jessenius Faculty of Medicine, Martin, Slovakia and [2]School of Electrical & Electronic Engineering, The University of Adelaide, Adelaide, SA, Australia

New nonlinear methods are continuously developed to quantify novel aspects of heart rate variability (HRV) and blood pressure variability (BPV) with a potential to reveal subtle changes in the cardiovascular control system. Recurrence is a basic feature of many dynamical systems – it is defined as the repeated occurrence of a given state of the system in time. Recurrence plot (RP) is a graphical representation of such recurrences in a dynamical system. The structures exhibited by RP reveal information on system properties and can be described quantitatively by recurrence quantification analysis (RQA).

The aim of this study was to assess the effect of orthostatic challenge on RQA measures of HRV and BPV in healthy young subjects. The change from supine to standing position is a well-described autonomic stress paradigm that is characterised by an immediate reduction in vagal outflow to the sinus node and an increase in sympathetic nerve activity.

HRV and BPV were assessed in 28 healthy subjects over 15 minutes in the supine and standing positions. Complexity of HRV and BPV was assessed by recurrence quantification analysis from RPs constructed using fixed percentage of recurrences.The magnitude of oscillations was quantified by linear time and frequency domain measures.

We found high sensitivity of RQA measures to the change in autonomic balance accompanying orthostasis. We have also demonstrated the positive properties of RPs with fixed percentage of recurrence points in detection of qualitative change in cardiovascular dynamics. The different behavior of complexity and variability indices was observed: HRV complexity was reduced along with HRV magnitude after changing from supine to standing position; contrary, the BPV magnitude increased and BPV complexity decreased upon standing.

We conclude that RQA of HRV and BPV are sensitive to orthostatic challenge and might therefore be suited to assess changes in autonomic neural outflow to the cardiovascular system. Since analysis of variability and complexity can provide independent information on cardiovascular system control, it is beneficial to use both groups of measures simultaneously in the studies demanding the application of HRV and BPV analysis as a noninvasive tool for the assessment of cardiovascular autonomic nervous system function. We suggest that simultaneous use of both groups of measures can increase the information value and thus improve the sensitivity and reliability of the detection and monitoring of the cardiovascular system dysregulation during various pathological conditions.

Causal baroreflex sensitivity analysis from spontaneous heart rate and blood pressure oscillations in obese children and adolescents

M. Javorka, I. Tonhajzerova, B. Czippelova, Z. Turianikova, L. Chladekova and K. Javorka

Department of Physiology, Comenius University, Jessenius Faculty of Medicine, Martin, Slovakia

Obesity is an important risk factor of arterial hypertension. The impairment of baroreflex – a principal blood pressure control mechanism – could contribute to the development of hypertension in obese patients. Previous studies found a decreased baroreflex sensitivity (BRS) measured by transfer function analysis of spontaneous blood pressure (BP) and heart rate (HR) oscillations in obese subjects. However, this method ignores the causality and directionality of HR and BP oscillations interactions. The novel method for separate analysis of feedback (baroreflex) and feedforward (mechanical) interactions between HR and BP was recently developed. The aim of the study was to analyse BRS in obese normotensive children and adolescents using causal baroreflex analysis method.
Continuous recordings of BP (volume-clamp method) and R-R intervals (ECG) were obtained from 40 obese subjects (aged 10-18 years) and 40 age and gender matched controls. Causal close loop model was used to measure classical (noncausal) BRS and causal feedback interaction from BP to HR (causal BRS).
The noncausal BRS did not show any significant difference between groups. On the other hand, causal BRS was significantly lower in obese group.
In conclusion, the causal BRS analysis is more sensitive in early detection of baroreflex impairment in obese children and adolescents compared to classical BRS method. The results points towards baroreflex as one of the mechanisms involved in future hypertension development in obese patients.

The study was supported by project of CEPV no 26220120036, ESF project ITMS26110230031 and grants VEGA 1/0059/13 and 0223/12.

At matched oxygen delivery (DO_2) chronically hypoxic male Wistar rats have increased skeletal muscle fatigue versus normoxic controls

R.F. Cook, A.M. Coney and C.J. Ray

School of Clinical & Experimental Medicine, University of Birmingham, Birmingham, UK

Patients with chronic heart failure (CHF) and chronic obstructive pulmonary disease (COPD) suffer from exercise intolerance and may also be chronically hypoxic. It is not clear whether this exercise intolerance is due to skeletal muscle dysfunction or changes in oxygen delivery (DO_2). Acclimation to chronic hypoxia involves, increased haematocrit and angiogenesis, which may normalise DO_2, and changes in skeletal muscle. We hypothesised that changes in skeletal muscle that occur with 3 weeks acclimation to chronic hypoxia (CH; 12% O_2) would lead to greater skeletal muscle fatigue. Therefore, the objective of this study was to investigate the effect of changing DO_2 by isovolaemic haemodilution on muscle fatigue, in normoxic (N) and CH male Wistar rats.
CH rats were housed at 12% O_2 in a hypoxic chamber for three weeks before experiments and breathed 12% O_2 throughout the following protocol. In all animals, anaesthesia was induced using isoflurane, 4% in O_2, and maintained with a continuous infusion of Alfaxalone (13.5-18.0 $mg.kg^{-1}.hr^{-1}$ I.V.). Arterial blood pressure, femoral blood flow and tension in the extensor digitorum longus (EDL) muscle were recorded before and during peroneal nerve stimulation (15Hz) to evoke EDL contraction for five 3 minute periods; baselines were allowed to recover between stimulations. In the CH group (n=4) and one group of N animals (NHD; n=5) isovolaemic haemodilution was performed between each period of stimulation to reduced DO_2. A further group of N animals acted as a time control (TC; n=5).
In the TC group the responses to the five 3 minute muscle contractions were consistent (tension time index ~1200$g.s^{-1}$ and fatigue ~40%). CH rats fatigued ~10% more than NHD rats at matched DO_2 achieved by isovolaemic haemodilution. It is therefore possible that skeletal muscle adaptations, evoked by chronic hypoxia, play a greater role in the mechanisms limiting exercise tolerance than reductions in DO_2.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Vascular reactivity and salt sensitivity in normotensive and hypertensive adults

S.O. Elias[1], O.A. Sofola[2] and S.I. Jaja[2]

[1]Physiology, Lagos State University College of Medicine, Lagos, Lagos State, Nigeria and [2]Physiology, College of Medicine of the University of Lagos, Lagos, Lagos State, Nigeria

Vascular Reactivity and Salt Sensitivity in Normotensive and Hypertensive Adults
Exaggerated vascular reactivity is a possible mechanism in the development of hypertension and cardiovascular disease (Stewart and France, 2001). Whereas there has been a lot of attention paid to the relationship of dietary salt intake with the development of hypertension there are not many studies designed to study the relationship between vascular reactivity and salt sensitivity in a black population. Fifty-two hypertensive (HT) (age 44.42±1.28y) and forty-seven age-matched normotensive (NT) subjects (age 41.23±1.40y) took part in the study after informed consent was obtained from them. Ethical clearance was obtained from the College of Medicine, University of Lagos. After control parameters were obtained, vascular hyperreactivity was determined as ΔSBP or ΔDBP ≥ +15mmHg in subjects following exposure to the Cold Pressor Test for 1 minute using cold slurry maintained at 4oC (Flaa et al., 2008). Subjects were then salt-loaded with 200mmol Na+/day for 5 days and salt sensitivty determined as earlier (Elias et al., 2011). Test for vascular reactivity was repeated after the salt load. Values are means±SEM, compared with student t test. Salt-loading led to significant increases in systolic blood pressure among the normotensive subjects from 117.5±1.54 mmHg to 121.1±2.1 mmHg (p = 0.03) and among the hypertensive subjects from 144.9±2.6 mmHg to 1519±3.0 mmHg (p = 0.0001); diastolic blood pressure increased signi-

ficantly only among the hypertensive subjects from 95.73±1.5 mmHg to 100.5± 1.62 mmHg (p = 0.0003). Sytolic and diastolic hyperreactivity were higher among the HT (49% and 39% respectively) compared to NT (44% and 39% respectively) at baseline. However sysstolic hyperreactivity (SHP) increased from 44% to 64% after salt-loading among the NT while diastolic hyperreactivity (DHP) reduced from 39% to 36%. Among the HT, both SHP and DHP reduced from 49% to 33% and from 41% to 31% respectively following salt-loading. Salt sensitivity was higher among HT (56%) compared to NT 34%. Salt sensitivity was positively correlated with systolic reactivity (before salt: r = 0.33; p < 0.05 and after salt: r = 0.25; p > 0.05) but negatively correlated with diastolic reactivity (before salt: r = -0.38; p < 0.05 and after salt: r = -0.40; p < 0.05) among NT. Our results suggest that systolic hyperreactivity may be significant in the development of salt sensitive hypertension among this population.

Heart valve operations during pregnancy: does cardiopulmonary bypass provide a safe and physiological state?

N. Ergene[1], I.Z. Solak Gormus[2], Y. Dereli[2], O. Tanyeli[2] and N. Gormus[2]

[1]Physiology, Meram Medical School, Konya, Turkey and [2]Cardiovascular Surgery, Meram Medical School, Konya, Turkey

Background: Heart valve operations during pregnancy still have some significant risks for mother and child. Cardiac operations during the third trimester of pregnancy more confident than the first and second trimesters. If a valve treatment needed during the first and second trimesters trans-catheter valve interventions can be preferred. Valve operations can be performed with the use of cardiopulmonary bypass which has a foreign surface that contacts with blood and causes a systemic inflammation. On the other hand patients had a linear flow which provides an arterial tension between 50 to 80 mm Hg during the cardiopulmonary bypass.
Methods: Between 2000 and 2012 6 patients who had mitral valve operation during their pregnancy were evaluated. Out of 2 cases had a mitral valve replacement with a mechanical valve before the pregnancy. They had severe pulmonary edema and stuck valve needing urgent delivery of the child and on-pump cardiac operation. Remaining 4 patients had severe pulmonary edema because of mitral stenosis (3 cases) or mitral regurgitation (1 case). Out of 1 patient had successful transcatheter mitral balloon valvuloplasty, while an other patient had unsuccessful balloon valvuloplasty and needed urgent closed commissurotomy with left thoracotomy.
Results: There were no deaths among the patients. Out of 2 cases had sectio and healthy childs after interventions. Among these cases one of them had a mitral balloon valvuloplasty. The other patient had a 24 week pregnancy, severely calcified mitral stenosis and pulmonary edema needing urgent mitral valve replacement with a mecahnical valve. The operation was performed by using the cardioplumonary bypass with a pulsatile pump flow and continous intrauterin monitoring of the child during and after the operation. The patient and child did well after the operation, 12 weeks later she had a successful sectio and a healthy girl. Out of 4 patients had urgent heart valve operations which can not protected the life of child, even one patient had a closed mitral commissurotomy without using the cardiopulmonary bypass.
Conclusion: The timing of open heart surgery is very significant in pregnancy. Open heart surgery after the delivery of the baby with sectio is the most advised method, if possible. However, urgent surgery may be needed before maturation of fetus, in this situation cardiopulmonary bypass may be used with pulsatile flow in order to protect the life of child during and after the early term of open heart surgery.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Baroreflex modulation of sympathetic nerve activity during deep brain stimulation in humans

Y.B. Sverrisdottir[1,2], A.L. Green[2], F.A. Bahuri[2], S.D. Basanayake[1], T.Z. Aziz[2] and D.J. Paterson[1]

[1]Physiology, Anatomy and Genetics, Oxford University, Oxford, UK and [2]Nuffield Department of Surgical Sciences, John Radcliffe Hospital, Oxford, UK

Modulating the activity of midbrain structures in humans has proven a successful therapy for chronic neuropathic pain and movement disorders. Electrical stimulation of these neurocircuitries is recently shown to change cardiovascular parameters in humans1, indicating that these circuitries may also be of importance in autonomic reflex control of the cardiovascular system.
This study aimed to test the hypothesis that midbrain structures can affect cardiovascular outcome by modulating baroreflex restraint of central sympathetic outflow.
Direct recordings of multiunit efferent postganglionic muscle sympathetic nerve activity (MSNA) was obtained in patients undergoing deep brain stimulation of the periaqueductal gray (PAG) and subthalamic nucleus (STN) for chronic neuropathic pain and Parkinson's disease, respectively. MSNA was expressed as burst frequency, burst incidence and relative median burst amplitude. Blood pressure, heart rate and respiration were monitored during the recording session and spontaneous vasomotor and cardiac baroreflex sensitivity diagrams were assessed. Our results show differentiated changes in sympathetic outflow during on/off stimulation phases of midbrain structures, which are reflected in the hemodynamic response.
Evidence of a differentiated control of probability and amplitude of sympathetic bursts has been reported previously2. While it is not known how the differentiated control of sympathetic bursts is brought about, it has been suggested that the baroreflex modulation of sympathetic outflow occurs at two CNS locations. One site is thought to determine the probability of discharge, and the other site is thought to determine the strength of that discharge3.Our results on the effects of deep brain stimulation on the STN and PAG show differentiated changes in sympathetic outflow during on/off stimulation periods, which are reflected in a differentiated hemodynamic response. As baroreflex modulation of sympathetic

nerve traffic is of vital importance for cardiovascular regulation, our results may shed light on where and how this modulation occurs in the central nervous system.

Hydrogen peroxide in the medial septal area decreases the activation of vasopressinergic neurons within paraventricular nucleus of the hypothalamus induced by cholinergic activation of the medial septal area

M.D. Melo[2,1], J. Menani[1], D.S. Colombari[1] and E. Colombari[1,2]

[1]Physiology and Pathology, UNESP, Araraquara, Brazil and [2]Physiology, UNIFESP, São Paulo, São Paulo, Brazil

The microinjection of carbachol, a cholinergic agonist, into the medial septal area (MSA) induces anti-diuresis and increase in arterial pressure which is respectively due to vasopressin release and/or increase in sympathetic nerve activity (SNA). MSA projects directly to the paraventricular nucleus of hypothalamus (PVN), an important forebrain area involved in vasopressin release and SNA regulation. In the brain, reactive oxygen species (ROS) may modulate autonomic and behavioral responses. Previously, we have demonstrated that hydrogen peroxide (H2O2) microinjected into the MSA reduced the antidiuresis and the pressor response induced by carbachol into the same area. In the present study we investigate the effects of carbachol combined or not with H2O2 into the MSA on c-FOS expression in vasopressinergic cells of the PVN. Male Holtzman rats (280-320 g) were anesthetized with ketamine (80 mg kg-1) combined with xylazine (7 mg kg-1, both i.p.) and implanted with stainless steel guide-cannulas into the MSA.The Ethics Committee for Animal Care and Use of the Dental School of Araraquara, UNESP, approved the experimental protocols used in the present study (Proc. CEUA 02/2012). Seven days later, rats were randomly assigned for 3 groups (n = 3/group): PBS into ASM + saline into ASM; PBS into ASM + carbachol into MSA and H2O2 into MSA + carbachol into MSA. H2O2 (2.5 μmol/ 0.5 μl) or PBS (0.5 μl) was injected into MSA 1 minute before of the injection of carbachol (4 nmol/0.5 μl) in the MSA. After 90 min, rats were deeply anesthetized with sodium thiopental (50 mg/kg, ip), perfused with 4% paraformaldehyde and sections of PVN underwent double-staining immunohistochemistry for c-FOS and AVP using DAB staining with 1% cobalt chloride and 1% nickel ammonium sulfate to intensify the cell nucleus. Values are means ± S.E.M., compared by ANOVA. Carbachol into the MSA increased c-FOS expression on parvocellular (pPVN) (24.2 ± 4.2, vs. PBS + saline: 0.2 ± 0.1 cells/section, $p < 0.05$) and on magnocellular (mPVN) vasopressinergic cells (98.5 ± 5.9, vs. PBS + saline: 1.1 ± 0.4 cells/section, $p<0.05$). Previous injection of H2O2 reduced the double-labeling on both pPVN (12.7 ± 4.6 cells/section, $p<0.05$ compared to PBS + carbachol) and mPVN (46.4 ± 11.2 cells/section, $p<0.05$ compared to PBS + carbachol). These data show that the pre-treatment with H2O2 into the MSA decreases the activation of PVN vasopressinergic cells induced by carbachol into the same area, which could explain the reduction of the anti-diuresis and in the increase of arterial pressure induced by carbachol into the MSA in H2O2 pre-treated rats.

Increased sodium transporter expression induced by sympathetic renal nerve stimulation is dependent of angiotensin II

R.B. Pontes[1], E.B. Oliveira-Sales[2], M.A. Boim[2], G.R. Veiga[1], H.A. Futuro[3], R.R. Campos[1] and C.T. Bergamaschi[1]

[1]Physiology, UNIFESP, Sao Paulo, Brazil, [2]Nephrology, UNIFESP, São Paulo, Brazil and [3]UFES, Vitoria, Espirito Santo, Brazil

It is well known that increase in renal sympathetic nerve activity induces renin release, sodium reabsorption and decrease renal blood flow. However, the exactly mechanism underlying how the sodium reabsorption is processed it is still not well understood. The present study evaluated the effects of renal acute sympathetic nerve electrical stimulation (RSNS) over the gene expression (PCR) of sodium–hydrogen exchanger type 3 (NHE3), epithelial sodium channel (β-ENaC) and water (aquaporin 2 - AQP2) transporters in the kidney in the presence or not of AT1Angiotensin II receptor blockade. Male Wistar rat (250g-300g), were divided in four independent groups: A) Sham (renal sympathetic nerve activity registered for 1h, n=6); B) RSNS for 1h, [15V, 1Hz and 0,5 ms], n=6); C) Sham+Losartan, n=6 (30 mg/kg/day) and D) Losartan+RSNS (n=6). All procedures were performed in anaesthetized animals (sodium tiophental 60mg/Kg, ip). Values are means±SEM compared by ANOVA. Electrical stimulation of renal sympathetic nerve leads to a significant increase in NHE3 (Sham1.0±0.01 vs RSNS 1,6±0,2AU), however, a reduction in β-ENaC (Sham 1,02±,012 vs 0,6±0,1AU) and in AQP2 (Sham 1,06±0,18 vs 0,6±0,1AU) gene expression was found. Animals just treated with Losartan did not present differences at NHE3 expression but a significant reduction of basal renal sympathetic nerve activity was observed (89±4 vs 63±7 pps). Furthermore, a significant reduction in ENAC (0,4±0,1AU) and AQP2 (0,3±0,1UA) expression was induced by losartan when compared to SHAM animals. Treatment with Losartan+RSNS had no effect over the studied transporters. Taken altogether, RSNS produces differential alterations in sodium and water transporters in the renal tubule that can be important for the sodium homeostasis. Apparently, such effects are dependent of AT1 angiotensin II receptor.

Vagal afferent control of abdominal motor activity during hypercapnia and hypoxia in rats

E. Lemes[2] and D. Zoccal[1,2]

[1]Physiology and Pathology, School of Dentistry of Araraquara, São Paulo State University, Araraquara, SP, Brazil and [2]Physiological Sciences, Center of Biological Sciences, Federal University of Santa Catarina, Florianópolis, SC, Brazil

Stimulation of central and peripheral chemoreceptors increases inspiratory and expiratory motor outputs significantly. With respect to the expiratory component, studies demonstrated that a group of neurons in the parafacial respiratory group (pFRG) are critical for the processing of abdominal expiratory response to these metabolic challenges. Besides, it has been suggested that excitatory and inhibitory mechanisms determine the level of excitation of the pFRG expiratory neurons and then the strength of abdominal muscle contraction. In this regard, we hypothesized that vagal afferent information may modulate the magnitude of expiratory response to hypercapnia and hypoxia. To elucidate this hypothesis, we used anesthetized (urethane, 1.2 g/kg), tracheostomized, spontaneously-breathing male Wistar rats (290-320 g), in which we recorded the electromyographic activity of diaphragm (DIA) and oblique abdominal (ABD) muscles as well as the air flow in response to hypercapnia (5 min 10% CO2) or hypoxia (1 min 7% O2) before and after bilateral vagotomy. Before vagotomy, hypercapnia (n=12) and hypoxia (n=6) produced increases of DIA amplitude contraction (69.1±11.5 and 31.4±9.8 %) combined with a minor increase in ABD activity (4.4±2.2 vs 19.3±5.8 %). After vagotomy, the magnitude of DIA responses to hypercapnia and hypoxia (94.8±20.4 and 50.9±7.8 %) did not differ from those before vagotomy ($P>0.05$). In contrast, we verified a substantial increase in ABD responses to hypercapnia and hypoxia (47.1±7.9 and 63.3±15 %) in relation to the responses observed prior to vagotomy ($P<0.01$). These amplified expiratory responses to hypercapnia and hypoxia after vagotomy were associated with enhanced expiratory air flow ($P<0.01$) and augmented tidal volume responses ($P<0.01$). Our data indicates that, in anesthetized conditions, peripheral afferent inputs, potentially from pulmonary stretch receptors, exerts an inhibitory effect on the processing expiratory motor activity in response hypercapnia and hypoxia, and the removal of this information potentiates the processing of active expiration.

Expression of "pacemaker" channels in the turtle heart: Effects of anoxia and cold-acclimation

J.A. Stecyk[1,2], C.S. Couturier[2] and G.E. Nilsson[2]

[1]Biological Sciences, University of Alaska Anchorage, Anchorage, AK, USA and [2]Molecular Biosciences, University of Oslo, Oslo, Norway

Heart rate of the freshwater turtle (*Trachemys scripta*) is markedly depressed with anoxia exposure and arises in part from a resetting of intrinsic heart rate. Hyperpolarization-activated and cyclic nucleotide-gated (HCN) channels ("pacemaker" channels) constitute an important component in the control of cardiac rhythmicity. HCN channels are tetramers, and four HCN channel subunit isoforms exist, which are encoded for by four genes (HCN1-4). The four isoforms can form homotetramers and heterotetramers, resulting in a number of HCN channels with distinct biophysical properties. Using real-time RT-PCR, we examined the effects of anoxia and subsequent reoxygenation on the expression of HCN1-4 mRNA in the cardiac chambers (sinus venosus, right atrium, left atrium and ventricle) of 21°C- and 5°C-acclimated turtles. With 24 h of anoxia at 21°C, the relative abundance of HCN2 increased in all cardiac chambers, and following 24 h reoxygenation, HCN2 expression returned to control levels. In contrast, at 5°C, few and only minor changes in HCN channel subunit expression occurred with anoxia (14 d) and reoxygenation (13 d). However, compared to 21°C normoxic turtles, cardiac chambers of 5°C normoxic turtles exhibited a pronounced increase in the relative abundance of HCN2. Combined, the findings suggest that modified HCN expression with cold acclimation may prime the turtle cardiac muscle for the approaching anoxic winter, and that cardiac anoxia survival at 21°C may be aided by the circumvention of this priming and through rapid induction of similar changes in HCN expression. The altered HCN expression may serve to facilitate a slowed heart rate during anoxia by fine-tuning the sensitivity of HCN channels to the changing levels of intracellular and extracellular modulators of HCN activity that occurs with anoxia exposure. Indeed, the turtle HCN isoforms show high sequence similarity to their mammalian counterparts, notably at the location of key regulatory motifs.

Cardio- toxicity induced by inhalation of petroleum products-the role of oxidative stress

O.M. Azeez[2,1], C.N. Anigbogu[1,2], W.A. Saka[1,3] and R.E. Akhigbe[1,4]

[1]Veterinary Physiology and Pharmacology, University of Ilorin, Ilorin, Kwara, Nigeria, [2]Physiology, College of Medicine University of Lagos, Lagos, Lagos, Nigeria, [3]Physiology, Ladoke Akintola University of Technology, Ogbomoso, Oyo, Nigeria and [4]Physiology, Ladoke Akintola University of Technology, Ogbomoso, Oyo, Nigeria

OBJECTIVE: To investigate the effect of inhaling diesel, kerosene and petrol on cardiovascular functions and involvement of oxidative stress in Sprague Dawley rats
METHODOLOGY: Adult male Sprague-Dawley rats were divided into 4 groups with ten in each group. The animals were acclimatized for two weeks, before the commencement of the study. The control was not exposed to any petroleum product. The diesel, kerosene and petrol sub-groups, were exposed to their corresponding contaminants via inhalation. The diesel, kerosene and petrol groups inhaled diesel, kerosene and petrol, respectively for five minutes once a day in fume chamber for

eight weeks. The animals were placed in fume chamber with 1000ml beaker containing 500ml of petroleum products. The difference between the volume before and after the exposure gave the volume consumed. At the end of exposure period, rats were anaesthesized with 1% chloralose and 25% urethane mixture. Blood pressure (BP), heart rate (HR) and Baroreflex response over 30 seconds were measured using blood pressure transducer attached to the polygraph(model 7D); the rate pressure product (RPP) was thereafter calculated. The activities of superoxide dismutase (SOD), catalase (CAT) and concentrations of reduced glutathione (GSH) and Malondialdehyde (MDA) were evaluated in homogenate of lung and heart. The guidelines of the Institution animal ethics Committee was strictly adhered to.
RESULTS: There was significant increase in BP, HR and RPP of all treated groups relative to control. There was also significant increase in baroreflex response in diesel and kerosene, but not in petrol-treated when compared with control. The increase in BP and HR persisted in all the treated groups, one week after withdrawal of exposure. There was significant ($p<0.05$) decrease in the activities of SOD, CAT and GSH and significant ($p<0.05$) increase in MDA concentration in the serum and tissue homogenate of all treated groups relative to control. The cardiac muscle showed varying degrees of degeneration in the myocytes and the fibres. The lung showed degeneration of parenchyma and the alveolar wall.
CONCLUSION: The study showed that oxidative stress induction may have been partly responsible for the cardiotoxicity and alterations of the cardiovascular functions induced by inhalation of petroleum products

The effects of different styles of musical auditory stimulation on cardiac autonomic regulation in healthy women

A.L. Roque[1], M.F. Campos[1], H.L. Guida[1], A. Knap[1], L. de Abreu[2], L.M. Vanderlei[3] and V.E. Valenti[1]

[1]Departamento de Fonoaudiologia, Faculdade de Filosofia e Ciências, UNESP, Marília, Brazil, [2]Departamento de Morfologia e Fisiologia, Faculdade de Medicina do ABC, Marília, Brazil and [3]Departamento de Fisioterapia, Faculdade de Ciências e Tecnologia, UNESP, Presidente Prudente, Brazil

Introduction: The literature investigated the effects of chronic classical music auditory stimulation on the cardiovascular system. However, it lacks in the literature the acute effects of different styles of music on cardiac autonomic regulation. We aimed to evaluate the acute effects of classical and heavy metal music on heart rate variability (HRV) in women. Method: The study was performed in 21 healthy women between 18 and 30 years old. All subjects signed a consent letter and all procedures were approved by the Ethic Committee in Research of UNESP. We excluded persons with previous experience with music instrument and those who had affinity with the song styles. We analyzed HRV in the time (SDNN, RMSSD, NN50 and pNN50) and frequency (LF, HF and LF/HF ratio) domains. HRV was recorded at rest for ten minutes. Subsequently they were exposed to classical or heavy metal music for five minutes through an earphone. After the first music exposure they remained at rest for more five minutes and them they were exposed again to classical or heavy metal music. The sequence of songs was randomized for each individual. Results: In relation to the time-domain index, we did not observe significant changes during exposure to classical and heavy metal musical auditory stimulation. The SDNN index tended to be reduced during heavy metal music style exposure (39.1+10 ms) compared to the control condition (47.3+19 ms), however, there was no statistical significance ($p=0.12$). The RMSSD (control: 40.8+23 ms vs. classical music: 38+19 ms vs. heavy metal music: 39.1+20 ms; $p=0.8$) and pNN50 (control: 22.5+22 vs. classical music: 20.6+20 vs. heavy metal music: 22.5+23; $p=0.9$) indices were not changed during musical auditory stimulation with the both styles. The LF index was significantly reduced during heavy metal music auditory stimulation compared to the control condition (control: 685.7+571 ms2 vs. classical music: 595.7+837ms2 vs. heavy metal music: 328.8+143 ms2; $p=0.025$). On the other hand, there was no significant changes with respect to the HF (control: 1059+1191ms2 vs. classical music: 638.2+639ms2 vs. heavy metal music: 695.3+678ms2;$p=0.1$) and LF/HF (control: 2+2 vs. classical music: 1.4+1 vs. heavy metal music: 2+3; $p=0.7$) indices. Conclusion: Acute exposure to heavy metal musical auditory stimulation reduces the sympathetic activity on the heart.

Renal denervation leads to a reduction in angiotensin II receptors in central cardiovascular nuclei in renovascular hypertensive rats

E.E. Nishi[1], C.T. Bergamaschi[1], J.C. Perry[2], G.S. Lincevicius[1] and R.R. Campos[1]

[1]Physiology, Universidade Federal de Sao Paulo, Sao Paulo, SP, Brazil and [2]Psychobiology, Universidade Federal de Sao Paulo, Sao Paulo, SP, Brazil

Aim: to investigate whether renal sympathetic nerves play a role in the modulation of Ang II receptors expression in the central nuclei (RVLM, NTS and PVN) in renovascular hypertension.
Methods and results: Denervation of clipped kidney (DnX: visible bundles were dissected + 10% phenol) was performed in ketamine and xylazine (40 and 20 mg/kg, respectively, i.p.)-anaesthetised Wistar male rats (n=5/group) 4-5 weeks after clip implantation (gap width: 0.2mm). Ten days after DnX, mean arterial pressure (MAP) was significantly ($p<0.05$) reduced (15%) in the 2K-1C rats. AT1R was upregulated within the RVLM (76%) and PVN (70%) in the 2K-1C group, DnX normalized these expressions in both nuclei. AT2R expression was increased in the RVLM (57%) and PVN (60%) of 2K-1C group and DnX reduced AT2R in both regions. No change in both Ang II receptors expression was found within the NTS before or after DnX. DnX unchanged plasma renin activity in control and 2K-1C rats. In order to distinguish the effects of DnX from blood pressure reduction 2K-1C rats were treated orally with hydralazine (25 mg/kg/day for 7 consecutive days). Hydralazine significantly reduced MAP (26%) and AT1R within the PVN (30%) in the 2K-1C, however, unchanged AT1R or AT2R within the RVLM and NTS.
Conclusions: the present data show that renal nerves may modulate Ang II receptors within the RVLM independently of blood pressure reduction or plasma renin activity in the 2K-1C model of arterial hypertension.

Administration of hydrogen sulfide attenuates the oxidative stress in spontaneously hypertensive rats

H.A. Rathore[1], F. ud Din[1], M.A. Sattar[1], A.I. Hussain[1], T.Y. Chia[1], N.A. Abdullah[2] and E.J. Johns[3]

[1]School of Pharmaceutical Sciences, Universiti Sains Malaysia, Pulau Pinang, Malaysia, [2]Faculty of Medicine, Universiti Malaya, Kuala Lumpur, Malaysia and [3]Department of Physiology, University College Cork, Cork, Ireland

Vascular oxidative stress has been demonstrated in spontaneous (genetic) hypertension (1). Hydrogen sulfide (H_2S) has been recognized as a potential antihypertensive agent in various forms of experimental hypertension (2). The present study was aimed to evaluate the antioxidant potential of hydrogen sulfide in SHR. NaHS was used a s a donor of H_2S. For *in vivo* study WKY and SHR rats were divided in 4 groups namely WKY (I), WKY + NaHS (II), SHR (III) and SHR + NaHS. Groups II and IV received NaHS at a dose of 56 μM/kg i.p. daily for 4 weeks. Blood pressure, renal cortical blood perfusion and pulse wave velocity were measured in acute study under pentobarbitone anesthezia (60mg.kg-1).
In vitro , NaHS was found as a free radical scavenger, reductant and inhibitor of lipid peroxidation. *In vivo* study showed NaHS treatment reduced blood pressure, increased renal cortical blood perfusion and increased H_2S and NO plasma levels, and up-regulated the antioxidant defenses in SHR. The findings of this study suggest that the administration of NaHS not only reduces the blood pressure but also attenuates the oxidative stress in spontaneously hypertensive rats.

Systolic blood pressure, diastolic blood pressure, means arterial blood pressure, heart rate, renal cortical blood perfusion, pulse wave velocity and body weight of all the groups.

Parameters	WKY	WKY + NaHS	SHR	SHR + NaHS

Isolated use of methyltestosterone in ovariectomized rats improves baroreflex control of cardiovascular system with geno- and cytotoxic safety

E. Lima, D.G. Terra, I.C. Kalil, A.M. Nascimento and T.U. Andrade

Pharmacy, UVV, Vila Velha, ES, Brazil

The addition of testosterone to hormone replacement therapy (HRT) in women has beneficial effects on sexual function, being oral methyltestosterone (MT) indicated for androgen replacement in post-menopause women. There are evidences that MT improves sexual symptoms of menopause, but little is known about its safety and its cardiovascular effects used as isolated androgen therapy. We evaluate the effects of MT in ovariectomized (OVX) rats on the cardiovascular system, especially on the baroreflex sensitivity (BRS). Additionally, general, geno- and cytotoxic safety of the treatment was evaluated. Female Wistar rats were divided into 4 groups (n=6), each): control receiving vehicle (SHAM), control receiving MT (SHAM+MT), OVX receiving vehicle (OVX), and OVX receiving MT (OVX+MT), by gavage. After 21 d of castration treatment with MT (0.04 mg/day) or vehicle (methylcellulose) was performed for 28 days. The surgical procedures were executed under ketamine (100mg/Kg) and xylasine (10mg/Kg) anesthesia. The experiments were performed in accordance with the ethical principles for animal experimentation by the Brazilian College of Animal Experimentation and were approved by our Institutional Ethics, Bioethics and Animal Welfare Committee (Protocol n 118/2010). BJR was analyzed by measuring the bradycardia and hypotension responses elicited by phenyldiguanide administration (1.5–24 μg/kg). BRS was evaluated by phenylephrine (PE: 0.5-8.0μg/Kg) and nitropusside (NP: 1.0-16.0μg/Kg) randomly administration. Mean arterial pressure (MAP) and heart rate (HR) was assessed. Testosterone (T), 17β-estradiol (E2), troponin I, urea, creatinine, ALT, and AST were measured in blood samples, and geno- and cytotoxicity were evaluated by the micronucleus test. Values are expressed as the mean ± S.E.M, compared by ANOVA, followed by the post-hoc Tukey test. There was no change in MAP (SHAM: 106±2; SHAM+MT: 107±3; OVX: 106±7; OVX+MT: 107±3 mmHg), HR (SHAM: 339±13; SHAM+MT: 318±13; OVX: 340±15; OVX+MT: 337±9 bpm), and BJR sensitivity among the experimental groups. As shown in figure 1 BRS was impaired in OVX rats after MT treatment. MT treatment increase the value of T but not change E2 (SHAM 1.43±0.05, 43±3; SHAM+MT 1.38±0.03, 45±2; OVX 1.10±0.03, 15±2; OVX+MT 1.24±0.03ng/mL, 17±5pg/mL) as well as the other biochemical parameters, neither the micronucleus test (Table 1). Rats OVX+MT presented an increase in blood T, with no change in E2. These data suggest that MT as HRT improves BRS, with no lesion on kidney, liver and heart, and with geno- and cytotoxicity safety.

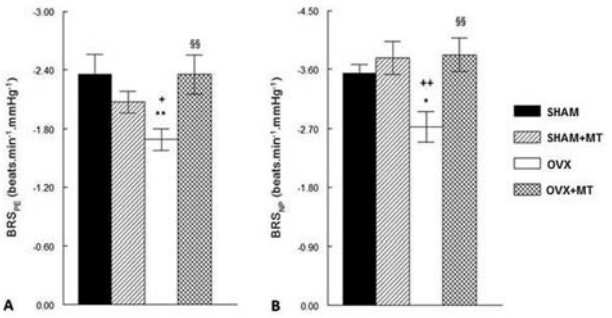

Figure 1: Baroreflex sensitivity (BRS) measured by phenylephrine (Panel A; BRSPE) or nitroprusside (Panel B; BRSNP) in conscious rat. SHAM: sham operated animals; SHAM+MT: sham operated rats plus methyl testosterone treatment; OVX: castrated animals; OVX+MT: castrated animals plus methyl testosterone treatment. Values are expressed as the mean ± S.E.M, compared by ANOVA, followed by the post-hoc Tukey test. **p<0.01 and *p<0.05 compared with SHAM group. ++p<0.01 and +p<0.05 compared with SHAM+MT group. §§p<0.01 compared with OVX group.

A hypothermic and hypometabolic state produced by A1 adenosine receptor activation in the nucleus of the solitary tract: implication for stroke

D. Tupone, C.J. Madden and S.F. Morrison

Nerurological Surgery, Oregon Health and Science University, Portland, OR, USA

The positive outcome that hypothermia contributes to neuroprotection following brain ischemia has stimulated recent clinical interest in the development of techniques to induce a hypothermic and hypometabolic state. Despite, the increased use of therapeutic hypothermia, the available induction techniques, employing various cold-exposure approaches rather than pharmacological methods, could be of limited utility in reaching an appropriate hypothermic state due to the activation of the central thermoregulatory responses that counteract the fall in temperature by reducing heat loss (cutaneous vasoconstriction) and increasing thermogenesis through brown adipose tissue (BAT) and shivering. Hibernating animals can reduce their energy expenditure by suspending both shivering and non-shivering thermogenesis, even in the face of marked falls in skin and core temperatures. In these species, activation of A1 adenosine receptors in the brain is thought to play a key role in triggering the torpor state. In the current studies, we investigated: 1) the potential for the A1 adenosine receptor agonist, N6-cyclohexyladenosine (CHA), to induce hypothermia in the rat (a non-hibernating species); 2) the pre-

cise thermo-effector mechanisms contributing to the fall in body temperature; 3) the brain circuits involved in the adenosine agonist-induced hypothermia; and 4) the effect of CHA-induced hypothermia on the outcome of ischemic stroke. In inactin-anesthetized (85mg/kg i.v.), Wistar rats, icv administration of CHA (10μl, 1mM) decreased core, skin and BAT temperatures, reduced expired CO2, heart rate (HR), BAT sympathetic nerve activity (SNA) and shivering EMG activity. In awake rats in a 15°C ambient, a similar icv injection of CHA decreased BAT temperature and induced a torpor-like state, in contrast to icv injection of saline vehicle which had no effect on BAT temperature or observed behavioral state. In urethane/chloralose anaesthetized rats, direct nanoinjection of CHA (60nl, 1mM) in the nucleus of the solitary tract (NTS) produced reductions in cold-evoked BAT SNA, BAT temperature, expired CO2 and HR concomitant with an increase of mean arterial pressure. These effects were reversed by local nanoinjection of muscimol (60nl, 1mM) and prevented by pretreatment of the NTS with an A1 adenosine receptor antagonist. We conclude that A1 adenosine receptor stimulation in the NTS produce hypothermia and torpor-like effect in the rat through inhibition of BAT and shivering thermogenesis. This pharmacological approach could provide the basis for induction of a rapid, sustained and controlled hypothermia, improving current methods for inducing hypothermia for neuroprotection following brain ischemia.

Effect of glucose-enriched drink on orthostatic tolerance in young African men

T.M. Abiodun, O.S. Michael, T.O. Usman and L.A. Olatunji

Department of Physiology, University of Ilorin, Ilorin, Kwara, Nigeria

Ingestion of glucose has been confirmed to lowers blood pressure in individuals with autonomic dysfunction (1). Whether glucose drink affects cardiovascular responses during orthostatic stress in young healthy individuals, particularly in Africans is not known. We therefore sought to investigate the hypothesis that glucose drink will reduce orthostatic tolerance in normal young African men. In a randomized controlled cross-over design, eleven men (19.8 ± 0.4 kg/m2; 22.4 ± 0.8yr) ingested nothing, water (250ml) and 30% glucose drink 10min before standing on three separate days. We measured supine and standing systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR) and blood glucose levels. Orthostatic tolerance was evaluated as the time to presyncope for the period of motionless standing or until presyncopal symptoms were observed (2) and syncope have been found to accounts for 1–3% of admissions to the emergency room (3–4). Throughout the first 60min of upright posture, 81.8%, 23.9% and 45.1% of 11 subjects experienced presyncopal symptoms when ingested nothing, water and 30% glucose drink, respectively. Water ingestion improves tolerance to orthostatic stress significantly while ingesting glucose drink significantly reduced orthostatic tolerance. Increased HR induced by standing was significantly improved, while the increase in SBP was attenuated when 30% glucose water was ingested. Conversely, increased DBP was not significantly affected by glucose drink. Ingestion of glucose drink led to a considerable increase in blood glucose level during orthostatic challenge when compared to when nothing or water was ingested. This study shows that glucose-enriched drink reduces orthostatic tolerance, and this is correlated with enhanced tachycardia and attenuated SBP response. The findings imply that glucose-enriched fluid may not be suitable for individuals predisposed to orthostatic intolerance.

3-Mercaptopyruvate sulfurtransferase is expressed in medulla oblongata and can be up-regulated by intrauterine cigarette exposure in neonatal rats

L. Nie[1,2], Y. Hu[1], X. Yan[1], M. Li[1], L. Chen[1], H. An[1], H. Zhou[1] and Y. Zheng[1]

[1]Department of Physiology, West China School of Preclinical and Forensic Medicine, Sichuan University, Chengdu, China and [2]Department of Physiology, School of Basic Medical Sciences, Ningxia Medical University, Yinchuan, China

Noxious substances released from burning cigarettes may cause hypoxia and neurotoxic effects that impede the development of the central nervous system, including brainstem. Our previous studies demonstrated that endogenous hydrogen sulphide (H2S) participate in regulation of respiration (Hu et al. 2008) and play roles in protection of medullary respiratory centres against injury caused by hypoxia (Pan et al. 2010, 2011) in medullary slices of neonatal rats. 3-Mercaptopyruvate sulfurtransferase (3MST) is one of three enzymes found to produce H2S in mammalian. The present study was conducted to investigate whether 3MST exists in the medulla oblongata and its expression can be affected by intrauterine cigarette smoke exposure in the neonatal rats. Sprague-Dawley pregnant rats were randomly divided into 2 groups, control group and cigarette smoke exposure group (n=8 for each). Cigarette smoke exposure rats were exposed to smoke for 60 min (2 cigarettes for 10 min, at an interval of 2 min, repeated 5 times) twice a day (starting at 09:00 and 16:00, respectively) during gds 7-20. The neonatal (P 1) offspring rats were used in the experimental observation. 3MST mRNA and protein expression in the medulla oblongata were analysed by RT-PCR (n=8) and Western blotting (n=8), respectively, and the levels of 3MST expression in the neurons of some medullary nuclei were examined with immunohistochemical technique (n=6). Values are means ± S.E.M., compared with independent-samples t-test. The results of RT-PCR and Western blotting were repeated 2 times, respectively. RT-PCR and Western blotting analyses showed that 3MST mRNA and protein were expressed

in the medulla oblogata in the control group and their expression were promoted in the group of intrauterine cigarette exposure of neonatal rats (1.00 ± 0.13 vs 1.51 ± 0.19 for mRNA, P<0.05; 0.20 ± 0.01 vs 0.43 ± 0.07, P<0.05). Immunohistochemical staining indicated that 3MST existed in the neurons of pre-Bötzinger complex, hypoglossal nucleus, ambiguous nucleus, facial nucleus and nucleus tractus solitarius in the control group and the mean optical densities of 3MST-positive neurons in all the nuclei mentioned above except for the nucleus tractus solitarius were significantly increased in the group of cigarette smoke exposure (values not shown, P<0.05). It can be concluded that 3MST exists in the neurons of medullary nuclei of neonatal rats and its expression can be upregulated by intrauterine cigarette exposure of the animals. These data preliminarily suggest that 3MST-H2S pathway may be involved in response of medullary neurons to injury induced by intrauterine cigarette exposure.

Identification of vagal preganglionic neurones that control ventricular contractility using transoesophageal atrial pacing (TAP) and spinal cord transection

A. Machhada[1,2], N. Marina[1], M.F. Lythgoe[2] and A.V. Gourine[1]

[1]Neuroscience, Physiology and Pharmacology, University College London, London, UK and [2]Medicine, University College London, London, UK

The role of the parasympathetic innervation of the left ventricle remains controversial, although there is evidence that vagus nerve stimulation decreases left ventricular contractility in vivo in the human and pig heart (1). The aim of this study was to identify the anatomical location of vagal preganglionic neurones that control ventricular contractility using an anaesthetised rat model. Male Sprague-Dawley rats (350–400g, n=6) were anaesthetised with pentobarbitone sodium (induction 60 mg/kg i.p.; maintenance 15–20 mg/kg/hr i.v.) and artificially ventilated. The left femoral artery and both femoral veins were cannulated for the measurement of arterial pressure and infusion of fluids and drugs. The right carotid artery was cannulated for left ventricular pressure recording using a Millar pressure probe. Lead II ECG was also monitored. The animal was placed in a stereotaxic frame and the dorsal surface of the brainstem was exposed. To activate vagal preganglionic neurones, an excitatory neurotransmitter glutamate (10mM, 40 nl, pH 7.4) was microinjected into three discrete locations (separated by 0.5 mm) along the rostro-caudal extent of the left and right dorsal motor nuclei of the vagus nerve (DVMN). Responses were measured in a second group (n=3) with transoesophageal atrial pacing (TAP) to abolish chronotropic changes. A third group (n=2) underwent a spinal transection at C1 to remove sympathetic influences followed by gelofusine and vasopressin infusion to maintain mean arterial blood pressure at ~100mmHg. Values are means ± S.E.M., compared by two tailed paired student's t-test. Glutamate microinjections into the most caudal part of the left DVMN caused a significant (p<0.01) decrease in dP/dtmax (-1635 ± 301 mmHg/s), dP/dtmin (1527 ± 322 mmHg/s), mean arterial blood pressure (-27±6 mmHg) and heart rate (-15 ± 4 bpm). Glutamate had no effect on cardiovascular variables after microinjections into the rostral part of the left DVMN or after delivery into the right DVMN. With TAP, Glutamate microinjections into the most caudal part of the left DVMN caused a significant (p<0.05) decrease in dP/dtmax (-1790 ± 279 mmHg/s), dP/dtmin (1270 ± 94 mmHg/s), mean arterial blood pressure (-12±2 mmHg) and end systolic pressure (-16±2 mmHg). Responses elicited following activation of the left caudal DVMN were present after C1 transection, although they were significantly reduced by ~50%. Thus, parasympathetic control of ventricular contractility is provided by a group of vagal preganglionic neurones located in the caudal part of the left DVMN. The role of ventral groups of the brainstem vagal preganglionics (in the nucleus ambiguus) has yet to be determined.

Acetylcholine analogue mimics the protective effect of cardiac vagal nerve stimulation on ventricular fibrillation threshold

M. Kalla, M. Chotalia, G. Hao, D.J. Paterson and N. Herring

Department of Physiology, Anatomy & Genetics, University of Oxford, Oxford, Oxfordshire, UK

Purpose: Implantable cardiac vagus nerve stimulators are a promising new treatment for heart failure, which may improve both quality of life and ejection fraction[1]. Animal studies also suggest an anti-fibrillatory effect of stimulating the cardiac vagus nerve that may involve a nitric oxide (NO) dependent pathway[2], although the exact site of action in the cardiac-neural axis is still debated. We investigated whether carbamylcholine (CCh), a stable analogue of the neurotransmitter acetylcholine, can mimic the effect of vagus nerve stimulation on ventricular fibrillation threshold (VFT), and whether this mechanism is dependent on muscarinic receptor stimulation and/or generation of NO.

Methods: Experiments conformed to "Principles of laboratory animal care" (NIH Publication No. 85-23, revised 1996) and the Animals (Scientific Procedures) Act 1986 (UK). Hearts were isolated from adult male Sprague Dawley rats (300-350g) and Langendorff perfused with tyrode solution in constant flow mode (11ml/min, baseline perfusion pressure 54.75±7.27mmHg, LV developed pressure 77.5±5.6mmHg, heart rate 282.8±3.4bpm, n=6). VFT was reproducibly determined by pacing at a fixed cycle length (150msec) for 20 beats followed by a 5sec 50Hz burst at increasing current amplitude (mA) until sustained VF was induced. VF was cardioverted to sinus rhythm by perfusion with 1ml of high concentration potassium chloride solution (50mmol/L). VF could be induced on three successive occasions without a significant change in VFT (n=6). All data is presented as mean±SEM.

Results: CCh (200nM, n=9) significantly (p<0.05) reduced baseline heart rate from 292±8 to 224±6bpm). Independent of this heart rate change, CCh also caused a significant increase in VFT in paced hearts similar to vagus nerve stimulation that could be reversed with washout of the drug (control 1.5±0.25 vs. CCh 2.4±0.4 mA vs. wash out 1.14±0.18 mA). The effect of CCh on VFT was completely abolished by atropine (10μM,

n=4) or the non-specific competitive NOS inhibitor N-omega-nitro-L-arginine (L-NA 100μM, n=6). The inhibitory action of L-NA could be reversed by the addition of the NOS substrate L-arginine (5mM). The NO donor sodium nitroprusside (SNP 10μM, n=8) mimicked the effects of CCh and significantly increased VFT (baseline 1.4±0.125 vs, SNP 2.9±0.83 vs. wash out 1.18±0.23 mA).
Conclusions: These data demonstrate that the protective effect of cardiac vagal nerve stimulation on VFT is mimicked by CCh in the rat. Muscarinic receptor stimulation and the generation of NO appear to be involved in mediating this protective effect, presumably via a pre-synpatic and post synaptic coupled pathway.

Site specific impairment of the norepinephrine transporter in the hypertensive rat

J. Shanks, S. Mane, R. Ryan, D. Li and D. Paterson

DPAG, Oxford Univeristy, Oxford, UK

Hypertension is associated with an increase in cardiac sympathetic transmission, although the exact mechanism underlying this is unknown. Enhanced intracellular calcium transients and cardiac norepinephrine (NE) release have been reported in pre-hypertensive and hypertensive spontaneously hypertensive rats (SHR) compared to normotensive controls (WKY: Wistar-Kyoto). This neural phenotype might also result from defective NET-1 transport (uptake-1). The dynamic kinetics of NET were monitored temporally using a novel fluorescent assay (NTUA) of the transporter in cultured postganglionic sympathetic neurons from the cardiac stellate ganglion, the superior cervical ganglion, the celiac ganglia/superior mesenteric ganglia, and the renal sympathetic chain. All NET activity was blocked by desipramine. NET rate was significantly impaired in stellate sympathetic neurons from the pre-hypertensive SHR compared to age matched normotensive WKY (4 week SHR, n=24, WKY, n=21, P<0.05, unpaired t test). A similar response was seen in hypertensive SHR cardiac sympathetic neurons (16 week SHR, n=20, WKY, n=19, P<0.05, unpaired t test). However, no reduction in transporter rate was observed at either age in the other major non-cardiac sympathetic ganglia. NET is modulated by receptor coupled pathways. In particular brain naturitic peptide (BNP) plasma levels are dramatically increased during cardiac stretch, volume overload and left ventricular dysfunction. Interestingly they have also been linked to regulating cardiac sympathetic neurotransmission since BNP reduces intracellular calcium transients and transmitter release. We found BNP significantly reduced the NET transporter in the WKY (S1/S2 ratio control, n=18, BNP 250nM, n=25, P<0.0001, unpaired t test). Taken together this could allow NE to stay at appropriate levels in the synapse. Whether this pathway is dysregulated in the SHR remains to be determined.

Peripheral cardiac sympathetic dysfunction in the pre-hypertensive spontaneously hypertensive rat

J. Shanks, S. Manou-Stathopoulou, C. Lu, D. Li, D. Paterson and N. Herring

DPAG, Oxford Univeristy, Oxford, UK

The adult spontaneously hypertensive rat (SHR) has increased peripheral cardiac sympathetic activity compared to Wistar Kyoto (WKY) controls. Recent studies in 4 week old pre-hypertensive SHRs have also shown increased calcium transients1, and a reduction in NET activity2 in isolated stellate ganglion neurons compared to age matched WKYs. The functional significance of these changes in terms of NE release and change in heart rate during sympathetic stimulation is unknown. We therefore hyposthesised that peripheral sympathetic responsiveness in the SHR at 4 weeks of age would be exaggerated compared to the WKY. Ventricular weight/body weight ratios (WKY: n=7, SHR: n=8) and mean arterial pressure (WKY: n=20, SHR: n=19) measured via the left carotid artery (under 2% isoflurane) demonstrated that SHRs were without left ventricular hypertrophy and were normotensive at this age compared to WKYs. However, a small but significant (p<0.05, unpaired student t-¬test) tachycardia is observed in the young SHR in vivo (WKY: 298±11 bpm, n=20 vs. SHR: 335±8 bpm, n=19) although the heart rate response to vagus nerve stimulation (3Hz and 5Hz, 30sec, 20V, 1msec) is unchanged compared to the WKY (WKY, n=10, SHR, n=12). In an isolated organ bath atrial preparation with intact right stellate ganglion (37±0.5oC) there was a greater heart rate response to stellate stimulation (5 and 7Hz, 30sec, 20V, 1msec) in SHRs compared to WKYs (SHR, n=9, WKY, n=7). There was also a significantly greater release of 3H-NE to field stimulation (5Hz, 20V, 1msec) of right atria (n=7 for both groups) and higher plasma levels of the sympathetic co-transmitter neuropeptide Y sampled from the right atria (measured with ELISA, n=12 for both groups). The difference in 3H-NE release between the young SHR and WKY could be normalized by the NET inhibitor desipramine (1μM, SHR n=10, WKY n=8) but not the α2 receptor antagonist yohimbine (1μM, SHR n=7, WKY n=8). Increased cardiac sympathetic neurotransmission driven by a larger neuronal calcium transient and reduced NE reuptake may therefore represent an early marker in the development of hypertension and contribute to a resting tachycardia in vivo.

Exercise training improves cardiac autonomic imbalance following physical activity

T. Masters, P. Barrow and J. Fletcher

School of Applied Science, University of Wolverhampton, Wolverhampton, UK

Low levels of cardiac vagal tone have been shown to be a predictor of future cardiac dysfunction and mortality[1]. Post-exercise recovery is significant as strenuous physical activity is associated with an increased risk of cardiac events for a period of around 1 hour[2], thought to be linked to poor return of vagal tone[3].

Delayed parasympathetic return and prolonged sympathetic activity following exercise may have important medical implications. However, improvements in cardiac autonomic control as a result of exercise training may attenuate the delay or imbalance[1]. This study aims to examine how endurance training in middle-aged subjects alters the autonomic recovery following acute exercise.

Baseline ECG was recorded in 15 healthy human subjects (aged 36-49 years, 5 male, 10 female) (ADInstruments Powerlab) during paced breathing (0.25 Hz). Subjects then completed cycle ergometer exercise comprising of a 2 minute warm-up, 10 minutes at 75% age-predicted maximum HR (Karvonen formula), and 1 minute of recovery. Recordings were then taken at 0, 15, 30, 45, and 60 minutes post-exercise. This procedure was then repeated following 12 weeks of endurance exercise training (13 kilocalories/kg/week). Heart rate variability (HRV) and QT measures were assessed offline (Chart, ADInstruments). Changes from baseline were assessed by paired t-test. Values are presented as mean ±SD.

Training improved the rate of recovery of HRV indices of cardiac vagal tone, with the root mean square of successive R-R interval differences (RMSSD) recovering to within baseline values ($P>0.05$) 30 mins post-exercise, whereas pre-training (PRE) time to recovery was 60 mins. High-frequency power took 45 mins to recover PRE, and 30 mins post-training (POST). HR remained elevated above baseline for 45 mins PRE (mean 69 ± 6.3 BPM at baseline, 73.5 ± 8 at 45 mins, $p<0.05$), and 60 mins POST (mean 65.3 ± 11 at baseline, 66.7 ± 11 at 60 mins, $p<0.05$), potentially demonstrating on-going and concomitant sympathetic activity. Markers of this are much more difficult to derive however. The low/high frequency power (LF/HF) ratio remains elevated ($p<0.05$) for 30 mins PRE, and 45 mins POST, suggestive of sympathetic activity. QT interval has been suggested to reflect cardiac sympathetic influences[4]. This remained significantly lower than baseline ($p<0.05$) at all time points PRE and POST, but only at 15 mins PRE and POST when corrected for heart rate using the Bazett formula.

These data suggest that sympathetic activity remains elevated for a considerable period post-exercise, even when parasympathetic markers have recovered. This underlying sympathetic activity along with depressed recovery of vagal tone also may be contributing to the period of increased cardiac risk after exercise. However, neither LF/HF ratio nor QT interval appeared to provide any strong indication of this.

Tachycardia and increased baroreflex sensitivity in mice with conditional deletion of GalphaO in the pre-sympathetic area of the brainstem

R. Ang[1], L. Birnbaumer[2], A.V. Gourine[1] and A. Tinker[3]

[1]University College London, London, UK, [2]National Institute of Environmental Health Sciences (NIEHS), Research Triangle Park, NC, USA and [3]William Harvey Heart Centre, Queen Mary University of London, London, UK

Introduction

Inhibitory G proteins are known to mediate vagal influences on the heart. However, their role in the central nervous mechanisms of cardiovascular control remains unclear. Previous data have shown mice with global deletion of GalphaO (GαO) exhibit tachycardia, loss of diurnal variation and fairly selective loss of LF component of HRV with preserved total power suggestive of increased sympathetic tone, likely to be of central origin (1). We hence hypothesised that in mice, conditional deletion of GαO in the rostral ventrolateral medulla oblongata (RVLM), which contains sympathoexcitatory (pre-sympathetic) neurones, will have a significant impact on autonomic cardiac reflexes.

Methods

Using the Cre/LoxP approach, GαO was deleted in the RVLM of GαO flx/flx mice aged between 8 to 12 weeks (CKO) by stereotaxic delivery of an adenoviral (AdV) vector to trigger expression of Cre and GFP driven by a CMV promoter. Littermates injected with a GFP-only-expressing AdV served as controls. After 1 week, these mice (under urethane anaesthesia, 1.3 g/kg IP) were given alternating doses of phenylephrine (0.5-2mg/kg, IV) and sodium nitroprusside (0.1-1mg/kg, IV) and the obtained heart rate (HR) and blood pressure (BP) data were used to individually fit sigmoidal baroreflex curves (Figure 1). The animals were then sacrificed and transgene expression was confirmed histologically.

Results

Compared to controls, CKO mice (n=4 in each group) were tachycardic (median minimum HR 608 bpm, IQR 604-639 vs 580 bpm, IQR 576-598) and displayed an increased baroreflex gain (mean BR gain 0.65 bpm/mmHg, 95% CI 0.46-0.83 vs 0.35 bpm/mmHg, 95%CI 0.33-0.37, $p=0.03$ by unpaired t-test).

Conclusion

Mice with conditional deletion of GαO within the sympathoexcitatory circuits of the brainstem display enhanced baroreflex sensitivity consistent with an increased sympathetic tone. This suggests an important role for GαO-mediated signalling in the central nervous inhibitory mechanisms controlling sympathetic outflow.

Construction of asthma susceptivity model by conditional deletion of integrin beta 4 on airway epithelial cell

C. Liu, X. Qin, H. Liu, Y. Xiang, X. Qu and Y. Wang

Central South University, Changsha, China

Integrin β4 was found downregulated on the airway epithelial cell of asthma patients which induce the damaged anti-oxidation ability, inhibited wound repair ability and suppressed Th1 differentiation after OVA stress. These results strongly suggested that decreased expression of integrin β4 may relate to asthma susceptibility. To verify this correlation, in this paper, we construct a model that integrin β4 was conditional knocked out by Tetracycline. Integrin β4 floxed heterozygous mice have been constructed by transgene technology. Cre-CCSP-(otet) double transgenic mice was constructed by double crossing CCSP-rtTA line and (otet)-Cre line. Then floxed integrin β4 Cre-CCSP-(otet) triple transgenic mice was comstructed by crossing Cre-CCSP-(otet) line and integrin β4 floxed mice. By RT-PCR and immunohistochemistry detection, our results showed that integrin β4 expression was deleted successfully after Tetracycline induction in floxed integrin β4 Cre-CCSP-(otet) triple transgenic mice.

Early changes in sympathetic nervous system activity following coronary artery ligation in the in situ rat

L.M. Passamani[2,1], A. Abdala[1], J. Mill[2], K. Sampaio[3] and J. Paton[1]

[1]Pharmacology and Physiology, University of Bristol, Bristol, Avon, UK, [2]Physiological Sciences, Federal University of Espírito Santo, Vitória, Espírito Santo, Brazil and [3]Pharmacological Sciences, Federal University of Espírito Santo, Vitória, Espírito Santo, Brazil

Aims: Sympathetic nervous system (SNS) over activity post myocardial infarction (MI) has been implicated in morbidity and mortality. The time course and degree of sympathetic activation and loss of cardiac parasympathetic tone post MI remain unclear in rats. Our aim was to investigate the basal sympathetic activity and its reflex regulation immediately following ligation of the left anterior descending coronary artery (LAD) in the rat. Methods and Results: Experiments were performed in an in situ unanaesthetized decerebrated working heart-brainstem preparation (Paton, 1996) of Wistar rats (60-100g). After baseline recordings of phrenic (PNA) and thoracic sympathetic nerve activities (tSNA), heart rate (HR), ECG and perfusion pressure (PP), either occlusion of the LAD was performed or a sham operation. The myocardial area at risk was assessed post-hoc with Evans Blue dye (0.5%) and was 36.3±1.1% of the left ventricle. One hour after LAD there was: (a) a higher level of tSNA and HR in the LAD rats (from 4.1±0.2 to 6.8±0.5μV, from 343±13 to 352±13bpm, n=21, P<0.01) versus a sham group (from 3.7±0.2 to 3.8±0.3μV, from 321±10 to 326±12.bpm, n=19, P>0.05) (paired t-Test). No changes in PP and respiratory rate (RR) were found between the groups; (b) a greater sympathoexcitatory response to peripheral chemoreceptor stimulation (see Table 1; n=7 each group, P<0.01, unpaired t-Test). No differences in peripheral chemoreflex evoked changes in PP, RR and HR were observed;(c) an elevated pressor response to a bolus injection of phenylephrine (30μg, i.a.) and depressed sympathetic (non-cardiac) baroreflex gain (see Table 2; n=6 each group, P<0.01, unpaired t-Test). The baroreflex bradycardia was unaffected; (d) An elevated cardiac sympathetic tone as assessed with atenolol (20μg/ml) showing a greater fall in HR in LAD rats (-108±8bpm, n=7) compared to sham rats (-82±7bpm; n=5, P<0.05, unpaired t-Test). Cardiac vagal tone was unaffected by LAD. Conclusion: The SNS is activated within minutes after myocardial infarction yet cardiac vagal tone appears unaffected. The mechanisms that produce these initial alterations remain to be investigated.

Table 1: Peripheral chemoreceptor reflex response 60 min following LAD

NaCN (0.03%)	Δ Sympatho-excitation (%)		Δ Bradycardic (bpm)		Δ Respiratory rate (%)		Δ Pressor (mmHg)	
	Sham	LAD	Sham	LAD	Sham	LAD	Sham	LAD

Investigating changes in calcium homeostasis caused by a cardiotoxic drug

F.E. Mason[1], D.A. Eisner[1], M.J. Morton[2], C.E. Pollard[2] and A.W. Trafford[1]

[1]Institute of Cardiovascular Sciences, University of Manchester, Manchester, UK and [2]AstraZeneca R&D, Macclesfield, UK

Intracellular calcium (Ca) dynamics are finely tuned in the healthy heart. This homeostasis may be interrupted during a response to a cardiotoxic substance, leading to contractile dysfunction and arrhythmogenic activity. Here we aim to investigate the changes in cellular Ca homeostasis occurring upon acute application of the cardiotoxic drug clozapine (atypical anti-psychotic). Clozapine use has previously been associated with cases of myocarditis, arrhythmia and sudden cardiac death. Such in vitro analysis may highlight important new drug-screening targets for the future.

Ventricular myocytes were isolated from male rats (200-250g). Myocytes were perforated-patched and stimulated under voltage clamp control (1mM external Ca), inducing systolic Ca transients. Ca handling parameters were measured both in control conditions and upon acute application of 10μM clozapine. Cytosolic Ca was quantified by Ca-sensitive indicators fluo-3 or fura-2. 10mM caffeine was applied to discharge the sarcoplasmic reticulum (SR) and quantify SR Ca content. Changes in cytosolic Ca extusion (SERCA – sarco-endoplasmic reticulum ATP-ase, NCX – sodium-calcium exchanger) were calculated by comparing the decay rate of Ca transients. The protocol was repeated in cells from a phospholamban knockout mouse model (PLB-KO) in order to assess whether any effects were PLB-dependent. In a protocol to induce spontaneous SR Ca release and waves, external Ca was elevated to 5mM; immediately after a wave 10mM caffeine was applied to discharge the SR. Threshold for spontaneous Ca release was calculated by combining SR content value with the amount of Ca leaving the cell on the wave. Statistical tests used were one way RM ANOVA and student's t-test. Data presented as mean ±SEM. Clozapine reduced mean Ca transient amplitude by 47.7±2.5% ($p<0.001$ n=19) and peak L-type Ca current (ICaL) by 49.7±1.8% ($p<0.001$ n=20). SR content was decreased by 15.5±4.2% ($p=0.004$ n=9), SERCA activity (rate constant) by 33.9±2.6% ($p<0.001$ n=16) and NCX rate constant by 16.6±3.8% ($p=0.005$ n=6). The effect of clozapine on SERCA persisted in PLB-KO indicating that the effect on SERCA is not PLB-dependent. Results suggest that clozapine does not significantly alter the threshold for spontaneous SR Ca release and waves.

Acute application of clozapine to isolated myocytes causes several changes to Ca dynamics, most noticeably a reduction in peak ICaL. It remains unclear if or how the observed effects on Ca handling contribute to the clinical cardiotoxicity of clozapine. One possibility is that the effects on ICaL predispose to refractory heterogeneity across the heart. We also speculate that in the clinical setting there may be accumulation of clozapine in cardiac myocytes over time, supported by our results that the effect of clozapine on systolic Ca transient amplitude is not fully reversible upon wash-out of the drug.

Reduced heart rate in left lateral decubitus position in healthy adults

K. Sasaki, M. Haga, H. Sato, Y. Kimura, E. Kanno and R. Maruyama

Health Sciences, Tohoku University Graduate School of Medicine, Sendai, Japan

Recently, some studies have demonstrated enhanced cardiac vagal nerve activity during the right lateral decubitus position in patients with chronic heart failure and coronary artery disease (Fujita *et al*, 2000 and Yang *et al*, 2008). However, there has been little research on the autonomic nervous system and circulation in the lateral decubitus position for normal healthy volunteers. In the present study, we compared the impact of the left and right lateral decubitus positions and the supine position on heart rate variability (HRV), including circulatory regulation. We performed electrocardiographic measurements in 58 healthy volunteers aged 23.0 ± 3.2 (mean ± SD) years. Further, a skilled cardiologist conducted echocardiographic assessment of the inferior vena cava (IVC) in each posture for 3 of 58 volunteers. A male patient with situs inversus totalis (63 years) also participated in this study. Subjects randomly maintained each lateral position at an angle of over 45° for 10 min after remaining in the supine position. Postural change was performed manually by two trained researchers. The measured data is represented as mean ± SEM. A value of $p < 0.05$ is considered statistically significant. No statistically significant differences were observed either in low frequency (LF) or high frequency (HF) HRV or in their ratio (LF/HF) using multiple comparison among three positions. However, the heart rate (HR) was significantly lower in the left lateral position than in the supine position (61.5 ± 0.9 bpm vs. 64.7 ± 1.1 bpm, respectively, $p < 0.05$, multiple comparison: Dunnet). The shape of the IVC in the supine position appeared oval in echocardiogram, and became more like a plane and a circle while in the left and right lateral decubitus positions, respectively. Both the diameter and area of IVC decreased, and hence, blood flow in IVC became more rapid in the left lateral position compared to the supine position. The echocardiographic evaluation also revealed that the two lateral decubitus positions caused different changes in circulation in the IVC. Unlike the 58 healthy subjects, the patient showed a decrease in HR in the right lateral position compared with the supine position (52.2 ± 0.3 bpm vs. 55.7 ± 1.5 bpm, respectively, $p < 0.05$, paired t-test). The HRV findings suggest that the two recumbent positions have no influence on the autonomic nervous system in healthy volunteers. However, the reduction in HR in the left lateral position may be affected by anatomical changes, especially in the shape of the IVC.

Higher risk of hypertension and autonomic nervous system imbalance in Mongolian young adults with low birth weight compared to Japanese counterparts

S. Bao, W. Gumula, E. Takahashi, M. Dendo, K. Sasaki, E. Kanno and R. Maruyama

Health sciences, Tohoku University Graduate School of Medicine, Sendai, Japan

Objective: Low birth weight (LBW) was confirmed as a risk of high blood pressure in later stages of life (1, 2). Although, a number of studies have shown that Mongolian people have a higher prevalence of hypertension compared to other ethnic groups (3), including the Japanese, the underlying mechanism is still unclear. The purpose of this study was to identify whether there are differences in the relationship of LBW and the risk of hypertension between Japanese and Mongolian.
Method: We performed electrocardiographic measurements in 13 Japanese and 16 Mongolian healthy volunteers aged between 19 and 33 years. We measured blood pressure (BP) and heart rate variability (HRV) at resting condition and postural change for both Japanese as well as Mongolian volunteers with LBW and normal birth weight (NBW) [LBW: 2,065 ± 179.7 g; NBW: 3,044 ± 141.2 g for Japanese vs LBW: 2,500 ± 131 g; NBW: 3,360 ± 67 g for Mongolian], respectively. All the data are expressed as mean ± SE. Student t-test and simple linear regression analysis were performed to compare the two variables. One-way repeated measures ANOVA were also performed to identify the influences of postural change.
Results: In the resting condition, heart rate (HR), BP, high frequency (HF), the ratio of low frequency to high frequency (LF/HF) showed no differences between LBW group and NBW group in the Japanese volunteers. On the other hand, HR, LF/HF were inversely related with birth weight (HR: $r = -0.518$, $p < 0.05$; LF/HF: $r = -0.647$, $p < 0.01$) in Mongolian volunteers. Japanese LBW group showed a significant increase in HR ($p < 0.05$) from supine to sitting position. However, there was no significant increase in HR for Mongolian LBW group. NBW group in both Japanese and Mongolian showed significant decrease in HF after postural change. While the Japanese LBW group showed a significant increase ($p < 0.05$) in LF/HF immediately after sitting position, the Mongolian counterparts did not show any such increase.
Conclusion: Although, there was no relationship between birth weight and BP in the Japanese young adults who participated in the present study, the Mongolians showed an inverse correlation of birth weight with resting HR and sympathetic activity. In Mongolian LBW group, no significant increase in HR, sympathetic activity and decrease in parasympathetic nervous activity were observed after postural change. These results support that LBW is associated with increased sympathetic activity and reduced baroreflex sensitivity in young adults. We conclude that Mongolian young adults have a higher risk of hypertension compared to their Japanese counterparts.

Effects of estrogen replacement on blood pressure elevation induced by chronic intermittent hypoxia in ovariectomized rats

S. Omoto[1], S. Tazumi[1], R. Yoshida[1], H. Nagai[2], K. Yoshida[2], R. Kudo[3], K. Hatake[3] and K. Morimoto[1]

[1]Department of Environmental Health, Faculty of Life Science and Human Technology, Nara Women's University, Nara, Nara, Japan, [2]Department of Forensic Medicine, Graduate School of Medicine, University of Tokyo, Bunkyo-ku, Tokyo, Japan and [3]Department of Legal Medicine, Nara Medical University, Kashihara, Nara, Japan

Clinical studies suggest that sleep apnea causes systemic hypertension. There is gender specificity in the incidence of sleep apnea. Premenopausal women have a lower occurrence of sleep apnea, whereas in postmenopausal women the incidence of sleep apnea is same as in males. Therefore, female sex hormone, estrogen, may protect women against the sleep apnea-induced hypertension. Intermittent hypoxia (IH) is used to mimic the arterial hypoxemia that occurs during sleep apnea. We examined whether chronic estrogen replacement affects blood pressure (BP) responses to IH in ovariectomized rats. Female Wistar rats aged 9 wk were ovariectomized and implanted with radiotelemetry devices for BP and heart rate measurements. After 4 wk, the rats were assigned either to a placebo-treated (Pla; n=15) group or a group treated with 17β-estradiol (E2; n=15) subcutaneously implanted with either placebo- or 17 β -estradiol (2.5 mg/90-day release) pellets. The atmosphere in IH chamber was controlled by the electronically regulated solenoid switches in a two-channel gas mixer, which gradually lowered oxygen in the chamber over 90 s from 21% to 4% O_2. Chamber ware rapidly flushed with compressed air for the following 90 s to restore O_2 to 21%. Rats were exposed to 20 cycles/h of IH or air-air for 8 h/day during the light phase (9:00-17:00) for 14 days. In the day after the series of IH exposure, mesenteric arteries were dissected from IH-exposed or control rats euthanized by overdoses of pentobarbitone. Using the arteries contracted with 3×10^{-6} M phenylephrine, we test relaxation responses to acetylcholine (Ach, 10^{-8}-10^{-5} M) under inhibitions of endothelium-dependent vasodilators. The expression of endothelial nitric oxide synthase (eNOS) in the mesentery was examined by Western blot analysis. After 7 days, resting mean arterial pressure (MAP) was significantly elevated in IH rats of the Pla and E2 groups similarly during the light phase (IH-phase). On the other hand, during the dark phase (non-IH phase), only the Pla group exhibited the MAP elevation on day 7. However, the MAP in the E2 group was increased to the same level in the Pla group during light or dark phase on day 14. Sensitivity of Ach-induced endothelium-dependent NO (ED_{50}) in mesenteric arteries was higher in the E2 group than that in the Pla group of IH rats. In addition, Western blot analysis showed that eNOS expression in mesentery was increased in the E2 group compared with the Pla group. This study suggests that estrogen replacement delayed the development of IH-induced hypertension in non-IH phase, at least partly, though enhancement in NO sensitivity in mesenteric arteries and overexpressed mesenteric eNOS in ovariectomized rats.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC071

TRPV1 blockade restores the high-pressure baroreflex control of renal sympathetic nerve activity in cisplatin induced renal failure rats

M.H. Abdulla[1], M. Duff[1] and E.J. Johns[1,2]

[1]Physiology, University College Cork, Cork, Ireland and [2]Allianze University, College of Medical Sciences, Penang, Malaysia

Renal failure and injury are associated with inflammatory responses within the kidney which could be mediated through transient receptor potential vanilloid type 1 (TRPV1) receptors. This study investigated whether TRPV1 receptors contribute to the modulation of high-pressure baroreceptor regulation of renal sympathetic nerve activity (RSNA) in cisplatin induced renal failure rats. Wistar rats (300-350g) were divided into a renal failure (RF, n=7) or control (C, n=7) group which received IP either cisplatin (5mg/kg) or saline (0.9% NaCl), respectively, 4 days before the acute study. Rats were anaesthetised with chloralose:urethane mixture (1ml, 16.5:250mg/ml, IP). Cannulae were inserted into the right femoral artery, for mean arterial pressure (MAP) and heart rate (HR) measurement, and vein for saline (3ml/h) infusion. The right kidney was exposed and a small cannula inserted 4.5mm into the rostral pole of the kidney to lie at the corticomedullary border for intrarenal infusion of saline or a TRPV1 blocker capsazepine (CPZ). The left kidney was exposed, a renal sympathetic nerve bundle was dissected and sealed onto recording electrodes. After 2h stabilisation, baroreflex gain curves were generated using IV phenylephrine and sodium nitroprusside (50μg/kg/min). Saline (1ml/h) was infused into the right kidney 20min before, and during the first baroreflex gain curve was generated and then CPZ (5μg/ml) was infused (1ml/h) for 20min before, and during the second baroreflex challenge 2hr after the first baroreflex curve. The animal was euthanized at the end of the experiment and the background noise obtained. Data, mean±SEM were compared using t-test with significance at $P<0.05$. In C, the MAP, HR and RSNA values measured during CPZ infusion were not different from their respective values before CPZ (84±5 vs. 83±5 mmHg, 405±16 vs. 399±16 bpm, 0.68±0.15 vs. 0.65±0.14 μV.s, respectively). Similarly, in RF, the MAP, HR and RSNA were similar to their respective values before CPZ (94±5 vs. 94±5 mmHg, 379±12 vs. 382±10 bpm, 0.82±0.19 vs. 0.75±0.16 μV.s, respectively). In RF, the slope of the baroreflex curve of RSNA following saline infusion was significantly smaller than C (RF vs. C; 0.09±0.01 vs. 0.15±0.02, $P<0.05$). The intrarenal infusion of CPZ in C had no effect on the slope of the baroreflex curve (CPZ vs. Saline; 0.14±0.01 vs. 0.15±0.02). However, in RF, the slope of the baroreflex curve increased significantly following CPZ (CPZ vs. Saline; 0.17±0.02 vs. 0.09±0.01, $P<0.05$). These findings demonstrate that normally TRPV1 receptors have little influence on the baroreflex gain curves. However, in renal failure there is an attenuation of the sensitivity of the baroreflex gain curve which is mediated via TRPV1 receptors as it can be normalised by blockade of TRPV1 receptors.

The carotid body is crucial for the full development of renovascular hypertension in rats

W. Pijacka, F.D. McBryde, A.P. Abdala, E.B. Hendy, P. Marvar and J. Paton

Physiology and Pharmacology, University of Bristol, Bristol, UK

We have shown recently that carotid sinus denervation (CSD) reduced arterial pressure (AP) in spontaneously hypertensive rats (SHR) but was without effect in normotensive Wistar rats. It remains unknown whether this anti-hypertensive effect is specific to the SHR. However, since the peripheral chemoreflex is sensitised in the Goldblatt (2 kidney, 1 clip; 2K1C) renovascular hypertensive model, we have tested whether established 2K-1C hypertension can be ameliorated by CSD.
Under ketamine/medetomidine anaesthesia (75mg/kg + 0.5mg/kg, IP), the left renal artery of 6 week old Wistar rats was partially occluded with a silver clip. At 11 weeks of age, rats were instrumented to record AP telemetrically, and after a 7 day baseline recording underwent CSD or Sham surgery. Prior to CSD/Sham surgery, AP rose steadily during baseline at 1.0±0.5 mmHg/day. This continued in Sham (+1.3±1.0 mmHg/day) but not CSD (-0.3±0.9 mmHg/day). Thus, at 14 weeks of age AP was unchanged from baseline in CSD rats (183±16 vs. 182±17 mmHg), but had continued to increase in Sham rats (201±18 vs. 210±21mmHg). Spontaneous baroreflex gain increased in CSD (-1.16±0.16 vs. -1.25±0.15 bpm/mmHg) but not Sham (1.1±0.09 vs. 1.0±0.12 bpm/mmHg). Reductions in low (6.3±0.5 vs. 6.0±0.8 mmHg2) and very low frequency (2.8±0.5 vs. 1.8±0.2 mmHg2) spectral power of systolic AP were seen in CSD but not Sham, suggesting sympathoinhibition. In addition, we have observed a reduction in macrophage infiltration in the brainstem after CSD in 2K1C rats, a response not observed in Sham animals. Using metabolic cages, we are now assessing any alterations of CSD on renal function in 2K1C rats and comparing with a Sham group. Preliminary data indicate that CSD improves glomerular filtration rate. We will present these data in full at the meeting.
In conclusion, CSD appears to stunt the continued increase AP in 2K-1C rat. The mechanisms for this include: sympathoinhibition, improved baroreflex gain and renal function as well as reduced systemic inflammation.

PCC073

Chronic inhibition of acetylcholinesterase activity improves the sympathovagal balance during the development of hypertension in spontaneously hypertensive rats (SHR)

R.M. Lataro, C.A. Silva, R. Fazan and H.C. Salgado

Physiology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

The autonomic imbalance in experimental models of hypertension is characterized by an increase in sympathetic and decrease in parasympathetic function. While sympathetic overactivity has received most of the attention, the same appraisal has not been given to the decrease in parasympathetic function. Therefore, it was investigated whether an increase in the availability of acetylcholine will improve the sympathovagal balance during the development of hypertension in SHR. To accomplish this, it was performed the blockade of central acetylcholinesterase with donepezil (DON), a compound that crosses the blood-brain barrier, and also pyridostigmine (PYR), a compound which does not cross the blood-brain barrier, acting particularly in the peripheral synaptic cleft. Thus, it was investigated the chronic effect (16 weeks) of DON or PYR on the following variables: arterial pressure (AP); heart rate (HR); vagal tone; AP and pulse interval (PI) variability in time and frequency domain; plasma norepinephrine (NE) and cardiac function. Acetylcholinesterase blockade started when SHR were 5 weeks old, receiving DON (1.5 mg/kg/day) or PYR (2mg/kg/day) given by osmotic minipump. After 16 weeks, femoral AP was recorded in conscious state and atropine provided the vagal tone, while the combined administration of atropine plus propranolol provided the intrinsic HR (iHR). Cardiac function was assessed under isofluorane anesthesia, with the Millar catheter, 24h after the hemodynamic measurements. Systolic AP (Control: 202±5; DON: 178±8; PYR: 200±7 mmHg) and HR (Control: 354±13; DON: 304±9; PYR: 334±10 bpm) was reduced by DON, but was not affected by PYR. Vagal tone was increased by DON or PYR (Control: 64±5; DON: 105±11; PYR: 132±8 bpm). PYR increased the iHR while DON did not (Control: 340±3; DON: 351±5; PYR: 381±8 bpm). DON decreased the systolic AP variance (Control: 63±5; DON: 39±7) and the power of the low-frequency (LF) band of PI (Control: 32±2; DON: 18±2 nu), while decreased the power of the high-frequency (HF) band (Control: 68±2; DON: 82±2 nu) and the LF/HF ratio (Control: 0.5±0.05; DON: 0.2±0.03) of the PI spectrum. PYR did not promote significant changes in the AP or PI variability. Moreover, DON or PYR did not affect NE concentration (Control: 8.7±0.7; DON: 12±2.2; PYR: 9.6±2 ng/mL) or cardiac function [+dPdt (Control: 9469±574; DON:11461±1156; PYR:9640±1041 mmHg/s), -dPdt (Control: -11665±1085; DON: -11015±570; PYR: -9999±1294 mmHg/s), end diastolic pressure (Control:9±2; DON: 11±3; PYR: 7±1 mmHg)]. In conclusion, despite the increase in cardiac vagal tone elicited by either DON or PYR, the anticholinesterase agent that crosses the blood brain barrier, i.e. DON, was more effective improving the cardiovascular function during the development of hypertension in SHR.

High speed macro imaging of co-cultures

R.B. Burton, S. Bilton, G. Stephens, H.E. Larsen, D. Li, D.J. Paterson and G. Bub

Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, UK

Introduction: The release of noradrenaline (NA) from the sympathetic nervous system (SNS) exerts powerful chronotropic and inotropic effects (Zaika et al., 2011) and can be pro-arrhythmogenic. Many cardiac arrhythmias have been attributed to formation of macroscopic excitation patterns, but the influence of the SNS on wave dynamics is not well understood. In the current work, we describe new methodologies for dye free mapping of waves in myocyte monocultures and neuron/myocte co-cultures and report the effect of nicotine

and nerve growth factor (NGF) on macroscopic wave dynamics.
Methods: Hearts were isolated from neonatal SD rat pups (P1-P3) and killed by Schedule 1 in accordance to UK Home Office regulations. Briefly, ventricles were isolated, enzymatically digested, and enriched for myocyte content before plating on poly-L-lysine coated petri-dishes. After 24 hours, stellate neurons were isolated from litter mates and plated on top of the myocytes in 1:20 ratio.
We used dye-free imaging techniques to record macroscopic wave patterns and beat rate in myocyte-only and co-culture preparations. Experiments were carried out in an Okolab stage incubator controlled for heat (37°), CO2 (5%) and humidity.
Results: (i) We find that co-culture wave speed is significantly faster than myocyte-only cultures (52%±14%, $p<0.001$, n=7); (ii) Addition of nicotine to co-cultures systems causes an altered behaviour by change in initiation sites of wave patterns, but no significant changes in conduction velocity (n=7); (iii) Application of 10 μM nicotine to co-cultures produced a transient increase in contraction rate of up to 37%, and this was significantly sustained in 3 of 5 experiments; (iv) DAPI-stained images of both myocyte and co-culture plates grown either in the presence or absence of NGF were analysed in terms of a clumping factor (CF), a newly developed statistical measure of cell-cell spacing. CF were significantly higher (indicative of more clumped cells) for cultures grown in the absence of NGF compared to those grown in the presence of NGF (50ng/ml), for both myocyte-only (8.02±0.99, n=6 vs. 5.48±0.51, n=5) and co-culture (9.33±1.17, n=5 vs. 5.99±0.74, n=4) plates (all mean ± S.E.M, comparisons were performed with a t-test, $p<0.05$).
Discussion: Our observations may be relevant to understanding the onset and evolution of complex waves during life threatening cardiac arrhythmias, which can be attributed to large scale spiral waves (Bub et al., 2002; Bub et al., 2005). The finding that NGF modulates the patterning of myocytes raises the question of how NGF and its receptors interact to generate changes in cardiac and synaptic function.

Intrinsic electrophysiological properties of late-expiratory and CO2-sensitive neurones in the Retrotrapezoid/parafacial respiratory group of rats

D.J. Moraes, D.B. Zoccal and B.H. Machado

Physiology, School of Medicine of Ribeirao Preto, Ribeirao Preto, Sao Paulo, Brazil

The Retrotrapezoid/parafacial Respiratory Group (RTN/pFRG) contains late-expiratory (late-E) and CO2-sensitive neurones involved with active expiration and central chemoreception, respectively. Here we evaluated whether or not RTN/pFRG late-E and CO2-sensitive neurones present distinct electrophysiological properties and CO2 sensitivity. Using an in situ working heart brainstem preparation of rats (7 weeks old), we performed recordings of abdominal (AbN) and phrenic (PN) nerves activities simultaneously with whole cell path-clamp recordings of late-E or CO2-sensitive neurons in the RTN/pFRG. The data shows that late-E and CO2-sensitive neurones constitute heterogeneous neuronal populations with respect to several electrophysiological properties. During normoxic/normocapnic condition the late-E neurones were silent, while CO2-sensitive displayed continuous frequency discharge (0.83 ± 0.02 Hz; n=8) during the respiratory cycle. The emergence of late-E activity, in late-E neurons, and the coincidently late-E burst in AbN motor activity, both preceding PN bursts, occurred only during hypercapnia (10% CO2; 9.1 ± 0.08 Hz; n=7) or hypoxia (5% O2; 8.5 ± 0.09 Hz; n=7). Input resistance (354 ± 21 vs 235 ± 17 MΩ; $p<0.05$), resting membrane potential (-67 ± 3 vs -54 ± 2mV; $p<0.05$) and rheobase (35 ± 3 vs 58 ± 7 pA; $p<0.05$) were different, suggesting that the expression or properties of some ion channels differ between these neuronal types. Common features of RTN/pFRG late-E and CO2-sensitive neurones included the expression of transient outward potassium current (TOC; at 60 mV: 365 ± 65 vs 380 ± 57 pA/pF), hyperpolarization-activated inward current (at -120 mV: 35 ± 3 vs 47 ± 7 pA/pF) and absence of persistent sodium current. Nevertheless, after synaptic blocked, hypercapnia increased the firing frequency (+1.83 ± 0.05 Hz) and decreased the potassium-mediated leak current (- 3.1 ± 1 nS) of CO2-sensitive neurones, but did not change the late-E neurones activity. This body of electrophysiological evidence indicates that RTN/pFRG late-E and CO2-sensitive neurones from juvenile/adult rats constitute heterogeneous neuronal populations regarding intrinsic electrophysiological properties and CO2 sensitivity, and provide a cellular basis for a better understanding of their involvement in the pathophysiological conditions, such as obstructive sleep apnoea, hypertension and heart failure.

***Mesobuthus tamulus* venom augments the phenylbiguanide and capsaicin-induced cardiorespiratory reflexes involving two disparate mechanisms**

A. Akella, A. Dutta and S.B. Deshpande

Department of Physiology, Institute of Medical Sciences, Banaras Hindu University, Varanasi, U.P, India

Indian red scorpion (*Mesobuthus tamulus*, MBT) venom is known to augment the cardiorespiratory reflexes elicited by phenylbiguanide (PBG) or phenyldiguanide (PDG) [1,2]. These chemicals mediate the action via 5-HT_3 receptors on the vagal C-fibers. Similar to PBG/PDG, capsaicin (a TRPV1 agonist) also produces cardio-respiratory reflexes involving vagal C-fibers [3]. However, the effect of MBT venom on the capsaicin-induced responses is not known. Therefore, the present study was undertaken to ascertain whether MBT venom also augments the capsaicin-induced responses. Further, to delineate the underlying mechanisms.
Animal experiments were performed after obtaining the approval from the Institutional Ethical Clearance Committee. Adult rats of Charles foster strain were used. They were anesthetized with urethane (1.5 g/kg, i.p). The trachea, jugular vein and femoral artery were cannulated. The ECG, respiratory

excursions and blood pressure were recorded. At the end of each experiment, the pulmonary water content was determined by physical method.
Both PBG (10μg/kg) and capsaicin (10μg/kg) produced bradycardia, apnea-bradypnea and hypotension. After exposure to MBT venom (100μg/kg) for 30 minutes, the responses induced by PBG as well as capsaicin were augmented. Pulmonary edema was seen in these animals. The augmentation of PBG-induced responses and pulmonary edema were blocked after pretreatment with prostaglandin synthase inhibitor (indomethacin, 10mg/kg); kinin synthase inhibitor (aprotinin, 6000 KIU) and guanylate cyclase inhibitor (methylene blue, 5mg/kg). The augmentation of capsaicin-induced responses was blocked in indomethacin pretreated animals only but not in aprotinin and methylene blue pretreated animals even though pulmonary edema was not seen in these groups. Elevation of the endogenous cGMP levels by phosphodiesterase-V inhibitor (sildenafil, 100μg/kg) augmented the PBG-induced responses but not the capsaicin-induced responses. Sildenafil pretreated animals exhibited pulmonary edema.
The present results demonstrate that MBT venom also augments the capsaicin-induced responses similar to PBG but involves distinctly different mechanisms. The PBG-induced responses are augmented by pulmonary edema-dependent mechanisms involving prostaglandins, kinins and guanylate cyclase-cGMP pathway whereas the capsaicin-induced responses are independent of pulmonary edema and involve nociceptive action of prostaglandins. The present study substantiates the existence of functionally different types of vagal-afferents. Our results with indomethacin, also implicate the direct and indirect action of prostaglandins in mediating the C-fiber reflexes.

Non-invasive vagus nerve stimulation enhances parasympathetic influence on autonomic output in healthy humans and heart failure patients

J.A. Clancy, S.A. Deuchars and J. Deuchars

University of Leeds, Leeds, UK

Heart failure (HF) is a debilitating and fatal condition characterised by sympathetic activation and parasympathetic withdrawal. Tackling the underlying autonomic imbalance through parasympathetic stimulation can improve cardiac function and quality of life scores in HF patients[1], however, the current method of cervical vagus nerve stimulation (VNS) is invasive and associated with side effects. This study investigated the autonomic effects of a non-invasive method of VNS - transcutaneous electrical stimulation of the auricular branch of the vagus nerve (tVNS) - in healthy participants (n = 111; 58 female, 53 male; aged 20-66 years) and HF patients (n = 6; 1 female, 5 male; 51-86 years). The study was approved by the University of Leeds Ethics Committee and the National Research Ethics Service and was conducted in accordance with the Declaration of Helsinki. Heart rate (ECG), blood pressure and respiration were recorded continuously. Heart rate variability (HRV) was calculated using spectral analysis of beat-to-beat intervals derived from ECG data. Low frequency (LF; 0.04-0.15Hz) and high frequency (HF; 0.15-0.40Hz) power were calculated. HF power represents parasympathetic/vagal modulation of heart rate and the ratio of low to high frequency power (LF/HF) can be used as an indicator of sympathovagal balance, such that a decrease in LF/HF indicates a shift in autonomic balance towards parasympathetic dominance. Microneurography was also used to record muscle sympathetic nerve activity (MSNA; n = 10). tVNS was applied at either low pulse width and pulse frequency (L-tVNS), high pulse width and pulse frequency (H-tVNS) or sham stimulation. Data were analysed at baseline, during tVNS and during recovery. Repeated measures ANOVAs were used to analyse results (data presented as mean ± S.E.M). L-tVNS (n = 63) and sham tVNS (n = 14) had no significant effect on HRV whereas HRV improved significantly during H-tVNS in healthy participants with a decrease in LF/HF ratio from 1.26 ± 0.15 at baseline to 1.04 ± 0.14 during H-tVNS (n = 34; p = 0.026). There was a significant reduction in single unit MSNA frequency and incidence during H-tVNS (p = 0.001 and p = 0.002 respectively). H-tVNS significantly improved LF/HF ratio in HF patients from 4.78 ± 1.49 to 3.13 ± 1.39 (n = 6; p = 0.028). There was also a significant reduction in LF power during H-tVNS in HF patients (p = 0.028). Based on the results of this study, tVNS can improve HRV in both healthy participants and HF patients. Furthermore, microneurography revealed that the improvement in HRV during H-tVNS is, at least partly, due to a reduction in sympathetic activity in healthy participants. tVNS could be a practical, non-invasive and economical therapy for heart failure patients and warrants further investigation.

Anatomical and functional characterisation of pro-opiomelanocortin neurones in the nucleus of the solitary tract of the mouse

S. Cerritelli, N. Balthasar and A.E. Pickering

Physiology & Pharmacology, University of Bristol, Bristol, UK

One of the two main central clusters of pro-opiomelanocortin (POMC) containing neurones is in the nucleus of the solitary tract (NTS), which receives vagal afferent inputs. POMC can be cleaved into the endogenous opioid β-endorphin. Thus, β-endorphin release by POMC neurones may modulate vagal afferent processing within the NTS. To map the anatomical organisation and projection pattern of NTS POMC neurones we used an adeno-associated viral vector (AAV) to drive channelrhodopsin2-mCherry expression in mice selectively expressing cre-recombinase/GFP in POMC neurones (1). We examined the cardiorespiratory effects of NTS POMC neuronal activation in the working heart-brainstem preparation (WHBP, 2). POMC-

Cre mice (n=3) received NTS microinjections of AAV-EF1α-DIO-hChR2-mCherry under anaesthesia (ketamine 70mg.kg-1/medetomidine 0.45mg.kg-1 i.p.). Three weeks later mice were anaesthetised with 5% halothane (until decerebration) for set-up of the WHBP. NTS POMC neurones were activated using a laser and cardiorespiratory responses measured. Naloxone (1-5μM) was used to block opioid receptors and effects compared with responses to DAMGO (2mM), a μ-opioid agonist, microinjection into the NTS and vagal preganglionic cell groups (n=2). Brains were post-fixed and histology performed to determine the location and projection pattern of NTS POMC neurones, based on mCherry fluorescence. Immunohistochemistry was performed for choline acetyltransferase, to label vagal preganglionic neurones, and GFP, to label POMC neurones and imaged using fluorescence microscopy. Immunofor POMC neurones (GFP) and β-endorphin was also performed in the NTS/hypothalamus. GFP positive cells were seen in the hypothalamic arcuate nucleus and NTS (200-300 somata in the caudal NTS). β-endorphin positive POMC neurones were found in the arcuate but not NTS. β-endorphin labelled fibres were found close to NTS POMC neurones. The AAV efficiently and selectively transduced NTS POMC neurones (~180); mCherry was distributed over a 1.4mm rostrocaudal distance. Most mCherry-labelled fibres were seen within the NTS but fibres also projected ventrally and ventrolaterally to the dorsal motor nucleus of the vagus (DMV) and nucleus ambiguus (NA) (n=2). Opto-activation of transduced NTS POMC neurones caused a reproducible, frequency dependent bradycardia, transient apnoea and exaggerated respiratory sinus arrhythmia. These cardiorespiratory responses were reversibly abolished by naloxone (n=1), but not mimicked by DAMGO microinjection into the NTS (n=2). This subgroup of POMC neurones forms an output path from the NTS to other brainstem autonomic centres, including the DMV and NA. Our results suggest that NTS POMC neurones can play a role in modulating vagal afferent processing via opioid release and may mediate cardiorespiratory responses.

Increased baseline arterial pressure and ventilatory responses to hypercapnia in rats fed with high-fat diet

G. Speretta[1], M. Bassi[1], K. Borsari[1], R.C. Vendramini[2], J.V. Menani[1], E. Colombari[1] and D. Colombari[1]

[1]Pathology and Physiology, UNESP, Araraquara, SP, Brazil and [2]Clinic Analyses, UNESP, Araraquara, SP, Brazil

It has been demonstrated that the respiratory responses to hypercapnia are enhanced in obese adult humans. In rats, high-fat diet induces dyslipidemia and hyperglycemia and increases body fat. Thus, the aim of the present study was to evaluate the ventilatory responses to hypercapnia, the mean arterial pressure (MAP) and the angiotensin type 1 receptors (AT1r) expression in the nucleus of the tract solitary (NTS) in rats treated with high-fat diet for 6 weeks. Male Hotzman rats (300-320 g) had ad libitum access for 6 weeks to either the standard rat chow diet (CD) that contained 23 g of protein, 49 g of carbohydrates and 4 g of total fat per 100 g of diet or the high-fat diet (HFD) composed of 20 g of protein, 20 g of total fat and 48 g of carbohydrate per 100 g of diet (n = 8-10/group). Changes in ventilation (VE), respiratory frequency (fR), tidal volume (VT), mean arterial pressure (MAP) and heart rate (HR) to chemoreflex activation by hypercapnia (7% CO2) were measured in conscious rats using pletismography method 6 weeks after starting the access to CD or HFD. Values are means ± S.E.M., compared by ANOVA or Student t test. Rats treated with HFD showed increased body mass (422 ± 6, vs. CD: 409 ± 3 g), glycemia (157 ± 6, vs. CD: 133 ± 5 mg/dl), total plasma cholesterol (72.3 ± 3, vs. CD: 64.5 ± 2 mg/dl), plasma triacylglycerol (56.4 ± 4, vs. CD: 38.6 ± 2 mg/dl), baseline MAP (116 ± 2, vs. CD: 106 ± 2 mmHg) and AT1r in the NTS (0.14 ± 0.03, vs. CD: 0.05 ± 0.02) (all $p < 0.05$), without changes in baseline VE, VT and fR. However, HFD treated rats had increased VE (1250 ± 58, vs. CD: 1021 ± 69 ml/min/kg) and fR (140 ± 7, vs. CD: 122 ± 4 breath/min) without changes in VT (8.9 ± 0.3, vs. 8.3 ± 0.5 ml/kg respectively) during 5 minute exposure to hypercapnia. These results suggest that high-fat diet increases baseline MAP and VE to hypercapnia. Although the mechanisms involved on respiratory changes are not known yet, AT1r overexpression in the NTS may contribute to the hypertension in HFD animals.

Assessing the upper limit of cerebral autoregulation in anaesthetised rats

E.L. Thompson, A.M. Coney and J.M. Marshall

School of Clinical and Experimental Medicine, University of Birmingham, Birmingham, West Midlands, UK

Cerebral autoregulation allows cerebral blood flow (CBF) to be maintained in the face of changes in systemic arterial blood pressure (ABP): cerebral vasoconstriction occurs when ABP rises and *vice versa*. Ageing is associated with impaired autoregulation, the upper limit being reduced, but the mechanisms are not known. The aim of this study was to develop a protocol to reliably assess the upper limit in rats by using phenylephrine (PE) to increase ABP: PE has limited ability to cross the blood brain barrier and α-adrenoreceptor density on cerebral vessels is low.

In 14 male Wistar rats (333 ± 6g) anaesthetised with Alfaxan (17-20 $mg.kg^{-1}.h^{-1}$ i.v.), PE (0.1–60$\mu g.kg^{-1}.min^{-1}$) was infused i.v. to cause graded increases in ABP. CBF was recorded via a Transonic probe on the right common carotid artery after ligating the external carotid to minimise extra-cranial flow (RCBF). In Group 1, femoral (muscle) BF was also recorded (n=9); in Group 2, left CBF was recorded without ligation (LCBF; n=5). Vascular resistances (CVR, FVR) were computed as ABP/CBF or FBF. Arterial blood gases and pH were monitored at intervals. All procedures were carried out in accordance with UK legislation.

While ABP increased from 125±3 to 141±4 mmHg, RCBF was *not* constant, but fell from 1.3±0.1 to 1.1±0.1$ml.min^{-1}$ due to vasoconstriction: RCVR increased from 106±8 to 134±11 RU ($P<0.05$, unpaired t-test). Thereafter, RCBF achieved a plateau while ABP increased to ~155mmHg and RCVR increased, demonstrating autoregulation. The upper limit of autoregu-

lation, defined as the intersect of two linear regression lines fitted to the 'plateau' and 'rising' portions of mean RCBF was 165mmHg, after which RCBF rose to a maximum of 2.1±0.3ml.min^{-1}. The *changes* induced in LCBF were similar to those in RCBF, but LCBF was 0.98±0.20ml.min^{-1} higher (P<0.05, paired t-test) than RCBF, indicating constant extra-cranial flow. FBF tended to rise (1.7±0.3 to 2.5±0.3ml.min^{-1}) while ABP increased, but fell to 1.8±0.1ml.min^{-1} at the top dose of PE: the trend for FVR to increase did not reach significance (89±15 to 105.6±7.5 RU, P>0.05, one-way ANOVA). P_aCO_2 and pH remained constant, but P_aO_2 fell with increasing doses of PE (to 63±3mmHg), suggesting progressive pulmonary vasoconstriction.

These data indicate that i.v. PE can be used to assess the upper autoregulatory limit in the rat. However, PE induced an initial cerebral vasoconstriction and fall in CBF before the autoregulatory plateau was apparent. This was not an artefact of ligating the external carotid artery. Further, such initial vasoconstriction did not occur in muscle, suggesting it was peculiar to cerebral circulation: it may be that induction of anaesthesia induced cerebral vasodilatation. We are currently investigating the mechanisms contributing to the upper autoregulatory limit that may change with ageing.

A model of sympathetic transmission to smooth muscle cells: the importance of respiratory modulation in understanding neurogenic hypertension

L.J. Briant[1,2], M. Desroches[1], J. Paton[2], A. Champneys[1] and A. Pickering[2]

[1]Engineering Mathematics, University of Bristol, Bristol, UK and [2]Physiology and Pharmacology, University of Bristol, Bristol, UK

Sympathetic nerve activity (SNA) is elevated in hypertension. The question of how the end-organ vasculature responds at a cellular and molecular level to the bursty respiratory component of SNA remains unknown, although this is believed to underlie Traube-Hering waves. Experimental studies have shown that 'irregular' activity generates a larger contractile force in arterial smooth muscle cells (SMCs) than tonic activity of the same average firing frequency [1]. This suggests that the respiratory modulation that SNA exhibits could be a key determinant of blood pressure, and that the change in the respiratory component could cause an increase in blood pressure, as seen in the spontaneously hypertensive rat [2].

To test this hypothesis we have constructed a high-fidelity mathematical model of the pathway of transmission from a sympathetic preganglionic neurone (SPN) to a SMC. A single-cell model of a SPN, previously presented [3], was used to drive the pathway. The presynaptic, intracellular calcium trace was used to drive a model of noradrenaline release. The released transmitter, with a profile fitted to carbon fibre electrode studies [4], activated α1-receptors on the SMC, triggering a G-protein cascade and was modelled with a 6-variable system. The subsequent release of calcium was modelled using a 2-dimensional system describing the calcium fluxes across the sarcoplasmic reticulum. These calcium dynamics were used to drive equations describing binding of myosin to actin and therefore the contractile force generated in the SMC. The resulting 25 dimensional system was run on BlueCrystal at Bristol University, using a commercial software package (MATLAB R2010a).

To mimic the change in the respiratory component of SNA seen in the spontaneously hypertensive rat (SHR) versus the normotensive rat (WKY), the model was stimulated with bursts which had varying within-burst frequencies. The sympathetic inputs had the same average firing frequency of 1Hz. The simulations, shown in the figure, indicate that the respiratory component of SNA is a key determinant of blood pressure, producing a larger change in contractile force than tonic input at the same average firing frequency. Arteries have therefore adapted to the challenge of converting high-frequency output from the sympathetic nervous system, to a lower frequency contraction, and in doing so respond with some specificity to respiratory modulation. These modelling data suggests that alterations to the respiratory component need to be investigated in order to understand hypertension.

Developing methods for electrophysiological assessment of cell-cell communication between cardiac myocytes and neurons using co-culture model systems

H.E. Larsen, R. Burton, G. Stephens, S. Bilton, A. Sharkey, G. Bub, E. Mann and D.J. Paterson

Dept of Physiology, Anatomy and Genetics, University of Oxford, Oxford, UK

Hypertension is associated with increased activation of the sympathetic nervous system and cardiac beta adrenergic

responsiveness (Anderson et. al., 1989, Li et. al., 2012). However, the exact mechanism remains poorly understood. The physiology and pharmacology of the individual ion channels and signalling molecules on the single neuron and myocyte as isolated systems are well described. However, relatively little is known about the cell-to-cell interaction that takes place. Tao et. al., (2011) have modelled this dual cell coupling using bioinformatics on single cell data to re-assemble the cell network from individual ion channels. Nevertheless the predictive power of this modelling is limited because it has not been experimentally validated against physiologically coupled neurons and myocytes. Here we describe a method of culturing cells as a macroscopic confluent monolayer that will enable detailed in vitro electrophysiological investigations of the communication between the neurons and the myocytes in health and disease. Neonatal ventricular myocytes and stellate ganglia were excised from Spontaneously Hypertensive Rats (SHR), Wistar Kyoto (WKY) and Sprague Dawley (SD) rats in accordance with the Home Office Animals (Scientific Procedures) Act 1986 (UK). The heart and ganglia were enzymatically digested to obtain isolated cells using pancreatin, collagenase and trypsin respectively. Cells were pre-plated for one hour in order to reduce fibroblast contamination before cells were plated on their own, or together to create co-cultures at a ratio of 1:20 neuron:myocyte.

We established a stable co-culture model system (Fig. 1 A-C) and report functional communication between neurons and myocytes by stimulating neurons with 10μM nicotine in which the beat rate increased by 25%, 20% and 33% respectively in three experiments. We have also performed pilot patch clamp studies on control SD cultures and shown how these neurons behave under whole cell current clamp conditions (Fig. 1D). In conclusion, the successful co-culture of ventricular myocytes and stellate ganglion neurons has enabled us to simultaneously investigate different parameters in myocyte-neuron signalling. In particular, the preparation will enable us to establish the electrophysiological profiles of these cell types in cardiac-neural regulation in normal and diseased tissue.

Key words: Hypertension, myocyte, neurons, culture, electrophysiology

The responses induced by obstructive apnea in spontaneously hypertensive rats (SHR) are reduced after inactivation of carotid chemoreceptors

J.M. Angheben, G.H. Schoorlemmer, M.V. Rossi, T.A. Silva and S.L. Cravo

Physiology, Federal University of Sao Paulo, Sao Paulo, Brazil

Introduction: Obstructive sleep apnea is characterized by recurrent episodes of cessation of airflow due to the collapse of the airway during sleep. Patients with sleep apnea tend to have hypertension and increased sympathetic activity. Hypertension and increased sympathetic activity are also observed in spontaneously hypertensive rats. This rat strain also seems to have increased chemoreceptor drive. Objective: We investigated cardiovascular and respiratory responses induced by apnea in SHR, and the role of carotid chemoreceptors in these responses. Method and Results: Rats were anesthetized with ketamine (100 mg/kg i.p.) and xylazine (20 mg/kg i.p.). A balloon was implanted in the trachea that allows the induction of apnea without causing tracheal pain. A thoracic balloon was implanted to measure thoracic pressure, and cannulas were implanted in the femoral vein and artery. Rats received keto-

profen (2 mg /kg s.c.) after surgery. A week later, with the rat awake, 5 apneas, 15 s each, were induced. The effects of apnea were larger in SHR than in WKY. Blood pressure increased by 57±3 mmHg during apnea in SHR, and 28±3 mmHg in WKY (mean ± SEM, $p < 0.05$, n = 8/11). Respiratory effort increased by 53±6 mmHg in SHR, and by 34±5 mmHg in WKY. Heart rate fell by 209±19 bpm in SHR, and by 155±16 bpm in WKY. The carotid chemoreceptors were then inactivated by ligation of the carotid body artery, and apneas were induced two days later. Inactivation of chemoreceptors reduced the responses to apnea, and abolished the difference between SHR and WKY. The apnea-induced hypertension was 11±4 mmHg in SHR, and 8±4 mmHg in WKY. Respiratory effort was 15±2 mmHg in SHR, and 15±2 mmHg in WKY. Heart rate fell 45 ±16 bpm in SHR, and 49±16 bpm in WKY. Similarly, when the chemoreceptors were unloaded by giving 100% oxygen to breath, the responses to apnea were reduced, and the difference between SHR and WKY was small. Blood pressure increased by 24±6 mmHg in SHR, and 13±1 mmHg in WKY. Respiratory effort increased by 18±3 mmHg in SHR, and by 16±3 mmHg in WKY. Heart rate fell 74±17 bpm in SHR, and 93±10 mmHg in WKY. Conclusion: Chemoreceptors contribute to the responses induced by apnea both in normotensive and hypertensive rats, but they are more important in SHR, and account for the exaggerated responses induced by apnea in SHR.

Brain stem areas activated by obstructive apnea in rats with or without carotid chemoreceptors

C.B. Ferreira[1], S.H. Guus[1], A.C. Takakura[2], B.F. Barna[3], T.S. Moreira[3] and S.L. Cravo[1]

[1]Physiology, Federal University of Sao Paulo, Sao Paulo, Brazil, [2]Pharmacology, University of Sao Paulo, Sao Paulo, Brazil and [3]Physiology and Biophysic, University of Sao Paulo, Sao Paulo, Brazil

Several evidences suggest that obstructive sleep apnea may contribute to the development of cardiovascular diseases such as hypertension. However, the mechanisms involved and the role of carotid chemoreceptors are not clear yet. Recently we developed a method to produce obstructive apnea in rats that reproduces the respiratory effort, hypoxia, and hypercapnia observed in sleep apnea patients. In this study, we investigated the brain stem areas activated by apnea in non-anesthetized rats with or without carotid chemoreceptors. Male Wistar rats (300-350 g) were anesthetized i.p. with ketamine (100 mg/kg) and xylazine (20 mg/kg), and tracheal balloon, femoral vein cannula, and subcutaneous EKG electrodes were implanted. One week later, 14 s apneas were induced every 2 min for 1 h in 4 rats. The control group (with tracheal balloon) had no exposition to apnea protocol. Thirty min after the end of apnea rats were perfused. The brain was removed and processed for immunohistochemistry to Fos and tyrosine hydroxylase (TH) (a marker for catecholaminergic neurons). In another group of rats (n=4), the arterial chemoreceptors were inactivated 7 days after implantation of the tracheal balloon by ligation and section of the carotid body arteries. In these rats, carotid chemoreceptor function was abolished (no bradycardia after i.v. injection of 40 μg KCN). Two days after chemoreceptor inactivation, the animals were subjected to the same apnea protocol described previously. In control rats very few or no Fos was detectable. Apnea induced intense Fos expression in commissural and intermediate nucleus of the solitary tract (NTS), and in caudal and rostral ventrolateral medulla (CVLM and RVLM). With respect to the catecholaminergic groups in the brain stem, we observed Fos in 42% of the C1 neurons, 11% in the A1 neurons, 18% in the A2 neurons, and 18% in the C2 neurons. Inactivation of the carotid chemoreceptors reduced apnea-induced Fos expression in the comissural NTS (from 210 ± 5 to 153 ± 3 neurons, mean ± SEM) and intermediate NTS (from 94 ± 13 to 57 ± 7 neurons), but not in CVLM and RVLM. Fos expression in the catecholaminergic cell groups was also reduced (C1: 42% to 23%, A1: 11% to 2%, A2: 18% to 9%, C2: 18% to 4%). We conclude that apnea actives neurons in regions involved with processing the baroreceptors, chemoreceptors, pulmonary stretch receptors, and regions responsible for autonomic and respiratory activity both in the presence and absence of carotid chemoreceptors. Signals from carotid chemoreceptors contribute to activation in NTS region, but apnea induces additional signals that contribute to neuronal activation. This is compatible with the presence of apnea-induced pressor responses, bradycardic, and breathing effort after carotid chemoreceptor activation.

Effect of regular obstructive apnea in rats on sleep structure and the cardiovascular effects of awakening

A.P. Pansani, M.V. Rossi, G.H. Schoorlemmer and S.L. Cravo

Physiology, Federal University of São Paulo, São Paulo, Brazil

Objective: Obstructive sleep apnea (OSA) can provoke cardiovascular impairments. Animal models that mimic OSA can help clarify the roles of changes in sleep architecture and direct effects of apnea on these impairments. This study analyzed the effect of obstructive apneas on sleep structure, and the cardiovascular responses induced by apnea during wakefulness, non-REM sleep, and REM sleep, followed or not by awakening. Methods: Intermittent apneas, 6 s each, once a minute, were made for 8 h in male adult Wistar rats by inflation of a tracheal balloon (Schoorlemmer et al., 2011). Sleep staging was done by analysis of cortical EEG and EMG of the trapezoid muscle as described by Louis et al. (2004). Arterial pressure and ECG were obtained by telemetry. Heart rate and mean pressure were calculated each second, starting 5 s before apnea onset until 10 s after the end of apnea. Results: Apneas did not alter the total time awake (52% with, 44% without apnea), non-REM sleep (39% with, 47% without apnea) and REM sleep (8% with, 10% without apnea (n = 4 rats). Rats awoke in 76% of the apneas made in non-REM sleep, and in 35% of the apneas made in REM sleep. Heart rate and arterial pressure did not change during apnea, independently of the stage of the sleep-wake cycle, and independently of wake-up. Tachycardia was seen after the end of apnea. Heart rate increased by 12 bpm in awake subjects (152 apneas), by 27 bpm when subjects awoke from non-REM sleep (129 apneas), by 3 bpm when subjects failed to wake up from non-REM (28 apneas), by 14 bpm when subjects failed to wake up from REM (19 apneas), and by 29 bpm when subjects woke up from REM (16 apneas). After

the end of apnea, arterial pressure fell by 17 mmHg in subjects that woke up from REM, but did not change in the other conditions. Conclusion: This protocol of apneas did not provoke sleep deprivation, which is suggestive of low stress in rats. Apneas that caused awakening were followed by tachycardia, and if the subject woke up from REM sleep, hypotension. Awakening may exert considerable influence on autonomic changes that occur immediately after apnea.

Aldosterone contributes for the autonomic changes in renovascular hypertension in Wistar rats

G.S. Lincevicius[1], C.G. Shimoura[1], E.E. Nishi[1], A.A. Ribeiro[2], J.C. Perry[3], D.E. Casarini[2], C.T. Bergamaschi[1] and R.R. Campos[1]

[1]Physiology, UNIFESP, Sao Paulo, Sao Paulo, Brazil, [2]Nefrology, UNIFESP, Sao Paulo, Sao Paulo, Brazil and [3]Psicobiology, UNIFESP, Sao Paulo, Sao Paulo, Brazil

Sympathetic hyperactivity, baroreflex dysfunction and intrarenal alterations are all involved in the renovascular hypertension. It's already known that most of these changes are mediated by high level of circulating angiotensin II (Ang II) which also releases aldosterone. The aim of this study was to evaluate the effects of spironolactone (Spiro) (200mg/Kg/day) treatment, in a renovascular model of hypertension, the 2 kidney-1 clip (2K-1C). We evaluated in conscious rats changes on mean arterial pressure (MAP) and reflex control of renal sympathetic nerve activity (rSNA) in urethane anaesthetized rats (1.2-1.4 g/Kg). The tonic and reflex control of rSNA was evaluated (1 min infusion of phenylephrine 100 μg/mL/min and sodium nitroprusside 200μg/mL/min). Furthermore, the plasma renin activity (PRA) and the intrarenal renin protein expression; renal fibrosis process (expression of α-actin by imunohistochemistry); type 1 Ang II receptor (AT1) and mineralocorticoid receptor (MR) protein expression in renal tissue and central nervous system (CNS) specifically in regions involved with cardiovascular regulation such as the nucleus of tractus solilaty (NTS) and the rostral ventrolateral medulla (RVLM) were investigated. In 2K-1C group Spiro treatment decreased MAP (2K-1C: 198±4,n=9; 2K-1C+Spiro: 170±9 mmHg,n=8; p<0.05 ANOVA -Tukey) and normalized the rSNA (2K-1C: 147±9,n=6; 2K-1C+Spiro: 96±10 spikes/s,n=8; p<0.05 ANOVA-tukey). Spiro treatment increased rSNA baroreceptor reflex sensitivity in both groups (CT: -0,3±0,04, n=6; CT+Spiro: -0,9±0,03, n=5; 2K-1C: -0,2±0,03, n=5; 2K-1C+Spiro: -0,4±0,03 spikes/s/mmHg, n=5; p<0.05 ANOVA-Tukey). Furthermore, the Spiro treatment decreased expression of α-actin in nonclipped kidneys in 2K-1C group (2K-1C: 5±0,6,n=4; 2K-1C+Spiro: 1,1±0,2, %,n=3; p<0.05 ANOVA- Tukey). There was no changes in PRA in 2K-1C, but a decrease in renin protein expression in nonclippped kidney was found (2K-1C: 217±30, n=5; 2K-1C+Spiro: 160±19, %, n=5; p<0.05 Kruskall Wallis-Dunns). In clipped and nonclipped kidneys of 2K-1C, the AT1 and MR receptors protein expression was not modified by treatment, however, Spiro treatment promoted downregulation of AT1 receptors at the CNS in hypertensive group (RVLM= 2K-1C: 129±10, n=10; 2K-1C+Spiro: 84±12, %, n=5; p<0.05 ANOVA -Tukey; NTS= 2K-1C: 148±29,n=5; 2K-1C+Spiro: 68±14, %, n=4; p=0.06 ANOVA -Tukey). Taken altogether, the results suggest that aldosterone has differential effects in kidneys and CNS. Aldosterone is an important mediator in the tonic and reflex control of rSNA as well as contributes for intrarenal fibrosis process in renovascular hypertension.

Cardiac arrest produced by ATP in isolated right atrium from normotensive and hypertensive rats

J.Q. Rodrigues, E.D. Silva Junior, H. Camara, G.A. Alves, N.H. Jurkiewicz and A. Jurkiewicz

Pharmacology, UNIFESP, São Paulo, São Paulo, Brazil

Introduction and Aims: The P1 and P2 receptors are expressed in cardiac tissue and activated by purines such as ATP, which are released by sympathetic neurons, endothelial cells and other tissues such as cardiomyocytes (Burnstock, G 2008). However, the role of these receptors in hypertension is still unclear. Therefore, this study proposed to investigate the role of the purinergic receptors and the signaling pathway on cardiac arrest induced by ATP in isolated right atria (RA) from normotensive (NWR) and spontaneously hypertensive rats (SHR). Materials and Methods: RA from NWR and SHR (4-6 months old) were isolated and mounted in isolated organ bath. The RA presented spontaneously beatings and the frequency between 220 and 520 bpm was considered as inclusion criterion. We study the effect of ATP (1 μM to 1 mM) on frequency of RA in the absence and presence of DPCPX (Dipropylcyclopentylxanthine) – a potent and selective antagonist for the adenosine A1 receptor (0.01 to 1 μM / pre-incubated for 20 min), 4-Aminopyridine – a potassium channel blocker (0.1 to 10 mM) and Bay k 8644 – which increases influx of calcium specifically at voltage-gated calcium channels (0.01 to 1μM). The results were analyzed by unpaired t test and one-way ANOVA. All experiments procedures were approved by the Ethics Committee of UNIFESP (n° 0778/11). Results: ATP (1 μM to 30 μM) produced an initial negative chronotropic effect (NCE) which lasted 60-90 s, followed by a negative inotropic effect (NIE) (n = 8). After that, the chronotropism gradually increased, showing a positive chronotropic effect (PCE) lasted 400 s followed by a positive inotropic effect (PIE). ATP 100 μM exerted in 40% of the experiments a biphasic effect. ATP 100 μM and 300 μM induced only a NCE in 60% and 100 % of the experiments, respectively. ATP 1 mM abolished the atrial contraction in SHR and NWR. The DPCPX (1 μM) blocked the NCE produced by ATP (300 μM) in 71.0 ± 1.3% (NWR) and 62.0 ± 1.2% (SHR) of the basal chronotropic effects. The DPCPX (1 μM) blocked the cardiac arrest produced by ATP (1 mM) in SHR and NWR. The 4-amino-pyridine (10 mM) and Bay k 8644 (1μM) blocked the cardiac arrest induced by ATP (1 mM). Conclusion: The results suggest that the cardiac arrest induced by ATP was due to the activation of A1 receptors followed by stimulation of outward K+ currents and blockade of inward Ca2+ currents in RA of NWR and SHR.

The lumbar sympathetic nervous system does not contribute to chronic intermittent hypoxia induced hypertension

E.F. Lucking[1], K.D. O'Halloran[2] and J.F. Jones[1]

[1]School of Medicine and Medical Science, University College Dublin, Dublin 4, Ireland and [2]Department of Physiology, School of Medicine, University College Cork, Cork, Ireland

Obstructive sleep apnoea (OSA) is associated with cardiovascular morbidity and recognised as an independent risk factor for hypertension. Sympathetic nervous activity is commonly reported to be increased in OSA patients and animal models exposed to chronic intermittent hypoxia (CIH) and thought to result in increased vasoconstrictor tone. Our previous results indicate that CIH-induced hypertension is not a result of decreased femoral vascular conductance (FVC). We hypothesised that CIH induced systemic hypertension is driven by increased cardiac output and that the lumbar sympathetic chain does not significantly contribute to the hypertensive state. Age-matched adult male Wistar rats (335±4g) were exposed to CIH (n=23) consisting of 90s hypoxia (5% O2 nadir)/210s normoxia cycles, or sham (n=23) treatment (normoxia), for 8h/day for 2 weeks. Under urethane anaesthesia (1.5g/kg, administered via intraperitoneal injection), the cardiac output was determined using transthoracic echocardiography. FVC was determined by placement of a flow probe on the femoral artery. Lumbar sympathetic activity/stimulation was performed using bipolar silver wire electrodes placed at the L3-L4 region. Lumbar sympathetic network density was determined using a glyoxylic acid stain. Data are presented as mean ± S.E.M and were analysed by Student's t-test or two-way ANOVA. CIH exposure significantly increased mean arterial pressure (81.4 ± 2 vs. 91.6 ± 2 mmHg; p= 0.001 n=23) and hematocrit concentration (42.4 ± 0.4 vs. 45 ± 0.4 %; p <0.0001, n=23). In addition, CIH exposure significantly increased cardiac output (25.8 ± 2.6 vs. 19.3 ± 1.7 ml/min/100g; p=0.027, n=8) without any change in FVC or blood volume. Lumbar sympathetic activity was not significantly different, nor was vascular sensitivity to lumbar sympathetic nerve stimulation. Sympathetic hyperinnervation within hindlimb arteries was increased in CIH animals (p=0.012, n=8), however vascular sensitivity to phenylephrine was significantly blunted (p=0.049, n=7). Our findings show that CIH-induced hypertension is a result of increased cardiac output and that the lumbar sympathetic chain does not significantly contribute to the hypertensive state through its influences on FVC. We conclude that hypertension is a compensatory response to CIH exposure whereby the cardiac output is increased, in combination with increased hematocrit, in an attempt to increase oxygen flow to the hypoxic tissues.

Diabetes mellitus blunts nociceptive-dependent stem cell liberation following limb ischemia

Z. Dang and P. Madeddu

School of Clinical Sciences, University of Bristol, Bristol Heart Institute, Bristol, UK

Background: Previous work from our group showed that tissue ischemia activates a nociceptive reflex that through the local release of the neuropeptide Substance P (SP) leads to attraction of proangiogenic cells from the bone marrow to the ischemic site thereby supporting revascularization and tissue healing.
Objective: To investigate if diabetes mellitus, a known cardiovascular risk factor, inhibits nociceptive signalling following induction of unilateral limb ischemia.
Methods and Results: CD1 mice were induced diabetes by streptozotocin and studied 17 weeks after first confirmation of overt glycosuria. Age-matched non diabetic mice served as controls. Mice were anesthetized with 2,2,2 tribromo ethanol(0.3gm/kg, i.p.) and Limb ischemia was produced by ligature of the left femoral artery. We found that diabetes reduces the density of SP-positive sensory nerve fibers in bone marrow (H: 368±4.5mm vs T1D: 169±2.5mm in per 20x magnification section, p<0.05. n=5). But the expression of the SP receptor NK1 was not significant modified by diabetes. The responsiveness of total and lineage negative bone marrow cells to SP-induced migration in a Boyden chamber assay was significantly reduced by diabetes (Total BM cells migration, H: 6.51±0.2% vs T1D: 5.11±0.2 %, p<0.05. n=5. lineage negative bone marrow cells migration, H: 9.18±0.3%vs T1D: 7.66±0.2%, p<0.05. n=5)). Likewise lineage negative cKit+Sca+ cells expressing NK1R from bone marrow of diabetic mice were depleted in the migrated fraction by 61% percent (p<0.05. n=5). Furthermore, limb ischemia increases the levels of SP in adductor muscles of nondiabetic mice (SP positive staining: 1939329.4±42 pixel) with this effect being reduced in diabetic mice (SP positive staining: 324262.3±21pixel. p<0.05. n=4). Ischemia increased the peripheral blood levels of NK1R positive progenitor cells in nondiabetic mice with concomitant reduction in bone marrow thus indicating cell mobilization. The NK1R positive progenitor cell mobilization was reduced by 67% and 32% in diabetic mice at 3 and 7 days post-ischemia, respectively. (p<0.05. n=4).
Conclusions: We show for the first time the altered sensory innervation of bone marrow in a murine diabetic model. Furthermore, diabetes inhibits the in vitro and in vivo attractive action of nociceptive mediator SP on proangiogenic bone marrow cells. Depression of pain-induced stem cell mobilization following ischemia might contribute to failed reparative response in patients with diabetes.

Optimal efferent vagus nerve stimulation in large animals and its effect on wall motion during ventricular fibrillation

I. Naggar, K. Nakase, L. Salciccioli, J. Lazar and M. Stewart

SUNY Downstate Medical Center, Brooklyn, NY, USA

The vagus nerve modulates electrical activity of the cardiac ventricles. However, whether the vagus nerve mediates these effects through the conduction system or directly on the myocardium is unknown. Accordingly, we studied vagus nerve stimulation (VNS) during sinus rhythm and during ventricular fibrillation (VF) in porcine and ovine preparations. We sought to determine: 1) what is the most potent frequency with which to stimulate the vagus nerve and 2) whether VNS at that frequency produces any change in cardiac wall motion during ventricular fibrillation. We studied 8 pigs and 10 sheep that were anesthetized with urethane 1 mg/kg intravenously and placed on a ventilator. Platinum vagus nerve electrodes were wrapped around the nerves. Simultaneous electrocardiogram (EKG) and carotid artery blood pressure (BP) recordings were made. VNS was performed in animals with 1-millisecond pulses for 20 seconds at 1, 2, 5, 10, 20, 50, and 100 Hz. This was done on both vagus nerves separately and bilaterally. Potency of the VNS was evaluated by counting the number of beats within the 20 seconds. VF was produced in 4 pigs by opening the thorax and applying direct current to the ventricles. Epicardial echocardiography during VF was performed, and both vagus nerves were stimulated at 50 Hz for 20 seconds. Wall motion data was extracted during VF for three periods—before, during, and after VNS. All data are presented as means with S.E.M. and were compared using repeated measures ANOVA, and p-values are reported. Tukey post-hoc analysis was performed, and statistical significance was taken as p-values < 0.05. In both sheep and pigs, 50 Hz was found to be the optimal frequency required to produce cardiac standstill. Bilateral VNS in pigs at 20, 50, and 100 Hz produced 21 ± 13, 1 ± 1, and 24 ± 14 beats in 20 seconds of stimulation, respectively (p = 0.003, 50 Hz was significantly different from 20 and 100 Hz). Bilateral VNS in sheep at 20, 50, and 100 Hz produced 14 ± 6, 2 ± 2, and 18 ± 7 beats in 20 seconds of stimulation, respectively (p = 0.002, 50 Hz was significantly different from 20 and 100 Hz). Wall motion data during VF showed 0.065 ± 0.005, 0.030 ± 0.008, and 0.057 ± 0.004 centimeters mean displacement before, during, and after VNS, respectively (p = 0.005, wall motion during VNS was significantly smaller than the other groups). We conclude that 50 Hz is the optimal frequency for VNS to exert its optimal cardiac effects. Vagus nerve stimulation affects the ventricles in large animals in both sinus rhythm and VF. These findings suggest VNS may provide an alternative adjunct therapy to treat ventricular arrhythmias.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Carotid body activity is increased in rat hypercaloric models of insulin resistance and hypertension

M.J. Ribeiro[1], J.F. Sacramento[1], C. Gonzalez[2], M.P. Guarino[1] and S.V. Conde[1]

[1]Pharmacology, CEDOC, Faculdade Ciências Médicas, Universidade NOVA, Lisboa, Portugal and [2]Departamento de Bioquímica y Biología Molecular y Fisiología, Universidad de Valladolid, Facultad de Medicina. Instituto de Biología y Genética Molecular, CSIC. Ciber de Enfermedades Respiratorias, CIBERES, Instituto de Salud Carlos III, Valladolid, Spain

The carotid bodies (CB) are peripheral chemoreceptors that classically respond to hypoxia, hypercapnia and acidosis. When activated CB chemoreceptor cells release neurotransmitters that increase chemosensory activity in the carotid sinus nerve (CSN), causing hyperventilation and activation of the sympathoadrenal system (Gonzalez et al. 1994; Marshall et al. 1994). Besides its role in the control of ventilation, the CB has been proposed as a glucose sensor being implicated in the control of energy homeostasis (Pardal and Lopez-Barneo, 2002; Koyama et al. 2000). Since, increased sympathetic activity is a well-known pathophysiological mechanism in IR and hypertension (HT) we hypothesize that overactivation of CB can contribute to the development of IR and HT. Therefore, the objective of this study was to investigate if CB activity is increased in IR and HT animal models.

Experiments were performed in 3 months Wistar rats (200–420 g) of both sexes. anaesthetized with pentobarbitone (60mg/Kg, ip). Two diet-induced IR and HT animal models were used: the rat submitted to a high-fat (HF) diet, a model that combines obesity, IR and HT and the rat submitted to a high-sucrose (HSu) diet, a lean model of combined IR and HT. CB activity was assessed through the evaluation of: in vivo ventilatory responses by measuring spontaneous ventilation and in response to ischemic hypoxia and in vitro by monitoring catecholamines release in basal conditions and in response to acute hypoxia (5%O2) and the expression of tyrosine hydroxylase.

We have observed that spontaneous ventilation as well as ventilation in response to ischemic hypoxia (assessed as the increase in ventilation produced by common carotid artery occlusions for periods of 5, 10 and 15 seconds) were increased in HF and HSu animals, with a more pronounced effect in HF animals. Surgical CSN cut completely abolished the increases in ventilation induced by the diets, showing that these effects are mediated by the CB. Basal release of dopamine was not significantly modified by hypercaloric diets, however the release induced by hypoxia (5%O2) was increased 3.15 and 2.12 fold in HF and HSu rat models, respectively. Also, CBs weight was significantly increased by 36.71% and 27.13% in HF and HSu models, respectively, as well as tyrosine hydroxylase expression, the rating enzyme for catecholamine biosynthesis, that increased by 64.4% in HF ($p<0.01$) and 30.8% in HSu animals ($p=0.12$).

In conclusion, we demonstrated for the first time that CB activity is increased in diet-induced animal models of IR and HT suggesting that CB is involved in the development of IR and HT. Additionally, the more pronounced increases in spontaneous ventilation and in ischemic hypoxia induced-hyperventilation observed in HF animals suggest that these animals hold a higher degree of CB activation.

Increase in circulating endocannabinoids worsens the drop in the blood pressure and decreases the tachycardiac response observed during septic shock

F. Alves, D. dos Reis, L. Resstel and F. Corrêa

Pharmacology, University of São Paulo, Ribeirão Preto, Brazil

During sepsis, there are changes in the cardiovascular system that are characterized by a drop in the blood pressure (BP), and increased heart rate (HR). It has been reported that during the septic shock the endocannabinoid system is active, and both anandamide and 2-AG endogenous endocannabinoids could act on CB1 and CB2 receptors. Moreover, the endocannabinoids, acting on CB1 receptors, are potent vasodilators and CB2 receptors modulate the immune response during sepsis. Thus, the increase in the concentration of endocannabinoids may worsen the cardiovascular and immunological response to sepsis. Thereby, we studied the cardiovascular effects of an increase in endocannabinoids by the inhibition of the FAAH (fatty acida mine hydrolase), which is the enzyme responsible by the degradation of endocannabinoids, during the septic shock induced by cecal ligation and puncture (CLP). To that, we utilized male Wistar rats. Animals were anesthetized with 2,2,2-tribromoethanol (250 mg/kg i.p., Sigma-Aldrich, St. Louis, MO, USA) and had a radiotelemetry probe implanted into the descendent aorta, to measure cardiovascular activity. At the same time, tsepsis was induced by cecal ligation and puncture (CLP). The FAAH inhibitor URB597, in the dose of 0,6mgl/kg, was injected intravenous immediately after the end of the surgery, and the cardiovascular parameters were measured during a period of 8h. Institution's Animal Ethics Committee (N-082/2010). The intravenous treatment with URB597, a FAAH inhibitor, did not affect the basal BP (PAM = 97±4 vs 96±3 mmHg; t= 0.6, p>0.05 n=5) and HR, and HR (343±4 vs 345±4 bpm; t=0.2; p>0.05). However, the treatment with URB597 increased the fall in the BP ($F(1,294)= 17$, $p<0.0001$) and decreased the characteristic tachycardia ($F(1,294)=54$, $p<0,0001$) observed during the septic shock caused by CLP.
The present results indicate that endocannabinoids participate in the genesis of the cardiovascular changes observed during septic shock caused by CLP.

Cardiovascular autonomic reflex tests in early detection of background lead exposure in children

S. Tymchenko and H. Evstafyeva

physiology department, Crimea State Medical University Named After S.I.Georgievsky, Simferopol, Ukraine

Cardiovascular autonomic reflex tests based on heart rate variability (HRV) have proven useful for noninvasive detection of autonomic nervous system (ANS) regulation failure in numerous pathological conditions. Although previous studies have suggested that exposure to toxic metals might alter HRV, there were a number of potential limitations in those studies, including the determination of HRV in adults occupationally exposed to heavy metals. The aim of this study was to investigate the relation between lead and HRV in children using cardiovascular reflex tests.
An assessment of cardiac autonomic regulation in children of both genders, aged 10 to 16 years (n=57), who had never been occupationally exposed to lead (Crimea, Ukraine) was carried out using the HRV markers and hair lead concentration determined by X-ray spectophotometry (ElvaX-Med). Five-minute HRV recordings by three-lead electrocardiography (Cardio, Ukraine) were obtained in supine position and during cardiovascular reflex tests (active tilt test, after exercises, during deep breathing, oculocardiac reflex and the psychometric strain test) and standard time and frequency domain HRV parameters were examined. Time-domain indexes included: normal-to-normal intervals (RRNN) between adjacent QRS complexes, the standard deviation of the NN intervals (SDNN), square root of the mean sum of squares of the differences between adjacent NN intervals (rMSSD), and proportion of pairs of adjacent NN intervals differing by more than 50 ms (pNN50). The frequency domain indexes were: high (HF), HF in normalized units (HFn), low (LF), LF in normalized units (LFn), very low (VLF), total power (TP), and the LF/HF ratio.
The results showed no statistically significant correlations between Pb and HRV indices recorded at rest. Statistically significant positive Spearman correlations were found only for lead and SDNN, VLF in oculocardiac reflex ($0.27<r<0.40$; $p<0.05$); lead and SDNN, TP, LF, HF during deep breathing ($0.28<r<0.31$; $p<0.05$); lead and rMSSD, pNN50, HF ($0.26<r<0.29$; $p<0.05$) during active orthostatic test. Most of the correlations were observed between Pb and HRV parameters recorded after exercises: positive with RRNN, SDNN, rMSSD, pNN50, TP, LF, HF, VLF, HFn and negative with LF/HF and LFn ($0.27<r<0.42$; $p<0.05$). Revealed correlations suggest an increased parasympathetic activity in participants with higher lead concentrations during various cardiovascular tests, indicating that lead affects the vagal nerve more than other cardiac nerves. Pb levels were also associated significantly with heart rate during oculocardiac, orthostatic test and after exercises, suggesting negative chronotropic effect of lead ($-0.29<r<-0.36$; $p<0.05$). These findings suggest that recording HRV during simple cardiovascular tests may be more sensitive than recordings during supine rest in low-level lead exposure in children.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC096

Aliskiren and L-arginine reduce the renal sympathetic activity and improves renal function in rats with renovascular hypertension

V. Mengal, R. Tiradentes, H. Futuro Neto, N. Silva, P. Matos, A. Carvalho, S. Gouvea and G.R. Abreu

Physiological Sciences, Federal University of Espirito Santo, Vitoria, Espirito Santo, Brazil

Studies indicate that the renal sympathetic activity plays an important role in progression of renovascular hypertension and tissue damages. The aim of this study is to elucidate the effects of combination Aliskiren (ALK) and L-arginine (L-ARG) on the blood pressure and renal sympathetic activity. Renovascular hypertension (2K1C) was produced in Male Wistar rats (140-160 g). Seven days after the renal artery clipped was performed by plethysmography to measure systolic blood pressure (SBP). The rats were divided in groups:Sham (n=6), 2K1C (n=7), 2K1C treated with aliskiren 50 mg/kg (ALK, n=9), 2K1C treated with L-arg 300 mg/kg (L-ARG, n=9) and 2K1C treated with a combination of ALK and L-arg (ALK + L-ARG, n=10). The treatment was performed for 21 days by gavage. At the end of treatment was made new plethysmography and the urine collection of 24 hours. The animals were anesthetized with urethane (1.2 g/Kg) for direct measurement of SBP and recording of renal nerve activity (RNA). At the end of the protocol, blood samples were taken and analyzed the expression of endothelial nitric oxide synthase (eNOS) in both kidneys by Western blotting. Statistical analysis was determined using 1-way ANOVA and Tukey test. Values are expressed as mean ± SEM and the significance of $P < 0.05$. Only the treatment with the combination of ALK + L-arg was able to normalize SBP (138 ± 4.4 mmHg) compared to groups 2K1C, ALK and L-ARG (204 ± 12.7; 202 ± 17.7 and 176 ± 9 mmHg), since values were similar to SHAM (114 ± 5.2 mmHg). Similarly, the basal RNA in ALK + L-ARG and L-ARG was also normalized (SHAM: 62 ± 6.4; 2K1C: 97 ± 8.4; ALK: 84 ± 2.5; L-ARG: 71 ± 3.1 and ALK + L-ARG: 64 ± 3.4%) and an improvement of sympathetic responsiveness to changes in SBP in ALK + L-ARG group (SHAM: -54 ± 6.1; 2K1C: -25 ± 3.2; ALK: -30 ± 3.8; L-ARG: -34 ± 3.6 and ALK + L-ARG: -55 ± 6.1% Δ ANR with phenylephrine and SHAM: 78 ± 15.6; 2K1C: 13 ± 2.8; ALK: 21 ± 3.67; L-ARG: 38 ± 3.4 and ALK + L-ARG: 49 ± 8.79% Δ ANR with NPS). The animals L-ARG and ALK + L-ARG had natriuretic effect (SHAM: 148 ± 14.13; 2K1C: 48 ± 7.93; ALK: 48 ± 9.25; L-ARG: 121 ± 8.1 and ALK + L-ARG: 129 ± 7.8 mEq/L) and a tendency to present diuretic effect (SHAM: 20 ± 2; 2K1C: 11 ± 0.5; ALK: 9 ± 0.7; L-ARG: 17 ± 2.3 and ALK + L-ARG: 16 ± 2.1 mL/day) and improve urinary flow (SHAM: 0.014 ± 0.001; 2K1C: 0.008 ± 0.001; ALK: 0.006 ± 0.001; L-ARG: 0.011 ± 0.001 and ALK + L-ARG: 0.011 ± 0.001 ml / min), besides improving glomerular filtration rate (ALK + L-ARG: 2.06 ± 0.49; L-ARG: 1.73 ± 0.38; 2K1C: 0.35 ± 0.1; ALK: 0.45 ± 0.1). There was an increased eNOS expression only in the kidney clipped. The combination of ALK and L-ARG was able to reduce the sympathetic hyperactivity, increased diuresis, natriuresis and improved glomerular filtration rate, that contribute to reduce the arterial pressure levels.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC098

Combined acute hyperglycaemia and airway occlusion significantly increases nitrosative stress and poly(ADP) ribose polymerase activation

Z.A. Siddiqui, A.A. Tahrani, P. Kumar and C.J. Ray

School of Clinical and Experimental Medicine, University of Birmingham, Birmingham, UK

Hyperglycaemia in diabetes can cause nitrosative/oxidative stress and subsequent Poly(ADP)Ribose Polymerase (PARP) activation that are implicated in the pathogenesis of microvascular complications. Obstructive sleep apnea (OSA) causes nitrosative/oxidative stress and is common amongst patients with diabetes. We hypothesised that diabetes and OSA together cause greater nitrosative/oxidative stress than either alone and tested this in an acute rat model of hyperglycaemia and airway occlusion.

In 26 male Wistar rats anaesthesia was induced with 3.5% isoflurane in oxygen and was maintained by continuous infusion of Alfaxan ($5mg.ml^{-1}$ at $0.8ml.hr^{-1}$ I.V.). Animals were exposed to one of the following four conditions for six hours: normoglycaemia airway unoccluded (NGAU, n=7), normoglycaemia airway occluded (NGAO, n=6), hyperglycaemia airway unoccluded (HGAU, n=7) and hyperglycaemia airway occluded (HGAO, n=6). In all groups blood glucose was monitored throughout the protocol and in HG groups, glucose was administered via the femoral vein to maintain glucose levels at $12mmol.L^{-1}$. In AO groups, airway occlusions occurred for 15 seconds every minute by mechanical occlusion of a cannula placed in the trachea. Rats were killed by exsanguination followed by cervical dislocation for confirmation and organs were harvested. 3-nitrotyrosine (NT) levels were measured in plasma samples using commercially available ELISA kits (Oxiselect, San Diego) and liver sections were stained for Poly(ADP)Ribose (PAR) using immunohistochemistry. Values are expressed as means ± S.E.M. and significance ($P<0.05$) was determined by one-way ANOVA.

In control NGAU plasma NT was 88±17 nM; 6 hours of hyperglycaemia or airway occlusion alone did not cause a significant increase in plasma NT (114±19 nM and 149±16 nM respectively), however 6 hours combined hyperglycaemia and airway occlusion did significantly increase plasma NT (289±44 nM, $p=0.017$). The same response was seen for PAR staining in the liver with combined HG and AO significantly ($p<0.001$) increasing % PAR stained nuclei (NGAU 19±3 %, HGAU 29±5 %, NGAO 35±3 % and HGAO 49±5 %).

In our model, just 6 hours of combined HG and AO increased levels of NT and downstream effects that influence the progression of microvascular complications than either insult alone. This suggests that OSA in patients with diabetes may exacerbate the development of microvascular complications.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC099

Chronic suppression of paraventricular nucleus of the hypothalamus neuronal activity produces sustained hypotension in spontaneously hypertensive rats

V. Geraldes[1], N. Gonçalves-Rosa[1], R. Laires[1], R. Lopes-Gonçalves[1], J. Paton[2] and I. Rocha[1]

[1]Cardiovascular Autonomic Laboratory, Instituto de Medicina Molecular and Faculty of Medicine, University of Lisbon, Lisbon, Portugal and [2]Bristol Heart Institute, Medical Sciences Building, University of Bristol, Bristol BS8 1TD, Bristol, UK

Several studies suggest that changes in the sympathetic nervous system (SNS) are responsible for the initiation, development and maintenance of hypertension. SNS over activity may result from an inappropriately elevated sympathetic drive from brain centers. One important central sympatho-excitatory region is the paraventricular nucleus of the hypothalamus (PVN), which may become more active in hypertensive conditions, as shown in acute studies.
Objective: Depress chronically the activity of PVN neurons by the over-expression of an inwardly rectifying potassium channel (hKir2.1) in order to evaluate the consequences upon blood pressure regulation in an animal model of hypertension.
In telemetry instrumented spontaneously hypertensive rats (SHRs) lentiviral vectors: LVV-hKir2.1 (LV-TREtight-Kir-cIRES-GFP5 4x10E9: LV-Syn-Eff-G4BS-Syn-Tetoff 6.2x10E9 in a ratio 1:4) were as microinjected bilaterally into PVN stereotaxically. Sham SHRs were bilaterally microinjected with LVV-eGFP (LV-Syn-Eff-G4BS-Syn-Tetoff 6.2x10E9: LV-TREtight-GFP 5.7x10E9 in a ratio 1:4) in the PVN. Blood pressure (BP) and heart rate (HR) were monitored continuously and evaluated using radiotelemetry for 75 days. Baroreflex function was evaluated by measuring HR changes induced by BP variation produced by phenylephrine (25μg/ml, iv) injection. Lobeline (25μg/ml, iv) was used to evaluate peripheral chemoreflex sensitivity. These procedures were performed under anaesthesia.
Heart, kidneys and vessels were collected post-mortem to evaluate, by RT-PCR, the expression of 20 key genes involved in the pathways regulating blood vessel tone.
Results: LVV-hKir2.1 expression by PVN activity in SHRs produced a time-dependent and significant decrease in systolic (158±1 to 134±1mmHg), diastolic (137±1 to 115±1mmHg) and mean BP (144±1 to 121±1mmHg) as well as in HR (314±3 to 295±3bpm) 60 days post-microinjection of LVV-hKir2.1. In SHRs the cBRG significantly increased after LVV-hKir2.1 microinjection (0.51±0.06 and 1.3±0.18bpm/mmHg). The chemoreceptor reflex evoked pressor response and the LF-band decreased in the LVV-hKir2.1-SHR group (0.71±0.3 to 0.42±0.26mmHg2) suggesting reduced sympathetic vasomotor tone. RT-PCR analysis showed a downregulation of angiotensin II receptors together with a decrease on calcium transport.
Conclusion: Our data showed, for the first time, that PVN neuronal excitability plays a major role in the long term control of blood pressure and SNS activity in SHRs. This may be mediated, in part, by improved baroreflex sensitivity and reduced peripheral chemosensitivity and respiratory-sympathetic modulation. Molecular studies showed that the microinjection of LVV-hKir2.1 interfere mainly with the endocrine regulation of BP through angiotensin II. Our results support the PVN as a therapeutic target in the control of blood pressure in neurogenic hypertension.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC100

Depression of rostroventrolateral medulla neurons excitability maintains normotensive values of blood pressure in spontaneously hypertensive rats

N. Gonçalves-Rosa[1], V. Geraldes[1], R. Laires[1], R. Lopes-Gonçalves[1], J. Paton[2] and I. Rocha[1]

[1]Cardiovascular Autonomic Function Lab, Instituto de Medicina Molecular and Faculty of Medicine, University of Lisbon, Lisboa, Portugal and [2]Bristol Heart Institute, Medical Sciences Building, University of Bristol, Bristol BS8 1TD, UK, Bristol, UK

Background: The sympathetic nervous system (SNS) is responsible for the onset, development and maintenance of neurogenic hypertension. It was shown an increased activity of central sympathoexcitatory regions such as the rostroventrolateral medulla (RVLM) in an animal model of hypertension. Changes in autonomic balance can be achieved through spectral analysis of systolic blood pressure and heart rate.
Objective: Depress the activity of RVLM neurons by over-expression of an inwardly rectifying potassium channel (hKir2.1) in order to establish their relative roles in the long-term regulation of blood pressure (BP) in conscious spontaneously hypertensive rats (SHR).
Methods: In telemetry instrumented SHRs (n=7), a lentiviral vector LVV-hKir2.1 (LV-TREtigh-Kir-cIRES-GFP5.4x10E9: LV-Syn-Eff-G4BS-Syn-Tetoff6.2x10E9 in a ratio 1:4) was bilaterally microinjected (0.05μL) into RVLM using stereotaxic coordinates. Sham SHRs (n=4) were bilaterally microinjected with LVV-eGFP (LV-Syn-Eff-G4BS-Syn-Tetoff6.2x10E9: LV-TREtight-GFP5.7x10E9 in a ratio 1:4) in the same region. BP and Heart Rate (HR) were continuously monitored and evaluated using radio-telemetry for 75 days.
Baroreflex gain was calculated by measuring heart rate changes induced by arterial pressure variation produced by phenylephrine (25μg/ml, IV) injection. The chemoreflex activation was evaluated through variations in respiratory rate evoked by the injection of lobeline (25μg/ml, IV). These procedures were performed under anaesthesia.
Heart, kidneys and vessels were collected post-mortem to evaluate, by RT-PCR, the expression of 20 key genes involved in the pathways regulating blood vessel tone.
Results: Depression of RVLM neurons activity in SHRs leads to a significant decrease in of systolic (157±18 to 125±25 mmHg), diastolic (126±11 to 97±25 mmHg), mean (137±12 to 106±25 mmHg) BP and HR (306±35 to 292±29 bpm) 60 days post-injection. In sham rats no significant changes were detected in all parameters.
In SHRs the LF-band decreased after the LVV-hKir2.1 microinjection (0.75±0.46 to 0.53±0.16 mmHg^2). In sham rats there was an increase in LF-band. RT-PCR showed an upper regulation of endothelin a and b receptors together with an expression trend to normality of endothelin 1 and endothelin 2 genes.
Conclusion: These results show that a reduction of RVLM neurons excitability caused a sustained decrease of blood pressure in SHRs. This was probably due to a reduction in sympathetic output, as evidenced by the decrease in the LF and LF/HF bands. This action is supported by changes in endothelial function due to vascular remodeling. By identifying the role of this central area in the long-term control of BP, we expect to

provide realistic targets for therapeutic interventions in hypertension.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Impact of smoking on microcirculation and of its relationships with smoker's clinical characteristics or smoking habit: an observational study

M. Rossi[1], L. Carrozzi[2], F. Pistelli[2], M. Pesce[1], F. Aquilini[2] and G. Santoro[1]

[1]Unit of Sport Medicine, Clinical and Experimental Medicine, University Hospital of Pisa, Pisa, Italy and [2]1st Pulmonary Unit, Cardio-Thoracic and Vascular, University Hospital of Pisa, Pisa, Italy

The impact of smoking on microcirculation has been studied in small groups of subjects, preventing the evaluation of possible influences of smoker's clinical characteristics or smoking habit variables on microcirculation. In order to fill this gap, we measured forearm skin blood flux under basal conditions and in response to ischemia in 100 current smokers (duration of smoking habit: 33.4 + 12.3 years), mean age 51 + 11 years (range: 8 to 86 yrs) consecutively enrolled at the smoking cessation clinic of the University Hospital of Pisa, and in 66 never-smoker controls matched by sex and age, using laser Doppler fluximetry (LDF). Information on smoking exposure and presence of other cardio-vascular risk factors were collected by standardised procedures. Skin post-occlusive reactive hyperaemia (PORH) was expressed as maximal post-ischemic flux (peak-flux) and as post-ischemic percentage change from baseline of the area under the LDF curve (AUC %). The skin LDF tracings were analysed in the frequency domain using an adapted version of Fourier analysis. Using this method we measured: the normalized (%) spectral power within 0.009-1.6 Hz total spectrum of the frequency intervals 0.009–0.02 Hz, related to endothelial-dependent skin vasomotion (SV); 0.021–0.06 Hz, related to sympathetic-dependent SV; 0.061–0.2 Hz, related to myogenic-dependent SV. Basal skin blood flux, peak-flux, AUC % and the sum of the normalized spectral power of endothelial-, sympathetic- and myogenic-dependent SV, were significantly lower (Wilcoxon test) in smokers than in non smokers (table). Smokers with at least one associated cardiovascular risk factor, such as arterial hypertension, diabetes or hypercholesterolemia, showed a significantly ($p = 0.02$) lower AUC %, compared to non-smokers. At the linear regression analysis, an inverse relationship was observed in smokers between AUC% and the smoking habit duration ($r = 0.23$, $p = 0.018$), age ($r = 0.26$, $p = 0.008$) and body mass index ($r = 0.21$, $p = 0.037$) of smokers. This study confirms that smoking is associated with microcirculatory impairment and shows that this impairment is negatively influenced by smoking habit duration, subjects' age, BMI and presence of other cardiovascular risk factors.

Results of skin Laser-Doppler test in smokers and control subjects

	Control subjects	Smokers	p
Basal skin blood flux (PU)	14.6 (10.6 - 6.5)	7.76 (5.74 - 11.79)	0.03
Skin peak-flux (PU)	73.5 (51.9 - 32.4)	39.0 (27.7 - 52.8)	0.004
Skin AUC %	216.8 (190.1 - 156.3)	162.5 (139.3 - 183.0)	0.00016
Normalized skin vasomotion (%)	77.4 (67.9 - 84.6)	71.7 (64.9 - 79.8)	0.017

Data are as median and inter-quartile range.

AUC=area under laser-Doppler curve.

PU=perfusion unit.

The endothelium of pulmonary arterial hypertension patients shows a disturbed adaptation to high levels of shear stress

R. Szulcek[1,3], T.A. Leyen[2], R. Fontijn[2], V.W. van Hinsbergh[3], A.J. Horrevoets[2], A. Vonk-Noordegraaf[1], H.J. Bogaard[1] and G.P. van Nieuw Amerongen[3]

[1]Pulmonology, VU University Medical Center, Institute for Cardiovascular Research (ICaR-VU), Amsterdam, Netherlands, [2]Molecular Cell Biology and Immunology, VU University Medical Center, Institute for Cardiovascular Research (ICaR-VU), Amsterdam, Netherlands and [3]Physiology, VU University Medical Center, Institute for Cardiovascular Research (ICaR-VU), Amsterdam, Netherlands

Rationale We hypothesize that severe pulmonary vascular remodelling in pulmonary arterial hypertension (PAH) is triggered by sustained endothelial injury in pre-capillaries caused by increased shear stress (SS). Therefore we tested whether human pulmonary microvascular endothelial cells (HPMVEC) from PAH patients are capable to adapt to high levels of SS.
Methods and Results HPMVEC were isolated from PAH patients (autopsies and lung transplantations) and controls (rest material from lung tumor surgeries). The study has been approved by the IRB as non-WMO and consent was given. Static controls were compared to cells under physiological low (LSS, 2.3 dyn/cm^2) and pathological high shear stress (HSS, up to 25 dyn/cm^2). Different flow profiles (laminar, bifurcation-like) were applied and electrical resistance of the monolayers was recorded with ECIS (applied biophysics), as a measure for barrier function and cell behavior. Most striking are our findings in structural adaptation to HSS. Control HPMVEC re-aligned in flow direction, whereas HPMVEC from PAH patients failed to align after 72 hrs HSS challenge. Specifically, 65.3%±1.4 of the total number of control HPMVEC elongated, whereas 72.4%±4.4 of those cells re-aligned within an angle of less then 20 degrees relative to the flow direction (n=4, mean±SEM). Opposing only 47.2%±8.5 of PAH cells showed a stretched morphology and alignment randomly in the direction of flow (n=5, mean±SEM). Interestingly, upon HSS stimulation expression of the tested genes, known to play a role in shear sensing and adaptation (e.g. KLF2 and TGF-β), was up-regulated in both PAH and control samples. Under static culture conditions, PAH cells showed an irregular distribution and organization as well as decreased protein expression of the shear sensors VE-cadherin and CD31 (immunostaining and Western blot, n=4). Modeling of the electrical data gave further proof for weakened cell-cell adhesions in PAH cells. On the contrary, PAH and control HPMVEC formed similar endothelial barriers with a baseline resistance of 7767 vs. 8102 ohms. Here the ECIS modeling indicated an increased cell-matrix adhesion as possible cause. Furthermore, application of HSS to PAH HPMVEC caused severe cell loss, when bifurcation-like flow patterns were used. Control HPMVEC on the other hand were able to withstand those flow patterns.

Conclusion and Relevance We showed that HPMVEC from PAH patients have a hampered ability to adapt, but not to sense pathological HSS, which can result in severe endothelial damage at vascular bifurcations. The causes for the failing adaptation are under testing and point towards a misbalance in cell-cell and cell-matrix adhesion. Our findings support the idea for a role of SS in the disease progression of PAH and imply, that new treatment strategies should consider normalization of the pulmonary blood flow to protect endothelial cells from injury and prevent vascular remodelling.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Age dependent changes of carotid intima-media thickness and their possible linkage with activity of sympathetic nervous system in healthy volunteers

V. Fokin, N. Ponomareva and G. Kuncevitch

Brain Research, Research Center of Neurology of Russian Academy of Medical Science, Moscow, Russian Federation

One of the signs of atherosclerosis is the intima-media thickness (IMT) in the common carotid artery (CCA). The development of atherosclerosis is a multifactorial process which besides the age depends on many other factors, including the states of the autonomic nervous systems. In 29 healthy volunteers (12 men and 17 women from 19 to 70 years) IMT of both CCA was measured using ultrasound duplex scanning. Millivolt-scale DC potentials were recorded from 5 sites on head with AG/AgCl electrodes. Scalp electrodes were situated in frontal, central and occipital positions by sagittal line as well as in left and right temporal areas according to 10x20 international scheme (reference electrode on the wrist). Electrode potentials and dermal resistances were controlled (Voipio at al., 2003). IMT correlated with age of volunteers: for the right CCA r =0.60 (p <0.001), for the left CCA r=0.51 (p =0.004). IMT was significantly (p=0.026) thicker in the right than in the left CCA in the volunteers over 45 years. The difference between the right and left IMT=0.10+/-0.04; N=19. DC potential in right temporal area was factor influencing IMT in the right and left CCA: F=5.04 (p=0.033) and F=7.14 (p=0.012) by ANOVA, accordingly. High-amplitude DC potentials in the right temporal area corresponded to high values of IMT in the right and left CCA. Onbas at al. (2007) showed that handedness was a significant factor of IMT asymmetry. In our investigations only right handers women had significant predominance of rightward asymmetry of IMT of the CCA in any age (p<0.05). Right frontotemporal area is representative of cortical afferents of sympathetic nervous system (Craig, 2005) and DC potentials in this area may reflect its activity. This suggestion was confirmed by the investigations of cardiovascular regulation (Fokin et al., 2010).Chronic stress related to the activation of sympathetic nervous system leads to increasing probability of thickening of artery wall (Roepke at al., 2012). The correlation of high sympathetic activity was most pronounced with respect to DC potentials of temporal area of the right hemisphere than of the left hemisphere (Fokin, et al., 2010). Increase of IMT of the CCA was associated with age and a rise of DC potential in right temporal area. The increase of DC potential probably reflected the activation of sympathetic nervous system. Significant rightward asymmetry of IMT of the CCA was found and it was particularly noticeable after 45 years.

Mechanisms of central cardiovascular effects of H2S in SHR rats: the role of reactive oxygen species

H. Yu, D. Cao, H. Xu, R. Wang and N. Lu

Department of Physiology and Pathophysiology,, Fudan University, Shanghai, China

Hydrogen sulfide (H2S) is considered to be a new gaseous molecular alongside with NO and CO. It is produced mainly by cystathionine β-synthase (CBS) in brain. Lots of evidences indicate that H2S performs a wide range of physiological and pathological functions. However, the central cardiovascular effects of H2S are not fully identified. In present study, we tested the hypothesis that H2S in CNS may inhibit NADPH oxidase and decrease the production of reactive oxygen species (ROS), thus mediate central cardiovascular effects. Experiments were completed in Wistar-Kyoto (WKY,250g-300g) rats and spontaneous hypertensive rats (SHR, 250-300g). We used immunohistochemistry method to observe the expression of CBS in rostral ventrolateral medulla (RVLM) of both SHR rats and WKY rats. Artifcial cerebrospinal fluid, NaHS (the H2S donor),or Apocynin (an inhibiter of NADPH oxidase) was given through a cannula implanted into the lateral cerebral ventricle, and mean arterial blood pressure(MAP)and heart rate (HR) were recorded. Lucigenin-enhanced chemiluminescence was used to estimate the level of ROS and the activity of NADPH oxidase in RVLM of rats in each group. One-way ANOVA was used for data stastistics. The following observations were made:1) Expressions of CBS of RVLM were increased in WKY rats compared with SHR rats(P<0.05, n=5). 2) Intracerebroventricular (ICV) infusion NaHS (4nmol/10μl),or Apocynin (100nmol/10μl)significantly decreased MAP and HR in SHR rats.(P<0.05 both, n=6). 3) The level of ROS and the activity of NADPH oxidase in RVLM of SHR control group was higher than the level in WKY control group(P<0.05, n=8), and after infusion with NaHS (4nmol/10μl) or Apocynin (100nmol/ 10μl), the level of ROS and activity of NADPH oxidase was decreased in SHR rats compared with that in SHR controls(P<0.05, n=8). The results of present study suggest that H2S in central nervous system could decrease blood pressure and heart rate in SHR rats by inhibiting the activity of NADPH oxidase in the RVLM in SHR.

Modulation of cholinergic and nitric oxide signaling pathways at the local efferent regulation of small intestine of rat by acute exposure of inorganic pentavalent arsenical

G. Paul, M. Ghosh, K. Sarkar and P. Tarafder

Department of Physiology, University of Kalyani, Kalyani, West Bengal, India

Arsenic is a ubiquitous poison that crowns the list of hazardous substances as cataloged by the Agency of Toxic Substances and Disease Registry. Arsenic occurs naturally in over 200 different mineral forms, of which approximately 60% are arsenates. Humans are exposed to pentavalent arsenicals through groundwater and ecological food chains. Absorption of sodium arsenate (As V) through the gastrointestinal tract has been reported to be 94% in humans. However, to date, no basic study has been done on the effect of As V exposure on the response of neurotransmitter pathways and enzymes related to those neurotransmission pathways in the mammalian gastrointestinal system. Intestinal motility is crucial to digestive and absorptive functions of gastrointestinal tract and as such is regulated by a myriad of excitatory and inhibitory neurotransmitters and enzymes catalyzing or synthesizing them. To bridge this knowledge gap we adopted a novel combination of crossover and placebo controlled study (1). The study was designed in two sets. In set A -in vitro organ bath experiments were conducted (following the protocols of crossover methodology) on isolated intestine of Charles foster rats (male, 35±5 day, 100 ± 17g, n=7) with a combination of different neurotransmitters and As V applied postmortem in the tissue chamber. In the first set isolated duodenal segments were first incubated with As V and the neurotransmitter in that order and also in the reversed order. The motility records were obtained by isotonic transducer IT-2245 coupled to RMS-Polyrite D software [RMS (P) Ltd, Chandigarh, India, 2010]. Our study showed that As V induced additive effect to acetylcholine and counteractive effect to nitric oxide. In set B – the test group rats (n=7) were exposed orally to LD50 dose of As V for 24 hours for a placebo controlled study, whereas the control rats were treated with arsenic free distilled water. Rats were humanely killed by cervical dislocation following the institutional guidelines foregoing anesthesia due to the nature of the experiment. In the second set we compared acetylcholinesterase activity (2) and nitric oxide synthase expression profile (3) of male Charles Foster rats (100 ± 17 g) orally exposed to LD50 24h As V to sham-treated animals. The results showed As V treatment inhibited both acetylcholinesterase and nitric oxide synthase in the duodenal smooth muscle of rat. Hence, we may conclude that As V stimulates cholinergic transmission and inhibits nitric oxide mediated neurotransmission in controlling movement of small intestine of rat efferently at the local level.

Preinduction of HSP-70 by hypobaric hypoxia preconditioning attenuates ischemia, inflammation, oxidative stress and apoptosis in rat brain in heat stroke

C. Chang[1], L. Wang[2], C. Wang[3,4], B. Chio[5], J. Yu[5] and B. Cheng[1,3]

[1]Department of Biotechnology, Southern Taiwan University of Science and Technology, Tainan, Taiwan, [2]Graduate Institute of Clinical Medicine, National Cheng-Kung University Medical School, Tainan, Taiwan, [3]Department of Surgery, Chi Mei Medical Center, Tainan, Taiwan, [4]Department of Recreation and Health-Care Management, Chia-Nan University of Pharmacy and Science, Tainan, Taiwan and [5]Department of Chinese Medicine, Chi Mei Medical Center, Tainan, Taiwan

Despite the indication that the beneficial effects of hypobaric hypoxia preconditioning (HHP) in heatstroke are related to induction of heat shock protein (HSP) 70 in vital organs, there has not been any studies focusing on the relationships among HHP, brain HSP-70, and brain apoptosis, ischemia, inflammation, and oxidative stress in heatstroke. This study was to test whether HHP diminished apoptosis, ischemia, inflammation, and oxidative stress in heatstroke by up-regulating HSP-70. Anesthetized rats were randomly assigned to a) non-heated+non-HHP group, b) heated+non-HHP group, c) heated+HHP rats, and d) heated+HHP+HSP-70 antibodies (Ab) rats. All heated groups were exposed to heat stress (43 °C), 70 minutes) to induce heat stroke. We reported here that HHP induced overexpression of brain HSP-70, which could be ameliorated by HSP-70 antibody treatment in rats. When anesthetized non-HHP (or without brain HSP-70 overexpression) rats, HHP (or with brain HSP-70 overexpression) rats, and HHP+HSP-70 Ab (or without brain HSP-70 overexpression) rats were exposed to heat stress, their survival time values were found to be 89-95 mins, 409-431 mins, and 99-113 mins, respectively. Compared to non-HHP rats or (HHP+HSP-70 antibody) rats, HHP rats displayed higher values of cerebral blood flow and partial pressure of oxygen. In contrast, HHP rats had lower values of apoptotic cells, cellular ischemia and damage markers, pro-inflammatory cytokines, oxidative damage markers, and an indicator for neutrophils accumulation in the brain. The beneficial effects of HHP in improving apoptosis, ischemia, inflammation, and oxidative stress in rat brain in heatstroke could be ameliorated by HSP-70 Ab therapy. These results suggest that HHP improved survival and prevented heat damage to the brain and that the underlying mechanism involved induction of HSP-70 and inhibition of ischemia, inflammation, oxidative stress, and apoptosis.

Antipyretic effect of Ocimum gratissium on brewer's yeast induced fever in wistar rats

G.I. Grace[1], B.S. Alisa[1], I.U. Vincent[1,2] and S.O. Mercy[1]

[1]physiology, Bingham university, Nasarawa, Nasarawa state, Nigeria and [2]Physiology, University of Sokoto, Sokoto, sokoto, Nigeria

Pyrexia or fever is a disease caused as a result of secondary impact of other diseased states due to the resetting of the hypothalamic set-point. From scientific discovery, antipyretic drugs such as asipirin, NSAIDs, opiods have been developed for use and of which mostly produces side effects including gastrointestinal bleeding,renal,hepatic effect,etc(Cheng et al.,2005,Sharma et al., 2010).Therefore, many herbal plants have been found to be having antipyretic effects.Ocimum gratissimum is a shrub commonly found in Africa and has been used to treat bacterial fevers locally. This study investigates the antipyretic activity of the methanolic extract of Ocimum gratissimumon brewer's yeast induced fever in experimental rats.30 albino rats weighing 150g-200g were used. They were divided in to six groups of five rats each. Group one serve as control(n=5) and was given 1ml of normal saline,group two (n=5)was treated with brewer yeast alone, group three(n=5) was given 100mg/kg of asipirin, while groups four,five and five were treated with 300mg/kg,200mg/kg and 100mg/kg (n=5)of Ocimum gratissimum respectively. A suspension of brewer's yeast was injected subcutaneously to induce fever in all the experimental animals. After 18hrs, the rectal temperature was taken and the animals were administered Ocimum gratissimum(100mg/kg.200mg/kg,300mg/kg) and aspirin (standard group,100mg/kg) orally. The body temperature of the rats was measured rectally over a period of 4hours.Ocimum gratissimum(100mg/kg, 200mg/kg and 300mg/kg) significantly reduced yeast induced pyrexia,36.88±0.39°C, 36.43±0.26°C and 35.83±0.46°C when compared the group two(20ml/kg, brewer's yeast) temperature of 37.80±0.18°C(*p<0.05,respectively). The group three(asipirin,100mg/kg) also show significant reduction 36.55±0.22°C,*p<0.05,compared with group two(20ml/kg,brewer yeast) with temperature 37.80±0.18°C.Thus, this experiment shows that the antipyretic effect of ocimum gratssimum is dose dependent and the effect is as a result of the flavonoid component of the extract.These data therefore suggest that methanolic extract of Ocimum gratissimum leaves possesses significant antipyretic activity and it mechanism could be by inhibition of/release inflammatory mediators.

Acute oral pseudoephedrine administration decreases latency time to central nervous system oxygen toxicity seizures in rats

H.E. Held, R. Pilla and J.B. Dean

Molecular Pharmacology and Physiology, University of South Florida, Tampa, FL, USA

People exposed to high partial pressures of oxygen, such as scuba divers, risk the onset of central nervous system oxygen toxicity (CNSOT). CNSOT presumably results from an accumulation of free radicals such as reactive oxygen species in the brain and produces epilepsy-like grand mal seizures, which may be fatal in an underwater environment. Many divers also use the neuro-excitatory drug pseudoephedrine (PSE) to reduce sinus inflammation. Incident reports from the Divers Alert Network (DAN) suggest a link between PSE use and an increased risk of diving accident or injury. The purpose of this study was to determine whether or not increasing doses of PSE decrease the latency to seizure (LS).

Male and female rats (250 to 350g) were included so that gender-dependent differences could also be elucidated. Rats were surgically implanted under isoflurane anesthesia with radiotelemetry units, which allowed measurement of electroencephalograms without restraint. One week after surgery, each rat received a single 1 mL dose of PSE in saline (0, 40, 80, 100, 120, 160, and 320 mg/kg) via oral gavage. Nine rats were included in each group. Rats breathed 100% oxygen during a dive to 5 atmospheres absolute in a hyperbaric chamber. LS was defined as the duration of time between reaching maximal pressure and onset of seizure (increased electroencephalogram activity coupled with tonic-clonic spasms of forelimbs and head).

Data are presented in Table 1 (mean ± SEM). Males exhibited decreased LS and decreased variability with increased dosage. The decrease in LS was significant at 100 mg/kg and higher. Females exhibited decreased LS following doses of 80 mg/kg, 100 mg/kg, and 320 mg. The decreases at 120 mg/kg and 160 mg/kg did not reach statistical significance, apparently due to increased variability. There were no significant differences between males and females.

We conclude that only high doses of PSE decrease LS. Further testing is underway to determine the effects of menstrual cycle phase, age, and history of pregnancy on LS in female rats.

The first two authors contributed equally.

Table 1

PSE Dose (mg/kg)	0	40	80	100	120	160	320
Male LS (min)	39.4 ± 8.3	50.7 ± 12.7	33.2 ± 11.1	14.8 ± 5.7	9.9 ± 1.7	9.1 ± 1.0	17.7 ± 4.5
Female LS (min)	26.9 ± 4.8	26.7 ± 11.7	14.2 ± 2.3	14.7 ± 3.6	18.2 ± 6.5	22.8 ± 9.9	8.1 ± 1.1

Large-scale correlated wave in the embryonic mouse CNS: Development, origins and pharmacological natures

K. Sato[1,3] and Y. Momose-Sato[2]

[1]Department of Health and Nutrition Sciences, Komazawa Women's University, Faculty of Human Health, Tokyo, Japan, [2]Department of Health and Nutrition, Kanto Gakuin University, College of Human and Environmental Studies, Yokohama, Japan and [3]Opto-Medical Institute, Tokyo, Japan

Spontaneous embryonic movements, called embryonic motility, are produced by correlated spontaneous activity in the cranial and spinal nerves, which is driven by brainstem and spinal networks. Using optical imaging with a voltage-sensitive dye, we have revealed previously that this correlated activity is a widely propagating wave of neural depolarization, which we termed the depolarization wave. We have observed in the chick and rat embryos that the activity spread over an extensive region of the central nervous system, including the spinal cord, hindbrain, cerebellum, midbrain, and forebrain. One important consideration is whether a depolarization wave with similar characteristics occurs in other species, especially in different mammals. Here, we provide evidence for the existence of the depolarization wave in the mouse embryo by showing that the widely propagating wave appeared independently of the localized spontaneous activity detected previously with Ca2+ imaging. Pregnant mice were anesthetized with ether, and the spinal cord was dislocated at the cervical level. Their fetuses were then surgically removed, and the whole brain-spinal cord or brainstem-spinal cord preparation was dissected in an ice-cold solution. We mapped the origin of the depolarization wave and revealed that the wave generator moved from the rostral spinal cord to the caudal cord as development proceeded, and was later replaced with mature rhythmogenerators. Furthermore, we examined the pharmacological nature of the mouse depolarization wave and its developmental changes. We show here that two types of switching in pharmacological characteristics occur during development. One is that the depolarization wave is strongly dependent on nicotinic acetylcholine receptors during the early developmental stage (E11-E12), but is dominated by glutamate at the later stage (E13~). The second is that GABA, which acts as an excitatory mediator of the depolarization wave during the early phase, becomes an inhibitory modulator by E14. These changes seemed to occur earlier in the hindbrain than in the spinal cord. We also show that the second switching causes the loss of synchronization over the network, resulting in the disappearance of the depolarization wave and a segregation of the activity into discrete regions of the medulla and spinal cord. The present study shows that a synchronized wave with common characteristics is expressed in different species, suggesting fundamental roles in neural development.

Could the foetal brain be damaged by molecules released from the placenta?

V. Leinster[1], S. Sanderson[2], J. Henley[3], K. Simon[2] and P. Case[1]

[1]Musculoskeletal Research Unit, University of Bristol, Bristol, UK, [2]BRC Translational Immunology Lab, Experimental Medicine Division,, Oxford University, Oxford, UK and [3]MRC Centre for Synaptic Plasticity, University of Bristol, Oxford, UK

Abnormal blood flow in the placenta, leading to hypoxia or reperfusion is linked to damage to the foetal brain and may occur in a variety of conditions including miscarriage, pre eclampsia and intrauterine growth restriction (1). This may lead to lifelong disability ranging from cerebral palsy to Autism spectrum disorders. Our data shows that hypoxia reperfusion of a cellular model of the placenta induces the release of toxic factors that damage neurons and astrocytes in cortical cultures. In vitro barriers that model the placenta were made from BeWo cells and exposed to various concentrations of oxygen (2%, 2-8%, 2-12%, 2-21%, 21%) and the tissue culture media was collected as conditioned media (CM). Dissociated neurons from rat E18.5 cortical cultures were grown for 12 days before being exposed to CM for 6 days. Hippocampal slices were also taken from P7 rats and grown as organotypic cultures for 14 days before being exposed to CM for 6 days. Cultures/ hippocampal slices were then fixed and fluorescently stained with MAP2 and GFAP to identify the neuronal and astrocyte cell populations. Images were captured using confocal microscopy and cell morphology was analysed using ImageJ. Flow cytometry analysis (LSRII) was also performed on cortical cultures to analyse the effects of the CM on cell death, cell cycle, mitochondrial free radicals and autophagy. Both culture models showed similar results. Control conditions (21% oxygen) showed good neuronal growth and the astrocytes had long process with many branch points and end plates. In cultures that were exposed to hypoxic (2%) CM, there was poor neuronal growth with blebbing. Similarly astrocytes were reduced in number showing a distinct change in morphology with very few processes. Exposure to CM after re-oxygenation (2-8% and 2-21% oxygen) also caused poor neuronal outgrowth. However the astrocytes were increased in number and well branched (2-8% vs 2% and 2-21% vs 2%). These results show that in CM produced in 2% oxygen there are harmful molecules released from trophoblast that damage neurons and astrocytes. Neuronal damage is seen using hypoxic and re-oxygenated CM where as astrocytes appear to be mainly affected by the hypoxic (2% oxygen) CM. Thus, when a hypoxic condition is sustained there is dendritic shortening in neurons and morphological changes in astrocytes. The reduction in process length and cell volume in astrocytes could lead to a reduced contact between neurons and astrocytes. Abnormal signaling between the two cell types results in abnormal neurite outgrowth having an effect on neuronal development, an underlying cause of many neurological diseases. Re-oxygenation does not appear to induce a survival or regenerative affect on the neuronal population in cultures indicating that a therapeutic / pharmacological treatment would be required to overcome any damage from sustained hypoxia.

PTEN regulates hair cell proliferation, differentiation and innervation in the mammalian inner ear

Y. Dong[1], L. Sui[1], F. Yamaguchi[1], K. Kamitori[1], Y. Hirata[1], A. Hossain[1], A. Suzuki[2] and M. Tokuda[1]

[1]Cell Physiology, Faculty of Medicine, Kagawa University, Kitagun, Kagawa, Japan and [2]Division of Embryonic and Genetic Engineering, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Kagawa, Japan

PTEN (phosphatase and tensin homolog deleted on chromosome 10) is a tumor suppressor gene that regulates various cell processes including proliferation, growth, synaptogenesis and the dynamics of the actin-myosin cytoskeleton. We studied the expression pattern of PTEN in the mouse inner ear during development and explored its function by analysis of PTEN heterozygous null mice. Immunolabeling revealed that PTEN is expressed primarily in differentiating sensory neurons and hair cells, coinciding with the temporal and spatial gradients of hair cell differentiation. In heterozygous null mice the sensory epithelial progenitors withdraw later from the cell cycle than wild type and this is associated with an increase in hair cell number. Disorganization and loss of hair bundles is uniquely associated with the formation of ectopic hair bundles on the inner pillar cells. These results show that PTEN plays an important role in regulating the proliferation, differentiation and innervation of mammalian cochlear hair cells. PTEN signaling pathways provide potential therapeutic targets for the regeneration of mammalian inner ear sensory epithelia.

Derivation of oligodendrocyte precursors from bone marrow stromal cells for remyelination therapy

Y. Tsui[1,2], R.S. Li[3], A.C. Lo[3], Y. Chan[2] and D.K. Shum[1]

[1]Department of Biochemistry, The University of Hong Kong, Hong Kong, China, [2]Department of Physiology, The University of Hong Kong, Hong Kong, China and [3]Department of Ophthalmology, The University of Hong Kong, Hong Kong, China

Myelin is crucial for survival of neurons and maintenance of neural network function. Demyelinating disorders are debilitating and are often associated with failure of resident oligodendrocyte precursor cells (OPCs) to differentiate into mature, myelinating oligodendrocytes. Derivation of OPCs from a safe source that evades ethical issues offers a solution to remyelination therapy. We therefore hypothesized that neural progenitor cells harboured at a pre-commitment stage among stromal cells of the adult bone marrow (BMSCs) can be directed to differentiate along the oligodendroglial lineage. We started with adherent cultures of adult rat BMSCs >90% of which were CD90-, CD73- and STRO-1-positive (stromal cell markers) but were CD45-negative (haematopoietic cell marker) and 10% nestin-positive. Tranfer to non-adherent culture fostered expansion of the nestin-positive neural progenitors (NPs) in sphere formation at the expense of stromal cells. The BM-NPs were maintained in adherent culture supplemented with glia-inducing factors, beta-Heregulin, basic fibroblast growth factor and platelet-derived growth factor-AA. Within two weeks, cells positive for OPC markers - NG2, Olig2, PDGFRa and Sox10, were detectable. These cells could be expanded in culture for more than 3 months with no observable decline in marker expression. Co-culture with dorsal root ganglion neurons induced maturation of the BM-OPCs into myelinating oligodendrocytes. We further transplanted BM-OPCs into the retina of adult rats and demonstrated that by 8 weeks, some of the BM-OPC extended, myelin basic protein-positive processes along the otherwise unmyelinated retinal axons. The results not only suppport our hypothesis, but also provide pointers to the adult bone marrow as a safe and accessible source for the derivation of OPCs towards transplantation therapy in demyelinating disorders. Dark exposure promotes accelerated recovery from monocular deprivation in adult mice

I. Erchova and F. Sengpiel

School of Biosciences, Cardiff University, Cardiff, UK

Dark exposure has been reported to enhance plasticity in the adult visual cortex and to promote recovery from deprivation amblyopia both in rats [1] and in cats [2]. The physiological substrate of this recovery is as yet unknown. We employed optical imaging of intrinsic signals to monitor shifts in ocular dominance (OD) in the primary visual cortex (V1) of mice aged between postnatal day (P) 60 and P90.

C57BL/6J mice were normally reared on a 12-h light/12-h dark cycle. Monocular deprivation (MD) by eyelid suture was carried out under isoflurane anaesthesia (2% in O2, 0.5 L/min). A control group of 7 non-deprived mice was imaged under general anaesthesia (1-2% of isoflurane in O2, 0.5 L/min, supplemented with 25 μg i.m. chlorprothixene as described previously to measure OD [3]. ECG and body temperature were monitored continuously. Animals were stimulated with horizontal white bars on a black background presented in the binocular visual field, drifting periodically across the screen at a rate of 0.125 Hz, with the stimulated eye determined by computer-controlled eye shutters. The magnitude of contra- and ipsilateral eye responses (C, I) was determined for each pixel within the V1 binocular zone by fast Fourier transformation, and an OD index (ODI) was calculated as $(C - I)/(C + I)$.

Compared with the control group, the ODI in 6 mice after 7 days of MD was shifted from 0.18±0.02 (mean ± SEM) to 0.04±0.01 ($p < 0.001$, t-test). We then re-opened the deprived eye under isoflurane anaesthesia and investigated the time course of recovery from MD. In a group of normally reared mice, 5 out of 7 animals (70%) recovered normal ODI values within 72 h (for all 7 mice, ODI=0.15±0.04, p=0.016). In contrast, 72 h of dark exposure immediately after the end of MD did not result in OD recovery; instead a further small OD shift

towards the non-deprived eye was observed (ODI=0.08±0.01, n=7). However, when dark-exposed mice were returned to a normally lit environment, recovery of OD was accelerated. After only 36 h animals showed partial recovery of OD (ODI = 0.09±0.01, n=9, p=0.016), more prominent in the anterior segment of the V1 binocular zone; recovery was complete within 72 h (7 mice; ODI=0.19±0.01). In all groups, both the MD-induced OD shift and subsequent return to baseline were mediated by up- and down-regulation of ipsilateral (non-deprived) eye responses, with little change in deprived eye responses. These data suggest that brief periods of dark exposure, at least in mice, promote recovery from MD on the basis of the existing adult plasticity mechanisms.

Regulatory role of neuronal proheparanase in synaptic plasticity

C. Ma[1,2], Y. Lam[2], W. Cham[2], Y. Chan[1] and D. Shum[2]

[1]Department of Physiology, The University of Hong Kong, Hong Kong, China and [2]Department of Biochemistry, The University of Hong Kong, Hong Kong, China

Perineuronal heparan sulfates (HS) have been implicated in controlling the open-state of AMPA-type glutamate receptors (AMPARs) which govern excitatory synaptic transmission in the hippocampus. We hypothesize that neuronal mechanisms modulate peri-synaptic HS level and as a result regulate synaptic function. Our finding of neuronal heparanase expression in adult rats led us to test if neuronal heparanase is secreted to act on perineuronal HS, thereby contributing to synaptic plasticity. Following phorbol ester stimulation of hippocampal neurons in culture, Western blot analysis of the secreted product revealed proheparanase but not the active heparanase. Synaptosomes prepared from phorbol ester-treated cortex slices were enriched in proheparanase; co-immunoprecipitation studies further showed association of AMPAR subunits (GluA1 and GluA2/3) with both syndecan-3 (transmembrane HS-proteoglycan) and proheparanase, suggesting their clustering as a functional complex. Treatment of hippocampal neuron cultures with recombinant proheparanase triggered internalization of proheparanase, perineuronal HS-proteoglycans and AMPARs. Heparitinase pre-treated hippocampal neuron cultures showed reduced proheparanase-induced internalization of AMPARs, suggesting that proheparanase binds to syndecan-3 via the HS moiety. Consistent with these findings, treatment of hippocampal slices with exogenous proheparanase resulted in declines in both basal synaptic strength and LTP. Proheparanase treatment also prevented glutamate-induced calcium influx of the hippocampal neurons in culture. These results reveal a novel role of neuronal proheparanase in regulating synaptic plasticity by resetting AMPARs and perineuronal HS levels at the synapse. [Supported by HKRGC 774608]

Brain derived neurotrophic factor-mediated GABAergic transmission in the vestibular nucleus modifies developmental acquisition of graviceptive behaviour

F. Botelho, C. Lai and Y. Chan

Physiology, The University of Hong Kong, Hong Kong, China

Brain-derived neurotrophic factor (BDNF) has been implicated in the maturation of GABAergic transmission(1). We demonstrated that neonatal rats implanted with BDNF-loaded Elvax slices over the vestibular nuclei showed an accelerated re-orientation of body against gravity. We hypothesized that this acceleration caused by BDNF is due to changes in the GABAergic transmission. To test this, long-term changes of inhibitory synaptic transmission were studied using whole-cell patch-clamp experiments in medial vestibular (MV) neurons of rats. We found that MV neurons exhibited inhibitory long-term depression (iLTD) and long-term potentiation (iLTP) of GABAA receptor-mediated signal transmission in early and late postnatal stages, respectively. In neonatal neurons, BDNF incubation could induce a slight reduction in GABA-mediated iLTD whereas at late postnatal neurons, iLTD, which is indicative of early developmental stages, could be re-induced with BDNF treatment. These results indicate that developmental acquisition of spatial orientation can be modified by BDNF-mediated refinement of neural networks in the vestibular nucleus.

Plasticity of GABAergic synapses in the developing vestibular nucleus governs the expression of spatial navigation in mature rats

W. Chen[1], W. Shi[1], C. Ma[1,2], C. Lai[1], D. Shum[2] and Y. Chan[1]

[1]Physiology, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China and [2]Beiochemistry, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China

Vestibular input has been implicated to provide idiothetic cues for spatial navigation. It remains unresolved as to whether GABAergic synapses in the vestibular nucleus (VN) during a postnatal critical period regulates the acquisition of spatial recognition.

To assess the role of GABAergic VN transmission on the acquisition of spatial navigation, we implanted above the VN of postnatal day 1 (P1) rats with a slice of Elvax loaded with GABAA

receptor agonist (muscimol) or antagonist (bicuculline). These pups were allowed to recover and were tested for either activity-dependent plasticity of GABAergic synapses in the developing VN or for navigation test at the adult stage.
First, whole-cell patch clamp recordings were conducted in brainstem slices. In normal animals, theta-burst stimulation delivered to vestibular afferents could induce long-term depression of GABAA receptor-mediated evoked-IPSCs (iLTD) in VN neurons of P7 rats but these responses became hardly inducible by P14. In rats pretreated with muscimol at P1, iLTD observable at P7 was abolished. In rats pretreated with bicuculline at P1, the emergence of iLTD was delayed to P9-14.
To assess the impact of these GABAergic responses on the acquisition of spatial navigation, a path integration task (viz. dead reckoning) that primarily relies on sensory cues from vestibular organ was used. When compared with the sham controls, rats pretreated with muscimol at P1 showed no significant difference in light, dark, and new location probe tests. However, pretreatment with bicuculline at P1 significantly prolonged the training days, searching time, returning time, heading angle, and number of errors in both dark and new location probe tests. Taken together, we have provided evidence that the efficacy of GABAergic synapses in the developing VN constitutes a crucial component required for the expression of spatial navigation behavior in adults.

Impaired synaptic plasticity in the primary motor cortex and motor skill consolidation after dopamine depletion

Q. Li[1,2], Y. Ke[1,2] and W. Yung[1,2]

[1]School of Biomedical Sciences, Faculty of Medicine, the Chinese University of Hong Kong, New Territories, Hong Kong and [2]Shenzhen Research Institute, the Chinese University of Hong Kong, Shen Zhen, Guang Dong, China

The ability to learn and retain new motor skills is important in daily life. After repeated exposure to a specific procedure, motor skill becomes more accurate and automatic. In Parkinson's disease (PD), in spite of the cardinal motor symptoms like akinesia and bradykinesia, patients suffer deficits in motor skill learning. The impaired synaptic plasticity of basal ganglia circuitry has been suggested to be involved. In PD, dopamine innervation originating from the mesocortical pathway is reduced in the primary motor cortex (MI), an area that also contributes to motor learning. However, the impact of dopamine depletion on cortical synaptic plasticity and motor skill learning is not clear. The present study addresses these questions based on in vivo long-term potentiation (LTP) in the MI and motor training on PD rats.

6-hydroxydopamine was bilaterally injected into the MI (AP: +2.5, ML: ±3.0, DV: 1.7mm) of SD rats. After one week's recovery, arm-reaching for food task was conducted (10 trials) to confirm the preferred forelimb being used. A 16-channel microwire recording electrode and a bipolar stimulus electrode (300μm apart) were implanted into contralateral MI forelimb territory, targeting at layer V. In the first set of experiments, intermittent high frequency stimulation (iHFS, 90 trains delivered every 10s; each train consisted of 50 pulses in 250Hz) was delivered to the MI of freely moving rats and evoked local field potential (LFP) was monitored. In the sham-operated group, LTP level was measured as the increment of evoked LFP amplitude 90 mins after the induction protocol (132.8±3.1%, n=4). In contrast, the cortical LTP in the 6-OHDA group was significantly reduced (110.8±3.0%, n=3, $^{**}p<0.01$, compared with sham). In the second set of experiments, arm-reaching task was performed to investigate the correlation between cortical LTP impairment and performance of motor skill. The skillfulness was assessed by the rate of 'single success', namely food pellet obtained on the first reaching attempt. The performance of the PD rats in the initial learning phase was comparable to that of the sham-operated group (1st day: sham, 32.4±1.1%, n=3; 6-OHDA lesion, 30.2±1.8%, n=3; p=0.36). As training continued, PD animals exhibited deficit in consolidating the motor skill, even if they could reach a good success rate in the previous day. After 1 week's training, a significant difference in the 'single success' rate between the two groups was found (sham: 45.1±2.8%, n=3; 6-OHDA lesion: 30.9±4.1%, n=3; $^{*}p<0.05$).

Our study showed that dopamine depletion confined to the MI could lead to impairment in cortical LTP which may preferentially affect the consolidation, but not the acquisition of motor skills.

Haploinsufficiency of SynGAP phenocopies hippocampal deficits reported in the mouse model of fragile X syndrome

S.A. Barnes[1], A.D. Jackson[1], E.M. Osterweil[2], M.F. Bear[2], P.C. Kind[1] and D.J. Wyllie[1]

[1]Centre for Integrative Physiology, University of Edinburgh, Edinburgh, UK and [2]Picower Institute for Learning and Memory, Massachusetts Institute of Technology, Cambridge, MA, USA

The genetic causes of intellectual disability (ID) and autism spectrum disorder (ASD) are frequently associated with mutations in genes that encode synaptic proteins. A recent screen of ID patients has revealed that approximately 4% of individuals carry spontaneous autosomal-dominant *de novo* mutations in the *SYNGAP1* gene some of which result in complete absence of the synaptic GTPase activating protein SynGAP (1). Investigations into the pathological consequences of SynGAP haploinsufficiency ($Syngap^{+/-}$) in mice have reported abnormalities in both behaviour and dendritic spine development. These are analogous to findings from the mouse model of fragile X syndrome (FXS; $Fmr1^{-/y}$), the most common inherited form of ID. One of the prominent phenotypes reported in the $Fmr1^{-/y}$ mouse is that a form of hippocampal long-term depression (LTD) mediated by the activation of Group 1 (Gp1) metabotropic glutamate receptors (mGluRs) is enhanced and independent of new protein synthesis (2). The cause of these deficits in synaptic plasticity, together with other cognitive abnormalities observed in FXS, are thought to arise in part

from an increase in basal protein synthesis, which can be corrected by either inhibiting mGluR5 (3) or reducing Ras and subsequent ERK activity (4). In the present study we examined mGluR-LTD at Schaffer collateral/commissural inputs to CA1 pyramidal neurones in hippocampal slices obtained from *Syngap*$^{+/-}$ mice. Extracellular field recordings reveal that acute application of the Gp1 mGluR agonist dihydroxyphenylglycine (DHPG; 50 μM) induces a form of mGluR-LTD that is greater magnitude in *Syngap*$^{+/-}$ mice relative to wild-type (WT) littermate controls (50 μM: 57 ± 7 %, *Syngap*$^{+/-}$, n = 14 versus 75 ± 3 %, WT, n = 19). Furthermore mGluR-LTD in *Syngap*$^{+/-}$ mice is insensitive to protein synthesis inhibitors (unpaired t-test $P<0.05$, n = 15). In addition, we find basal levels of protein synthesis to be elevated in hippocampal slices from*Syngap*$^{+/-}$ mice relative to their WT counterparts (145 ± 15 %, *Syngap*$^{+/-}$ versus 100 ± 4 %, WT n = 12). The comparable neuropathophysiology we observe between *Syngap*$^{+/-}$ and *Fmr1*$^{-/y}$ mice suggests that SynGAP and fragile x mental retardation protein (FMRP) may converge on similar biochemical pathways raising the intriguing possibility that therapeutic strategies used in the treatment of FXS may also be of benefit in treating individuals with ID caused by mutations in *SYNGAP*.

Optogenetic manipulation of presynaptic activity in the ciliary ganglion during embryogenesis of the chick

S. Hososhima[1,3], T. Ishizuka[1,2] and H. Yawo[1,2]

[1]Molecular and Cellular Neuroscience Laboratory, Department of Developmental Biology and Neuroscience, Graduate School of Life Sciences, Tohoku University, Sendai, Japan, [2]CREST, JST, Tokyo, Japan and [3]Research Fellow of Japan Society for the Promotion of Science, Tokyo, Japan

[Introduction] In various nervous systems, a presynaptic neuron once branches extensively and projects its axons to many postsynaptic neurons in early developmental stages. The number of branches is reduced with development and the connections between presynaptic and postsynaptic neurons become refined. The ciliary ganglion of chick embryo has been one of model systems of synaptogenesis. As early as in embryonic day 8 (E8), postsynaptic ciliary neuron is multiply innervated by the presynaptic axons. Before E14 a postsynaptic ciliary neuron receives only one calyx-type presynaptic terminal of a midbrain neuron in the Edinger-Westphal nucleus. It has been hypothesized that the refinement of neuronal connections is dependent on the activity of presynaptic and/or postsynaptic neurons. Here, we invented new system using *in ovo* electroporation and shell-less culture and investigated if the activity of presynaptic neurons is necessary and sufficient for the synapse refinement in the ciliary ganglion using optogenetics.

[Method] CAGGS plasmids containing a tandem construct of chimeric variants of channelrhodopsins (ChRs), such as ChRWR, ChRGR and ChRFR(C167A), and yellow florescence protein (Venus), were introduced in the midbrain of E2 embryo and incorporated in the neuroblasts using *in ovo* electroporation method (Egawa et al., 2013). Some chick embryos that expressed channelrhodopsin were cultured using shell-less culture method. These embryos were LED-flashed between E8 and E14, and examined under confocal microscopy at E14. The unflashed embryos were used as control. The synaptic current was measured from the postsynaptic ciliary neuron at E14 under conventional whole-cell patch clamp.

[Results & Discussion] We found the expression of venus-conjugated ChRs in neurons of the Edinger-Westphal nucleus, axons in the oculomotor nerve and calyx-type presynaptic terminals in the ciliary ganglion of E8-14 embryo. When the ChR-expressing presynaptic terminal was flashed by LED, the light-dependent synaptic currents were evoked in the postsynaptic neuron. Although the ciliary ganglion was somewhat distorted in shape under shell-less culture during E2-14, the calyx-type presynaptic terminals were almost normally developed in appearence. It is suggested that the activity of a presynaptic axon/terminal should be optogenetically manipulated during embryogenesis in the shell-less culture to reveal the relationship between the presynaptic activity and the synapse refinement.

Cognitive functions are better during postovulatory phase of menstrual cycle

N. Upadhayay[1] and D. Guragain[2]

[1]Basic and Clinical Physiology, BP Koirala Institute of health Sciences, Dharan, —, Nepal and [2]Pharmacology, Manipal College of Medical Sciences, Pokhara, Nepal

Even though it has been established the neuroprotective effect of estrogen on cognitive functions in postmenopausal women, some discrepancy still exists. Moreover, emerging reports mention that progesterone stimulates reward center and has neuroprotective role on cognitive function, but some contradictory still exists. So this study was aimed to compare cognitive functions between menstruation (low estrogen phase) and postovulatory phase (high progesterone phase) of menstrual cycle (MC) in consenting 34 healthy female volunteers (age 19-37 years).

Menstruation-cognitive functions were assessed in between 2-5 days of start of menses and postovulatory-cognitive functions were assessed in between 23-27 days of the MC. Four aspects of cognitive functions were assessed (viz: attentional, perceptual, executive and working memory). Attentional task as visual reaction time (VRT) and Go/No-Go VRT (pattern), perceptual task as fast counting (FC), executive task as Erisken flanker test (EFT) and Stroop test (ST) i.e. color interference reading and, working memory task as remembering picture 2-back were assessed by using cognitivefun.net program. Data were expressed in median and interquartile range (IQR), compared by using Wilcoxon test.

Postovulatory phase showed better performance in Go/No-Go VRT average time (422.66 ms, IQR: 391.2 to 450 vs. 465.2 ms,

IQR: 425.6 to 504; p=0.003), Go/No-Go VRT combined time (450 ms, IQR: 422 to 457.32 vs. 541.67 ms, IQR: 465.2 to 605; p=0.000), ST percentage accuracy (100% with IQR: 100 to 100 vs. 95.24% with IQR: 90.12 to 100; p=0.000), ST color interference time (1105.3ms, IQR: 1100.3 to 1335.25 vs. 1428ms, IQR: 1346.39 to 1621.25; p=0.001), and FC speed (1081.51 ms, IQR: 902.6 to 1147.18 vs. 1130.6 ms, IQR: 1066.6 to 1209.18; p=0.041) than in menstruation phase. Other cognitive task variables (viz: VRT, EFT, working memory) were comparable between menstruation and postovulatory phase of MC.
Some aspects of cognitive function varied across the MC. But these two phases of MC had no effect on working memory. Thus, it can be concluded that postovulatory phase of menstrual cycle improves attentional (pattern recognition), perceptual, and executive function (as assessed by stroop test) of cognition. Probably progesterone, which is higher during postovulatory phase, is responsible to modulate the neurons action in the brain and enhancing the cognition.

Arginine vasopressin (AVP)-eGFP expression in the hypothalamus after hypovolemia in AVP-eGFP transgenic rats

Y. Ueta, M. Ohno, T. Ishikura, T. Maruyama, H. Hashimoto, T. Matsuura, J. Ohkubo, M. Yoshimura and H. Yamashita

Department of Physiology, School of Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan

Arginine vasopressin (AVP) release is known to be stimulated by hypovolemia as well as osmotic challenge such as dehydration and chronic salt loading. We have generated a transgenic rat that expresses the AVP-eGFP fusion gene in the paraventricular (PVN) and the supraoptic nuclei (SON) of the hypothalamus. Our previous studies revealed that acute and chronic osmotic stimuli up-regulated the expression of the AVP-eGFP fusion gene in the magnocellular neurons of the PVN and the SON. Here, we demonstrated that polyethylene glycol (PEG)-induced hypovolemia was able to cause the up-regulation of the AVP-eGFP gene expression in the PVN and the SON in the transgenic rats. Intraperitoneal (ip) administration of PEG induced isotonic hypovolemia. The intensity of eGFP fluorescence in the PVN and the SON were significantly increased 6 and 24 hours after ip administration of PEG in comparison with controls. Interestingly, the intensity of eGFP fluorescence in the parvocellular division of the PVN was also increased significantly. The present study revealed that PEG-induced hypovolemia caused a significant up-regulation of the AVP-eGFP fusion gene expression in the magnocellular and parvocellular neurons of the PVN and the SON in AVP-eGFP transgenic rats.

Dual effects of nobiletin, a citrus polymethoxy flavone, on catecholamine signaling in cultured bovine adrenal medullary cells

H. Zhang[1], N. Yanagihara[2], Y. Toyohira[2], K. Takahishi[2] and K. Takahashi[3]

[1]Research Center of Traditional Chinese Medicine, Tianjin University of Traditional Chinese Medicine, Tianjin, China, [2]Department of Pharmacology, University of Occupational & Environmental Health, School of Medicine, Kitakyushu, Fukuoka, Japan and [3]Department of Hospital Pharmacy, University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan

The peels of citrus fruits are a rich source of flavonoids, which have been shown to exert beneficial properties on human health. Nobiletin (5,6,7,8,3',4'- hexamethoxyflavone) is a major component of polymethoxylated flavones found in the peel of citrus fruits, and is used in a Chinese traditional herbal medicine. Nobiletin exhibits a broad spectrum of pharmacological activities, including anticancer, antioxidative, and anti-inflammatory properties. Furthermore, nobiletin possesses antiatherogenic and cardiovascular protective effects, and neuronal effects such as neurotrophic effects in vitro, and antidementia activities in vivo, although the precise mechanisms underlying these nobiletin's effects remain to be determined. Adrenal medullary cells derived from the embryonic neural crest are functionally homologous to the sympathetic postganglionic cells. In cultured bovine adrenal medullary cells, the Na+ influx induced by acetylcholine (ACh) via nicotinic ACh receptor-ion channels is a prerequisite for Ca2+ influx via the activation of voltage-dependent Ca2+ channels and subsequent catecholamine synthesis and secretion. Stimulation of catecholamine synthesis induced by ACh is associated with an activation of tyrosine hydroxylase, which catalyzes the conversion of tyrosine to L-3,4-dihydroxyphenylalanine (DOPA), the rate-limiting step of catecholamine biosynthesis.
We previously demonstrated that nobiletin enhances catecholamine secretion and Ca2+ influx in cultured bovine adrenal medullary cells (J Neurochem., 114: 1030-1038, 2010). Here we report the effects of nobiletin on catecholamine synthesis in the cells. Nobiletin increased the synthesis of 14C-catecholamines from [14C]tyrosine in a time (20-30 min) and concentration (1.0 -100 microM)-dependent manner. Nobiletin (10-100 microM) also activated tyrosine hydroxylase activity. The stimulatory effect of nobiletin on 14C-catecholamine synthesis was not observed when extracellular Ca2+ was deprived from the incubation medium. Several protein kinase inhibitors such as H-89 and KN-93, inhibitors of cyclic AMP-dependent protein kinase and Ca2+/calmodulin-dependent protein kinase II, respectively, suppressed the stimulatory effects of nobiletin on catecholamine synthesis as well as tyrosine hydroxylase activity. On the other hand, nobiletin (1.0-100 microM) inhibited 14C-catecholamine synthesis induced by acetylcholine. The present findings suggest that nobiletin, by itself, stimulates catecholamine synthesis and tyrosine hydroxylase activity, whereas it inhibits catecholamine synthesis induced by acetylcholine in bovine adrenal medulla.

Alterations of CRH mRNA expression levels and neurogenesis in hypothalamic after rats exposure to heat

G. Li[1], X. Zhou[1], H. Tao[1], Y. Luo[1] and O. Shido[2]

[1]Ningxia Medical University, Yinchuan, China and [2]Shimane University Faculdy of Medicine, Izumo, Japan

The hypothalamic-pituitary-adrenal axis (HPA axis) is activated by various stresses. The objective of this study was to observe the acute heat exposure on the expression of hypothalamic corticotrophin-releasing hormone (CRH) mRNA and content of serum adrenocorticotropic hormone (ACTH) and corticosterone (CORT) in rat, and investigate hypothalamic neurons proliferation and differentiate. Male Wistar rats (160-180g) were randomly divided into two groups and exposed to heat at 32 degree (heat exposure, HE) or to a room temperature at 24 degree (control, CN). After 7 days of heat exposure, the body core temperature was measured by telemetry (n=4). The relative weight of the pituitary and adrenal gland were determined (n=4), and the expression of hypothalamic CRH mRNA was detected by using real-time fluorescence quantitative polymerase chain reaction (RT-PCR), and content of serum ACTH and CORT were detected by applying enzyme-linked immunosorbent assay (ELISA) (n=6). Another batch rats (male, 180-200g, n=4) was intraperitoneally injected Bromodeoxyuridine (BrdU) daily (50mg/kg) for 6 consecutive days. After commencing heat exposure, on the 7th day of exposure to heat, rats' brains were removed. Immunohistochemical analysis the numbers of BrdU-positive cells and double-stained by a mature neuron marked cell in the hypothalamus were observed. All rats were anesthetized via intraperitoneal administration of petobarbital sodium (70 mg/kg). Values are means ± S.D., compared by ANOVA. Compared with control group, heat exposure did not obviously affect body core temperature ($p>0.05$) or body weight of the rats ($p>0.05$). Seven days heat exposure increased the relative weight of pituitary and adrenal gland (e.g. CN: 0.026±0.002 vs. 0.17±0.02 mg/g, HE: 0.031±0.001 vs. 0.24±0.02 mg/g, $p<0.05$ respectively), and significantly increased ACTH and CORT contents of serum (e.g. CN: 11.66±1.21 vs. 12.38±3.21 mmol/L, HE: 15.23±2.09 vs. 18.45±2.06 mmol/L, $p<0.05$, $p<0.01$ respectively). The CRH mRNA expression levels increased but had no statistical difference ($p>0.05$). The number of BrdU-positive cells were significantly increased (67.8±11.2 for control rats and 117±12.3 for heat exposure, $p<0.05$), while the number of BrdU-positive cells double-stained by a mature neuron marker no significantly increased after 7 days of heat exposure. Acute heat stress affect hypothalamic pituitary-adrenal (HPA) axis, and may lead to the activation hypothalamic proliferation.

Large conductance calcium- and voltage-gated potassium (BK) channels promote bursting behaviour in murine anterior pituitary corticotroph cells

P.J. Duncan and M.J. Shipston

Centre for Intefgrative Physiology, The University of Edinburgh, Edinburgh, UK

Corticotroph cells from the anterior pituitary are an important component of the hypothalamic-pituitary-adrenal (HPA) axis, which controls the neuroendocrine response to stress. HPA axis dysfunction can have many consequences on health. In response to a stressor, the hypothalamic neuropeptides corticotrophin-releasing hormone (CRH) and AVP act synergistically on corticotrophs to stimulate synthesis and release of adrenocorticotrophic hormone (ACTH). Corticotroph cells are electrically excitable and fire single-spike action potentials as well as showing complex bursting patterns. There is evidence to suggest that large conductance calcium- and voltage-gated potassium (BK) channels promote bursting behaviour in multiple pituitary cell types. The aim of this project was to establish the role of BK channels in corticotroph excitability.

Corticotrophs were cultured from male mice (aged 2-5 months) constitutively expressing green fluorescent protein (GFP) under control of the POMC promoter (POMC-GFP). Electrophysiological recordings were obtained using the perforated patch clamp technique in the current clamp configura-

tion. Under basal conditions, cells had a resting membrane potential of -53.7 ±1.5mV (n = 7, Data are Means ± SEM) and showed low frequency spontaneous action potentials (0.34 ±0.14Hz). CRH and AVP (0.2nM and 2nM respectively) caused a significant ($p < 0.01$, ANOVA) depolarisation of the resting membrane potential to -47.4 ±0.74mV. There was also a significant ($p < 0.01$) increase in firing frequency from 0.34 ±0.14Hz to 0.99 ±0.27Hz. The increase in firing frequency was associated with a transition from a predominantly single-spike firing pattern to a bursting-like behaviour.

To address whether BK channels control bursting activity, experiments were performed on cells treated with BK channel blocker paxilline (1μM). Bursting was quantified by calculating mean event length and mean peaks/event (burst factor, BF). While CRH/AVP significantly increased bursting in control cells, pharmacological inhibition of BK channels greatly reduced, but did not abolish bursting. The role of BK channels in promoting bursting was further investigated using cells isolated from BK knockout mice. These cells also failed to significantly transition from spiking to bursting following CRH/AVP stimulation.

In summary, it can be concluded that the BK channel plays an important role in the generation of bursting behaviour in corticotroph cells. Interestingly, bursting was not completely abolished in paxilline treated or BK knockout cells. This would indicate that although the BK channel is an important component in the generation of bursting behaviour in corticotroph cells, there may be contribution from other ion channels.

PCC131

Electrophysiological distinction between OT and VP magnocellular neurons does not match their molecular phenotypes

M.P. Silva, R.M. Merino, A.S. Mecawi and W.A. Varanda

Physiology, School of Medicine of Ribeirao Preto - University of Sao Paulo, Ribeirao Preto, SP, Brazil

The phenotypic distinction of magnocellular neurons (MNs) from the supraoptic (SON) nucleus is thought to be relevant to understanding of the effects of specific substances on the electrical activity of these neurons. Although the firing patterns of oxytocin (OT) and vasopressin (VP) neurons differ, they might appear the same both in vivo, and in vitro, making impracticable the phenotypic determination based solely on this feature. The recording of sustained outward rectifying potassium currents (SOR) and inward rectifying hyperpolarization activated currents (IR), presumably present in OT and absent in VP neurons, has been used to determine the phenotype of MCs. Nevertheless, this protocol clearly fails to identify the neurons that produce both peptides in equivalent concentration, i.e., the intermediate phenotype. For this reason, we aimed to analyze the confidence of the electrophysiological protocol by comparing their results with the molecular phenotype of the cells. For this purpose, we used hypothalamic slices containing the SON (200 μm) from Wistar rats (100g). Whole-cell patch-clamp was used to record currents in response to hyperpolarizing voltage steps (from -40 mV to -130 mV). I x V curves were built and the presence or absence of SOR and/or IR was used to distinguish between OT and VP neurons. At the end of the electrophysiological recordings, the cytoplasm of the neuron was sucked into the pipette and used for mRNA reverse transcription, cDNA pre-amplification and qPCR. Our results show that, from a total of 69 neurons, 20 showed a linear IxV relationship typical of vasopressinergic neurons, 48 showed IR and/or SOR current, characterizing oxytocinergic neurons, and one neuron could not be identified by its electrophysiological profile. On the other hand, the molecular analysis showed that 71% (n =49) of the phenotypes did not match the electrophysiological characterization, indicating that vasopressinergic neurons can exhibit both outward and inward rectifying currents. Moreover, 39% of the neurons were identified as intermediate in the qPCR experiments (n=27). Since the amount of cDNA collected from single cells is very small and needed to be amplified prior to the qPCR, a positive control of the pre-amplification was made to check if this process could modify the molecular phenotype of cell. For this purpose, the cDNA was amplified once for a first qPCR followed by a second amplification and another qPCR quantification. We observed that this procedure did not interfere with the molecular phenotype of the cells (n=10). In conclusion, due to the high specificity and reliability offered by RT-qPCR, we suggest that the electrophysiological protocol is not sensitive enough to be used as a single criterion to discriminate the different phenotypes of magnocellular neurons.

Anti-ulcerogenic and proton pump (H+, K+ ATPase) inhibitory activity of Kolaviron (Garcinia kola biflavonoid) in rats

A.S. Onasanwo[1,2], N. Singh[2], B.S. Olaleye[1] and G. Palit[2]

[1]Physiology, University of Ibadan, Ibadan, Nigeria and [2]Pharmacology, Central Drug Research Institute (C.S.I.R.), Lucknow, India

Kolaviron, isolated from Garcinia kola seed (Family: Guttiferae), is known for numerous medicinal and therapeutic values. The anti-ulcer, anti-inflammatory and antioxidant properties of Garcinia kola seed have been reported. The main mechanisms through which kolaviron exert its anti-secretory with cyto-protective potential has not been elucidated. So, the present research work therefore evaluated anti-secretory and cyto-protective potentials of the anti-ulcer properties of kolaviron using different ulcer models in rats. Cold-restraint (CRU), aspirin (ASP), alcohol (AL), pyloric ligation (PL) induced gastric ulcer models were used to assess its anti-ulcerogenic activity in rats. KV's effects on gastric juice for free and total acidity, peptic activity and mucin secretion were evaluated. The H+,K+-ATPase activity was assayed in gastric microsomes, spectrophotometrically. In CRU model, which is the basic model for screening anti-ulcer agent, KV (100, 150 and 200mg/kg, p.o.) showed percentage protection of 52.1%, 53.5% and 69.0% ($P<0.01$) respectively while omeprazole (10mg/kg, p.o.) showed a protection of 84.6% ($P<0.001$) with reference to the control group. In ASP and PL -induced gastric ulcer model, KV (200mg/kg, p.o.) showed protection index of 68.6% and 67.6% ($P<0.01$) respectively, whereas omeprazole (10mg/kg, p.o.) exhibited 84.3% and 69.0% ($P<0.01$) protection respectively. KV (200mg/kg, p.o.) produced 51.5% ($P<0.01$) protection against gastric mucosal damage, induced by absolute alcohol. Sucralfate (500 mg/kg, p.o.) exhibited 76.3% ($P<0.001$) protection

under the same condition, when compared with the control group. Likewise, KV (200mg/kg, p.o.) reduced free acidity, total acidity and peptic activity by 32.6%, 56.2% and 35.4% (P<0.05) respectively, while omeprazole (10mg/kg, p.o.) significantly reduced free acidity, total acidity and peptic activity by 61.8%, 69.9% and 46.7% (P<0.01) respectively, compared with the control group. The same dose of KV and omeprazole (10mg/kg, p.o.) increased the mucin secretion by 40.1% and 47.9% (P<0.01) respectively, compared with the control. The incubation of KV (60-100μg/ml) with the microsomes, inhibited the inorganic phosphate release from gastric proton pump activity proportionately from 17.2% (288.3μM/hr/mg protein) to 74.3% (89.5μM/hr/mg protein) respectively, with IC50 of 43.8μg/ml. Likewise, omeprazole (10-50μg/ml) inhibited the enzyme from 12.5% (304.5μM/hr/mg protein) to 87.5% (87.0μM/hr/mg protein) respectively, with IC50 = 32.3μg/ml. Kolaviron possesses anti-ulcer activity against experimentally-induced peptic ulcer models and exhibited a proton pump inhibitory activity. So, it has both cyto-protective and anti-secretory potentials. Hence, kolaviron may emanate as a potent anti-ulcer compound.

Disrupted functional connectivity in neural circuit of cardiac vagal baroreflex of mice with neurogenic hypertension

C. Tsai, C. Su and S. Chan

Chang Gung Memorial Hospital, Kaohsiung, Taiwan

A clinical hallmark of hypertension is impairment of the cardiac vagal baroreflex, which maintains stable blood pressure and heart rate under physiological conditions. There is also evidence that oxidative stress in the brain is associated with neurogenic hypertension. However, whether an oxidative stress-induced disruption of the functional connectivity between nucleus tractus solitarii (NTS), the terminal site of baroreceptor afferents, and nucleus ambiguus (NA), the origin of the vagus nerve, underpins the impaired cardiac vagal baroreflex during neurogenic hypertension has not been assessed. the present study tested the hypothesis that an augmented superoxide level in the NTS contributes to the depression of cardiac vagal baroreflex during neurogenic hypertension by disrupting the functional connectivity between the NTS and NA. An experimental model of neurogenic hypertension that employed intracerebroventricular infusion of angiotensin II by osmotic minipump in male adult C57BL/6 mice was used. Based on tractographic evaluations using magnetic resonance imaging/diffusion tensor imaging of the brain stem, we found that the functional connectivity between the NTS and NA was disrupted during neurogenic hypertension, concurrent with depression of the cardiac vagal baroreflex detected by radiotelemetry. We further found that the disrupted NTS-NA functional connectivity was reversible, and was related to oxidative stress induced by augmented levels of NADPH oxidase-generated superoxide in the NTS. We conclude that depression of the cardiac vagal baroreflex induced by oxidative stress in the NTS during neurogenic hypertension may be manifested in the form of dynamic alterations in the functional connectivity between the NTS and NA.

Identification of sites of sympathetic outflow at rest and during emotional arousal: concurrent recordings of skin sympathetic nerve activity and fMRI in humans

V.G. Macefield[1,2], C. James[1] and L.A. Henderson[3]

[1]School of Medicine, University of Western Sydney, Sydney, NSW, Australia, [2]Neuroscience Research Australia, Sydney, NSW, Australia and [3]Discipline of Anatomy & Histology, University of Sydney, Sydney, NSW, Australia

The sympathetic innervation of the skin primarily subserves thermoregulation, but the system has also been commandeered as a means of expressing emotions. In order to understand the central neural processes involved in emotional processing and the generation of autonomic markers of emotion we recorded skin sympathetic nerve activity (SSNA) concurrently with functional magnetic resonance imaging (fMRI) of the brain at rest in thermoneutral conditions, or while showing subjects neutral or emotionally-charged images from the International Affective Picture System (IAPS). Methods: SSNA was recorded via tungsten microelectrodes inserted into the peroneal nerve in 21 subjects. Gradient echo, echo-planar fMRI was performed using a 3T scanner (Philips Achieva). Two hundred volumes (46 axial slices, TR=8 s, TE=40 ms, flip angle=90 deg, raw voxel size =1.5x1.5x1.5 mm) were collected in a 4s-ON, 4s-OFF protocol. Total sympathetic burst amplitudes were measured during the period between scans. Blood Oxygen Level Dependent (BOLD) changes in signal intensity (SPM5, uncorrected p<0.001) were measured during the subsequent period to account for neurovascular delays. Results: Resting SSNA was positively correlated to signal intensity in the orbitofrontal, frontal and insular cortices on the right side, midcingulate and precuneus, and negatively correlated to signal intensity in the left orbitofrontal and left insula. Positive and negative emotionally-charged images evoked significant increases in total SSNA and signal intensity in the orbital, dorsolateral and ventromedial prefrontal cortices, amygdala, nucleus accumbens and anterior insula. Increases in signal intensity during increases in SSNA occurred in a number of brain regions, including the central and lateral amygdala, dorsolateral pons, thalamus, nucleus accumbens, and cerebellar cortex. Signal intensity decreases during emotionally evoked increases in SSNA occurred in the left orbitofrontal, frontal and right precuneus cortices. Conclusions: We have identified structures in the brain differentially engaged in the generation of sympathetic markers of introspection and emotional arousal.

A new method to quantify the activity of axonal transport of cultured neurons

T. Katakura[1], R. Isonaka[1], T. Takenaka[2] and T. Kawakami[1]

[1]Physiology, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan and [2]Facuty of Physical Education, Kokushikan University, Tama, Tokyo, Japan

Introduction: Takenaka and co-workers had developed a video-enhanced microscopy technique to visualise axonal transport without staining nerves nor transporting organelles in 1980s. Their method to evaluate axonal transport is very useful but requires a special talent, a keen dynamic vision. We have recently developed another new method to quantify axonal transport with an aid of microcomputer with the open source programme, ImageJ. Method: Preparation of video clips and pretreatment on NIH Image J (1)Enhanced video images were digitized and converted to QuickTime video clips (sampling rate, 10 Hz, duration time,120 seconds). Make video clip every 3 minutes intervals for about an hour. (2) Run ImageJ 1.46, read each video clip and rotate video image 90˜180 degrees if necessary in order to fix the orientation of organelles movement from the left to the right as anterograde axonal transport direction, and the opposite direction as retrograde axonal transport. (3) 128 pixel x 128 pixel area is cropped on ImageJ, in which axonal transport is displayed appropriately. The dimension of the cropped area is fixed and adapted for all the video clips of the same experiment. (4) Subtract adjacent frame (slice) image successively in order to reduce background noise and not moving organelles. Quantification of the activity of axonal transport (Flow analysis) Using KBI plugin, the activity of axonal transport is quantified as the sum of particles which moves more than 3 pixels per second. The velocity of the particle is 0.1 um/s or more. Velocity vectors are calculated (the velocity and the degree of an angle of the moving particle within a fixed area at a given resolution pixels, such as 4, 8, 16, 32 pixels). We can easily distinguish and sum up the number of anterograde transporting particles and retrograde transporting particles by the sign of an angle of velocity vector, where the former has a plus sign and the latter has a minus sign respectively. Results: Parameters of widthXy and stepXy 4 pix and greater value is suitable for the velocity calculation. With 4 pix or 8 pix value, the results from flow analysis are coincided with the results obtained from our traditional quantification method. 16 pix or more value sometimes dismissed moving particles and thus the calculated values are not consistent with our previous results. Concluding Remarks: Using NIH ImageJ with KBI plugin, the progressive movement of particles can be analyzed. Orientation, velocity, and the number of transported organelles within a fixed area are calculated easily from one video clip. (1) We define the activity of axonal transport as the sum of a particle which possesses the moving velocity more than 0.1 um/s within an limited area. (2) We suppose the velocity of particles is directly proportional to the activity of axonal transport.

Visceral nociceptive afference could facilitate the response of subnucleus reticularis dorsalis to Acupoint stimulation

P. Rong, L. Li, L. Yu, X. Gao and B. Zhu

Physiology, Institute of Acup.-Moxi., Beijing, China

Objective: To explore the area and sensitization variance of acupoint when internal organs is under pathological condition. To observe quantity-effect variance of subnucleus reticularis dorsalis to electro-acupuncture under both physiological and pathological condition. To explain medulla oblongata mechanism of acupoint sensitization. Method: Mustard oil (20μl2.5% Sigma-Aldrich, St.Louis, MO) was imported into colon and rectum of male SD rats (anaesthetised with pentobarbital sodium 50-60mg.kg-1) in order to observe its influence to acupoint sensitization. SRD Neuron activities were recorded. Visceral nociceptive stimulus was generated by colorectal distension (CRD with an intensity 40 mmHg). Quantity-effect variance of neuron activity to electroacupuncture to “Zusanli-Shangjuxu” area both before and after CRD was observed. Result: Visceral inflammation could facilitate SRD neuron activity to acupoint stimulation. Visceral nociceptive afference could enhance neuron activity to acupoint acupuncture. WDR neuron activity caused by electro-acupuncture increased when visceral nociception is raised. Conclusion: the area of acupoint could be changed if visceral function changes, also, sensitivity of acupoint would change too.
Key words: Sensitization of acupoints, Neurogenic inflammatory reaction, subnucleus reticularis dorsalis, colorectal distension (CRD)

Peripheral nerve conduction correlation with body mass index of healthy individuals

D. Thakur[1], B.H. Paudel[1] and C.B. Jha[2]

[1]Basic & Clinical Physiology, B.P.Koirala Institute of Health Sciences, Dharan, Nepal and [2]Anatomy, B. P. Koirala Institute of Health Sciences, Dharan, Nepal

Nerve conduction study (NCS) assesses peripheral nerve functions and its parameters are known to vary with anthropometric measurements. This cross sectional normative study was done in Electro-diagnosis Lab II of department of Basic and Clinical Physiology. It was aimed to study the relation of BMI on NCS variables of the peripheral nerves of upper and lower limbs. The study was done in 34 consenting healthy adults of either sex. The anthropometric factors, compound muscle

action potential (CMAP) and sensory nerve action potential (SNAP) were recorded using standard technique. The relation of BMI with NCS variables were analyzed using Pearson's correlation test. After the adjustment of other anthropometric factors, BMI (21.8±2.11 Kg/m2) showed a negative correlation with the CMAP duration of most of the motor nerves: right median (r= -0.388, p<0.005), left median (r= -0.342, p<0.05), left ulnar (r= -0.375, p<0.005), left tibial and right common peroneal (r= -0.347, p<0.05). The CMAP amplitudes of the right median (r= -0.341, p<0.05), left median (r= -0.456, p<0.01) and right common peroneal (r= -0.361, p<0.05); CMAP latencies of bilateral ulnar, left radial and right common peroneal were also negatively correlated. However, a positive correlation was seen with the SNAP amplitude of the right sural (r= 0.441, p<0.01) and a negative correlation with conduction velocity of left median sensory nerve (r= -0.420, p<0.05). The SNAP duration, latency and CMAP F-waves latency did not show any correlation. BMI showed a significant correlation with the NCS parameters of most of the motor and few sensory nerves. Diagnostic conclusions made from the nerve conduction data without corrections for the BMI may be invalid in patients who are at its extreme. This must be also considered while developing standard/reference normative data for different nerves.

We would like to acknowledge the technical staffs and the participating volunteers for supporting the research.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Autoantibodies and relation to clinical features in Sudanese patients with acquired autoimmune myasthenia gravis: a case control study

R. Badi[1], M. Elzubeir[2], A. Musa[1], L. Jacobson[3], E. Khalil[2], A. Vincent[3] and A.E. Ahmed[1]

[1]Physiology, University of khartoum, Khartoum, Sudan, [2]University of Khartoum, Khartoum, Sudan and [3]Oxford University, Oxford, UK

Prevalence of autoantibodies targeting the neuromuscular junction in autoimmune myasthenia gravis (MG) varies among different populations, probably due to genetic and environmental differences. We present a cross sectional, case-control study carried in the years 2011- 2012. The study aimed to detect the prevalence of AChR-Abs, and MuSK-Abs in Sudanese MG patients, and to relate the autoantibodies status to their clinical presentation. The study was ethically approved. 59 MG cases were recruited from two national MG centers in Khartoum and matched by age and sex to 157 controls. AChR-Abs and MuSK-Abs were measured in plasma, using radioimmunoprecipitation assay (RIPA) (1).Plasma from patients who tested negative for both autoantibodies by the RIPA were further tested for low affinity AChR-Abs by the Cell Based Assay (CBA) (2). AChR-Abs were detected in; 76.3% of all MG patients (median, IQR= 1.6, 0.2- 26 nmol/L), 80 % of generalized MG patients (GMG), 64 % of ocular MG patients, and 3.8% of the controls (median, IQR= 0.1, 0.01– 0.16 nmol/L). MuSK-Abs were detected in; 16.7% of AChR-Ab-ve GMG patients, 1/33 of AChR-Ab+ve GMG patients, and 1/106 of the controls. 20% of MG patients remained seronegative for both autoantibodies. AChR-Ab+ve GMG patients and seronegative GMG patients were not significantly different regarding disease severity. Seronegative GMG patients were all females (7/7) (P<.05, Fisher's Exact test). The prevalence of associated autoimmune diseases (AuID) was 86 %(6/ 7) in seronegative GMG patients and 14% (5/35) in AChR-Ab+ve GMG patients; relative risk 6 (2.5 to 14.27) (P= 0.001, Fisher's Exact test). MuSK-Ab+ve cases were two late onset MG males (onset >40 years), one early onset MG female, and had dominant bulbar symptoms. This study provided the first insight into autoantibody profile of MG patients in an Arabian- African population. The detection rates of AChR-Abs and MuSK-Abs were within the range of detection rates in other series. Some clinical features (sex and AuID) were found to be related to the autoantibody status of MG patients. These findings suggest involvement of factors like sex and genetic susceptibility to autoimmune diseases in determining the pathogenesis and homeostasis of autoantibodies in MG.

Noisy vestibular stimulation modulates neuronal activities of the substantia nigra through vestibulo-thalamo-striatal pathway in Parkinsonian rats

H. Koo[1,2], N. Kim[1,2], M. Kim[1,2] and B. Park[1,2]

[1]Physiology, Wonkwang University School of Medicine, Iksan, Republic of Korea and [2]Brain Research Institute, Wonkwang University, Iksan, Republic of Korea

Galvanic noisy vestibular stimulation (NVS) to Parkinson disease (PD) patients could relieve balance impairments. This study was designed to observe changes of the neuronal activity in the substantia nigra pars reticulata (SNr) of an animal PD model following NVS and its neural pathway. To make an animal model of PD, 6-hydroxydopamine (6-OHDA) was injected to the right medial forebrain bundle of Sprague-Dawley rats. Rats (male, 250~300g, n=35) were anesthetized with isoflurane. Two to three weeks after 6-OHDA lesion, extracellular single-unit activity of the ipsilesional SNr was recorded before and after NVS of the horizontal semicircular canal nerve unilaterally or bilaterally under anesthesia. The baseline neuronal activity was measured during 2 minutes before NVS. NVS continued for 5 minutes and then a recording was resumed for 2 minutes. Extracellular single-unit activity of the parafascicular nucleus (PFN) of the thalamus to stimulation of the vestibu-

lar nerve was recorded. Evoked field potentials with polysynaptic nature were recorded in the contralateral PFN to the stimulation site but not in the ipsilateral PFN. Recording the single-unit activity of the ipsilesional SNr revealed that slow oscillations (<2.5Hz) of SNr spike trains significantly increased following 6-OHDA lesion. These slow oscillations were remarkably reduced and the irregularity of firing pattern was also significantly decreased by unilateral or bilateral NVS. Furthermore, the contralateral or bilateral NVS to hemi-lesioned side tended to decrease the neuronal activity of SNr neurons, while the ipsilateral NVS showed the increase tendency of that, relatively. Theses electrophysiological evidences suggest that the noisy electrical stimulation to the peripheral vestibular apparatus may modulate abnormal neuronal activities of basal ganglia in an animal model of PD through the vestibulo-thalamostriatal pathway.

Modulation of immune function by the cerebellar fastigial nucleus via its GABAergic projections to the hypothalamus

Y. Peng, B. Cao, J. Lu and Y. Qiu

Nantong University, Nantong, China

We have previously reported that cerebellum modulates immune system function. Since there is no direct structural connection between cerebellum and immune system, exploring pathways mediating cerebellar immunomodulation is important to understand the phenomenon. It has been well known that hypothalamus is a crucial immunoregulatory center, which modulates immune cells via sympathetic system and hypothalamic-pituitary-adrenal axis. Moreover, direct bidirectional connections between the cerebellum and hypothalamus that constitute cerebellar-hypothalamic circuits have been found. Based on these findings, we hypothesized that direct cerebellar-hypothalamic projections transmit cerebellar immunoregulatory information to hypothalamus, through which the regulatory information is then conveyed to immune cells. Here, we focused on cerebellar fastigial nucleus (FN), one of three cerebellar nuclei, to investigate its immunoregulatory pathway via hypothalamus. Sprague-Dawley rats (either sex, 220-240 g) were deeply anesthetized with pentobarbital (55 mg/kg, i.p.) before any surgery and generally recovered to normal state 3-4 h after the anesthesia. Texas red dextran amine (TRDA), a neuroanatomical anterograde tracer, was delivered into FN of rats that had been mounted in a stereotaxic frame following deep anesthesia to observe cerebellar-hypothalamic projections. Fluoro-Ruby (FR), a retrograde tracer, was injected into lateral hypothalamic area (LHA) and 8 days later, the cerebellar sections were stained with immunohistochemistry for GABA. To change cerebellar-hypothalamic GABAergic transmission, we microinjected vigabatrin, an inhibitor of GABA-transaminase that degrades GABA, or 3-mercaptopropionic acid (3-MP), an antagonist of glutamic acid decarboxylase that synthesizes GABA, bilaterally into FN. Immune function, including concanavalin A-induced T cell proliferation, anti-sheep red blood cell (SRBC) IgM antibody and natural killer (NK) cell cytotoxicity, was measured by CFSE/CD3 double labeling, ELISA and flow cytometry, respectively, on day 3 after the drug injection. Simultaneously, GABA content in hypothalamus was tested by HPLC. We found that the TRDA-labeled fibers from FN traveled through superior cerebellar peduncle (SCP), crossed in decussation of SCP, and primarily terminated in LHA. The retrograde tracing with FR from LHA to FN confirmed the direct projection route. Many FR-positive neurons in FN were GABA-immunoreactive. Compared with intact or saline-treated rats, the vigabatrin treatment increased both number of GABA-immunoreactive neurons in FN-LHA projections and GABA content in hypothalamus. Simultaneously, vigabatrin led to a decrease in T cell proliferation, in serum anti-SRBC IgM antibody level and in NK cell cytotoxicity. In support of these findings, 3-MP caused changes that were all opposite to those induced by vigabatrin. These results show that cerebellar FN has a direct GABAergic projection to hypothalamus and suggest that this projection mediates cerebellar immunomodulation.

Analysis of parietal EEG following hippocampal injection with kainic acid in rats

A. Issuriya[1], E. Kumarnsit[1], U. Vongvatcharanon[2] and C. Wattanapiromsakul[3]

[1]Physiology, Faculty of science, Prince of Songkla University, Hadyai, Songkhla, Thailand, [2]Anatomy, Faculty of Science, Prince of Songkla University, Hadyai, Songkhla, Thailand and [3]Phamacognosy, Faculty of Phamaceutical Science, Prince of Songkla University, Hadyai, Songkhla, Thailand

Electroencephalogram (EEG) pattern represents the electric activity of brain cells. Its recordings have helped clinicians for decades to diagnose specific diseases of the central nervous system. The present study characterized behaviors and EEG patterns after injection with kainic acid (KA) in rats. Male Wistar rats (300-350g, n=6) were anesthetized with 60 mg/kg Zoletil® 100 (i.m.). Assessment of depth anesthetic was evaluated by gentle toe pinch withdrawal reflex. During the surgery, the depth of anesthetic was also evaluated periodically and additional anesthetic was injected to animal that was found with any reaction of too light anesthesia. Then rats were implanted stainless steel screw electrodes on both sides of the parietal cortices (AP; -4, ML; 4) for EEG recording and a cannula for KA injection into right dorsal hippocampus (AP; -4.2, ML; 3.6, DV; 3.8). Rats were sacrificed by thiopental sodium overdose injection. Results showed that the injection of KA (1 nmol/μl) 1 μl into hippocampus (continuously 7 days) induced hyperactivity of hippocampal neurons via kainate receptor. KA administration did not induce neither increase in explorative behavior nor change in learning and memory behavior, observed in Y-maze test (5min.). EEG signals of individual rats were recorded for 2-h period through connection of recording cables. EEG signals were digitized at 400 Hz by a PowerLab/4SP system (AD Instruments) with 12-bit A/D, and stored in a PC through the Chart program software. The EEG signals were processed through 1.25 – 45 Hz band pass filter. The digitized EEG data were segmented into 1024-point (50%

overlap) and the signals were converted to power spectra by the fast Fourier transform algorithm (Hanning window cosine transform). Intrahippocampal injection of KA induced paroxysmal discharges in the ipsilateral EEG. This abnormality of brain wave of frequent spikes occurred either in isolated or short bursts. Saline injection did not induce any change in EEG patterns. EEG spectral power analysis revealed the ipsilateral increase in power density (μV2/Hz) of slow wave activity (0.125-5 Hz, 18.55%) and decrease in power density of fast wave activity (23-45 Hz, 6.97%) compared to pretreatment levels ($p<0.05$,compared by T-test). The 7th day after injection (last day) rats with KA administration showed only the decrease in theta activity (4-7 Hz, 5.32%). No similar finding was observed contralaterally. This study demonstrated cortical EEG characteristics following activation of hippocampal neurons via glutamate receptor. The data suggest that EEG study is sufficiently accurate to identify brain site and time dependent effects of neurodegenerative induction.

Exercise promotes axon regeneration of newborn projection neurons in rats after stroke

Q. Zhang and F. Sun

Dept. Neurobiology, Fudan University, Shanghai, China

Neurogenesis exists in adult brains of mammalian, which can be stimulated by hypoxic/ischemic brain injury. Stroke-induced newborn striatal neurons can develop long axons to project into the substantia nigra and integrate with preexisted neural networks. Rehabilitative training improves striatal neurogenesis in brains after stroke. However, whether it can improve axon-regeneration of new striatonigral projection neurons remains unknown, which is critical anatomical basis for recovering motor function. Therefore, we investigated the effects of exercise on axon-regeneration of newborn projection neurons in rat brains following ischemic stroke. Adult male Sprague–Dawley rats (250-280g, n=25) were divided into stroke (MCAO) and stroke+exercise (MCAO+EX) groups. Rats were anesthetized with 10% chloral hydrate (360 mg/kg, i.p.) and then subjected to a transient middle cerebral artery occlusion (MCAO) to induce ischemic stroke, followed by 30 minutes of exercise training daily for 5 to 28 days after MCAO (MCAO+EX). Motor function was tested using the rotarod test. We used fluorogold (FG) nigral injection to trace striatonigral and corticonigral projection neurons, and GFP-targeting retroviral vectors combined with FG double labeling (FG+-GFP+) to detect newborn projection neurons. The results further showed that such exercise could improve recovery of motor function of rats after MCAO. Under this experimental condition, we observed that FG+-GFP+ cells were detected in ipsilateral cortex and striatum of rats to MCAO, suggesting existence of newborn striatonigral and corticonigral projection neurons in ischemic injured brain, which was consisted with our previous reports (1,2). Interestingly, exercise poststroke could significantly increase the number of FG+-GFP+ neurons in ipsilateral striatum and cortex. The number of GFP+-FG+ cells in MCAO+EX rats increased 2.52-fold and 1.78-fold of MCAO rats in the cortex and striatum, respectively. This data suggested that exercise enhanced the capacity for axon-regeneration of newborn neurons. Moreover, the tyrosine hydroxylase immunostaining results showed that exercise significantly increased dopaminergic neurons in the substantia nigra, a region remote from the ischemic territory, compared with the controls. In summary, present study provides the first evidence that passive exercise poststroke can effectively improve axon-regeneration of newborn projection neurons and accelerate the reestablishment of new neural circuitry within the basal ganglia after ischemic injury, which should provide very important anatomical foundation for the recovery of motor behavioral function. Our results illustrate mechanisms, at cellular level, for passive rehabilitative treatment poststroke in the clinic.

Multisensory integration in ferret auditory cortex: Effects of inactivating visual cortex

S.M. Town, K.C. Wood and J.K. Bizley

Ear Institute, UCL, London, UK

Neurons in ferret (*Mustela putorius furo*) auditory cortex respond to simple visual stimuli and auditory responses to broadband noise can be modulated by the presence of visual stimuli (Bizley et al., 2007). Visual interactions in auditory cortex may arise from input connections from neurons in visual cortex, parietal cortex and the suprageniculate nucleus of the thalamus (SGN). However the functional relevance of these inputs remains to be demonstrated. Here, we investigated the role of a sub-region of visual cortex – the suprasylvian cortex (SSY) - in multisensory integration. SSY sends dense projections to auditory cortex, particularly regions of anterior auditory cortex and we studied the effects of SSY inactivation on responses of auditory cortical neurons.

Multi-unit neural activity was recorded at 13 sites within the auditory cortex of three ferrets anesthetized through intravenous administration of ketamine (5 mg kg^{-1} hr^{-1}) and medetomidine (0.022 mg kg^{-1} hr^{-1}). Neural activity within auditory cortex was recorded before and during inactivation using cooling loops that reduced the cortical surface temperature of SSY to between 4 and 7°C. Simultaneous recording of neural activity within SSY of two ferrets confirmed the efficacy of inactivation through cooling.

Auditory cortical units were found in which cooling significantly reduced visual but not auditory responses. Furthermore units were found in which visual modulation of auditory responses was selectively reduced by cooling. We also found evidence for the involvement of regions outside of SSY as several units demonstrated visual responses robust to cooling. Units were also discovered for which cooling reduced visual responses but only within a circumscribed period of the response. Additionally in sporadic cases, cooling led to the

emergence of visual responses or the visual modulation of auditory responses within auditory cortex.
Together these preliminary findings support the role of SSY in multisensory integration within auditory cortex, but also indicate the involvement of additional brain regions possibly including other subdivisions of visual cortex, parietal cortex and SGN. Our results also suggest that SSY inputs to auditory cortex may involve both excitatory and inhibitory mechanisms. Future work will focus on elucidating the contributions of regions beyond SSY to visual activity within auditory cortex and their relevance for behaviour.

Magnesium L-threonate prevents and restores memory deficits associated with neuropathic pain by inhibition of TNF-α

J. Wang, L. Zhou and X. Liu

Department of Physiology, Zhongshan Medical School of Sun Yat-Sen University, Guangzhou, China

Clinical studies have shown that about two third of patients with chronic pain suffer from short-term memory (STM) deficits and effective drug for treatment of the neurological disorder is lack at present. We tested whether chronic oral application of magnesium L-threonate (MgT), which has been shown to improve memory in normal and aging animals by elevating Mg2+ in brain, could prevent or restore the STM deficits induced by spared nerve injury (SNI), an animal model of chronic neuropathic pain. The mechanisms underlying the effect of MgT on STM deficits were also investigated. The experiments were conducted in a random and double blind fashion in adult male rats. MgT was administrated via drinking water at a dose of 609 mg/kg/d for 2 weeks, starting either one week before SNI (preventative group) or one week after SNI (therapeutic group), and the water without drug served as control. STM was accessed with a novel object recognition test (NORT), followed by recording of long-term potentiation (LTP) in hippocampus in vivo and the measurement of the expression of tumor necrosis factor-α (TNF-α) with Western Blot or Immunohistochemistrical staining. AMPA and NMDA receptor (NMDAR) currents were recorded with patch clamp in CA1 neurons in acute and cultured hippocampal slices. We found that chronic oral application of MgT was able to prevent and restore the deficits of STM and of LTP at CA3-CA1 synapses in rats under urethane anesthesia induced by SNI. Furthermore, both preventative and therapeutic chronic oral application of MgT blocked the up-regulation of TNF-α in hippocampus, which has been previously shown to be critical for memory deficits. SNI reduced NMDAR current and the effect was dramatically attenuated by elevating extracellular Mg2+. In cultured hippocampal slices, chronic application of recombinant rat TNF-α (rrTNF-α) for 3d reduced NMDAR current in a concentration-dependent manner and the effect was again blocked by elevating extracellular Mg2+. Our data suggested that oral application of MgT was able to prevent and restore the STM deficits in animal model of chronic neuropathic pain by revising the dysfunction of NMDAR produced by over-expression of pro-inflammatory cytokines. Oral application of MgT may be a simple and potent means for handling this form of memory deficits.

An excitatory preoptic pathway for cutaneous vasoconstriction in fever

R. McAllen, M. Tanaka and M.J. McKinley

Florey Institute, Parkville, VIC, Australia

The central neural pathways for thermoregulation and fever are not well understood. It is known, however, that cutaneous vasoconstrictor nerves such as those to the rat's tail are under tonic inhibitory control from the preoptic area [1]. Thermoregulatory and febrile control of those vessels is thought to be brought about by variations in the inhibitory tone from preoptic warm-sensitive neurons, acting on sympathetic premotor neurons in the medullary raphé [2]. Recently, however, we identified an excitatory pathway from the preoptic area to the medullary raphé, and found that this mediated the reflex vasoconstrictor response to cooling the skin [3]. We wondered whether that excitatory pathway could also be responsible for the tail vasoconstrictor response in fever.
Two types of experiment were performed on urethane-anaesthetised rats (1.4 g/kg i.v), which were artificially ventilated but not paralysed. Experimental fever was induced by Prostaglandin E2 (PGE2), given by microinjection either into the rostromedial preoptic area [1] (0.2ng in 60nl) or into the lateral cerebral ventricle (50ng in 1.5μl). Single or few-unit nerve activity was recorded from tail vasoconstrictor fibres [1, 3].
In the first series, preoptic microinjections of PGE2 were followed by microinjections into the same site of either the inhibitory amino acid, glycine (0.5M, 60nl), or vehicle. Preoptic glycine (but not vehicle) injections roughly halved the tail vasoconstrictor fibre response to preoptic PGE2, suggesting that an excitatory output signal from that region had been blocked.
In the second series, the antagonist of ionotropic glutamate receptors, kynurenate (50mM, 120nl), was injected into the medullary raphé. Raphé kynurenate (but not vehicle) injections fully reversed the tail vasoconstrictor fibre response to intra-preoptic or intracerebroventricular injections of PGE2.
These findings suggest that in PGE2-induced fever, an excitatory output signal from the preoptic area contributes to the tail vasoconstrictor response. They also show that this response depends entirely on excitatory (ionotropic glutamatergic) neurotransmission in the medullary raphé. Directly or indirectly, therefore, a descending excitatory pathway from the preop-

tic area mediates rat tail vasoconstrictor responses to experimental fever. These findings alter our understanding of thermoregulatory mechanisms in fever. It remains to be shown whether fever uses the same descending excitatory pathway that mediates tail vasoconstrictor responses to cold skin [3].

Taste perception of coffee induces similar electroencephalographic response to drinking coffee

E. Kumarnsit[1], N. Samerphob[2] and S. Watanasit[2]

[1]Physiology, Faculty of Science, Prince of Songkla University, Hatyai, Songkhla, Thailand and [2]Biology, Faculty of Science, Prince of Songkla University, Hatyai, Songkhla, Thailand

Refreshing foods and beverages have been used in daily life to improve alertness and mood. Coffee is one of the most common drinks which are related to performance enhancement. However, its effects on brain function have been unclear in terms of coffee ingredient or taste perception impact. This study investigated electroencephalographic (EEG) patterns after receiving taste without swallowing and normal drinking of coffee in both genders of 20 subjects aged between 20 to 30 years old. This project was approved by ethical committee for using human subjects. Electrodes were placed on the scalp over the frontal and parietal cortices. Freeze dried instant coffee (Moccona, Royal gold) was purchased from commercial source. EEG signals from individual subject were recorded for 5 min for baseline levels and 10 min following taste alone or drinking of coffee. Fast Fourier Transform (FFT) algorithm was used to analyze EEG signal in frequency domain. The parietal EEG analysis showed that slow frequency activity (0.8 – 4.5 Hz, delta band) was reduced by both taste and drinking of coffee with similar magnitude. In addition, high frequency activity (18 – 35 Hz, beta2 band) of parietal EEG was increased by both types of trials. No significant change was detected in frontal EEG. These patterns are general characteristics of refreshing beverages. In summary, taste perception was demonstrated to be as effective as drinking of coffee ingredients. These findings suggest that taste perception might induce conditioned response through associative learning. Besides, coffee taste may be alternative choice to prevent relapse during coffee withdrawal period.

Nonlinear dynamical systems effects of homeopathic remedies on multiscale entropy and correlation dimension of slow wave sleep EEG in young adults with histories of coffee-induced insomnia Homeopathy, Volume 101, Issue 3, July 2012, Pages 182-192

Excitatory interneurons that mediate non-reciprocal excitatory reflex in primate spinal cord: their input-output relations and firing pattern during voluntary wrist movement

G. Kim[1,2], T. Takei[1,2] and K. Seki[1,3]

[1]Dept. Neurophysiol, Nat. Inst. Neurosci., Kodaira, Japan, [2]Dev. Physiol, Nat. Inst. Physiol. Sci, Okazaki, Japan and [3]PREST, Japanese Sci. Tech. Agency, Tokyo, Japan

Reflex circuit in the spinal cord has been extensively studied in the anesthetized animals, and several type of interneuron has been identified as a key neurons that define unique input-output relations for each reflex. However, there are no direct evidence showing their function in the generation and control of muscle activity during voluntary movement. To address this issue, we identified spinal interneurons (INs) mediating segmental reflex from proprioceptors and examined their activities during voluntary movements. Three macaque monkeys were trained to perform a wrist flexion and extension task with an instructed delay period. An oval spinal chamber was implanted to vertebrae (C4-T1) and a glass-coated elgiloy microelectrode was used to record the activity of INs. Electromyographic activities (EMGs) were recorded from wrist flexor and extensor muscles (n=8-12) by chronically implanted wire electrodes. In addition, nerve cuff electrode was implanted to the deep radial (DR) nerve that innervates most of wrist extensor muscles. Surgeries for these implants were performed while the animals were anesthetized with isoflurane (1.0% – 2.0% in 2:1 O2:N2O) or sevoflurane (1.5% – 3.0% in 2:1 O2:N2O) under aseptic conditions. Experiments in this study were performed in accordance with the National Institutes of Health Guidelines for the Care and Use of Laboratory Animals and were approved by the Animal Research Committee at the National Institute for Physiological Sciences, Japan. In the monkeys performing wrist movement, we identified the peripheral input to INs by their responses to the electrical stimulation to the DR nerve. The INs that responded within a segmental latency of 1ms were identified as the cells with direct projection (first-order INs) from DR afferent nerve. Output of these INs to muscles were examined by the spike-triggered averaging of EMGs. In the 81 INs that showed monosynaptic response to the DR stimuli, 32 INs (39%) showed postspike effects to one or more muscles (22 post-spike facilitations (PspF, 69%), 7 post-spike suppressions (PspS, 22%), or 3 PspF & PspS (9%)). Among 22 INs with PspF, 18 INs (82%) showed their PspF exclusively in the extensor muscles, and number of muscle that showed PspF from each INs ("muscle field") was 2.0±1.0. These results suggest that the spinal INs that mediating proprioceptive input from extensor muscles preferen-

tially facilitated the extensor muscles (autogenetic facilitation). Next, we analyzed the modulation of firing rate of the first-order INs as a function of task sequence. First-order INs with PspF to extensor muscles (n=18) showed sustained activity throughout the extension torque. In contrast, the first-order INs without PspF in any tested muscles (n=49) transiently increased their firing during torque onset, but it decreased significantly while monkey sustained extension torque ($p < 0.01$). These results suggest that disynaptic, excitatory reflex pathway that mediating autogenetic facilitation of extensor muscle is involved in the maintenance of static muscle force during voluntary movements. We propose that voluntary muscle activity could be automatically augmented by this reflex system.

Protective effects of Astragaloside IV on oxygen and glucose deprivation-induced ischemic injury in PC12 cells

B. Chiu[1], C. Chang[2], C. Wang[3,4], Y. Hsu[1], J. Yu[1], C. Chen[2], C. Hsu[5], M. Chang[6] and B. Cheng[2,3]

[1]Department of Chinese Medicine, Chi Mei Medical Center, Tainan, Taiwan, [2]Department of Biotechnology, Southern Taiwan University of Science and Technology, Tainan, Taiwan, [3]Department of Surgery, Chi Mei Medical Center, Tainan, Taiwan, [4]Department of Recreation and Health-Care Management, Chia-Nan University of Pharmacy and Science, Tainan, Taiwan, [5]Department of Surgery, School of Medicine, College of Medicine, Taipei Medical University and Division of Cardiovascular Surgery, Department of Surgery, Taipei Medical University, Taipei, Taiwan and [6]Department of Electrical Engineering, Southern Taiwan University of Science and Technology, Tainan, Taiwan

The Chinese medicine Astragali radix has been used to treat stroke sequelae for a long time. A few reports indicate that Astragali Radix extract or its purified components can affect brain function, protect the brain againt ischemia, promote neurogenesis and improve sensorimotor deficits and recovery of learning, memory and cognitive functions following ischemia. In addition, the mechanism of Astragalosides(AST) protection is not completely known. This study will observe the neurological protective effects of AST on ischemia and reperfusion injury model of PC12 cells and investigate what's the molecular mechanisms involved in apoptosis and autophagy. PC12 cells were exposed to oxygen and glucose deprivation(OGD) and restoration(OGD-rep) were used as an in vitro model of ischemia and reperfusion. PC12 cells were divided into three groups: Control, Ischemia-Reperfusion(I/R) and I/R+ AST(AST). The duration of ischemia and reperfusion was separately 5h and 24h. MTS assay and lactate dehydrogenase(LDH) leakage were used to evaluate the survival rate and protective effects of AST. DNA fragmentation were analyzed using DNA gel electrophoresis. Sub G1phase cell cycle arrest had identified by the flow cytometry analysis with PI stain. Caspase-3 protein expression and activities were measured by using assay kits with ELISA reader and Western blotting assay for apoptosis. Beclin-1 and LC3B-II expression, acridine orange staining assay were used to evaluate autophagy. Intrinsic apoptosis pathway were observed from ER stress involving Bip, caspase-12 expression and mitochondrial dysfunction involving mitochondrial membrane potential collapse and caspase-9 activation. Extrinsic apoptosis pathway were observed from caspase-8 expression. We found that, AST concentration-dependently attenuated neuronal damage with characteristics of increasing injured neuronal absorbance of MTS, decreasing cell apoptosis, subG1 phase cell cycle arrest, and caspase-3 activity induced by OGD-Reperfusion(OGD-R). AST treatment also alleviated the mitochondrial transmembrane potential dropped, mitochondria stress(caspase-9 activation), ER stress(Bip and caspase-12 activation) following OGD-R. In addition, OGD-R rapidly induced autophagy(evidenced by increased microtubule- associated protein-1 light chain 3(LC3) levels and punctured distribution of the autophagic vesicle-associated form LC3-II) and necrosis(evidenced by increased lactate dehydrogenase). AST treatment adopted at the start of OGD-R significantly reduced the OGD-R- induced apoptosis, autophagy and necrosis in PC12 cells. The appropriate concentration of AST can effectively protect PC12 against OGD-R injury by reducing apoptosis and autophagy through decreasing the oxidative stress, ER stress and mitochondrial dysfunction.

High-density EEG recordings from human motor cortices reveal deliberation process preceding a movement decision

D.F. Kutz[1], W. Hürster[3], F.P. Kolb[1] and J. Nida-Rümelin[2]

[1]Institute of Physiology, University of Munich, Munich, Germany, [2]Department of Philosophy IV, University of Munich, Munich, Germany and [3]Research & Consulting, Ulm, Germany

Question: Deliberation is the process of weighing alternatives. The aim of this study was to investigate neuronal correlates of a deliberation process leading to a motor decision.
Methods: In this study 23 young right-handed subjects (age: 18 - 27, 12 female) had to press a key with either the right or left hand, depending on a visual stimulus. The stimulus consisted of a word indicating a colour written either in the corresponding colour (e.g. word "red" written in red : match condition) or written in a different colour (mismatch condition). Subjects had to decide between responding with the right hand in the match condition, or with the left hand in the mismatch condition. High-density multi-channel EEG activity was recorded as well as behavioural data. In addition reaction times of the deliberation tasks were compared with those of a corresponding simple motor task.
Results: The reaction time in the deliberation task was significantly different from that observed during the simple motor task. Moreover, within the deliberation task the reaction times for the mismatch condition are significantly longer than those for the match condition.
The EEG patterns recorded from above the motor cortices during both tasks show clear differences. During the simple motor task a typical pre-motor positivity is observed preceding the key press whereas during the deliberation task a strong negativity approximately 300 ms before movement onset is found. Subtracting the motor task pattern from the EEG pattern of

the deliberation task augments the preceding negativity, presumably implying a required cognitive process.
Conclusions: The deliberation process during movement decision is represented by an increasing negativity in the motor region before movement onset. As both hemispheres show a similar activation it is assumed that competing motor plans are processed simultaneously. This result supports the idea for an involvement of the motor cortices in the deliberation process.

Extracellular hippocampal glutamate and GABA levels during spatial alternation testing in memantine/saline treated rats

G. Beselia[1], M. Sephashvili[2], T. Naneishvili[1], M. Burjanadze[1] and D. Mikeladze[2]

[1]Behavior and Cognitive functions, I.Beritashvili Center of Experimental Biomedicine, Tbilisi, Georgia and [2]Institute of Chemical Biology, Ilia State University, Tbilisi, Georgia

For over a decade intensive research has been dedicated to search for NMDA receptor antagonists as a potential neuroprotective treatment for both acute (e.g., stroke) and chronic neurodegenerative diseases. Although only very few such agents reached late stages of clinical development because of side effects, it was discovered that several compounds currently in clinical use such as memantine, amantadine and others have NMDA blocking properties which likely play a role in their therapeutic efficacy. It is still not clear, however, as to how memantine produces its symptomatological improvement of memory in demented patients. The effects of memantine on in vivo hippocampal glutamate levels has not been examined. The followimg investigation was conducted to determine the effects of chronic memantine treatment on hippocampal Glu and GABA release prior to, during, and after spontaneous alternation test. Also, we have investigated the effects of chronic treatment with memantine on basal and KCl-stimulated release of GLU and GABA in the hippocampus. A total of 18 male Wistar rats (Department of Animal Care, I. Beritashvili Center of Experimental Biomedicine) were used in the present study. All experiments were approved by the Animal Care and Use Committee of the Center and were in accordance with the principles of laboratory animal care. Two groups of rats were treated either with memantine (2,5 mg/kg/day; i.p. Sigma Chemical Co., St. Louis, MO) or with vehicle (saline) for a period of 4 weeks. Memantine-treated rats, relative to saline rats, had a significantly lower level in the number of arms entered during the testing session. However, the groups did not differ in the level of alternation behavior. The results indicate that memantine treatment produced decreased locomotor (exploratory) activity ($p<0,05$) but did not affect spatial working memory in adult rats assessed in spontaneous alternation task ($p>0,05$). Glu release during the 10 min samples taken at the time of the behavioral testing of memantine or saline treated animals increased during behavioral testing but were not significantly different ($p>0,05$) from those seen immediately before and after testing. We found increase in KCl-stimulated glutamate and GABA release in the hippocampus of memantine treated rat compared to the saline treated rat. This difference in KCl response between memantine treated and control rat was statistically significant ($p<0,05$). Our evaluation of memantine reveals that changes in Gluergic neurotransmission after chronic memantine treatment did not affect working memory in adult rats assessed in spontaneous alternation task.

The designated project has been fulfilled by financial support of Presidential Grant for Young Scientists (Grant #PG/55/7-276/12) .

Enriched environment improved anti-stress effects of antidepressants in repeated rat forced swimming test

C. Lino de Oliveira[1,3], F. Possamai[1,3], J. Santos[1], J. Marcon[1] and J. Marino-Neto[1,2]

[1]Ciências Fisiológicas, Universidade Federal de Santa Catarina, Florianópolis, Santa Catarina, Brazil, [2]Instituto de Engenharia Biomédica (IEB-CTC-UFSC), Universidade Federal de Santa Catarina, Florianópolis, Santa Catarina, Brazil and [3]Programa Multicêntrico de Pós-Graduação em Ciências Fisiológicas, Universidade Federal de Santa Catarina, Florianópolis, Santa Catarina, Brazil

Environmental enrichment is able to induce behavioral effects in rats and mice exposed to the forced swimming test as well as in the morphology of the central nervous system. Our aim was to evaluate the effects of environmental enrichment from weaning on behavioral output of control and antidepressants-treated adult rats in the repeated Forced Swimming Test (1). In addition, we investigated cell proliferation in the hippocampal dentate gyrus of these rats. Male Wistar rats (n=80) were housed for 40 days from postnatal day 21 in standard (SE) or enriched (EE) environment. After this period they were exposed to the Pre-test (day 1, 15 min of forced swimming). In the next day (day 2), rats were randomly assigned in one of 4 groups and 1 hour before the Test (i.e. 5 min of forced swimming) they received an intraperitoneal injection with saline (SAL), or imipramine (IMI, 2.5 or 5 mg/kg) or fluoxetine (FLX 2.5 mg/kg). A daily injection of these compounds was performed to the respective group from the day 3 (one day after the Test) until day 7 (the day of the Retest 1, i.e., 5 min of forced swimming) and until day 14 (the day of Retest 2, i.e., 5 min of forced swimming). Pre-test, Test and Retests 1 and 2 were videotaped for posterior analysis of behavior (latency, frequency, duration of immobility, swimming, climbing). Duration of immobility was considered an index of behavioral despair. After retest 2, rats were anesthetized and sacrificed for brain dissection and preparation for Ki-67 (proliferation marker) immunohistochemistry in hippocampal dentate gyrus. Effects of retesting were analyzed using repeated measures Anova. Between groups analysis were performed using One Way Anova. When appropriate post hoc Duncan's test was performed. Housing in EE failed to affect behavior in the Pre-test or Test but attenuated the effects of re exposure on behavior of control rats. Antidepressants decreased the index of behavioral despair after 7 (Retest 1) and 14 (Retest 2) days of treatment as compared to saline in SE groups. The efficacy of FLX, not IMI, in reduce behavioral despair increased with the time (from Test to Retest 2) in SE groups. In EE groups, antidepressants (IMI 5 mg/kg and FLX 2.5 mg/kg) decreased the index

of behavioral despair after 14 days of treatment (Retest 2) when compared to their effects after 1 day of treatment (Test). Surprisingly, these later treatments also decreased the counting of Ki-67 in the dentate gyrus as compared to saline. These data suggest that enriched environment improved the coping with forced swimming stress and improved the effects of chronic treatment with imipramine on behavioral despair in a fashion unrelated to the increased proliferation in dentate gyrus of adult rat hippocampus.

The effect of erythropoietin pretreatment on S100B and NSE serum levels and brain inflammation in pentylenetetrazole induced generalized seizures; Evaluation of antiseizure effect of erythropoietin

N. Bahcekapili[1], I. Albeniz[2] and G. Uzum[3]

[1]Neurology, Istanbul state hospital, Istanbul, Turkey, [2]Biophysic, Medical Faculty of Istanbul, Istanbul, Turkey and [3]Physiology, Istanbul Medical Faculty, Istanbul, Turkey

Epilepsy is a common neurological disorder often unresponsive to pharmacological treatment. Seizures initiate brain inflammation in glia and promote blood brain barrier (BBB)damage. Erythropoietin(EPO)has been suggested a promising therapeutic and prophylactic for epilepsies based on its neuroprotective, antiapoptotic, and antiinflammatory potency. Exogenously given EPO traverses BBB through EPO receptors.Our previous study showed that pretreatment with recombinant human EPO (rhEPO) suppresses epileptic seizures and prevents BBB damage, but the mechanisms are still unclear. The present study investigated a possible role of EPO pretreatment in reducing inflammatory events, in pentylenetetrazole(PTZ)-induced generalized epilepsy model. Adult male Sprague-Dawley rats were used (seven animal/each group). PTZ (80mg/kg i.p) was given to induce generalized seizures. rhEPO (3000 IU/kg i.p) applied 24 h before PTZ administration. The control group was given saline, the EPO control group was given the same dose of EPO.After injection of PTZ, seizures were observed for two hours and scored as seizure stage, latency. Under general anesthesia(thiopental sodium, 50mg/kg) blood samples were taken from heart and immediately the brain removed. NSE, S100B and imflammation biomarkers were performed with ELISA tests. The serum levels of neuron specific enolase(NSE) and S100B(astrocytic protein) as peripheral markers of neuronal and BBB damage, respectively and levels of proinflammatory cytokines, interleukin-1β (IL-1β), tumor necrosis factor-α (TNF-α),interleukin(IL-6) as indicator of brain inflammation were measured in brain tissue. Data represented as mean±SEM and were compared among groups by using oneway ANOVA. PTZ induced seizures significantly ($p<0.001$) increased proinflammatory cytokines (IL1β:1,584±0.187pg/ml vs 0.434±0.434pg/ml control, TNFα :0.488±0.083 pg/ml vs 0.120±0.015pg/ml control, IL-6:0.610±0.043 pg/ml vs 0.509±0.042 pg/ml control). Likewise, the serum levels of S100B and NSE significantly ($p<0.001$)were increased (S100B: 0.89±pg/ml vs 0.32±0.05pg/ml control, NSE: 0.83± 0.087pg/ml vs 0.051± 0.011pg/ml control). EPO pretreatment significantly($p<0.001$) reduced seizure stage. Serum markers of BBB and neuron damage and all cytokines fell to control levels (IL1β:0.593±0.065pg/ml vs 1.584±0.187pg/ml PTZ group, TNFα: 0.177±0.007pg/ml vs 0.488±0.083 pg/ml PTZ group, IL-6: 0.339±0.017pg/ml vs 0.610±0.043 pg/ml PTZ group). Likewise, S100B and NSE fell to control levels (S100B: 0.33±0.041pg/ml vs 0.89±0.03 pg/ml PTZ group, NSE: 0.2±0.075pg/ml vs 0.83± 0.087pg/ml PTZ group). We suggest that the anticonvulsive effect of EPO is result of BBB protection due to its antiinflammatory activity.

PCC154

The modulation of the hippocampal function by the cholinergic and noncholinergic cells of the septum

M. Dashniani, T. Naneishvili, M. Burjanadze, N. Chkhikvishvili and E. Abzianidze

Behavior and Cognitive functions, I.Beritashvili Center of Experimental Biomedicine, Tbilisi, Georgia

Although the importance of the septohippocampal projections in learning and memory is generally accepted, the degree to which damage to particular set of septohippocampal projections contributes to deficits within specific cognitive domains is less clear. In the present study, using novelty-preference paradigm, we tested the behavioral effects of electrolytic, neurotoxic (ibotenic acid) or immunotoxic (192 IgG-saporin) lesions of medial septum (MS) to gain insights into the differential roles of septohippocampal cholinergic and noncholinergic projections in exploratory behavior and recognition memory. A total of 39 male Wistar rats (Department of Animal Care, I. Beritashvili Center of Experimental Biomedicine) were used in the present study. All experiments were approved by the Animal Care and Use Committee of the Center and were in accordance with the principles of laboratory animal care. The size and location of the electrolytic and ibotenic acid lesions were determined by microscopic examination of serial coronal sections (25 μm) stained with cresyl violet. The immunotoxic lesions of MS were verified by observing decreased Acetylcholinesterase (AChE) staining of the MS and hippocampal sections. Statistical analysis was performed using ANOVA. The results indicate that the MS lesioned rats did not differ from control rats in the activity level measured by grid crossing. The MS electrolytic lesioned rats were impaired in habituating to the environment in the repeated spatial environment, but rats with immuno- or neurotoxic lesions of the MS did not differ from control ones. The MS electrolytic and ibotenic acid lesioned rats showed an increase in their exploratory activity to the objects and were impaired in habituating to the objects in the repeated spatial environment; rats with immunolesions of the MS did not differ from control rats. The electrolytic lesions of the MS disrupt spatial recognition memory; rats with immuno- or neurotoxic lesions of the MS were normal in detecting spatial novelty; all of the MS-lesioned and control rats clearly reacted to the object novelty by exploring the new object more than familiar ones. In conclusion, our results observed across lesion techniques demonstrates dissociation between the two major components (cholinergic and noncholinergic) of the septohippocampal pathway in exploratory behavior assessed in the open field and indicate that: deficits after nonselective damage of MS are lim-

ited to a subset of cognitive processes dependent on the hippocampus; the selective loss of septohippocampal cholinergic or noncholinergic projections does not disrupt the function of the hippocampus to a sufficient extent to impair spatial recognition memory.

Fast network oscillations in the lateral septum in vivo

T. Korotkova[1], N.P. Denisova[2] and A. Ponomarenko[1]

[1]Behavioural Neurodynamics Lab, Leibniz Institute for Molecular Pharmacology (FMP) / NeuroCure Cluster of Excellence, Berlin, Germany and [2]Behavioural Neurodynamics Lab, Charité University Clinic, Berlin, Germany

Animal's behavior relies on the processing of environmental cues and signals about bodily state, yet physiology of their coordination remains poorly understood. Hippocampal and cortical information is relayed to hypothalamus and midbrain in rodents and other mammals mainly via the lateral septal nucleus (LS). We used high-density single and dual-site electrophysiological registration of local field potentials and of neuronal discharge in behaving mice to study network synchronization in LS and its coordination with inputs from the medial prefrontal cortex (mPFC) and hippocampus. Local field potentials (LFP) and neuronal discharge in LS displayed intermittent episodes (40-120 ms duration) of synchronization at frequencies between 40 and 90 Hz. These fast oscillations were behavioral state-dependent, coordinated within LS and, strikingly, were coherent with concurrently recorded gamma oscillations in the mPFC and, less prominently, in the hippocampus during slow- and theta-rhythmic epochs, respectively. Neuronal activity in LS was modulated by locally recorded LFP gamma oscillations: the discharge of the vast majority of recorded cells was significantly modulated by the locally recorded rhythm. As a population, LS units fired near troughs of gamma cycles. LFP and the neuronal discharge
recorded simultaneously from LS and mPFC displayed coordinated patterns of activity
between the two regions in the gamma frequency band. Furthermore, our recordings
of LFP and neuronal activity in LS in novel and familiar environments suggest experience-dependence of network synchrony in LS and its potential relevance for shaping behavioral responses to novelty processed by hippocampus and mPFC.

Erythropoietin pretreatment suppresses pentylenetetrazole induced generalized seizures by inhibiting iNOS and increasing eNOS activity in hippocampus

G. Uzum[1], N. Bahcekapili[2], A. Kapucu[3], A. Kandil[3] and K. AkgünDar[3]

[1]Physiology, Istanbul University Istanbul Medical faculty, Istanbul, Turkey, [2]Neurology, Istanbul state hospital, Istanbul, Turkey and [3]Biology, Istanbul University Science Faculty, Istanbul, Turkey

Erythropoietin (EPO) is an antiapoptotic, neuroprotective and antiinflammatory hormone. EPO antiseizure effect elicits but the molecular mechanism is still not fully understood. Status epilepticus(SE) trigger inflammatory mediators in brain, produces neuronal damage preferential in the hippocampus, the underlying mechanism is still unsettled. Nitricoxide (NO) is synthesized from L-arginine (L-Arg) by three different isoforms of NO synthase (NOS), i.e. the constitutive neuronal and endothelial NOS (nNOS and eNOS) and the inducible NOS (iNOS). NO has been involved in the pathophysiology of epilepsy, but available data are conflicting and the role of NO in epilepsy still remains to be clarified. However, SE increases microglia activity and induces iNOS expression in hippocampal neurons, leading to apoptotic neuronal cell death in the hippocampus. In this study, the possible modulatory effect of recombinant human erythtopoietin (rhEPO) pretreatment on NO synthases (NOS; neuronal, inducible and endothelial) expressionin hippocampus after pentylenetetrazole (PTZ) induced seizures were analyzed. PTZ is a common convulsant agent used in animal models to investigate the mechanisms of seizures. Adult male Sprague-Dawley rats were used (seven animal/each group). PTZ (80mg/kg i.p) was given to induce generalized seizures. rhEPO (3000 IU/kg i.p) applied 24 h before PTZ administration. The control group was given saline, the EPO control group was given the same dose of EPO. After injection of PTZ, seizures were observed for two h and scored as seizure stage, latency. Under general anesthesia (pental sodium, 50 mg/kg) immediately brain removed and hippocampus was removed to examined NOS isoforms using immunohistochemistry. Data are expressed as mean± SD. Behavioral data were analyzed by one-way ANOVA followed by Duncan post host doc test. PTZ induced generalized seizures iNOS immunreactivity increased, eNOS immunreactivity decreased in hippocampus. EPO pretreatment significantly ($p<0.001$) reduced seizures stage (2.7 ±0.01 vs 4.8±0.2 PTZ-group), and did not effect seizure latancy. Besides, it increased markedly eNOS activity, decreased markedly iNOS activity, did not effect nNOS activity. The data suggest that anticonvulsant effect of EPO might be related to the decrease of iNOS and increase of eNOS.

Effects of medial septal electrolytic and immunotoxic lesions on place and response learning of rats in the Morris water maze

L. Kruashvili, D. Manana and G. Beselia

I.Beritashvili Center of Experimental Biomedicine, Tbilisi, Georgia

In this experiment the ability of medial septal electrolytic, selective ACh lesioned (by immunotoxin 192 IgG-saporin) and sham-operated rats, to learn the location of a visible, as well as submerged platform in a water maze was investigated. A total of 36 male Wistar rats were used in the study. Experimental protocol was approved by Animal Studies Committee of I. Beritashvili Center of Experimental Biomedicine and were in accordance with the principles of laboratory animal care. The size and location of the electrolytic lesions were determined by microscopic examination of serial coronal sections (25 μm) stained with cresyl violet. The immunotoxic lesions of MS were verified by observing decreased Acetylcholinesterase (AChE) staining of the MS and hippocampal sections. The rats' responses in the competition test were classified as either cue or place directed, based on the swim path for those trials. Sham-operated rats acquired both the visible and hidden platform versions of the task, but when required to choose between the spatial location they had learned and the visible platform in a new location, majority of them swam first to the old spatial location. The medial septal electrolytic lesioned rats acquired the visible platform version of the water maze task but failed to learn the platform location in space. When the visible platform was moved to a new location they often swam directly to it. The medial septal selective ACh lesioned rats, as well as sham-operated, acquired the platform location in space. Sham-operated and selective ACh lesioned rats identified as place responders, had significantly more accurate searches during hidden platform training, providing additional evidence of their effective use of a place learning strategy rather than medial septal electrolytic lesioned rats. These findings suggest that the septo-hippocampal system is essential for accurate spatial learning and suggest its role in processing information about the spatial environment, but deficits observed after septal electrolytic lesions cannot be accounted solely to the loss of hippocampal ACh and raised the unexpected possibility that hippocampal ACh is not essential for all types of hippocampal-dependent memory.

PCC158

Effect of toluene chronic exposure on exploratory behavior and recognition memory in adolescent and adult rats

N. Pochkhidze, M. Zhvania, N. Japaridze and L. Chilachava

I.Beritashvili Center of Experimental Biomedicine, Tbilisi, Georgia

Toluene and toluene-containing volatile substances are the most widely abused solvents with demonstrative addictive potential in humans. Several data indicate that as a result of toluene misuse alterations in learning and memory in organisms of different age take place. But because of differences in species, length of exposure, dose or rate of administration, it is not always possible to conclude whether adolescent experience results in changes in learning and memory are comparable to that seen in adults. The present study has been undertaken to determine whether toluene chronic exposure provokes immediate and/or persisting effect on exploratory behavior and recognition memory in open field in adolescent and adult rats. We exposed male Wistar rats at ages P 28-32 (adolescents) and P 70-75 (adults) to 2000 ppm inhaled toluene for 40 days. The immediate and persisting effects of toluene misuse (immediately after the end of toluene chronic inhalation and 90-day after the end of toluene chronic inhalation, correspondingly) were evaluated. Experimental protocol was approved by Animal Studies Committee of I. Beritashvili Center of Experimental Biomedicine. The major findings are: (1) toluene misuse alters exploratory activity and recognition memory in adolescent and adult rats; (2) the level of alterations depends upon the postnatal age of testing animals. In particular: in adolescent rats the most significant behavioral alterations were observed by the day following toluene chronic exposure. These alterations do not progress significantly during abstinence period: some altered parameters were almost the same as observed the day following immediately after toluene misuse and others were very close to observed in control animals. Therefore, in adolescent rats the most expressed was immediate effect of toluene misuse. Contrary to it: in adult rats most alterations significantly progress during 90 d period of abstinence. So, in these animals more substantial was persistent effect of toluene chronic exposure. On the bases of our data it is possible to suggest that adolescent rats may show partial recovery from once the toluene toxic effect no longer persists.

The designated project has been fulfilled by financial support of Presidential Grant for Young Scientists (Grant #PG/54/7-276/12) .

Activation of Epac has epic effects on diabetic sensory axon regeneration

D. Shewan, K. Steel, A. Murray, S.J. Tucker, N.E. Cameron and M.A. Cotter

School of Medical Sciences, University of Aberdeen, Aberdeen, UK

Neuropathy is a common complication of diabetes, reducing neuronal function, including impaired regeneration. Failure of CNS axons to regenerate after injury is at least partly due to intrinsic neuronal factors. Cyclic AMP (cAMP) activation promotes sensory axon regeneration through an Epac-mediated pathway. We therefore explored whether diabetic neurons are defective in cAMP-Epac signalling. We used cultured dissociated dorsal root ganglion (DRG) neurons from terminally-anaesthetised streptozotocin –induced diabetic and age-matched control rats to study their growth and responses to axon guidance cues. Growth of DRG neurons on a laminin substrate was significantly greater in controls compared with diabetic rats after 48 hours (35.9 ± 3.1% control neurons grew processes of at least 3 cell body diameters (3 cbd) vs. 27.4 ±

2.0% diabetic neurons, p<0.05; two-tailed, unpaired Student's t-test was used in all statistical analyses). The cAMP agonist, Sp-cAMPS (20μM), enhanced neurite outgrowth of diabetic and control neurons at both 24 and 48 hours, but a selective Epac agonist, 8 pMeOPT-2'-O-Me-cAMP (2μM), significantly increased neurite outgrowth in control neurons (18.8 ± 1.6%) compared to diabetic neurons (12.6 ± 1.8%, p<0.05) after 24 hours. By 48 hours, the Epac agonist significantly improved the outgrowth of diabetic neurons (39.1 ± 1.5% Epac agonist vs. 27.4 ± 2.0% control, p<0.05), which was similar to the effect of the Epac agonist on age-matched control rat neurons at this time point (33.1 ± 3.2%). Activating cAMP or Epac also reversed the repulsive response of diabetic DRG neuronal growth cones to a gradient of the cAMP-dependent trophic factor, nerve growth factor (NGF). After 48 hours 13 out of 16 control growth cones turned towards the gradient, with a mean turning angle (MTA) of 17.6 ± 6.5°, while 9 out of 11 diabetic growth cones were repelled by a NGF gradient, showing a MTA of -22.5 ± 9.1°(p<0.001). Bath application of 20μM Sp-cAMPS, to elevate cAMP activity in diabetic neurons, converted diabetic growth cone repulsion to attraction at the 48 hour time point (MTA with Sp-cAMPS was 11.9 ± 4.9° vs. -22.5 ± 9.1° without Sp-cAMPS, p<0.001), as did bath application of the Epac agonist (MTA of 5.7 ± 5.9° with agonist vs -22.5 ± 9.1° without agonist, p<0.01). Blocking cAMP with the Rp-cAMPS isomer (20μM), which binds to Epac but does not activate it, abolished both the attraction of control growth cones in a NGF gradient and repulsion of diabetic neurons. An 18.9% decrease (p<0.05) in Epac expression was seen in diabetic neurons by Western blot and a 35% decrease (p<0.05) of Epac expression in growth cones by immunocytochemistry. Together, these results suggest that adult diabetic rat neurons exhibit reduced expression of Epac, resulting in a compromised ability to regenerate neurites and an inability to respond to cAMP-dependent chemoattractive guidance cues.

PCC160

The excitation of rat primary afferent fibres by p-benzoquinone, a metabolite of paracetamol (acetaminophen APAP)

T.A. Sears, D.A. Andersson, C. Gentry and S. Bevan

Wolfson CARD, King's College London, London, UK

Recently, two metabolites of paracetamol were shown to activate TRPA1, a receptor involved in neurogenic airway inflammation1 and thermal, mechanical and chemical nociception.2 Thus p-benzoquinone (p-BQ) and n-acetyl-p-benzoquinoneimine (NAPQI) increased [Ca2+]i in CHO cells expressing TRPA1;and a subset of cultured DRG neurones displaying such Ca2+ responses was strongly depolarised, suggesting a spinal and presynaptic role in APAP analgesia2; our in-vivo studies address this possibility. In anaesthetised rats (Urethane, i.p.) the spinal cord was exposed, and L1-S1 dorsal roots prepared for recording either orthodromic sensory nerve action potentials or ones arising centrally and conducted antidromically (Fig1, lower trace). These arise in small diameter myelinated and C-fibres in contrast to the larger spikes recorded from the peripheral end of the same cut root in response to tactile or proprioceptive stimulation (not shown).
The upper trace shows the mean spike rate counted in 5.0 sec bins. Within seconds of application to the spinal cord root exit zone 10micro litres of 1.0 microM p-BQ evoked a five-fold increase in net impulse rate persisting for 2 minutes before return to baseline level. The next dose (10μl p-BQ at 10 microM) evoked a prompt sixteen-fold rate increase at its peak with recruitment of new spikes; this activity was sustained for a further 3 minutes after the illustrated trace. This response was elicited on each occasion (35 in 18 rats) with BQ concentrations ranging from 300nM to 600microM ; we attribute this to variations both in the integrity of the pia at the site and dispersion of the applied drug. Although retrograde impulse activity can be directly attributed to the depolarisation of TRPA1 afferent terminals some glutamatergic collaterals may excite internuncial pathways causing presynaptic depolarisation via GABA or glycine receptors. However, this does not seem relevant for APAP analgesia. The P-wave of the cord dorsum potential evoked by sural nerve stimulation, an electrical sign of presynaptic inhibition, was unaffected in 5 rats followed for up to 2 hours after s.c. injection of the same doses (300mg/kg) used in the behavioural studies. These results thus support the hypothesis that paracetamol analgesia is, in part, mediated by its metabolite p-BQ activating TRPA1 receptors leading to depolarisation and consequent presynaptic inhibition of pain pathway(s) mediating antinociception2.

Effects of chronic infusion of kisspeptin and its antagonist on cognitive functions and behavior in female rats

S. Eyuboglu Dinc[1], S. Canpolat[2], H. Akkaya[1], B. Elibol-Can[3], E. Kilic[4] and B. Yilmaz[1]

[1]Department of Physiology, Yeditepe University, Istanbul, Turkey, [2]Department of Physiology, Karadeniz Teknik University, Trabzon, Turkey, [3]Department of Biology, Middle East Technical University, Ankara, Turkey and [4]Department of Physiology, Medipol University, Istanbul, Turkey

Kisspeptin and its membran receptor (GPR54) are expressed in various brain regions, especially in the hypothalamus, hippocampus and cortex. Effects of this neuropeptide on reproductive functions and puberty onset have been investigated. However, functions of kisspeptin/GPR54 system in the hippocampus have not been clarified. Therefore, we have examined effects of kisspeptin and its antagonist on learning, memory, animal activity, depression and anxiety behavior and their underlying mecanisms. Adult female Sprague Dawley rats were devided three groups (n=8/group): Control animals received saline (osmotic minipump, icv) for 28 days. Rats in the second and third groups were administered with osmotic minipump driven infusion of kisspeptin-10 (10 nmol/kg/day, icv) and kisspeptin antagonist (p234; 10 nmol/kg/day, icv), respectively. Alzet miniosmotic pump and icv infusion kits were inserted by using a stereotaxic frame under anaesthetised with a mixture of ketamine (75mg/kg) and Xylazine (5 mg/kg). The experiments were approved by the local ethics committee. Cognitive functions (using Barnes maze), animal activity, anxiety behavior were determined before and after the treatment period. At the end, all animals were decapitated, brains removed and frozen. Coronal brain sections (15 μ) were cut. Number of neurons, changes in ERK1/2 of phosphorilation, NCAM and PSD-95 protein expression in hippocampus were evaluated by cresyl violet staining and western blotting, respectively. The results were statistically analyzed by using One-Way ANOVA. Kisspeptin significantly increased phosphorilation of ERK 2 ($p<0.05$). Cresyl violet stained sections showed no difference in the morphology and number of the neurons in the dentate gyrus, CA1, CA2 and CA3 regions of the hippocampus. Treatment with the kisspeptin antagonist significantly increased the distance and duration to find the target box in the Barnes maze ($p<0.05$) compared to the control group. No significant differences were observed in the other sensorymotor behavioral tests in any of the groups. In conclusion, our findings suggest that chronic inhibition of kisspeptin/GPR54 system in adult animals significantly reduces cognitive functions. Role of exogenous kisspeptin infusion should be studied in a memory deficit animal model.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Induction of brain kinin B1 receptor and its association with stereotypic nocifensive behaviour in diabetic rat

R. Couture, J. Dias, H. de Brito Gariépy and B. Ongali

Physiology, Université de Montréal, Montreal, QC, Canada

While brain kinin B1 receptor (B1R) is virtually absent in control rats, it is induced by the oxidative stress in various peripheral tissues and the spinal cord in type 1 and type 2 diabetic models. In the model of insulin resistance induced by high glucose feeding, B1R is associated with pain neuropathy, insulin resistance and hypertension. This study aims at determining whether B1R is also induced in the brain of glucose-fed rats via the oxidative stress and whether it can affect nocifensive behaviour. Male Sprague-Dawley rats (50-75 g) received either 10% D-glucose in their drinking water or only tap water (controls) and were maintained under a normal chow diet or a diet enriched with alpha-lipoic acid (antioxidant, 1g/kg diet) for 12 weeks. An intracerebroventricular (i.c.v.) guide cannula was implanted into the right lateral brain ventricle in isoflurane anesthetised rat 7 days before initiating experiments. After completion of experiments, rats were anaesthetized with CO2 inhalation and killed to collect the brain, which was frozen in 2-methyl butane cooled at -45°C with liquid nitrogen and kept at -80°C for determining B1R binding sites by autoradiography with [125I]-HPP-des-Arg10-Hoe 140 (150 pM) on brain tissue sections. Behavioural activity to the selective B1R agonist, Sar-[D-Phe8]-des-Arg9-BK (10 μg/1μl, i.c.v.) was measured before and after treatment with receptor antagonists (10 μg/1μl, i.c.v.) for B1 (SSR240612, R-715), substance P NK-1 (RP-67580) and glutamate NMDA (DL-AP5). Other studies included the nitric oxide synthase (NOS) inhibitor L-NNA (10 μg/1μl, i.c.v.). Results showed striking increases in the density of specific B1R binding sites in various areas of the cortex, diencephalon, basal ganglia, mesencephalon and medulla of glucose-fed rats in comparison with age-matched control rats. The latter increases in B1R binding sites were prevented by the antioxidant diet in all studied brain areas. The B1R agonist had no effect in control rats, yet it induced significant behavioural manifestations in glucose-fed rats (face washing, sniffing, head scratching, rearing, teeth chattering, grooming, digging, licking, biting, wet-dog shakes) when compared to aCSF. These responses were prevented by all antagonists and the inhibitor tested. The same pharmacological treatments had no direct effect on behaviour in the absence of B1R agonist. Data suggest that kinin B1R is induced and up-regulated by the oxidative stress in the brain of glucose-fed rats and that its intracerebral activation induces stereotypic nocifensive behaviour involving the release of several central mediators, notably substance P, glutamate and nitric oxide.

An experimental model to evaluate the whole-brain neurovascular coupling during spontaneous cerebral activity

A. Zagrean[1], A. Calin[1], S. Mirica[1], A. Gonzales[1], L. Zagrean[1] and M. Moldovan[2]

[1]Physiology and Neuroscience, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania and [2]Neuroscience and Pharmacology, Panum, University of Copenhagen, Copenhagen, Denmark

A transient increase in cortical neuronal activity is followed by a complex sequence of cellular, metabolic, and vascular processes resulting in a transient increase in cerebral blood flow occurring with a slower time-course. This physiological neurovascular coupling is used to infer neuronal activity in vascular-based modern functional brain imaging techniques. Nevertheless, the process of neurovascular coupling itself can become altered with aging and disease and the consequences of such alterations to interpretation of imaging studies remain poorly understood. It thus becomes increasingly important to develop methods to evaluate the process of neurovascular coupling at the whole brain level.
The current methodological approach is to investigate the mean hemodynamic changes in response to repeating somatosensory stimuli that generate identifiable cortical evoked responses that can be recorded non-invasively by electroencephalography (EEG). Here we proposed a novel approach. During general anesthesia, with increasing anesthetic concentrations the EEG becomes discontinuous consisting of whole-brain bursts of activity on a suppressed background referred to as burst-suppression (BS). We hypothesized that neurovascular coupling could be investigated by burst-triggered averaging of the hemodynamic changes during BS. We investigated the fluctuations in cerebral blood flow during BS induced by chloral hydrate overdose in adult male Wistar rats. The EEG recorded via fronto-occipital epidural electrodes (1-30Hz) was first rectified (rEEG) and then averaged in 200 ms bins. The corresponding binary BS signal, derived by an unsupervised statistical classifier, was then used to identify the bursts onset. The laser Doppler (LD) signal recorded from the frontal cortex was first filtered for cardiac cycle and respiratory fluctuations and then averaged in 200 ms bins. We could then construct a burst-onset triggered average of the change in rEEG and LD from the levels just prior to the burst. We found that following burst onset there was an increase in LD that peaked within 1 second after the rEEG peak, consistent with a neurovascular response. The magnitude of the response was several orders of magnitude smaller than the cardiac LD fluctuation so that averaging of more than 100 bursts was required to construct a reliable response. At a readily controllable burst suppression of 50-75% ratio (the relative time spent in suppression), a 10 minutes recording was typically sufficient. Our study provides proof of concept that whole-brain neurovascular coupling can be evaluated during spontaneous cerebral activity by inducing a safely reversible anesthetic BS state. This should be accounted for in the design of clinical neurovascular coupling studies combining non-invasive methods such as EEG and near-infrared spectroscopy.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC165

Are male cognitive functions better than female postovulatory phase cognitive functions?

S. Guragain[1] and N. Upadhayay[2]

[1]Pharmacology, Manipal College of Medical Sciences, Pokhara, Nepal and [2]Basic and Clinical Physiology, BP Koirala Institute of Health Sciences, Dharan, Nepal

Previous studies have shown gender differences in specific cognitive abilities. Female generally, showing an advantage in verbal fluency, perceptual speed and accuracy and in fine motor skills, while male generally showing an advantage in spatial, working memory and mathematical abilities. Many studies have also shown that estrogen and testosterone accentuate cognitive functions in a similar fashion. However, between male and female who performs better on specific cognitive abilities have contradictory reports. As well as studies with progesterone hormone on cognitive function have contradictory reports, whether it accentuates or attenuates the cognitive abilities.
So, we aimed to study and compare postovulatory phase cognitive functions of female with male cognitive functions. Female cognitive functions were assessed during postovulatory phase of menstrual cycle as it is well-known that blood progesterone level is high during postovulatory phase. The study was conducted in healthy 21 male and 21 female volunteers of age range 19-37 years. Four aspects of cognitive functions were assessed (viz: attentional, perceptual, executive and working memory). Attentional task as visual reaction time (VRT) and Go/No-Go VRT, perceptual task as fast counting (FC), executive task as Erisken flanker test (EFT) and Stroop test (ST) i.e. color interference reading and, working memory task as picture 2-back remembering were assessed by using cognitivefun.net program. Data were expressed in median and interquartile range (IQR), compared by using Mann-Whitney U test.
On comparing cognitive functions between male and female there were no significant differences in all cognitive task variables except in VRT and ST (percentage of color accuracy). Male performed better than female in VRT (331.66 ms, IQR: 286.99 to375.33 vs. 367.8 ms, IQR: 340.66 to 435.66; p=0.05). However, in ST female have higher accuracy in reading color interference than that of male (100%, IQR: 95.12 to 100 vs. 95.24%, IQR: 86.36 to 100; p=0.04). Male showed trend of better performance than female in EFT congruent and incongruent time, working memory accuracy and combined time and in FC speed and accuracy. However, male showed trend of poorer performance than female in Go/No-Go VRT accuracy, average and combined time, ST color reading normal time and interference time and in working-memory average time.
Thus, male performs better in attentional VRT than female postovulatory phase attentional VRT. Female has advantage in postovulatory phase and performs better than male in executive cognitive functions as assessed by ST. Perceptual and working memory in both male and female are comparable to each other. Therefore, in female at postovulatory phase progesterone hormone might be responsible to alter some aspects of cognitive functions.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC166

Glutamate microinjection in the preoptic area increases body temperature in freely moving rats

T. Sengupta, A.K. Jaryal and H. Mallick

Physiology, All India Institute of Medical Sciences, New Delhi, India

Role of preoptic area (POA) in thermoregulation is suggested by many studies. Thermosensitive POA neurons receives and integrates local and afferent thermal information from peripheral thermoreceptors(1). Thermoregulatory responses are exercised by its neural connections with brainstem thermoefferent structures and target tissues. Many endogenous substances affect thermoregulation by altering activity of the POA thermosensitive neurons. Microinjection and microdialysis studies reveal the role of different neurotransmitters in the POA regulating body temperature. Presence of excitatory neurotransmitter, glutamate at the POA is known(2). Its role in many physiological functions has been reported (3,4). However, role of glutamate per se on thermoregulation is not reported in awake rats. The present study was done as per the guidelines of the Institutional Animal Ethics, AIIMS and Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA). Under sodium pentobarbitone anesthesia (40mg/kg BW,i.p), 14 adult male Wistar rats (8 glutamate injected, 6 saline injected) were implanted with a K-type thermocouple at hypothalamus(5) and peritoneal transmitter to record brain and body temperature (Tbr, Tb) respectively. Voveron (0.1mg/kg BW) was given to reduce pain during postoperative recovery. Gentamicin (40 mg/kg BW,i.m) was given as antibiotic for 3days. Effect of intrapreoptic microinjection of glutamate (20ng/200nl) on Tb, Tbr (2h prior and 4h postinjection) was studied after 10 days of post-surgical recovery. Microinjection site was confirmed histologically. Tb and Tbr are expressed as mean±SD. There was a constant rise in Tb ranging from 38.3±0.7°C to 38.8±0.3°C which spanned the total post-injection recording period and the maximum Tb was 39.0±0.5°C. There was also rise in Tbr during the post-injection recording period, ranging from 38.6±0.3°C to 38.9±0.2°C and the maximum Tbr was 39.0±0.1°C. At each time-point (15 min interval), 4 h post-injection data of glutamate and saline was compared with the corresponding time-matched control data using independent sample T-test. It was found that glutamate microinjection led to significant increase in Tb and Tbr at all time-points ($p<0.05$, $p<0.005$, $p<0.001$). During most of the post-injection time of hyperthermia, rats maintained curled up posture with pilorection and immobility. Whereas, maximum rise in Tb and Tbr after saline microinjection was 37.9±0.3°C and 37.7±0.2°C respectively, which was significantly lower than the hyperthermia, observed after glutamate microinjection. Moreover, hyperthermia due to glutamate was decreased by intraperitoneal injection of propranalol, indicating involvement of brown adipose tissue thermogenesis. We propose that glutamate in the POA participate in both heat production and conservation mechanisms.

The effect of affective pictures on heart rate variability

S.K. Deo, D. Sharma and R. Khadka

Department of Basic and Clinical Physiology, B.P.Koirala Institute of Health Sciences, Dharan, Nepal

Emotion regulation depends critically on an individual's ability to adjust physiological arousal on a momentary basis. Heart rate variability (HRV) is a measure of the continuous interplay between sympathetic and parasympathetic influences on heart rate that yields information about autonomic flexibility and thereby represents the capacity for regulated emotional responding. Although researches still does not provide theoretical and empirical support for the emergence of Heart rate variability as a marker of emotion regulatory ability. The objective of this study was to assess Heart rate variability in response to negatively and positively valenced pictures. One hundred and two International Affective Picture System (IAPS) photographs were grouped into 3 sets of 34 photographs: neutral, positive and negative. Each picture in a set was displayed for 6 seconds followed by 3 second interval before the next picture. The study was conducted in 24 healthy male students [age= 25(24-26)]. Each student was shown three sets of stimuli and their ECG was recorded simultaneously for 5 minutes. Time and frequency domain variables of HRV were calculated and compared among different sets of stimuli. Statistical significance was tested with Friedman test. P value < 0.05 was considered significant. Sympathetic (LF pr, LFnu, LF/HF) and parasympathetic indices (SDNN, RMSSD, NN50cnt, HFpr, HFnu) of HRV analysis in three different sets of stimuli were insignificant when compared among the sets. These data suggest that the affective pictures from International Affective Picture System (IAPS) shown in our study have no effects on cardiac sympathetic and parasympathetic activity.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC169

Nerve conduction and short-term heart rate variability in football players

D. Sharma, B. Paudel, D. Thakur and R. Khadka

Basic and Clinical Physiology, BP Koirala institute of health sciences, Dharan, Nepal

Regular aerobic exercise causes autonomic/cardiac electrophysiological changes. Repetitive motions, muscle contractions, rapid & coordinated movements, and extreme foot positions in footballers influence somatic nerve electrophysiological properties. These training effects on somatic nerves are less clear. Heart rate variability (HRV) & nerve conduction study (NCS) variables together in athletes have been poorly studied. Thus we hypothesized that chronic exercise causes changes in HRV and NCS variables simultaneously and aimed at studying somatic nerve conduction and heart rate variability in football players. The football players (n=27, age 22.74±2.52 yrs) with excellent or good cardio-res-

piratory fitness, as assessed by simple three-minute step test, and sedentary controls (n=29, age 23.41±2.95 yrs) formed the study population. Their tibial and sural nerve conduction and short term heart rate variability were assessed following standard protocols. The difference between the groups was tested by Mann-Whitney U test. A p-value <0.05 was considered statistically significant. The football players had lower resting heart rate, systolic and diastolic BP than sedentary controls. In nerve conduction study; right tibial proximal compound muscle action potential (CMAP) amplitude [12.30(10-17.70) vs 11.10(8.0-13.50) mV, p=0.035], left tibial proximal [14.0(10.20-17.0) vs 11.20(7.33-14.30) mV, p=0.045] and distal [16.80(13.80-19.50) vs 14.20(10.15-17.80) mV, p=0.049] CMAPs amplitude were higher whereas right tibial proximal [7.50(7.0-8.80) vs 9.0(7.30-10.75) ms, p=0.005] and distal [7.20(6.70-8.10) vs 8.30(7-10.25) ms, p=0.046] CMAPs duration were lower in players compared to controls, similar results were obtained for left tibial CMAPs duration. They also had lower left sural sensory nerve action potential (SNAP) duration [1.80(1.50-1.80) vs 2.00(1.69-2.16) ms, p=0.018]. In HRV, high frequency power, a parasympathetic marker, was higher [1019(582-2127) vs 277(105.50-695.0) ms2, p=0.001] but low frequency in normalized unit [42.30(31.40-50.50) vs 57.80(43.60-70.55), p=0.001] and LF/HF [0.734(.459-1.02) vs 1.372(.775-2.40), p=0.001], the sympathetic markers, were lower in players compared to controls. Higher tibial CMAPs amplitude in football players suggests increase in size / number of muscle fibers / increase in efficiency of neuromuscular transmission. Less tibial CMAPs and sural SNAP duration indicate increase in synchronicity of muscle fibers and sensory nerve fibers discharge respectively. Increase in synchronicity of discharge may be due to narrow range of conduction velocities in motor axons and in sensory axons. Along with somatic nerve changes, football players had higher cardiac parasympathetic and lower sympathetic activity, suggesting synchronized autonomic and somatic adaptation in response to aerobic training.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Nerve conduction study and heart rate variability in obese persons

R.L. Yadav, R. Khadka, D. Thakur, K. Agrawal and B. Paudel

Department of Basic and Clinical Physiology, B.P.Koirala Institute of Health Sciences, Dharan, Nepal

Obesity increased worldwide (35.5% obese & 66% overweight in USA, 2012; 30%- Mexico, 2009) and in other South Asian countries, including Nepal & Bangladesh (from 1.6% - 10% & from 2.7% - 8.9% respectively, 2006). Studies have indicated an increase in all cause mortality (>300,000 deaths/year) with increased obesity, especially death from cardiovascular disease. Hence, obesity is considered as a major public health problem. Though measurement of body fat is too complex, body mass index (BMI, kg/m2) & waist-hip ratio (WHR) are used in daily practice. According to WHO, BMI≥30 kg/m2 is classified as obese & WHR cut-off being 0.9. There are controversial results of different studies regarding effects of obesity on autonomic nervous system and peripheral somatic nerves. Thus, our objective is to study the nerve conduction (NCS) and heart rate variability (HRV) in adult obese persons. The study was conducted on 30 adult obese persons (BMI>30, kg/m2) and 29 healthy normal weight persons (BMI, 18-24, kg/m2). In all subjects, short-term heart rate variability (HRV) and nerve conduction were assessed using standard protocol. The data obtained were analysed between the groups using Mann Whitney U test and presented as median (inter-quartile range). P value < 0.05 were considered as statistically significant. In comparison to normal weight persons, obese had lower compound muscle action potential (CMAP) amplitudes of right median [9.09(7.62-10.20) Vs 10.75(8.71-12.2), mV, p=0.025], and right [8.5(7.04-11.18) Vs 12.1(10.55-15), mV, p=0.000] and left tibial [9.08(6.58-11.65) Vs 13.05(10.2-15.6), mV, p=0.002] nerves. Whereas, obese persons had prolonged CMAP durations of right [10.5(9.62-12) Vs 10(8.4-10.3), mV, p=0.02] and left median 10.85(10-11.88) Vs 10(9-10.57), mV, p=0.019] nerves, and right tibial [10(9-11) 8.5(7.92-10), mV, p=0.032] nerve. Sensory NCS showed similar results. Among HRV variables, SDNN [35.55(26.77-49.25) Vs 46.15(37.22-58.57) ms, p=0.038], RMSSD [28.75(16.72-38.35) Vs 41.55(30.6-56.75), ms, p=0.018], NN50 count [15.5(2-39) Vs 83.5(32.75-116.25), p=0.010], pNN50, HF power and SD1, which reflect cardiac parasympathetic activities were significantly lower whereas, sympathetic marker LF/HF [1.2(0.65-2.20) Vs 0.79(0.5-1.02), p=0.045] was higher in obese persons than in the normal weight persons. Thus, we conclude that obesity affected autonomic modulation with an increase in sympathetic tone coupled with a reduction in vagal tone, indicating poor cardiac rhythm control. However, nerve conduction study showed a tendency of poorer amplitudes and lengthened CMAP and SNAP durations, which might lead to future somatic neuropathy in obese persons. The obesity affected predominantly parasympathetic function and the parasympathetic fibers are usually myelinated. Thus, both the NCS & HRV indicates that obesity might alter the myelination of both somatic & autonomic nerve fibers.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC171

Effects of yoga on surface electromyography (EMG) of upper trapezius muscle and pain score in cervical spondylosis

D.M. Limbu

Basic and clinical physiology, BPKIHS, Dharan, Nepal

Introduction: Cervical spondylosis is a degenerative disorder of intervertebral disk progressing with advancing age. It is characterized by pain in the neck and shoulders, and headache.
Objectives: The study aimed at investigating the effect of yoga on neck muscle EMG in cervical spondylosis and pain associated with it.
Hypothesis: Yoga will provide effective adjuvant therapy in cervical spondylosis patients.
Materials and Methods: EMG of upper trapezius and neck disability index (NDI) were recorded in cervical spondylosis patients (n=10). Pain was evaluated by 0-10 grade visual analogue scale (VAS). Then, the patients did selective yoga techniques (Tadasana, Pranayama and Schandhachakra) for four weeks. All the variables were recorded after four-week yoga. The pre- and post-yoga data were compared by Wilcoxon Sign Ranks test.
Results: Yoga decreased EMG amplitude on both sides of upper trapezius muscle during Tadasana. NDI and VAS were significantly reduced but EMG frequency showed decrement trend.

In addition, the doses of the nonsteroidal anti-inflammatory drugs were reduced by >50%.
Conclusion: It is concluded that four-week prescribed yogic techniques are useful as an adjuvant therapy for cervical spondylosis by reducing muscular tension and spasm possibly by correcting posture leading to better oxygen consumption in damaged tissue and reversal of abnormal bone growth.

Effects of acupuncture and moxibustion on mechanical and thermal pain threshold in master cell deficiency rats

X. Gao, K. Liu, H. Wang, Q. Qin, L. Qiao, C. Cui, Y. Zhao, L. Li and B. Zhu

China Academy of Chinese Medical Sciences Institute of Acupuncture and Moxibustion, Beijing, China

Objective: Previous study has showed that acupuncture analgesia is closely related to the functional status and degranulation of mast cells, and the analgesic effects of manual acupuncture rely on mast cell and its degranulation more. The present study recruited a c-kit gene knockout rats which mast cells are not expressed to explore the analgesic effects of manual acupuncture, different intensities of electroacupuncture- and moxibustion-like stimulation.
Methods: The present study was performed on WsWs—, a c-kit gene knockout rat which mast cells is not expressed, and homogenous wildtype WsRC++ rats, twenty of both kinds were recruited to be control. The thresholds to noxious thermal and mechanical stimuli were measured with Ugo Basile Tail Flick Unit and electronic Von Frey anesthesiometer respectively. Somatic stimulation as 43 and 46 degree centigrade warm water, electroacupuncture of 1mA, 3mA and manual acupuncture were selected before pain thresholds tested.
Results: For the WsRC++ rats, electroacupuncture, manual acupuncture and moxibustion increased the paw mechanical and thermal withdrawal latency, and high intensity stimulation showed better effect than low intensity stimulation, especially for electroacupuncture with high intensity. Compared in the WsWs—rats, the mechanical threshold increase induced by manual acupuncture in WsRC ++ was not attenuated, whereas the increased mechanical thresholds induced by electroacupuncture with low intensity and moxibustion were lower in knockout animals than those in wildtype, if not, even no increase was observed. Thermal threshold in c-kit knockout rats was not significant different from that of wildtype.
Conclusion: For mechanical threshold, the analgesic effect of electroacupuncture might be closely related to mast cells. Whereas, the analgesic effect of manual acupuncture is not dependant on mast cells. And for the thermal threshold, none of the three stimulations was dependant on mast cells obviously.

Effect of simvastatin on erythrocyte membrane proteins in endotoxemic rats

H. Yorulmaz[1], G. Ates[3], E. Ozkok[2], I. Albeniz[4] and A. Tamer[3]

[1]School of Nursing, Halic University, Istanbul, Turkey, [2]Neuroscience, The Institute for Experimental Medicine, Istanbul, Turkey, [3]Physiology, Isanbul University, Istanbul, Turkey and [4]Biophysics, Istanbul University, Istanbul, Turkey

Motivation/problem statement: Sepsis, which causes deterioration of the microcirculation homeostasis, biochemical and physiological changes in the blood vessels. Sepsis leads to death of the organism as a result of organ failure. Membran proteins are alpha- and beta-spektrin, ankyrin, actin (band 5) and band-3, protein 4.1 and glycophorin A,B,C have an important roles in the maintaining in structural and functional integrity and the protection of shapement of the red blood cells. Studies shown that sepsis causes increased free radicals and lipid peroxidation of membrane proteins and erythrocyte deformability in literatures. Recent studies in patients with acute systemic inflammation were reported that simvastatin inhibits vascular hyporeactivity and reduced the development of sepsis. In this study, we aimed the effects of simvastatin on membrane proteins in lipopolysaccharide (LPS) treated with Wistar albino rats.
Methods/procedure/approach : Following the approval of the ethical commitee adult rats were divided into 4 groups including control, endotoxemic, simvastatin and simvastatin plus endotoxemic.
Control group; was taken %0.9 NaCl (i.p.)(n=10).
Endotoxemic group; LPS (E.coli: O127:B8;20 mg/kg, i.p.) was given to occuring endotoxemia, after 4 hours, animals were taken experiment (n=10).
Simvastatin group: Simvastatin was given (20 mg/kg, p.o.) for 5 days and end of the 5th days animals were decapitated (n=10).
Simvastatin plus Endotoxemic group: Simvastatin was given for 5 days. At the 5th days, LPS was given and after 4 hours animals were taken experiment (n=10).
At the end of the experiment, blood samples were taken into tube with EDTA and erythrocytes were separated. Erythrocyte membrane proteins were detected with Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE). All of samples were applicated and run to SDS-PAGE with suitable molecular weight of markers. SDS-PAGE procedures were replicated three times for each samples.
RESULTS: In endotoxemic group, we shown decreased α-(280 kDa) and β-spektrin (MW: 246 kDa), ankyrin(MW: 210 kDa), compared to control group. However we found that there were

disappeared bands; actin (band 5) (MW: 43 kDa) and Band-3 (MW: 100 kDa), protein 4.1(MW: 82 kDa) and glycophorin A,B,C (MW: 30 kDa) in the endotoxemic group.There were same protein bands compositions between control and simvastatin groups.
CONCLUSION/IMPLICATIONS: We found that decreased membrane proteins; alpha-spectrin, beta-spectrin, ankyrin and disappeared Band-3, Actin, Protein 4.1 Glycophorin A,B,C, proteins in the endotoxemic group. We also observed that simvastatin administration in LPS treated animals, distrupted red cell membrane proteins were found to improve in the study. It may represent a compensatory defensive mechanism supporting RBC function for living organism.

Bevacizumab: modulation of the bone microenvironment to reduce angiogenesis and metastasis?

S. Lunj, M.W. Reed, K.J. Reeves, C.A. Staton, I. Holen and N.J. Brown

Oncology, University of Sheffield, Sheffield, UK

Introduction: Bone metastasis is a major cause of breast cancer associated morbidity. Currently bisphosphonates are used to treat bone metastasis however no effective preventative measures are available. Vascular Endothelial Growth Factor A (VEGF) and associated receptor expression has been identified in bones from patients with metastatic breast cancer, representing a potential therapeutic target. Bevacizumab (Bz) inhibits VEGF-receptor interactions so may be effective in inhibiting angiogenesis and hence the formation of bone metastasis.
Methodology: 6-week old Balb/c nude female mice were injected intra-cardiac in the left ventricle with $1x10^5$ MDA-MB-231 luciferase labelled breast cancer cells under anaesthesia (isoflurane). Once bioluminescence (IVIS-Lumina2) was detected in bone by *in vivo* imaging, treatment commenced with Bz (0.1 or 0.5mg/kg, intraperitoneal twice-weekly for 6 weeks) or control vehicle (n=6/group). Tumour growth was monitored by twice weekly bioluminescence imaging. At the end of the experiment, hind limbs were harvested and processed for μCT analysis and bone histomorphometry.
Results: Bz (0.1mg/kg) inhibits breast cancer-induced bone metastasis compared to the vehicle control (treatment vs. control; 1000000 vs. 790000 total flux [p/s]) however bone mineral density remains unchanged. Initial analysis of osteoblasts (Ob) and osteoclasts (Oc) not in direct contact with the tumour suggests there is no difference in Oc number present on the trabecular surfaces in Bz-treated or control animals (Osteoclasts: Bz vs control; 0.125 vs. 0 per mm trabecular bone surface). In contrast, there appears to be decreased Ob numbers in similar regions in the Bz treated group (Osteoblasts: Bz vs control; 2.6 Bz vs. 7.5 control).
Conclusions: Preliminary data from this study indicate for the first time, that Bz reduces the bone tumour burden, however further in-depth analysis into the molecular mechanisms by which this is occurring, is being performed (i.e., CD31 vessel analysis, Ob/Oc counts in contact with the tumour).

Cathepsin B is more active at acidic pH and regulates airway surface liquid through the cleavage of γENaC

C. Tan[1], M. Sameni[2], Y. Dang[1], H. He[1], B.F. Sloane[2], J. Stutts[1] and R. Tarran[1]

[1]Cystic Fibrosis/Pulmonary Research and Treatment Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA and [2]Department of Pharmacology, Wayne State University School of Medicine, Detroit, MI, USA

BACKGROUND: Na^+ transport via the amiloride-sensitive epithelial Na^+ channel (ENaC) regulates airway surface liquid (ASL) volume and mucus clearance. In cystic fibrosis (CF) airways, increased sodium absorption depletes the ASL resulting in dysfunctional mucocilliary clearance and bacteria colonisation of the lung. Although serine protease such as prostasin is an important regulator of ENaC activity, it is largely inactive at pH seen in the acidic environment of CF airways. Here, we investigate the effect of pH and Cathepsin B (CTSB) activity on the regulation of ENaC. METHODS: The activity and expression of CTSB in polarised primary human bronchial epithelial cultures (HBECs; normal and CF) and ASL lavage were examined using fluorogenic substrates that are specifically cleaved by CTSB (Z-Arg-Arg-MCA, 50 μM) and western blotting respectively. We studied the effects of CTSB on amiloride-sensitive ENaC whole-cell currents (Δ*Iami*) using two voltage clamp and cleavage of ENaC by surface biotinylation in *Xenopus* oocytes. To demonstrate the physiological relevance of CTSB in polarised HBECs, we used confocal microscopy to measure the ASL height in the presence and absence of a cell-impermeable CTSB inhibitor (CA074, 10 μM). RESULTS: The activity of CTSB on the apical membrane surface and ASL lavage harvested from normal and CF polarised HBECs was significantly greater at pH 6 compared to pH 7.5, 7 or 6.5. Western blotting revealed that CTSB was secreted into the ASL in both normal and CF HBECs. Basal Δ*Iami* in oocytes expressing rat αβγENaC and CTSB exposed to pH 6 or pH 7.3 were not significantly different. However, coexpression of ENaC and CTSB stimulated ΔIami by approximately 6-fold from 681.7 ± 61.4 to 4143.3 ± 417.1 nA ($p < 0.0001$, n = 6) at pH 7.3. In the presence of hCTSB, trypsin, but not chymotrypsin, further stimu-

lated the Δ*lami*. Importantly, western blotting indicated a reduction in the molecular weight of surface-expressed γENaC in oocytes expressing ENaC and CTSB. In normal and CF HBECs, exposure to pH 6 Ringer solution significantly affect ASL regulation and reduced height from 13.4 ± 1.1 to 11.4 ± 0.9 μm ($p < 0.05$, n = 5) and 12.1 ± 0.8 to 7.5 ± 0.5 μm ($p < 0.05$, n = 5), respectively. CA074 significantly increased the ASL height in normal (11.4 ± 0.9 to 15.2 ± 1.5 μm, $p < 0.05$, n = 7) and CF (7.5 ± 0.5 to 11.5 ± 0.6 μm, $p < 0.01$, n = 7) HBECs at pH 6 but not pH 7.5. CONCLUSIONS: Taken together, these results indicate that CTSB, is secreted into the ASL, is more active at acidic pH and can regulate ASL height through the cleavage of γENaC. This is the first study to implicate CTSB in the pathphysiology of CF, suggesting that inhibitors of CTSB could potentially be used for the treatment of the disease.

Inositol hexaphosphate modifies the mucin component of the intestinal barrier

E.M. Onyango[1], B.M. Habiyambere[1], C. Madsen[2] and S. Gendler[2]

[1]East Tennessee State University, Johnson City, TN, USA and [2]Mayo Clinic, Scottsdale, AZ, USA

Consumption of increased dietary fiber is generally positively correlated to improved colon cancer prevention (1). Inositol hexaphosphate (IP6 or phytic acid) is an ingredient in plant foods such as legumes and cereals and has variously been shown to have anti-cancer activity (2). Our goal is to understand the influence of IP6 on the intestinal mucosal barrier function that may contribute to its anticancer activity. The objective in this study was to investigate the effect of IP6 on intestinal morphology and on mucosa mucin proteins that are constituent components of the intestinal barrier in mouse. In particular, expressions of specific mucins (Muc2, Muc3 and Muc4) were examined in the study (3, 4). C57BL/6 mice were randomized into 3 groups of 6 mice. Mice were orally dosed with IP6 (0, 1, 2 g/kg body weight) for 5 days and killed on the sixth day. Sections of the intestine were removed, fixed in methacarn, sectioned, stained with Alcian blue-PAS to visualize mucins, and immunostained for the presence of Muc2, Muc3 and Muc4 proteins. Mucosa from the jejunum and colon were removed and total RNA prepared using Trizol®. cDNA was prepared using random hexamers and specific primers were used for quantitative PCR amplification of the message for Muc2, Muc3 and Muc4. The iQ5 software (Bio-Rad, Hercules, CA) was used to calculate the expression of each gene at the different IP6 dose levels. Expressions at 1 or 2 g/kg dose were then calculated as fold changes relative to expression at the 0 g/kg dose. Expression of Muc2 in the jejunum increased 6.9 fold at 1 g/kg dose and 9.2 fold at 2 g/kg dose. In the colon it increased 1.6 fold at 1 g/kg dose but didn't change at 2 g/kg dose in the colon. Expression of Muc3 in the jejunum was unchanged when IP6 was dosed. In the colon, the expression increased 2.1 fold at 1 g/kg dose but decreased 5 fold at 2 g/kg dose. Expression of Muc4 in the jejunum increased 1.5 fold at 1 g/kg dose but didn't change at 2 g/kg dose. In the colon, it increased 1.3 fold at 1 g/kg dose but didn't change at 2 g/kg dose. Immunostaining with specific antibodies confirmed similar expression of these mucin proteins in the respective intestinal sections. The goblet cell count increased in the duodenum but decreased in the jejunum and ileum in IP6-treated animals. Thus, IP6 seems to modulate the goblet cell count and mucin protein component of the intestinal mucosal barrier.

Significance of crosstalk α-d-mannose- and sialic acid-containing glycoconjugates and inflammation in compromised esophageal mucosal integrity

O. Zayachkivska, N. Hrytsevych, M. Savytska, M. Gzhegotsky, A. Yaschenko and A. Lutsyk

Physiology, Lviv National Medical University, Lviv, Ukraine

Inflammation and endothelial dysfunction are central to esophageal barrier impairment and starting point for abnormal restitutio ad integrum and neoplastic processes [1]. WHO indicated that risk for premalignant Barrett's esophagus increased with chronic esophagitis. Glycoproteins incorporated into plasma membrane are essential for the initiation and regulation of immune responses and effective tool of representing injury-cell-associated immunogenicity in vivo. We hypothesized that α-d-mannose (αdMan) and sialic acid (NEU5AC) containing glycoconjugates interacted at a defence/receptor level in much the same fashion as pro-inflammatory cytokine in esophageal integrity. We therefore evaluated the receptor αdMan and NEU5AC profiles and inflammatory signaling contributed for the esophageal phenotype of integrity and cytoprotection without/with L-tryptophan (L-Try) and melatonin (MT)-pretreatment, which enhancing esophageal barrier functions.

Erosive esophagitis (EES) by perfusion solution of 0,25 N HCl & pepsin and non-erosive esophagitis (NES) by Takagi, 1964 were induced in rats without/with L-Try (200 mg/kg per os) and MT (20 mg/kg/ip) treatment which were anaesthetized with intramuscular administration of ketamine (60 mg kg-1); after 24 h of injury rats were killing and the healing of esophageal lesions and estimation of esophageal mucosa destruction, inflammation and hyperplasia via histological score index (HSI), αdMan, NEU5AC expression by lectinhistochemistry; IL-1β, TNFα by ELISA.

Acidic perfusion induced topical EES and HSI was 2,5-folds time more than with MT treatment; NES was with constantly increased HSI in 150% in compare to MT treated rats showing the same effect as in model of acidic EES. Dynamic changes in

esophageal mucosa glycobiology features with higher intensity NEU5AC labeling in EES vs NES, and highest αdMan labeling was in endothelium of vessels in NES, indicated ion endothelial dysfuction in physiopathogenesis of non-erosive and erosive esophagitis. Basal IL-1β was 24,16±0,30 pg/ml, TNFα - 1,05±0,11 pg/ml. Induction of EES led to increased IL-1β to 55,35 ± 7,88 pg/ml, TNFα - 5,56 ± 0,55 pg/ml (p <0,05). In non-erosive lesions IL-1β increased at 38,7 %, TNFα - 65,6% relatively to control (p <0,05). Potent angiotropic Mel and L-Try effects were estimated on esophageal cytoprotection and repair via decreasing αdMan expression in esophageal vascular walls. Anti-inflammatory effect of L-Try was less then MT that caused decrease of IL-1β to 21,8%, TNFα – 35,1% compared to control.

This study suggests an important role for αdMan and NEU5AC in EES and NES cell survival. Novel findings relating to high αdMan expression in endothelium and NEU5AC in compromised esophageal mucosa integrity might be associated with the development low grade inflammation and metaplasia.

Ob/Ob mouse jejunum has dysfunctional chloride secretion compared to lean controls

L. Leung, J. Kang, E. Rayyan, A. Bhakta, B. Barrett, D. Wilson, L. Tamura, K. Corbell, T.L. Broderick and L. Al-Nakkash

Physiology, Midwestern.edu, Glendale, AZ, USA

The ob/ob leptin-deficient mouse is hyperglycemic and obese. We used 14-week old ob/ob and lean mice. The goal of this study was to characterize jejunal function in this clinically relevant mouse model. We measured transepithelial short circuit current (Isc), across freshly isolated segments of jejunum. Basal Isc was significantly decreased 2-fold, in the ob/ob mice (50.5±9.5 μA/cm2, n=5) compared to lean mice (95.2±20.3 μA/cm2, n=4, P<0.05). The Isc in response to forskolin (10 μM, bilateral), bumetanide (100 μM, basolateral), and acetazolamide (100 μM, bilateral) was similar for ob/ob and lean mice. Jejunum morphology indicates that crypt depth was similar for both groups, and thus structural changes do not contribute towards the reduced Isc of the ob/ob mice. Villi length was significantly increased (by ~100 μm) in the ob/ob mice, suggesting a greater surface area for absorptive function. Expression of the transporter protein, Glut5 (normalized to GAPDH), was significantly increased in ob/ob mice 0.74±0.06 (n=l4, P<0.05), compared to leans (0.37±0.06, n=l l), whereas, expression of the Glut2 transporter was similar for both groups. These data suggest that basal jejunal Isc in ob/ob mice is ~1/2 that of lean mice, and may reflect slower transit times in the gastrointestinal tract in the ob/ob mice, which may contribute towards increased nutrient absorption (specifically increased fructose uptake via Glut5), increased weight gain, and the associated diabetic phenotype. The contribution of key jejunal epithelial transporters is under investigation.

Involvement of TRPC channel in fibrogenic stenosis and inflammation in human colonic myofibroblast

R. Kurahara, M. Sumiyoshi and R. Inoue

Physiology, School of Medicine, Fukuoka University, Fukuoka, Japan

Purpose: Increasing attention has recently been directed to the pivotal role of myofibroblasts in the pathogenesis of fibrogenic stenosis and inflammation. Available evidence suggests that part of myofibroblastic function may reflect altered Ca2+ homeostasis. We thus explored a potential role of canonical transient receptor potential (TRPC) channels expressed therein by using human colonic myofibroblast cell line InMyoFib. Here we show that transforming growth factor (TGF)-β1, the major stimulator of intestinal fibrosis, requires TRPC4 and TRPC6-mediated Ca2+ influx for its effect on myofibroblast differentiation and interleukin synthesis.

Methods: InMyoFib were grown in SmBM medium supplemented with 5%FBS and growth factors (insulin, hFGF-B, hEGF, FBS and gentamicin/ amphotericin-B). Immunobotting and immunoprecipitation were performed to detect the expression and interactions of proteins, and Ca2+ influx through TRP channels was evaluated by digital imaging of Fura-2 fluorescence. The results were compared between control and TGF-β1(5ng/ml in 1%FBS/SmBM)-treated groups of InMyoFib and statistically evaluated by single and multiple comparison tests.

Results: the expressions of fibrosis marker α-smooth muscle actin (α-SMA) and cadherin were detected with TRPC6 and TRPC4, respectively. The expression level of α-SMA and cadherin was augmented by TGF-β1 stimulation, and this was significantly suppressed by treatment with SK&F96365 or transfection of TRPC4- and TRPC6-specific siRNA or their dominant negatives, respectively. Biochemical analysis indicated that the calcineurin-NFAT signaling is involved in the effects.

In realtime-PCR experiments, the production of four interleukins from InMyoFib was found significantly accelerated by siRNA knockdown and dominant negative transfection of TRPC6. Detailed immunoblotting and biochemical analyses suggested that Ca2+ influx through TRPC4 and TRPC6 may prevent the phosphorylation of Smad2, Erk1/2, and p38 MAPK proteins at the downstream of TGF-β receptors.

Conclusion: from these results, it is speculated that TRPC4 and C6 channels may play non-trivial roles in myofibroblast transformation/differentiation via NFAT signaling, thereby promoting fibrogenesis in the colon. It is also suggested that myfibroblast signaling pathways regulating interleukin production, which seem associated with the phosphorylation of Smad2, Erk1/2, and p38 MAPK as well as TRPC6-mediated Ca2+ influx, could be a promising target in treating fibrotic and inflammatory bowel diseases.

A polygalacturonic acid binding lectin from *Phaseolus vulgaris* induces selective toxicity on human liver carcinoma HepG2 cells

W. Pan, E. Fang and T. Ng

The Chinese University of Hong Kong, Hong Kong, Hong Kong

Lectins and hemagglutinins are proteins/glycoproteins, which have at least one non-catalytic domain that exhibits reversible binding to specific monosaccharides or oligosaccharides. They can bind to the carbohydrate moieties on the surface of erythrocytes and agglutinate the erythrocytes, without altering the properties of the carbohydrates. Being omnipresent in nature, lectins have been found in different kinds of organisms encompassing fungi, viruses, bacteria, plants, animals, and humans. Recently, lectins have been got much attention as therapeutic agents due to their diversity of function including anti-viral, anti-bacteria, anti-fungal anti-insect and anti-tumor activity.

We described here the purification and characterization of a *Phaseolus vulgaris* lectin that exhibits selective toxicity to human hepatoma Hep G2 cells and lacks significant toxicity on normal liver WRL 68 cells. This polygalacturonic acid–specific lectin (termed BTKL) was purified from seeds of *P. vulgaris cv. Blue tiger king* by liquid chromatography techniques. The 60-kDa dimeric lectin showed strong and broad-spectrum hemagglutinating activity toward human, rabbit, rat, and mouse erythrocytes. Bioinformatic analysis unveils substantial N-terminal sequence similarity of BTKL to other *Phaseolus* lectins. Among a number of tumor cells tested, BTKL exhibits potent anti-Hep G2 activity which is associated with (1) induction of DNA fragmentation, (2) production of apoptotic bodies and chromatin condensation, (3) triggering of cell apoptosis and necrosis, and (4) depolarization of mitochondrial membrane. Furthermore, BTKL could induce inducible nitric oxide synthase (iNOS) expression and subsequent nitric oxide production in vitro in mouse macrophages, which may contribute to its antitumor activity. In addition, BTKL could bring about a significant dose-dependent increase in the production of mRNAs of proinflammatory cytokines including interleukin-1 beta, interleukin-2, tumor necrosis factor alpha, and interferon-gamma. Taken together, the antitumor activity and mechanism of BTKL provided here suggest that it has potential therapeutic value for human liver cancer.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Effect of hypothermic perfusion in the isolated perfused rat liver (IPRL) on the proteasome

T. Carbonell[1], S. Sanchez[1], S. Dewey[2], N. Alva[1] and A. Gomes[2]

[1]Physiology and Immunology, University of Barcelona, Barcelona, Spain and [2]Physiology, Neurobiology and Behavior, University of California, Davis, Davis, CA, USA

Recently, much attention has focused on the use of hypothermic perfusion in isolated organs (Hessheimer, 2012). Preservation of livers at hypothermia (20 °C) lead to significant improvements (Vairetti, 2009) but also induces oxidative stress (Alva, 2013). The initial protection against oxidative damage may require the rapid removal of oxidized proteins by the ubiquitin-proteasome system (UPS). Whereas there is some consensus in that proteasomal activity degrades oxidized proteins, it remains controversial whether oxidized proteins are tagged by ubiquitin and then degraded by the 26S proteasome, or whether they are removed independently of ubiquitin (Shang, 2011).

The aim of the present work was to study the production of oxidative stress and the role of the UPS after hypothermic perfusion in isolated liver.

The procedure was approved by the Committee of Animal Care following EC guidelines. Male SD rats (n=6 per group) were anesthetized (sodium pentobarbital, 60 mg/Kg ip) and their livers removed for perfusion (3 mL/min/g) with Krebs-Henseleit buffer. Normothermic livers (NT) were perfused at 37 °C thoroughly the experiment (30 min). Hypothermic livers were perfused 15 min at 37 °C and then were switched to cold at 26 °C (HT26) or 22 °C (HT22) further 15 min. We measured 4-HNE protein adducts and advanced oxidation protein products (AOPP); the expression of ubiquitin conjugates and subunits of the proteasome 26S: the 19S regulator (Rpt1, Rpt6 and phosphoRpt6 proteasomal ATPases) and the 20S core. The 26S β5 proteasome proteolytic activity was also assayed. Data (mean ± SEM) was analyzed by ANOVA.

Our results showed that hypothermic perfusion leads to protein oxidation as demonstrated by increased HNE-protein adducts and AOPP ($p<0.05$). As regards to the UPS, the presence of poly-ubiquitinated proteins was higher in hypothermia ($p<0.001$). No differences were observed in the expression of the 20S. The expression of Rpt1 and Rpt6 did not change. However, we found a significant increase in the ratio phospho-Rpt6/Rpt6 from NT (0.59±0.06) to HT26 (1.06±0.09, $p<0.05$) and HT22 (1.24±0.1, $p<0.01$). Rpt6 S120 phosphorylation has been suggested to cause an enhancement in the 26S proteasome activity. Accordingly, the 26S β5 activity was significantly increased in HT26 (46%) and HT22 (42%) groups ($p<0.01$).

These results suggest that phosphorylation of 19S subunit, Rpt6 at S120, which is part of the 26S proteasome, activates the proteasome during hypothermia. This is likely to be an important mechanism to quickly increase in the activity to the proteasome independent of increasing the amount of the proteasome.

Conclusion: Hypothermic perfusion induces protein oxidation. The UPS is activated to repair this damage, which partly increases its activity due to the Rpt6 subunit phosphorylation.

Dietary plasma protein supplements prevent in part changes in colonic mucosal permeability that characterizes the mdr1a-/- mice model of colitis

M. Moretó[1,3], L. Miró[1,3], M. Maijò[1,3], J. Polo[2] and A. Pérez-Bosque[1,3]

[1]Departament de Fisiologia, Universitat de Barcelona, Barcelona, Spain, [2]APC Europe, Granollers, Spain and [3]Institut de Nutrició i Seguretat Alimentària, Universitat de Barcelona, Barcelona, Spain

Dietary supplementation with animal plasma proteins can prevent intestinal inflammation induced by enterotoxin B of S. aureus in rats, and reduce the lung inflammatory response induced by LPS in mice. The mechanism of action involves the modulation of the gut associated and nasal associated lymphoid tissue, respectively. We have also shown that dietary supplementation with plasma proteins can reduce the structural and functional changes observed in the colon during the development of spontaneous colitis. This study examined the effects of these supplements on the expression of mucosal mucins and of a representative tight-junction protein, as they are determinant for the permeability properties of the crypt epitheilium. Wild-type (WT) mice and mice lacking mdr1a gene (KO) were obtained from Taconic (Germantown, NY) and maintained in the Animal Facility Service of the Barcelona Science Park (n = 10-12 mice per group). Mice were grown and maintained in specific pathogen free conditions until week 4 when they were transferred to conventional housing. Animals were supplemented with spray-dried porcine plasma protein (SDP, 8% w / w) or milk proteins (control diet). Diets were fed from day 19 (weaning) until day 56. The index of disease activity (DAI) was recorded throughout the experimental period. The permeability of the mucosa of the colon was analysed ex vivo by confocal microscopy using FITC-dextran 10 kDa as marker; the expression of E-cadherin was measured by Western blot, and the expression of transmembrane mucines MUC1 and MUC4 and secretory mucin MUC2 by RT-PCR. DAI increased progressively from day 39, reaching a value of 2.8 ± 0.5 in KO mice (0.7 ± 0.3 in WT controls, $P < 0.05$) at 56 days and this correlated well with the Histopathological index and the goblet cell depletion index. MUC1 expression was increased 4 times and no effects of diet were observed; MUC4 expression was increased 3-fold and this effect was prevented in part by SDP. The expression of secretory MUC2 followed the profile of goblet cell depletion, as expected. SDP was also effective in reducing the changes in MUC4 and MUC2 observed during colitis consolidation. Increased mucosal permeability in the KO mice was inversely correlated with E-cadherin expression. Both effects were prevented by dietary SDP. We conclude that dietary supplementation with SDP is able to prevent in part the changes in the expression of transmembrane and secretory mucines, and of junctional E-cadherin during the development of spontaneous colitis. The good correlation between DAI and crypt permeability indicates that junctional proteins and mucine production are adequate markers of the colitis syndrome.

Protective effect of hypothermic preconditioning against ischemia/reperfusion in isolated rat liver. Assessment of the oxidative status

N. Alva[1,2], J. Palomeque[1], A. Negre-Salvayre[2] and T. Carbonell[1]

[1]Physiology and Immunology, Faculty of Biology, University of Barcelona, Barcelona, Spain and [2]Inserm U1048-I2MC, Paul Sabatier University, Toulouse, France

Introduction:
Some stressful stimuli are capable of inducing resistance when applied before ischemic events, which are known as preconditioning. The preconditioning by hypothermic perfusion has been validated in the heart perfused at 26 °C (Khaliulin et al. 2007). We have previously shown that perfusion of the liver at 22 °C improves antioxidant/oxidant profile compared with perfusion at 26 °C. Therefore, this study was designed to demonstrate the preconditioning effect of perfusion at 22 °C applied prior to an episode of ischemia in isolated rat liver focusing on oxidative stress indicators.
Material and Methods:
Fifteen male rats (200-250g) were anesthetized (sodium pentobarbital 60 $mg.g^{-1}$ I.P.) and then underwent laparotomy. The livers were perfused with oxygenated Krebs Henseleit buffer (95% O_2/5% CO_2, pH 7.4 at 37 °C) (Vairetti et al. 2006), excised and placed in an isolated perfused rat liver system at a flow rate of 4 $mL.min^{-1}.g^{-1}$. Livers were randomly divided into three experimental groups. The buffer temperature varied as follows: 20 min of normothermic perfusion in Ischemia/reperfusion (IR) group and 10 min of hypothermic perfusion (22 °C) + 10 min of rewarming (37 °C) in preconditioning + ischemia/reperfusion (PC + IR) group. Both groups underwent 40 min of ischemia and 20 min of reperfusion. Sham livers (S) were frozen without treatment. The levels of lipoperoxidation products (TBARS, 4-HNE and MDA), nitric oxide derivates, and protein oxidation indicators (AOPP) were measured in tissue homogenates. Paraffin-embedded liver sections were evaluated after incubation with antibodies anti-4-HNE.
Results and Discussion:
All data were expressed as percentage of Sham values ± S.E.M analysed by two-way ANOVA.TBARS increased after ischemia/reperfusión (IR) treatment but this harmful effect was reverted by preconditioning(from 207.2 ± 22.5 in IR to 95.6 ± 12.6 in PC+IR, $p<0.01$). The protection was also evident in MDA production (decreasing from 147.5 ± 16.9 to 83.1 ± 8.5, $p<0.01$) while was less clear in 4-HNE (from 182.2 ± 7.6 to 140.9 ± 6.0). The PC treatment also tended to diminish the liver content of nitric oxide products (from 216.3 ± 36.6 to 78.5 ± 48.21) and AOPP (from 108.8 ±8.4 to 72.4 ± 10.3). Histological examination of liver sections showed an increase in sinusoidal spaces in IR group that is less evident in the PC + IR group while immunohistochemistry assays showed a cytosolic location of 4-HNE antibodies in IR group.
Conclusion
A 10-min hypothermic perfusion was capable of reducing oxidative damage in the liver when applied just prior to an ischemic episode that shows its value as a preconditioning stimulus.

The tissue damage markers seem to indicate a modulation of the MDA production as main effect of this treatment.

A PKG inhibitor enhances Ca2+-regulated exocytosis in guinea pig antral mucous cells: cAMP accumulation by inhibition of PDE2A

S. Tanaka[1,2], C. Shimamoto[1], Y. Kohda[1], H. Matsumura[1] and T. Nakahari[2]

[1]Laboratory of Pharmacotherapy, Osaka University of Pharmaceutical Sciences, Takatsuki, Japan and [2]Physiology, Osaka Medical College, Takatsuki, Japan

In antral mucous cells, acetylcholine (ACh, 1μM) activates Ca2+-regulated exocytosis, consisting of an initial peak that declines rapidly (initial phase) followed by a second slower decline (late phase) lasting during ACh stimulation. The initial phase is enhanced by cGMP (1). This enhancement was inhibited by a PKG inhibitor (Rp8BrPETcGMPS, 100 nM). However, Rp8BrPETcGMPS produced a delayed, but transient, increase in the exocytotic frequency during the late phase. On the other hand, cGMP is known to stimulate phosphodiesterase 2 (PDE2) which degrades cAMP (2). The aim of this study is to confirm that the delayed, but transient, increase induced by Rp8BrPETcGMPS was caused by inhibition of PDE2.

Male guinea pigs were anaesthetized by pentobarbital-Na (70 mg/kg, ip.). Antral mucous cells were isolated by a collagenase digestion. The exocytotic events were observed by videomicroscopy. The experiments were performed in accordance with the Guidelines of the Animal Research Committee of Osaka Medical College and the Guiding Principles for the Care and Use of Animals in the Field of Physiological Sciences (Physiological Society of Japan).

ACh alone stimulated cGMP accumulation, which enhances the initial phase in ACh-stimulated antral mucous cells (1).

Rp8BrPETcGMPS induced a delayed, but transient, increase in the frequency of the late phase, while it decreased the frequency of the initial phase. We examined the effects of a PKA inhibitor (PKI-amide) on the delayed and transient increase during the late phase induced by Rp8BrPETcGMPS in ACh-stimulated exocytotic events. A PKI-amide abolished the delayed and transient increase during the late phase induced by Rp8BrPETcGMPS. This suggests that Rp8BrPETcGMPS accumulates cAMP.

Analyses of Western blot and immunohistochemistry demonstrated that PDE2A exists in antral mucous cells. A PDE2 inhibitor (BAY-60-7550) induced a delayed and transient increase in the frequency of the late phase in ACh-stimulated exocytosis similarly to Rp8BrPETcGMPS. The measurement of cAMP content in antral mucosae revealed that BAY-60-7550 accumulates cAMP similarly to Rp8BrPETcGMPS during ACh stimulation. These results suggest that, in antral mucous cells, Rp8BrPETcGMPS decreases the activity of the cGMP-dependent PDE2 by inhibiting PKG, leading to cAMP accumulation.

Rp8BrPETcGMPS inhibited PDE2 in antral mucous cells, leading to cAMP accumulation by inhibiting cAMP degradation. This accumulation of cAMP induced the delayed, but transient, increase in the frequency of the Ca2+-regulated exocytotic events.

PCC186

PPARα-induced enhancement of Ca^{2+}-regulated exocytosis in antral mucous cells of guinea pig

T. Nakahari[1], S. Tanaka[2], N. Sugiyama[2], C. Shimamoto[2] and H. Matsumura[2]

[1]Physiology, Osaka Medical College, Takatsuki, Osaka, Japan and [2]Pharmacotherapy, Osaka University of pharmaceutical Sciences, Takatsuki, Osaka, Japan

In antral mucous cells, acetylcholine (ACh, 1μM) activates Ca^{2+}-regulated exocytosis, consisting of an initial peak that declines rapidly (initial transient phase) followed by a second slower decline (late phase) lasting during ACh stimulation. We have reported that the initial phase is enhanced by PPARα in antral mucous cells (1). However, at present, it still remains uncertain how PPARα enhances $CaCa^{2+}$-regulated exocytosis in antral mucous cells. The aim of this study is to clarify the mechanism following the PPARα activation in antral mucous cells.

Guinea pigs were anesthetized by pentobarbital-Na (70 mg/kg, ip). Antral mucous cells were isolated by a collagenase digestion. The exocytotic events were observed by videomicroscopy. The procedures and protocols for these experiments were performed in accordance with the Guidelines of the Animal Research Committee of Osaka Medical College and the Guiding Principles for the Care and Use of Animals in the Field of Physiological Sciences (Physiological Society of Japan).

GW7647 (a PPARα agonist) enhanced the frequency of initial phase stimulated by 1 μM ACh. In the presence of GW6471 (a PPARα blocker), GW7647 did not enhance the initial phase, and rather the frequency of the initial phase was reduced to about 65 % of that seen in the absence of GW7647. However, GW6471 produced a delayed, but transient, increase in the frequency of late phase. A PKG inhibitor has been reported to produce a similar delayed, but transient, increase in the late phase, since the inhibition of PKG suppresses PDE2 leading to cAMP accumulation by inhibiting cAMP degradation. We examined the effects of a PKG inhibitor on the $CaCa^{2+}$-regulated exocytosis enhanced by GW7647. In the presence of a PKG inhibitor or a NOS inhibitor, GW7647 did not enhance the initial phase, and rather the frequency of the initial phase was reduced to about 65% of that seen in the absence of GW7647. However, a PKG inhibitor or a NOS inhibitor produced a delayed, but transient, increase in the frequency of the late phase. In the presence of GW6471, 8BrcGMP or NOC12 (an NO donor) still enhanced the Ca2+-regulated exocytosis without any delayed increase in the frequency of the late phase. This suggests that PPARα stimulates NO synthesis leading to cGMP accumulation. Moreover, 1 μM ACh or GW7647 increased NO production and cGMP contents in the antral mucosae. Analyses of Western blotting and immunohistochemistry demonstrated that NOS1 exists in antral mucous cells. Thus, PPARα stimulates NOS1 leading to NO synthesis and then NO accumulates cGMP resulting in the enhancement of Ca^{2+}-regulated exocytosis in antral mucous cells. A novel

autocrine mechanism mediated via PPARα maintains $CaCa^{2+}$-regulated exocytosis.

Sawabe Y et al. (2010) Peroxisome proliferation activation receptor alpha modulation of $CaCa^{2+}$-regulated exocytosis via arachidonic acid in guinea-pig antral mucous cells. Exp Physiol 95: 858-868.

Exercise attenuates ischemia-reperfusion injury of nonalcoholic fatty liver of the OLETF rat

T. Shibamoto, Y. Yamamoto, M. Tanida, Y. Kurata and S. Miyamae

Pysiology II, Kanazawa Medical University, Uchinada, Japan

Purpose: We sought to determine whether obesity prevention by exercise conferred protection against subsequent ischemia-reperfusion injury (IRI) to the fatty liver of the hyperphagic, Otsuka Long-Evans Tokushima Fatty (OLETF) rat after temporary vascular occlusion of 70% of the liver.
Methods: At 19 week of age, male OLETF rats (n= 7–8/group) were randomized to groups of sedentary (OLETF-SED)-IR, running exercise (OLETF-EX)-IR, or OLETF-SED-nonIR. Nonhyperphagic, control strain Long-Evans Tokushima Otsuka (LETO) rats were similarly assigned. Rats in the running exercise groups were subjected to running training on a motorized treadmill for 5 weeks. The rats anesthetized with pentobarbitone were cannulated in the carotid artery and jugular vein. After laparotomy, the bile duct was cannuated for measurement of bile flow rate. A laser Doppler probe was placed on the left lateral lobe to monitor peripheral liver blood flow (LBF). Regional ischemia was induced by applying an atraumatic vascular clip around the entire vascular supply to the median and left lateral lobes, enabling vascular occlusion of 70% of the liver, for 30 minutes. The animals were then monitored for 2 hours of reperfusion. Blood samples for alanine transferase (ALT) estimation (as a measure of parenchymal injury) were drawn immediately prior to ischemia, as well as 60 and 120 minutes after reperfusion. LBF and bile flow rate were measured at 15 min intervals.
Results: Exercise attenuated the increases in body weight and liver weight in the OLETF-SED rats. The ALT levels after reperfusion in the OLETF-SED rats were greater than that in the OLETF-EX rats as well as the LETO-SED rats. Exercise attenuated the reduction in LBF and bile flow rate due to ischemia-reperfusion in the LETO-SED group. In contrast, exercise did not provide significant influences on the LETO-SED rats.
Conclusion: Exercise attenuated the obesity and the ischemia reperfusion-induced disturbances of hepatic microcirculation and parenchymal injury of the hyperphagic, Otsuka Long-Evans Tokushima Fatty rats.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Concanavalin A-induced immune-mediated liver injury is attenuated by depletion of gastrointestinal bacteria

B. Mallard[1,2], A. Mabuchi[2], L. Quinlan[1] and A.M. Wheatley[1,2]

[1]Physiology, National University of Ireland Galway, Galway, Ireland and [2]Physiology, University of Otago, Dunedin, New Zealand

Background: Intravenous administration of Concanavalin (Con) A leads to an immune-mediated hepatitis in mice. Con A hepatitis involves the activation of T cells and Kupffer cells, which produce the cytokines interferon (IFN)-γ and tumour necrosis factor (TNF)-α. The lipopolysaccharide (LPS)/Toll-like receptor (TLR) 4 signalling pathway is involved in several forms of liver injury. Furthermore, several forms of experimental liver injury involve increased gut permeability. Con A-induced hepatitis is attenuated in mice deficient in TLR4. In the current study, the effect of depleting gut bacteria on Con A-induced hepatitis was investigated. The effect of Con A on gut permeability was also examined.
Methods: Groups of mice (C57BL/6) were treated for 5 days with Polymyxin B (150 mg/kg/day) and Neomycin (450/mg/kg/day) via drinking water to deplete Gram-negative bacteria in the gut. Control mice were given normal drinking water. Administration of Con A (20 mg/kg i.v) followed antibiotic treatment. Blood and tissue were harvested 8 or 24 hours later. Liver injury was assessed by measuring plasma ALT and histologically. In a separate group of mice, FITC-dextran was administered by oral gavage prior to Con A administration and its subsequent appearance in plasma was measured to assess gastrointestinal tract permeability. Permeability was further examined using an Ussing chamber to measure transepithelial resistance.
Results: Control mice developed severe liver injury following Con A administration, indicated by elevated plasma ALT and confirmed by histology. However, mice treated with antibiotics prior to Con A administration showed no significant elevation in plasma ALT at either 8 or 24 hours and reduced injury was seen on histological inspection. Mice treated with Con A displayed increased gut permeability, indicated by an increase in plasma FITC-dextran levels compared control (1578 ±370 ng/mL in Con A treated vs. 160 ± 26 ng/mL in control mice). Furthermore, Con A treated mice displayed a 20% reduction in transepithelial resistance compared to control mice, which is consistent with increased permeability.
Discussion: Our results show that Con A causes liver injury in mice with a normal bacterial population resident in the gastrointestinal tract. However, following the depletion of Gram-negative bacteria, Con A-induced injury is attenuated. Con A also increased gut permeability, indicating a disruption in the barrier function of the gastrointestinal tract. Together, these results suggest that the mechanism for Con A-induced liver injury involves increased translocation of LPS from the gastrointestinal tract by an as yet unknown mechanism and that the liver injury is dependent on activation of the LPS/TLR4 pathway.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Physiological roles of ezrin in the regulation of chloride secretion by cholangiocytes

R. Hatano[1], K. Akiyama[1], S. Hosogi[2], Y. Marunaka[2] and S. Asano[1]

[1]Department of Molecular Physiology, College of Pharmaceutical Sciences, Ritsumeikan University, Kusatsu, Shiga, Japan and [2]Dept of Molecular and Cellular Physiology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Kyoto, Japan

The secretin dependent biliary secretion of ions and water by transporters and/or channels, which located at apical membrane of cholangiocytes, is essential for the regulation of bile flow. The cystic fibrosis transmembrane conductance regulator (CFTR) plays a critical role in the chloride secretion into the bile. In the cystic fibrosis (CF) patients, totally 5 to 10% of patients develop the progressive biliary fibrosis resembling primary sclerosing cholangitis. The loss of cystic fibrosis transmembrane conductance regulator (CFTR) ion channel function leads to the onset of liver disease in human. The ezrin, radixin and moesin (ERM) proteins are identified as cross-linkers between the plasma membrane proteins and actin cytoskeleton. Ezrin interacts with NHERF1 via its N-terminal binding domain and crosslink it with actin cytoskeleton via its C-terminal binding domain. On the other hand, CFTR interacts with NHERF1 via its c-terminal PDZ binding motif. In the cholangiocyte, ezrin, but not radixin or moesin, is exclusively expressed and colocalizes with CFTR and NHERF1 at apical membrane of cholangiocyte. Here we investigated that physiological role of ezrin in the regulation of biliary chloride secretion by CFTR in vitro. In the normal immortalized cholangiocytes, ezrin colocalized with CFTR and NHERF1 at the apical membrane. The apical surface expression of CFTR was examined by immunofluorescent staining and surface biotinylation. In the normal and wild type ezrin transfected cholangiocytes, CFTR colocalized with NHERF1 and ezrin at apical surface. However, the surface expression of CFTR was significantly reduced in the dominant negative (DN) ezrin transfected cholangiocyte. The dibutyryl cAMP treatment increased the surface expression of CFTR in DN-ezrin expressing cholangiocyte whereas it was still lower than normal and wild type ezrin transfected cells, suggesting that ezrin plays an important role for the apical targeting of CFTR. Consistent with the reduction of surface expression of CFTR, chloride efflux activity was also decreased in the DN-ezrin expressing cholangiocytes. In conclusion, ezrin is required for the correct apical membrane localization of CFTR in the cholangiocyte.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Reversal of delayed gastric emptying in diabetic NOD mice by treatment with interleukin-10 (IL-10) is associated with restoration of network and function of intersitial cells of Cajal (ICC)

S.J. Gibbons, K. Choi, L. Sha, A. Beyder, P. Verhulst, J.E. Mason, T. Ordog, D.R. Linden, J.H. Szurszewski, P.C. Kashyap and G. Farrugia

Enteric Neurosciences Program, Mayo Clinic, Rochester, MN, USA

Delayed gastric emptying (GE) in non-obese diabetic (NOD) mice occurs in a subset of diabetic mice that fail to sustain elevated heme oxygenase-1 (HO1) expression in alternatively activated M2 macrophages (1). We demonstrated that mice with delayed GE and low HO1 expression have increased oxidative stress and loss of interstitial cells of Cajal (ICC). Induction of HO1 by treatment with hemin reverses delayed GE (2,3). Similar results were seen with interleukin-10 (IL-10) treatment. The aim of this study was to examine ICC morphology and function in IL-10 –treated mice. Methods: Mice were included if they developed delayed GE (T½ >118 min) within 10 weeks of start of hyperglycemia (glucose>250mg/dl). GE was measured every week. Mice with delayed GE were treated with vehicle (n = 5) or IL-10 (1 μg ip twice daily, n = 5). Smooth muscle membrane potential and electrical slow waves were recorded from circular muscle of the stomach at 12 regions distributed from the proximal body to distal antrum. After recording, tissues were doubly immunolabeled for HO1 and for Kit to identify ICC. Confocal images were also collected at 12 places distributed across the tissue. ICC and HO1 labeling were scored by 2 independent investigators blinded to the image source. Results: Prior to treatment, mean T½ value were 180±19 min (n = 8, all delayed). While GE remained delayed in mice treated with vehicle (T1/2 = 157±11 min, n = 5), GE returned to normal after 3.1 ± 0.9 weeks in IL-10-treated mice (T1/2 = 106 ± 4 min, n=5). There were significant abnormalities in the electrical slow wave of all vehicle treated mice; abnormalities were not observed in IL-10 treated mice. Slow waves had a higher frequency, the rise time was faster and the events were broader in IL-10 treated mice than in vehicle-treated mice ($p < 0.05$, paired sign test). The parameters in IL-10 treated mice were similar to previously recorded slow waves from mice with normal GE. The most pronounced differences were seen in the distal antrum where slow waves in IL-10 treated mice had a faster frequency (Veh: 0.04±0.01, IL-10: 0.07±0.02 Hz, Mean±SEM, $p<0.05$, ttest) and lower variation in peak amplitude than in vehicle treated mice (Veh: 3.85±0.71, IL-10: 0.58±0.41, Mean±SEM, $p<0.05$ ttest). HO1 expression was significantly higher in tissues from IL-10 treated mice. ICC networks in vehicle-treated mice had patchy damage and were scored as significantly less intact than networks from IL-10 treated mice. Conclusions: Uneven damage to ICC networks likely underlies electrical abnormalities in the stomachs of diabetic mice with delayed GE. Treatment of delayed GE with IL-10 normalizes delayed GE, changes to ICC networks and slow wave abnormalities.

Neuropeptide S reduce small intestinal motility in rats and humans

W. Wan Saudi[1], A. Halim[2], D. Webb[2], L. Gillberg[3], T. Rudholm Feldreich[3], M. Sundbom[4], E. Näslund[5], A. Sommansson[1], P.M. Hellström[2] and M. Sjöblom[1]

[1]Department of Neuroscience, Uppsala University, Uppsala, Sweden, [2]Department of Medical Sciences, Uppsala University, Uppsala, Sweden, [3]Department of Medicine, Gastroenterology Unit, Karolinska Institutet, Solna, Sweden, [4]Department of Surgical Sciences, Uppsala University, Uppsala, Sweden and [5]Clinical Sciences, Danderyd Hospital,, Karolinska Institutet, Stockholm, Sweden

Neuropeptide S (NPS) and its receptor are expressed by several cell types within the gastrointestinal (GI) tract, such as the epithelium, smooth muscle cells, submucosal neurons and enteroendocrine cells, in both rat and man. Polymorphisms of the NPS receptor are linked to increased risk of inflammatory bowel disease (IBD) as well as motor and sensory disturbances of the gut, suggesting a role for NPS in GI disorders. The aim of the present study was to elucidate the actions of NPS on duodenal mucosal barrier function and motility.

Male Sprague-Dawley (SD) rats (n=36; 300-350 g) were anaesthetized with thiobutabarbital 120 mg/kg body weight intraperitoneally The surgical and experimental protocol and methodology used have been described previously [1]. A brief summary is given here. A ~30 mm segment of the proximal duodenum was perfused in situ. The effects of intravenous (IV) administration of NPS and NG-nitro-L-arginine methyl ester (L-NAME) were investigated on mucosal paracellular permeability, bicarbonate secretion (DBS), motility and net fluid flux. In addition, studies of migrating motor complexes were carried out in SD rats (n=30; 300-350 g) with electrodes implanted in the small bowel. After baseline recordings with saline infusion, NPS was infused IV for 60 min and effects on myoelectric activity recorded. To relate the findings in rat to the human GI tract, circular muscle strips of human small intestine (n=7) was studied in an organ bath. The human tissue specimens were excised from patients during surgery for stomach or intestinal resection. All patients gave informed consent to enter the study. Tension changes were measured after stimulation with 1.0-20 nM NPS with and without electric field stimulation (EFS). Values are mean ± SEM, compared by 1-way ANOVA or paired t test when appropriate.

NPS (0.5, 5.0 and 50 nmol kg^{-1} h^{-1}) caused dose-dependent decrease in duodenal motility and paracellular permeability (e.g. from 431 ± 66 to 145 ± 51 AUC 10 min^{-1} and from 0.21 ± 0.03 to 0.09 ± 0.02 ml $min^{-1}100g^{-1}$, n=10, P<0.001 respectively). NPS did not induce any changes in DBS or net-fluid-flux. Pre-treating animals with L-NAME (3.0 mg kg^{-1} bolus dose followed by infusion of 1.0 mg kg^{-1} h^{-1}) abolished the effect of NPS on duodenal motility, but did not change that on permeability.

Similarly, NPS at 1.0 nmol $kg^{-1}min^{-1}$ increased irregular spiking, while 4.0 nmol $kg^{-1}min^{-1}$ (each dose n=6) significantly reduced spiking activity and increased the MMC cycle length (P=0.005).

In human smooth muscle strips, NPS (5.0 nM, n=7) dampened small intestine circular muscle contractility with and without EFS. In colonic muscle strips (NPS 5.0 nM) only sporadic dampening without EFS, but more consistent dampening (NPS 1.0 nM, n=5 P=0.04) with EFS, was observed.

In conclusion, these findings reveal evidence that NPS significantly decreases small intestinal motility and contractility in tissue of both human and rat origin. In addition, NPS decreases paracellular permeability. L-NAME abolished the effect of NPS on motility but was without effect on that to permeability. These results suggest important roles of NPS in the regulation of GI barrier functions and motility.

Acute and long-term administration of melatonin reduce ethanol-induced increases in duodenal mucosal permeability and motility in rat

A. Sommansson and M. Sjöblom

Department of Neuroscience, Uppsala University, Uppsala, Sweden

Melatonin is released from enterochromaffin cells in the intestinal mucosa, but the influence of melatonin on gastrointestinal function is still largely unknown. Recently we found that administration of melatonin decreases basal duodenal mucosal paracellular permeability and increases duodenal bicarbonate secretion (DBS).

The aim of the present study was to elucidate the acute and long-term effects of melatonin administration on ethanol-induced alterations of duodenal mucosal paracellular permeability and motility.

In this study male Sprague-Dawley (SD) rats (n=44; 250-375 g) were used. For evaluation of long-term effects of melatonin administration rats were given melatonin (0.1 mg/ml), or vehicle, in the drinking water for 14 days, while the other rats were given normal tap water.

Rats were anaesthetized with thiobutabarbital sodium (Inactin®) 120 mg/kg body weight intraperitoneally. The surgical and experimental protocol and methodology used have been described previously [1]. A brief summary is given here. A laparatomy was performed and a ~30 mm segment of the proximal duodenum, with an intact blood supply, was perfused in situ with saline for basal recordings followed by 15% ethanol (v/v) for 30 min. Effects on duodenal mucosal permeability [blood-to-lumen clearance of 51Cr-EDTA] and motility were investigated. Values are mean ± SEM, compared by 1-way ANOVA or paired t test when appropriate.

Luminal perfusion with 15% ethanol induced significant ($p<0.05$) increases in mucosal paracellular permeability and duodenal motility from 0.18 ± 0.06 to 1.67 ± 0.29 ml $min^{-1}100g^{-1}$ (n=9) and from 537 ± 46 to 1209 ± 148 AUC 10 min^{-1} (n=9) respectively. Pre-treating animals with an intravenous (IV) injection of melatonin 20 mg kg^{-1} 10 min before ethanol exposure reduced the ethanol-induced increase in 51Cr-EDTA clearance to 0.65 ± 0.23 ml min^{-1} $100g^{-1}$, $p<0.05$, n=6). In animals pretreated with 20 $mgkg^{-1}$ melatonin IV 15% ethanol failed to augment duodenal motility. Hexamethonium (10 $mgkg^{-1}$ IV followed by continuous IV infusion at a rate of 10 mg $kg^{-1}h^{-1}$, n=9) abolished the effects of IV melatonin.

In animals administered melatonin for 14 days 15% ethanol induced significantly ($p<0.05$) less increases in mucosal paracellular permeability compared to their corresponding vehicle (from 0.12 ± 0.02 to 2.30 ± 0.46 $mlmin^{-1}100g^{-1}$ (n=4) compared to 0.18 ± 0.06 to 2.94 ± 0.42 $mlmin^{-1}100g^{-1}$ (n=6) respectively). No increases in duodenal motility in response to 15% ethanol was observed in melatonin treated animals.
Our results show that melatonin reduces ethanol-induced increases in duodenal paracellular permeability partly via enteric neural pathways involving nicotinic receptors. In addition, melatonin inhibits ethanol-induced increases in duodenal motor activity. These results suggest that melatonin may serve important gastrointestinal barrier functions.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

P2Y1 receptors are developmentally regulated in mouse pancreatic acinar cells

W.J. Wilkinson, J.V. Gerasimenko, O.V. Gerasimenko and O.H. Petersen

School of Biosciences, Cardiff University, Cardiff, Wales, UK

Purinergic (P2) receptors for extracellular adenosine triphosphate (ATP) are widely distributed throughout the body where they play diverse roles in cell signalling. P2Y receptors are metabotropic receptors that are also able to respond to ADP and uridine nucleotides, mobilising intracellular Ca2+ via the production of inositol 1,4,5-triphosphate. Ionotropic P2X receptors respond to physiological ATP and have varying degrees of Ca2+ permeability. P2Y1 receptors have previously been implicated in exocrine glands where they are thought to play a developmental role in salivary gland.
The potential for purinergic signalling in the pancreas is great since ATP is a ubiquitous neuronal co-transmitter and millimolar concentrations of ATP are found in pancreatic zymogen granules. Purinergic signalling is implicated in exocrine pancreas pathophysiology since P2Y2, P2X7 and the ectonucleotidase CD39 are all upregulated in pancreatitis and pancreatic cancer and CD39 expression levels correlate with long term disease survival. The mouse is frequently used in models of pancreas pathophysiology, but the role of purinergic signalling in the mouse exocrine pancreas is unreported.
Experiments were carried out on acutely isolated pancreatic acinar cells from C57BL6 mice, killed by cervical dislocation in accordance with UK Schedule 1 regulation of the Animal (Scientific Procedures) Act, 1986. Intracellular Ca2+-responses were measured by loading cells with Fura-2.
We observed in adult animals only a minority (34 ± 4 %; N = 17) of pancreatic acinar cells responded to 100 μM ATP, whilst 19 % of cells responded to ADP and 8 % to UTP. In the absence of extracellular Ca2+, ATP responses were maintained. However no cells responded to ATP in the presence of extracellular Ca2+, but not in its absence; suggesting there were no functional P2X receptors at the plasma membrane.
The proportion of cells responding to ATP increased to 90 ± 4 % (N = 7) when acinar cells were isolated from juvenile (6-18 days) mice, suggesting a developmental role for purinergic signalling in exocrine pancreas. In juvenile animals 87 % of cells responded to ADP, and 79 % responded to 100 nM MRS2365 a specific agonist of P2Y1 receptors. This response could be blocked by 100 nM MRS2500 a specific P2Y1 antagonist. Taken together these results suggest the developmental expression of P2Y1 receptors in pancreatic acinar cells. We also found in these cells that P2Y1 receptors were functionally coupled to enzyme secretion via the detection of extracellular amylase activity (with fluorescent BIODIPY-DQ starch dye) following P2Y1 receptor activation.
These results show P2Y1 receptors are developmentally regulated in pancreatic acinar cells and suggests P2Y1 receptors play an important role in exocrine gland maturation.

L-glutamate secretion in the pancreatic juice involves transport and metabolism of neutral amino acids in exocrine pancreas and is influenced by the content of protein in the diet

S. Araya[1], C. Lutz[1], L. Mariotta[1], B. Herzog[1], F. Verrey[1], T. Reding[2], R. Graf[2] and S.M. Camargo[1]

[1]Institute of Physiology and ZIHP, University of Zurich, Zurich, ZH, Switzerland and [2]Department of Surgery, University Hospital of Zurich, Zurich, ZH, Switzerland

The pancreas efficiently absorbs amino acids for the synthesis of enzymes, but also secrets free amino acids in the pancreatic juice which are re-absorbed by the small intestine. Under free protein diet, the release of amino acids on the pancreatic juice (PJ) may play important role on the homeostasis maintenance of the small intestine. From the 20 proteinogenic amino acids analyzed in the PJ, L-glutamate (Glu) was 4 fold more concentrated in PJ when compared to plasma levels. The concentrative mechanism could be due to an increase in the transport of Glu and the synthesis of Glu in the exocrine pancreas. Since there is a high expression of neutral amino acids and L-glutamine (Gln) transporters in the pancreas and they localize to the basolateral membrane of the acinar cells, we hypothesize Glu is synthesized in acinar cells and secreted to the pancreatic juice. We analyzed at mRNA level the expression of the 2 glutaminase isoforms (gls1 and gls2), glutamine synthase (Glul), alanine aminotransferase 1 and 2 (GPT1, GPT2) and aspartate aminotransferase 1 and 2 (GOT1 and GOT2) in pancreas. Our results showed that the two glutaminase isoforms (Gls1 and Gls2) are expressed in the pancreas, GLS2 is localized in the acinar cells, and that the levels of gls2 and of the cytoplasmatic GPT were elevated in animals receiving diet free of protein. These results suggest Glu may be synthesized in the exocrine pancreas from Gln and L-alanine and that the dietary protein content can modulate the expression of enzymes involved in the synthesis of Glu. The secretory mechanism of Glu to PJ could involve zymogen vesicles and transport via apical membrane. Our experiments showed that Glu and its precursors were not concentrating in zymogen granules vesicles (ZGV) but were found at high concentrations in the cytoplasmic fraction, suggesting the secretory mechanism does not involve exocytosis. Immunofluorescence and western blotting of isolated ZGV suggested that the sodium-dependent Glu transporter EAAT1 (Slc1a3) is present on the zymogen vesicles membrane. Additionally, immunofluorescence of pancreatic tissue showed that EAAT1 localizes proximal to the apical membrane of acinar cells. Our results support the hypothesis that EAAT1 is involved in the secretion of

Glu during vesicular docking to the apical membrane of acinar cells. These preliminary exciting results suggest a new mechanism for Glu concentration and secretion on the pancreatic juice, as well a recycling of neutral amino acids (L-alanine, Gln) and Glu between the pancreas and intestine.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC197

Comparative levels of butyrate transporters in ulcerative colitis, Crohn's disease and normal patients

S. Roux[1], S. Daniell[2,1] and E.S. Fredericks[1]

[1]Biochemistry and Microbiology, NMMU (South Campus), Port Elizabeth, South Africa and [2]Pharmacy, NMMU (South Campus), Port Elizabeth, South Africa

It has long been known that butyrate manages oxidative stress and inflammation in the colon. Butyrate is absorbed in the colon and transported into colonocytes by monocarboxylate transporter isoform 1 (MCT1) and sodium-coupled monocarboxylate transporter (SMCT1). Butyrate is the major energy source for colonocytes and is produced by fermentation of carbohydrates by resident microbiota. Ulcerative colitis (UC) and Crohn's disease (CD) are two forms of idiopathic inflammatory bowel disease (IBD). Their exact etiologies are unknown, but a decrease in butyrate metabolism in colonocytes has been suggested to be a possible contributing factor. A transport deficiency of butyrate can possibly be a major contributing factor for the decreased butyrate metabolism.
AIM: To analyse and compare SMCT1 and MCT1 levels in colon biopsy samples of normal (n=19), ulcerative colitis (n=9) and Crohn's disease (n=8) patients.
METHOD: Colon biopsies were obtained with consent from normal, UC and CD patients. RNA was extracted from these samples and prepared for analyses using RT-qPCR. ALUSq, ALUSx and SF3A1 were used as reference genes.
RESULTS: The results of the RT-qPCR were analysed using one-way ANOVA and a Mann-Whitney test. SMCT1 is less expressed than MCT1 in the colon of all patients. MCT1 is significantly down regulated in colon samples of both UC and CD's patients when compared to normal patients with no colon pathology. MCT1 is also significantly less expressed in UC compared to CD patients.
CONCLUSION: MCT1 is the most important butyrate transporter in the colon. Lower butyrate transport expression can contribute to a less inflammatory inhibition in the colon. The lower expression of MCT1 in UC patients compared to CD patients could explain the higher incidence of developing colorectal cancer in UC patients.

Potential effects of selenium on liver functions after ischemia reperfusion in old female rats

N.N. Lasheen and A.A. Mohamed

Physiology, Faculty Of Medicine, Cairo, Egypt

Background and aim: Ischemia/reperfusion (I/R) injury of the liver is an important clinical problem encountered in hepatic failure after shock, liver transplantation, or liver surgery, and in diverse situations, including heart failure, liver trauma, and blood occlusion to the liver. Liver functions are decreased in old age and oxygen radicals probably mediate some of the structural and functional alterations associated with ageing and with reperfusion of ischemic liver. This study aimed at investigating the effects of pre-treatment with the antioxidant selenium in an experimental model of hepatic I/R in old female rats.
Materials and Methods: The study was carried out on 40 old female Wistar albino rats(250-300 grams), allocated into 4 groups; I. Sham-operated control group, II. Partial liver I/R group, under anaesthesia with pentobarbital 40 mg/kg B.W. subjected for partial hepatic ischemia for 20 minutes followed by reperfusion for 20 minutes, III. Selenium pretreated group with 20 μg/Kg B.W. i.p. for 2 weeks followed by partial liver I/R, and IV. Selenium treated group for 2 weeks. At the end of experimental procedure, blood samples were collected, and the separated plasma was used for determination of liver enzymes (SGPT, SGOT & γ-GT) and plasma total antioxidant capacity (TAC). Liver malondialdehyde (MDA) was measured and liver tissue was examined histologically.
Results: Values are in Mean ± SEM, compared by ANOVA. Compared to the sham operated control, in partial liver I/R group; significant increase in SGPT (373.8±35.5 vs 40±5.1, IU/L) SGOT(364.9±7.1 vs180.9±18.8, IU/L), γ-GT (11.7±1.9 vs 6.5±0.87, IU/L) and liver malondialdehyde (24.9±1.2 vs 17.2±1.5, μM/gm wet tissue) and a significant decrease in total antioxidant capacity (0.35±0.05 vs 0.66±0.07, mM/L), associated with leukocyte infiltration of liver tissue. Although selenium treatment for 2 weeks had a non-significant improving effect on normal liver functions of old rats (SGPT: 21.1±3.7, SGOT: 173.1±11.2, γ-GT:6.9±1.2, MDA: 18.4±2.8, TAC: 0.68±0.04), selenium pretreatment for 2 weeks before partial liver I/R resulted in amelioration of the I/R hepatic injury, evidenced by the significant decrease in liver enzymes SGPT (286.3±20.9), SGOT (312.1±8.9), γ-GT (5.5±0.54) and liver MDA (19.7±1.1) and a significant increase in plasma TAC (0.72±0.05) associated with decreased leukocyte infiltration of liver tissue when compared to the partial liver I/R group.
Conclusion: Liver I/R in aged rats induces oxidative stress that markedly impairs liver functions and structure. Pretreatment with the dietary antioxidant selenium slightly improves liver functions in old rats, and of much value in protection of the liver of aged rats against I/R injury.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC199

Villous movement of intestine is regulated by mutual interaction of subepithelial fibroblasts and afferent neurons via atp and substance-P

K. Furuya[1], S. Furuya[2] and M. Sokabe[3]

[1]FIRST Res Center Innovative Nanobiodevice, Nagoya University, Nagoya, Japan, [2]Natl Inst Physiol. Sci, Okazaki, Japan and [3]Dept Physiol, Med Sch, Nagoya University, Nagoya, Japan

Intestinal villi are a unique structural and functional unit for the luminal sensing, digestion, absorption, secretion and immune defense in the small intestine. Subepithelial fibroblasts of the intestinal villi, which form a contractile network beneath the epithelium, are in close contact with epithelial cells, neurons, capillaries, smooth muscles and immune cells, and play pivotal roles in the villous functions. Here, we investigate the functional roles of subepithelial fibroblasts physiologically and morphologically using a primary culture and isolated epithelium-free villi of duodenum isolated from rats, which were anesthetized by pentobarbital (0.1ml/100g) and decapitated. Villous subepithelial fibroblasts possess purinergic receptor P2Y1 and tachykinin receptor NK1. ATP and substance-P (SP) induce increase in intracellular Ca2+ and cell contraction in cultured cells and also isolated villi observed using a two-photon laser microscope with indo-1 calcium dye. The localization of NK1R and SP in the villi was examined by light and electron microscopic immunohistochemistry. NK1R-like immunoreactivity was intensely localized on the plasma membrane of villous subepithelial fibroblasts. The villous subepithelial fibroblasts form synapse-like structures with both SP-immunopositive and -immunonegative nerve varicosities, mostly intrinsic afferents nerve terminals. They are highly mechano-sensitive and stretch stimulation of the cells cultured on an elastic (PDMS) chamber, induced ATP release, which observed by real time luciferin-luciferase bioluminescence imaging system using an image intensifier and a high sensitive EM-CCD camera equipped on an upright microscope. Large transient ATP releases (peak concentration over 10 μM) were observed in sparse cells and the released ATP spreads to the surrounding over several hundred μm and keeps enough concentration to activate P2Y1 for several ten seconds, which forms propagating Ca2+ waves and contraction of the cells. From these findings, we propose that the mutual interaction between villous subepithelial fibroblasts and afferent neurons via SP and ATP plays important roles in refined and coordinate villous movement in intestine.

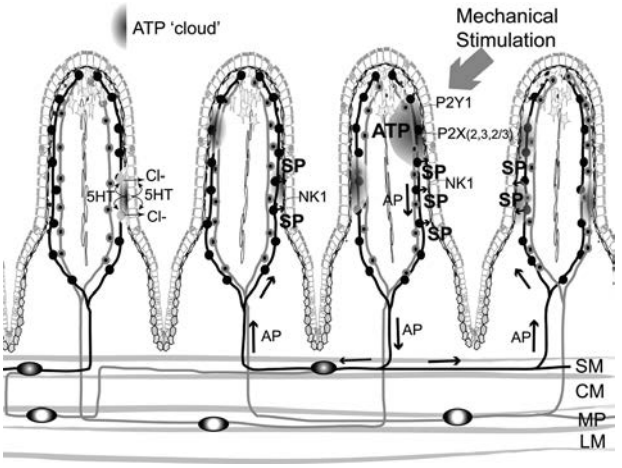

Fig. 1 Plausible contribution of the ATP and SP signaling to the coordinate movement of the intestinal villi.

Mechanically induced signal in a villus may spread to several neighboring villi through a trans-somatic reflex in an IPAN and also through synaptic connections. Activated IPAN may release SP from the varicosities in the surrounding villi, and the subepithelial fibroblasts are activated and contract by the SP via NK1. This inter-villus signaling via ATP and SP may contribute to coordinate movement and elegant mechanical properties of a mass of villi. ATP cloud (or circumstances) may be occurred here and there by mechanical and chemical (SP, ET or hypo-osmotic) stimuli of the subepithelial fibroblasts in the villi and enhance or modulate other signaling such as SP induced contraction of the subepithelial fibroblasts.

A physiological dietary regime for the management of gastroesophageal reflux disease - a pilot study

M.A. Randhawa[1], S.M. Mahfouz[2], N.A. Salem[3], T. Yar[4] and A. Gillessen[5]

[1]Pharmacology, College of Medicine, University of Dammam, Dammam, Saudi Arabia, [2]Endoscopy, King Faisal Hospital, Taif, Saudi Arabia, [3]Endoscopy, King Faisal Hospital, Taif, Saudi Arabia, [4]Physiology, College of Medicine, University of Dammam, Dammam, Saudi Arabia and [5]Internal Medicine, Sacred Heart Hospital, Muenster, Germany

The occurrence of gastroesophageal reflux disease (GERD) is increasing (1). Drug treatment is risky, particularly, in long term use, which is required in most cases. Irregular dietary habits possess strongest association with GERD (2). Transient lower esophageal sphincter relaxations (TLESRs) are important cause of GERD. Gastric distention in upper stomach is the strongest stimulus for generation of TLESRs and is aggravated by intake of food in between meals (3). Considering pathophysiology of GERD, it is suggested that increasing interval

between meals will reduce reflux episodes. The present pilot study was conducted on 20 patients, outpatients in Sacred Heart Hospital, Muenster, Germany and King Faisal Hospital, Taif, Saudi Arabia. All had heartburn symptoms and endoscopically proven reflux oesophagitis, Los Angeles grad a, b or c. They were offered to take two meals per day plus only soft drinks in between. On day 14 they were contacted to ensure compliance on study criteria, two meals per day and no medication; and evaluated for pain, heartburn and reflux during last two weeks. Patients, 9 males and 11 females, were aged between 15 and 68 years and continued our suggested meal regimen for two weeks. On day 14th 15 (75%) were free of pain and heartburn, etc, 2 (10%) had partial improvement and 3 (15%) reported no difference. Those who did not respond were advised omeprazole or ranitidine for further treatment. Results revealed that two meals a day and only soft drinks in between, was an effective and physiological dietary regimen for the management of GERD in 75% of cases.

Bile acids inhibit secretion of the proinflammatory cytokine, interleukin-8, from U937 monocytes

A.M. O Dwyer, J.B. Ward and S.J. Keely

Molecular Medicine, Royal College of Surgeons, Dublin, Dublin, Ireland

Inflammatory Bowel Disease (IBD) is a group of disorders characterised by chronic intestinal inflammation. The intestines of patients with IBD contain increased numbers of newly recruited monocytes, which augment the level of several inflammatory mediators in the gut. Among these inflammatory mediators is interleukin-8 (IL-8), a proinflammatory cytokine and potent neutrophil attractant that has been implicated in the initiation and perpetuation of IBD. Although bile acids are classically known for their role in lipid digestion they are also capable of activating nuclear and membrane receptors that regulate immune responses in the intestine and the liver. The aim of this study was to investigate the effects of the naturally-occurring bile acids, ursodeoxycholic acid (UDCA) and deoxycholic acid (DCA), on IL-8 secretion from U937 monocytes.

IL-8 release from U937 monocytes was induced with either bacterial lipopolysaccharide (LPS) [1 μg/mL] or the endogenous proinflammatory cytokine, TNFα [5 ng/mL] for 1hr. Cells were co-treated with either UDCA or DCA. Supernatants were then analysed for IL-8 protein by sandwich ELISA. IL-8 mRNA expression was assessed by qPCR. Cytotoxic effects of bile acids were determined by detection of lactate dehydrogenase release. Statistical analysis was performed using one way ANOVA with the Tukey-Kramer post test.

LPS and TNFα induced a 6.4 ± 1.5 and 2.2 ± 0.3 fold increase in IL-8 release from U937 monocytes, respectively ($n = 5$; $p < 0.05$). UDCA, at concentrations of 200 μM and 500 μM, attenuated LPS-induced IL-8 release to 75 ± 7.9% and 34 ± 4.5% of controls, respectively ($n = 5$; $p < 0.05$). DCA, 100 and 150 μM, also exerted a concentration-dependent inhibition of LPS stimulated IL-8 release to 54 ± 12.3% and 44 ± 8.7% of controls ($n = 5$ $p < 0.05$). TNFα-stimulated IL-8 release was inhibited to 39 ± 4.6% of controls by UDCA (500 μM) and to 42 ± 5.5% by DCA (200 μM) ($n = 4$ $p < 0.05$). UDCA (500 μM) and DCA (150 μM) also reduced LPS-induced IL-8 mRNA expression to 24.6 ± 9.7% of control ($n = 4$; $p < 0.05$) and 11.4 ± 7.7% respectively. UDCA and DCA did not exert toxic actions at any of the concentrations tested. The taurine-conjugates of the bile acids, tauroursodeoxycholic acid (TUDCA) and taurodeoxycholic acid (TDCA) did not have any effect on LPS or TNFα-induced cytokine production.

The results of this study demonstrate that the naturally-occurring bile acids, UDCA and DCA, attenuate IL-8 release from monocytes through inhibition of mRNA expression for the cytokine. Such actions suggest that UDCA and DCA may exert anti-inflammatory effects in vivo and that manipulation of the colonic bile acid pool could prove useful as a new therapeutic strategy for IBD.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Bile acids regulate innate barrier functions of colonic epithelial cells

N.K. Lajczak, M.S. Mroz, V. Saint-Criq and S.J. Keely

Molecular Medicine, Royal College of Surgeons in Ireland, Dublin, Dublin, Ireland

Intestinal epithelial cells constitute the first line of defence against the entry of toxins and pathogens from the lumen to the body, with several processes contributing to this innate barrier function. For example, fluid secretion flushes pathogens from the lumen, defensin production protects against bacterial invasion, autophagy aids in clearing bacteria from infected cells, and restitution repairs the epithelium after injury. Although bile acids are known to be involved in the pathogenesis of IBD, the mechanisms by which they regulate epithelial barrier function are not well understood. Therefore, the aim of this study was to investigate the effects of deoxycholic acid (DCA) on epithelial responses that contribute to barrier function.

T_{84}colonic adenocarcinoma cells were grown on permeable supports and were treated with DCA (50 μM -1 mM) for 1 h to 72 h. Protein expression was investigated by western blotting and mRNA expression by qPCR. Epithelial restitution in polarised T_{84} cell monolayers was investigated using a wound healing assay. Muscle stripped sections of human colonic mucosa were mounted in Ussing chambers for measurements of ion transport by monitoring changes in short circuit current (Isc) under voltage-clamped conditions. All experiments involving human tissue had the approval of Beaumont Hospital Ethical Committee.

DCA (150 μM, 48 h) attenuated restitution of mechanically wounded T_{84} cell monolayers by 2.08 ± 0.14 fold compared to untreated controls ($n = 3$; $p < 0.05$). Furthermore,

DCA (200 μM, 24 h) stimulated autophagy in T_{84} cells, as indicated by a 1.8 ± 0.9 fold increase in the expression of the autophagy marker, microtubule-associated protein light chain 3 (LC-3 II), when compared to controls (n = 5; p < 0.001). In contrast, the more hydrophillic bile acid, UDCA (50–500 μM) was without effect on LC-3 II expression. DCA also increased expression of mRNA for the constitutively expressed hβD-1 by 7.0 ± 0.9 fold, compared to untreated cells (n = 5; p < 0.001). Levels of inducible hβD-2 mRNA were also significantly upregulated by 4.3 ±0.4 fold in response to DCA (n = 4; p < 0.01). When added to voltage clamped sections of human colonic tissue, DCA, at concentrations of 200 μM and 500 μM, stimulated Isc responses of 4.0 ± 0.0 μA/cm2 and 24.0 ± 0.0 μA/cm2 (n = 2). Furthermore, DCA pretreatment attenuated Cl- secretory responses to the Ca^{2+} dependent agonist, carbachol (CCh, 100 μM) from 320 ± 274 μA/cm2 to 56 ± 3 μA/cm2, n = 2). At concentrations of > 500 μM, DCA rapidly damaged colonic tissues, as demonstrated by a 5.7 ± 0.9 fold increase in transmucosal conductance (n = 2).

Taken together, these data implicate colonic bile acids, such as DCA, as important regulators of intestinal epithelial barrier function and suggest they might be good targets for the development of new approaches to treat IBD.

High-fat diet increase the firmly adherent mucus layer in rat colon

T.B. Waldén, D. Ahl, A. Jägare, M. Phillipson and L. Holm

Medical Cell Biology, Uppsala University, Uppsala, Sweden

INTRODUCTION: The colon is subjected to a plethora of potentially damaging agents against which its first line of defense is the protective mucus bilayer, consisting of a removable loosely adherent layer and a firmly adherent layer difficult to remove [1]. We have recently shown that the firmly adherent mucus layer acts as a physical barrier to the microbiota. The mucus bilayer also reduces shear stress to the mucosa [2]. The colonic microbiota and mucosal health has been linked to different constituents in the diet [3]. The aim of this study was to investigate if a high-fat diet with or without prebiotic bilberry fibers influence on the thickness and secretion of the colonic mucus bilayers.

METHODS: Male Sprague-Dawley rats (80g) were given a diet consisting of either low-fat diet (LFD), high-fat diet (HFD), LFD with bilberry extract (LFD+BB) or HFD with bilberry extract (HFD+BB), for 8 weeks. On the last day of experiment, rats (n=8/group) were anesthetized (Inactin, 120 mg/kg) and operated on for in vivo measurements of mucus thickness. The distal part of the colon was opened up along the anti-mesenteric border and draped over a truncated cone with the luminal side up. A mucosal chamber with warm saline was placed over the mucosa. To ease visualization through the microscope, saline-suspended charcoal was dropped on the mucus gel. To perform measurements, micropipettes, held by a micromanipulator at an angle of 35-45 degrees to the cell surface, was pushed into the mucus gel. The distance (l) to the epithelial surface was measured with a "digimatic indicator". Mucus thickness (T) was then calculated using the formula: T =l x sin a. Mucus thickness was measured at different intervals, before and after removing the loosely adherent mucus by suction. Distal colon tissue was paraffin-embedded, sectioned and PAS-stained to count the number of goblet cells.

RESULTS: Here we have demonstrated that: (1) 8 weeks of HFD supplementation with or without BB leads to increased thickness of the firmly adherent mucus layer (e.g. the mean firmly adherent mucus thickness rats fed a HFD or a HFD+BB (84.2±1.2 and 82.7±0.7 μm) was significantly higher than the respective LFD and LFD+BB controls (78.7± 0.7 and 78.6±0.9; Students t-test p< 0.0002 and p<0.001); (2) the loosely adherent mucus thickness is only increased by a diet with a combination of bilberry extract and high-fat (e.g. the mean loosely adhesive mucus thickness in the rats fed HFD+BB (40.7±1.5 μm) was significantly higher than in rats fed a HFD only (31.3±3.2 μm; Students t-test p<0.05). (3) a pilot study indicate an increase in the number of goblet cells in rats fed HFD+BB and a decrease in rats fed HFD only.

SUMMARY: High-fat diet, with our without bilberries, increase the protective firmly adherent mucus layer, while only a combination of high-fat diet and bilberries increase the thickness of the loosely adherent mucus layer.

Intestinal biotransformation of maslinic acid, a natural triterpenoid from *Olea europaea* L

G. Lozano-Mena[1], M. Sánchez-González[1], A. García-Granados[2], M. Juan[1] and J. Planas[1]

[1]Department of Physiology and INSA-UB, Universitat de Barcelona, Barcelona, Spain and [2]Department of Organic Chemistry, Universidad de Granada, Granada, Spain

Maslinic acid is a bioactive compound found in olives and olive oil to which a myriad of beneficial effects have been attributed, such as antioxidant, antitumor and antidiabetic. Here, we present a high performance liquid chromatography coupled to mass spectrometry (HPLC-MS) method to determine maslinic acid and its metabolites in rat intestinal content after the oral administration. The pentacyclic triterpene was orally administered to three groups of male Sprague-Dawley rats at single daily doses of 5, 2 and 1 mg/kg, respectively. At 24 h after the last administration, the content of the duodenum and jejunum, ileum, caecum and colon was obtained. Analytes were extracted with methanol 80% by homogenization and stirring. Chromatographic separation was carried out using a gradient elution of water and acetonitrile and detection was performed in a single quadrupole mass spectrometer, with an atmospheric pressure chemical ionization (APCI) source. The metabolites were identified by LC-APCI-LTQ-Orbitrap-MS. The analytical method was validated by spiking blank intestinal content samples with maslinic acid at the concentrations of 0.1, 0.5, 1, 5, 10, 20 and 30 μM. The mean coefficient of correlation was 0.994, the mean recovery was 97.87 ± 0.76% and the limit of quantification was 5 nM. The intra- and inter-day precisions were 4.32 ± 1.69% and 6.22 ± 1.05%, respectively. After 24 h of the last administration of maslinic acid, the analysis of the content of the different intestinal segments demon-

strated the presence of maslinic acid ($C_{30}H_{48}O_4$) together with nine metabolites: five monohydroxylated derivatives ($C_{30}H_{48}O_5$) (M1-M5), two monohydroxylated and dehydrogenated metabolites ($C_{30}H_{46}O_5$) (M6-M7) and two dihydroxylated derivatives ($C_{30}H_{48}O_6$) (M8-M9). Metabolites of the same m/z differed by the retention time (t). The percentage that each compound represented over the total amount along the small and large intestine was calculated. Maslinic acid accounted for 18.9 ± 1.2% and the major metabolites were the monohydroxylated M1(t = 6.6 min), representing an average of 55.4 ± 2.3%, followed by M2 (t = 7.3 min), which accounted for 17.0 ± 5.8%. To a lesser extent, the monohydroxylated and dehydrogenated metabolites M6 (t = 6.8 min) and M7 (t = 8.1 min) represented an average of 4.9 ± 2.8% and 2.8 ± 0.7%, respectively, and the rest of the derivatives (M3, M4, M5, M8 and M9) accounted for less than 1%. These results show that 24 h after the oral administration, maslinic acid undergoes extensive phase I metabolism, following the same pattern at three different doses. Two monohydroxylated derivatives are the most abundant, one of them accounting for more than double of the maslinic acid fraction in the whole intestinal content.

Does DNA methylation play a role in B°AT1 transcriptional regulation along crypt-villus axis?

E. Tumer, T. Juelich and S. Broer

Research School of Biology, Australian National University, Canberra, ACT, Australia

Hartnup disorder is an autosomal recessive disorder caused by mutations in the B°AT1 (Slc6a19) gene encoding the major transport system for neutral amino acids in the intestinal brush-border membrane. B°AT1 protein is expressed at the apical membrane of enterocytes in increasing amounts along the crypt-villus axis.
Previously, we showed that HNF1a and HNF4a bind to the Slc6a19 promoter up-regulating transcription. Sox9, by contrast, suppressed the promoter activity induced by HNF1a and HNF4a. Sox9 is a transcription factor known to be involved in the differentiation of stem cells into mature enterocytes, and is highly expressed in the crypt region, but absent at the villus tip. Thus Sox9 expression could explain the gradient of B°AT1 in the intestine. However, despite HNF1a and HNF4a expression in the liver, B°AT1 is not expressed, while Sox9 is absent. As a result we considered DNA methylation as a mechanism to regulate B°AT1 expression. DNA methylation of a transcription factor binding sites can prevent transcription factor from binding to the DNA.
Kikuchi et al (2010) suggested that HNF1a binding to the B°AT1 promoter could be prevented by methylation in the liver. However, they observed particular methylation in the liver at position -1080, which is 940 bp upstream of the HNF1a binding site.
In this study we investigated the DNA methylation status of the B°AT1 promoter, using bisulfate sequencing. DNA methylation was determined in a 1.2 kb region upstream of the B°AT1 transcriptional start site in liver, kidney and crypt-villus preparations. From each experiment a minimum 10 independent clones were sequenced. Twenty CpG sites were analysed and found to be differentially methylated in the chosen tissues.
We found that CpG dinucleotides around HNF1a, HNF4a and TATA binding sites were hypomethylated in the villus, whilst being hypermethylated in the crypt and in liver tissue.
These results indicate that DNA methylation might play a role together with Sox9 in the repression of B°AT1 expression in the crypt, whereas in the liver cells DNA methylation itself might be sufficient.

Impact of simvastatin on hepatic tissue in lipopolysaccharides treated rats

G. Ates[1], E. Ozkok[3], I. Aydin[2], H. Yorulmaz[4] and A. Tamer[1]

[1]Physiology, Istanbul University, Istanbul, Turkey, [2]Histology and Embyriology, Istanbul University, Istanbul, Turkey, [3]Neuroscience, The Institute for Experimental Medicine, Istanbul, Turkey and [4]School of Nursing, Halic University, Istanbul, Turkey

Motivation/problem statement: Sepsis is defined systemic inflammatory response syndrome (SIRS) after serious microbial infection. The liver is the main organ for bacterial scavenging, bacterial products inactivation, and inflammatory mediator clearance and production. Macrophages in liver can clear the endotoxin and bacteria that initiate the systemic inflammatory response. The hepatic dysfunction can be viewed as a primary dysfunction that occurs in the first hours after sepsis. Simvastatins are a class of drugs used to lower cholesterol levels by inhibiting the enzyme HMG-CoA reductase, also it has anti-inflammatory activities. We aimed to investigate effects of simvastatin on hepatic tissue in rats with Lipopolysaccharides (LPS).
Methods/procedure/approach: Following the approval of the ethical commitee male Wistar albino rats were used in this study. The rats were divided into four groups as control (n=10) LPS(n=10). Simvastatin (n=10), LPS+Simvastatin groups (n=10). Sepsis was induced by administration of LPS (E.coli O127:B8; 20 mg/kg, i.p) in anesthetized rats. After 4 hours, animals were taken experiment. Simvastatin was given (20 mg/kg, p.o.) for 5 days.At the end of the 5th days animals were decapitated. Histopathologic changes in the liver sections stained with hematoxylin and eosin in all groups.
Results: We seen large sinusoidal structure, degenerative lobule and cell membrane, increment of glycogen droplets and collagen in LPS and simvastatin groups in hepatic tissue sections, compared to control. In LPS+Simvastatin groups, tissue histology is as same as control's. Also hepatic tissue has normal sinusoidal and lobule structure, and glycogen droplets.
Conclusion/implications: The changes in the histologic structure of the liver were significantly affected by only treated simvastatin or LPS. Simvastatin administration in LPS treated animals improved to hepatocellular degeneration.

Acute sacral nerve stimulation in an animal model has no effect on motor function of the anal canal but elicits a profound potentiation of cortical sensory input from this region

L. Devane, J. Evers, R. O'Connell and J. Jones

University College Dublin, Belfield, Dublin, Ireland

Sacral nerve stimulation (SNS) has an established role in treatment of faecal incontinence, however the mechanism of action remains unknown. Our laboratory has previously shown that acute SNS augments somatosensory cortical potentials evoked by anal canal stimulation in a rat model (Griffin et al., 2011). The aim of this study is to examine the effect of acute SNS on motor function of the anal sphincters in the same animal model.

Eight virgin female Wistar rats were anaesthetised with urethane (1.5g.kg-1 i.p.). The combined force of the internal anal sphincter (IAS) and external anal sphincter (EAS) was measured using a force transducer, by mounting the distal 4-5mm of the anal canal as an isometric ring preparation in situ. A novel method was used to separate the EAS and IAS force recordings by stimulating the inferior rectal nerve (which supplies the EAS) at 1Hz. The frequency and amplitude of the slow waves of the IAS were also measured. Three minute recordings were taken before, during and after SNS at S1 [1ms pulses at 10Hz and at 0.5-1.1 Volts (just above motor threshold)]. A balloon was then inserted into the rectum and inflated with 0.3ml saline for 10 sec to evoke the recto-anal inhibitory (RAIR) and recto-anal excitatory (RAER) reflexes. Cortical evoked potentials were recorded in 8 rats as described previously. The results were analysed with repeated measures ANOVA. The criterion for statistical significance was $p<0.05$.

SNS did not have any significant effect on the IAS force ($p=0.135$), EAS force ($p=0.126$), slow wave frequency ($p=0.239$), slow wave amplitude ($p=0.999$), RAIR ($p=0.202$) or RAER ($p=0.268$). However the amplitude of cortical evoked potentials increased by a mean of 62% (SEM=16) after SNS.

The experiment suggests that SNS does not have a direct motor effect. From our current and previous study of anal canal cortical evoked potentials, it appears that the mechanism of action is through augmentation of sensory feedback to the cortex. These results reflect the clinical use of SNS as the current is delivered at the sensory (sub-motor) threshold.

Protective effects of *L. reuteri* on DSS-induced colitis in CX3CR1 deficient mice

D. Ahl[1], M. Qundos[1], S. Roos[2], M. Phillipson[1] and L. Holm[1]

[1]Medical Cell Biology, Uppsala University, Uppsala, Sweden and [2]Microbiology, Swedish University of Agricultural Sciences, Uppsala, Sweden

INTRODUCTION: Preliminary results from our laboratory suggest that two strains of the probiotic bacteria *Lactobacillus reuteri* (rat-derived strain R2LC and human-derived strain ATCC PTA 4659) ameliorate DSS-induced colitis in mice. The underlying mechanisms involved in this protection are not known, but a link to intestinal resident immune cells can be assumed. The chemokine receptor CX3CR1 is expressed by circulating monocytes and by intestinal lamina propria resident cells believed to be macrophages and/or dendritic cells. Mice deficient in CX3CR1 ($CX3CR1^{GFP/GFP}$) develop an aggravated DSS-induced colitis, suggesting a role of CX3CR1 in the maintenance of colonic homeostasis.

AIM: To investigate if the protective mechanism of *L. reuteri* R2LC or ATCC PTA 4659 involve CX3CR1, colitis was induced by DSS in $CX3CR1^{GFP/GFP}$ mice.

METHODS: Colitis was induced by 3% DSS in drinking water, administrated for 8 days to C57Bl/6 (wt) and $CX3CR1^{GFP/GFP}$ mice (C57Bl/6 background). Two groups from each strain were given *L. reuteri* R2LC or ATCC PTA 4659 by gavage once daily for 15 days in addition to DSS for the last 8 days. Disease severity was assessed through scoring of clinical symptoms (DAI, disease activity index) and histology scoring of H&E stained paraffin sections of distal colon. Multi-array measurements of the pro-inflammatory cytokines IL1-β, IL-6, TNF-α and mKC were also performed from colonic tissue samples.

RESULTS: DAI was significantly reduced the last day of DSS treatment in the groups of wt mice treated with either strain of *L. reuteri* (2.9±0.17 for DSS (n = 20), 1.8±0.18 and 1.4±0.30 for DSS+4659 (n = 16) and DSS+R2LC (n = 11) respectively, SEM values). In the $CX3CR1^{GFP/GFP}$ mice DAI increased slightly more by DSS than in the wt, and the *L. reuteri* strains did not significantly reduce DAI. The levels of all proinflammatory cytokines measured in colon tissue were significantly higher in DSS treated $CX3CR1^{GFP/GFP}$ mice than in wt. Treatment with either strain of *L. reuteri* significantly reduced all cytokines in wt and $CX3CR1^{GFP/GFP}$ mice, with the exception of IL1-β in the latter group. Preliminary histology scoring demonstrates reduced inflammation in all *L.reuteri* treated groups.

CONCLUSIONS: These results indicate that the protective role of the two different strains of *L. reuteri* on DSS-induced colitis is slightly reduced in $CX3CR1^{GFP/GFP}$ mice, compared to wt mice. Thus, the mechanism by which *L.reuteri* bacterial strains ameliorate colitis might involve CX3CR1. However, the possibility that the reduced protection by *L. reuteri* in the $CX3CR1^{GFP/GFP}$ mice is due to higher DAI and cytokine levels in these mice can not be excluded.

Ursodeoxycholic acid inhibits colonic mucosal cytokine release and prevents colitis in a mouse model of disease

J.B. Ward[1], O.B. Kelly[1,4], J. Ní Gabhann[2], S. Smith[2], M.M. Tambuwala[3], C.T. Taylor[3], F.E. Murray[4], C. Jefferies[2] and S.J. Keely[1]

[1]Molecular Medicine Laboratories, Royal College of Surgeons in Ireland, Dublin 9, Ireland, [2]Molecular and Cellular Therapeutics, Royal College of Surgeons in Ireland, Dublin, Ireland, [3]Conway Institute of Biomedical and Biomolecular Research, University College Dublin, Dublin, Ireland and [4]Gastroenterology, Beaumont Hospital, Dublin, Ireland

Toll-like receptors (TLR) promote cytokine release from intestinal epithelia, thereby driving inflammation. Although ursodeoxycholic acid (UDCA) is well known to exert anti-inflammatory effects in the liver, its potential for treating intestinal inflammation has not been well-studied. Here, we investigated UDCA effects on TLR-driven colonic mucosal cytokine release and induction of inflammation in a mouse model of colitis. Resected human colonic mucosa and T84 colonic epithelial cells were treated with specific TLR agonists (TLR3: Polyinosinic-polycytidylic acid, 25 μg/ml; TLR4: lipopolysaccharide (LPS), 100 ng/ml), in the presence or absence of UDCA. Released cytokines were measured by ELISA and luciferase reporter assays were performed in HEK293T cells. Dextran sodium sulphate (DSS) colitis was induced by administering DSS (2.5 %) in the drinking water of male C57BL/6 mice, along with daily intraperitoneal injections of UDCA (30 or 100 mg/kg) or vehicle for 5 days. Colitis severity was recorded as disease activity index (DAI) and by histological inflammation score. Results were analysed by ANOVA using Tukey multiple comparisons test and are expressed as the mean ± standard error of the mean. In T84 cells, UDCA (200 μM) attenuated TLR3-stimulated tumour necrosis factor α (TNFα) release from 32.9 ± 4.1 to 23.8 ± 3.7 pg/ml; interleukin-8 (IL-8) release from 1197.5 ± 110.1 to 923.8 ± 110.3 pg/ml and IL-1β release from 2.0 ± 0.2 to 1.6 ± 0.2 pg/ml ($n = 4$, $p < 0.05$). Apical LPS (6 hours) induced basolateral IL-8 secretion from human colonic mucosa from 435 ± 46 in unstimulated controls to 959 ± 22 pg/ml and caused a 3 fold increase in secretion of Regulated on Activation, Normal T cell Expressed and Secreted (RANTES); increases that were abolished by UDCA (250 μM) ($n = 3$, $p < 0.001$). Using NFκB and P125 luciferase reporter assays we determined that UDCA (200 μM) exerts its anti-inflammatory effects at the level of TANK-binding kinase 1 (TBK1) ($n = 5$, $p < 0.01$). In the DSS model of colitis, UDCA (30 mg/kg and 100 mg/kg) significantly reduced disease severity from a DAI of 10.0 ± 0.3 in mice treated with DSS alone to 7.2 ± 0.7 and 5.8 ± 0.5, respectively ($n = 6 – 12$, $p < 0.001$). Furthermore, histologically the inflammation score was also significantly reduced in UDCA (100 mg/kg)-treated animals to 24.3 ± 4.4, compared to 37.3 ± 0.8 in mice treated with DSS alone ($n = 4 – 6$, $p < 0.05$). In conclusion, our data show that UDCA prevents inflammation in a mouse model of colitis and that the protective effects of UDCA may be due to inhibition of TLR-induced proinflammatory cytokine release. These findings suggest that UDCA represents a good target for developing new therapeutic approaches to treat IBD.

Condenser-free Zernike phase contrast microscopy

K.F. Webb

Institute of Biophysics, Imaging & Optical Science, University of Nottingham, Nottingham, Notts, UK

Background
Biological samples tend to be low in intrinsic contrast to visible transmitted-light microscopy. The development of contrast-enhancing methods such as phase contrast during the 20th century allowed the investigation of highly transparent yet detail-rich specimens by exploiting differences in refractive index and optical path difference to produce interference between two beam paths emerging from the sample plane[1]. Phase contrast microscopy has gone on to become a ubiquitous technique in cell biology and physiology, yet the optical design has remained relatively unchanged over recent decades; consisting of a light source, collimating optics, phase annulus, and condenser producing a hollow cone of illumination which passes through the sample. On the detection side, phase contrast objective lenses introduce a complementary ring of phase-retarding and attenuating material to alter the phase relationship of the undeviated illumination with respect to light deviated by passage through the sample. By recombining these two beams onto the detector contrast is obtained by exploiting constructive and destructive interference on the basis of the phase shift induced in transiting the sample.
Method
Presented here is a modified version of Zernike phase contrast microscopy[1], in which condenser optics are entirely dispensed with yielding a condenser-free yet highly effective method of obtaining phase contrast in visible light microscopy. A ring of light emitting diodes is positioned within the optical light-path such that observation of the back focal plane of the objective places this ring, observed at virtual “infinity” with respect to the objective focal length, in appropriate conjunction with the phase ring to produce phase contrast.
Results
It is demonstrated that true phase contrast is obtained, whose geometry can be arbitrarily manipulated to provide a range of working distances and form factors. LED-ring phase contrast is demonstrated at phase position L, 1, 2, 3 and 4 across a range of magnifications and numerical apertures up to 100x and 1.4NA. LED phase contrast illumination is further implemented in conjunction with scanning ion conductance microscopy (SICM) to image a range of cultured cell lines; including ARPE-19, 3T3 fibroblast, and Caco-2 cells.
Conclusion
Condenser-free phase contrast microscopy using LED rings has significant potential to benefit physiology and cell biology by providing for arbitrary working distances in illuminating optics. By eliminating the need for a condenser assembly a range of concurrent imaging and measurement techniques will be technically facilitated through the provision of extra room to work. In addition the compact, low power, and versatile nature of LED illumination will further lend itself to miniaturisation and

modification of existing phase contrast microscopy schemas in the future.

A morphological assessment of the autophagosomal fusion process using superresolution structured illumination microscopy

B.-. Loos

Physiological Sciences, Stellenbosch University, Stellenbosch, Western Cape, South Africa

Autophagy is a major protein degradation system, which targets primarily long-lived cytoplasmic proteins. A large body of evidence indicates that impaired autophagy is implicated in the onset and progression of human pathologies such as heart disease, neuro-degeneration and cancer. Central to the functional role of autophagy is the successful fusion event of autophagosomes with lysosomes, forming and autophagolysosome. Although substantial progress has been achieved in understanding the molecular machinery of the autophagic pathway and its regulation, a fundamental challenge remains to identify the driving forces that govern the fusion event. This however requires a highly resolved detail that describes the fusion process morphologically. By utilizing superresolution structured illumination microscopy (RS-SIM) techniques, the aim of this study was to characterize the three-dimensional morphology of autophagosomes and lysosomes in single mammalian cells, and to assess the fusion region between these 2 organelles.

Rodent derived cardiac myoblast H9c-2 cells were grown in Dulbecco's Modified Eagle's Medium (DMEM) supplemented with 10% foetal bovine serum (FBS), and incubated under 5% CO2 conditions. The light-chain 3 (LC3) and lysosomal associated membrane protein (LAMP) were utilized as markers for autophagosomes and lysosomes respectively. Cells were transfected with 800 ng of the LC-3-GFP-DSred tandem plasmid, GFP-LC3 as well as LAMP-YFP using GenJuice® Transfection Reagent (Novagen®) according to the manufacturer's protocol. SR-SIM image acquisition and processing was performed on a LSM-780 Elyra system and z-stack image acquisition was utilized to capture both autophagosomes and lysosomes at high resolution in three dimensions. Surface rendering was performed to assess the fluorescence signal distribution.

This study reveals a highly heterogeneous morphological distribution of both autophagosomes and lysosomes, indicating the dynamic membrane turnover process during autophagosome and lysosome formation. Moreover, a morphologically highly complex fusion zone is observed. These data indicate a previously unknown complexity of membrane morphology and dynamics of both organelles. Importantly, this study highlights the strength of SR-SIM in deriving numerical geometrical data that allow the prediction and modelling of the likelihood for a complete or incomplete fusion event to take place. This approach provides insights that may result in novel means to exploit the autophagic machinery for therapeutic purposes.

The authors acknowledge Prof Tamotsu Yoshimori, Osaka University Graduate School of Medicine, Japan, for providing the tf-LC3, the GFP-LC3 as well as the LAMP-YFP plasmids. This work was supported by the National Research Foundation (NRF) and Medical Research Council (MRC), South Africa.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Na^+/H^+ exchangers are differentially involved in cell migration in the gastrointestinal cell lines RGM-1 and Caco2bbe

A. Klöpper[1], F. Busch[1], S. Yeruva[1], B. Riederer[1], G. Chodisetti[1], M. Menon[2], A. Schwab[3] and U. Seidler[1]

[1]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany, [2]Institute of Biochemistry, Hannover Medical School, Hannover, Germany and [3]Institute of Physiology II, University of Münster, Münster, Germany

Background: The Na+/H+ exchanger isoform 1 (NHE1) is believed to be essential for directional cell migration during wound healing and tumour invasiveness. However, in the intestinal epithelium, which displays very rapid cellular restitution of surface wounds, other NHE isoforms (NHE2, NHE3) are expressed far more strongly. **Aim and methods**: We studied the role of NHE isoforms 1, 2 and 3 on wound healing velocity in RGM1 cells, a nontransformed rat gastric surface cell line and in Caco2bbe cells, a well differentiating human colonic tumour cell line. Migration velocity was studied during growth factor-stimulated and low pH-stimulated as well as serum starvation-inhibited wound healing. To assess cell migration speed objectively, a fluorescent dye-based plate reader assay was used [1]. NHE1 and 2 were dose-dependently inhibited by HOE642 [2], whereas NHE1 and 3 were selectively inhibited by S1611 [3]. 5-(N,N-Dimethyl)amiloride (DMA) was used to inhibit Na+/H+ exchangers less specifically [4]. Stable NHE3 overexpression was performed in Caco2bbe cells, while lentiviral transient NHE2 overexpression was achieved in RGM-1 cells. **Results**: In confluent monolayers, RGM1 cells express NHE1 mRNA in far higher levels than other NHEs, whereas NHE2 mRNA expression is higher than NHE1 and NHE3 in Caco2bbe cells. Both cell lines displayed cell migration after experimental wounding even after serum starvation, where migratory speed was independent of NHE activity in either cell line. Fetal calf serum (FCS) significantly stimulated cell migration in a partly NHE1-dependent fashion in RGM-1 cells, but in a NHE-independent fashion in Caco2bbe cells. Preincubation at low pH also stimulated migratory speed in a NHE1-dependent fashion in both RGM-1 and Caco2bbe cells. NHE2 overexpressing RGM-1 cells migrated more slowly in the presence of FCS, and more so after low pH preincubation, which was reversed by pharmacological NHE2 inhibition. NHE3 overexpression as well as inhibition did not result in a change in migratory speed. DMA impaired cell migration more strongly than Na+/H+-exchange inhibition could account for, implying nonspecific effects of the amiloride analogue. **Conclusions**: Wound closure is possible even in the absence of NHE functional activity in gastrointestinal epithelial cells. Dependency of cell migration velocity on NHE1 varies among cell types. Low pH enhances cell migration in a NHE1-dependent fashion, whereas stimulation by growth factors is predominantly NHE1-independent. NHE2 slows cell migration speed. Therapeutic NHE inhibition for gastrointestinal malignancy is therefore likely to

have a highly variable effect on tumour invasiveness depending on the cell type.

Hyperactivation of UNC-105 causes loss of mitochondrial membrane potential and impaired mitochondrial ATP production in *C. elegans*

C.J. Gaffney, D. Constantin-Teodosiu, P.L. Greenhaff and N.J. Szewczyk

MRC/ARUK Centre for Musculoskeletal Ageing Research, University of Nottingham, Nottingham, UK

Background: *C. elegans* is a free-living nematode known for its utility in genomics research. A dominant gain-of-function mutation in *unc-105*, a putative mechano-sensitive ion channel of the ENaC/Degenerin family, causes mitochondrial fragmentation in body-wall muscles (Szewczyk *et al*. unpublished data) and a movement defect (1). These defects are ameliorated in *unc-105; let-2* suppressed mutants (*let-2* encodes a collagen).
Objectives: Mitochondrial membrane potential and maximal rates of ATP production (MRAP) were determined in wild-type (WT) and *unc-105* mutants to quantify disruption, if any, of mitochondrial function. The *unc-105; let-2* mutants were also assessed to quantify any potential rescue of mitochondrial function.
Methods: Mitochondrial membrane potential was quantified *in vivo* using JC-10 and Mitotracker® CMXRos, which reflect potential-dependent accumulation. JC-10 fluorescence was quantified using ImageJ. Membrane potential was also quantified in isolated mitochondria (n=10 assays of mixed-age worms; n≈300 per assay) using JC-1 and flow cytometry (2). MRAP and citrate synthase (CS) activity were also determined in similarly isolated mitochondria. MRAP was determined through incubation with a bioluminescent luciferase-based monitoring reagent, and a combination of respiratory substrates and ADP. All data were analysed using one-way ANOVA.
Results: Mitochondrial accumulation of JC-10 was reduced in *unc-105* versus WT (P <0.001), suggesting the loss of membrane potential in *unc-105* mutants *in vivo*. Similarly, Mitotracker® CMXRos accumulated *in vivo* in WT (P <0.01) and *unc-105; let-2* suppressed mutants (P <0.01), but not in *unc-105* mutants. In keeping with these *in vivo* observations, JC-1 accumulation in isolated mitochondria was 25% lower in *unc-105* than in WT and *unc-105; let-2* (P <0.001). MRAP were reduced in *unc-105* mutants vs. WT and *unc-105; let-2* suppressed mutants (Figure 1). The respiratory substrate combinations were glutamate and succinate (GS), palmitoyl-L-carnitine and malate (PCM), pyruvate and malate (PM), succinate (S) and glutamate and malate (GM). Data were normalised for CS activity to account for mitochondrial content. * P <0.05 vs. WT and † P <0.05 vs. *unc-105*.
Conclusion: *Unc-105* mutants showed evidence of disrupted mitochondrial membrane potential compared to WT, which was accompanied by impaired MRAP. In *unc-105; let-2* suppressed mutants, mitochondrial membrane potential and MRAP were similar to WT. Thus, as in mammalian cells (3), constitutive cationic influx leads to pathological changes in mitochondrial function in *C. elegans* muscle. These results establish that it is possible to use *C. elegans* to understand the genomic control of mitochondrial function.

Lipid peroxidation and antioxidant status in preeclampsia

R. Begum

Physiology, Enam Medical College, Dhaka, Dhaka, Bangladesh

Preeclampsia is the most common & major medical complication of pregnancy with a high incidence of national health problem & also responsible for high maternal & fetal morbidity & mortality1,2. In preeclampsia there is an abnormally increase in the lipid peroxidation in maternal blood and also in normal pregnancy3.4. But serum antioxidants are significantly decreased that lead to pathogenesis of preeclampsia5,6. For this, the study was undertaken to assess the lipid peroxidation product, serum Malondialdiehyde(MDA) & antioxidant (vitamin-E)levels in women with preeclampsia as well as in normal pregnancy.The study was conducted on 40 pregnant women(Group-B as study group) age ranged from 25 to 35 years in the Department of Biochemistry, Budi Kemuliaan Maternity Hospital(BKMH) in Jakarta in the year of 2006. The study group was further divided into B1-(normal pregnant women) & B2(preeclamptic patient).For comparison age matched 20 apparently healthy non pregnant women (Group-

A as control group)was also included in the study. The study subjects were selected from outpatient department (OPD) of Obstetrics & Gynaecology of BKMH in Jakarta. The ethical permission was taken from Ethical Review Committee of BKMH, Jakarta. Serum MDA (lipid peroxidation product) was measured by Thiobarbituric acid reactive substances assay (TBRAS) method & vit-E was estimated Spectrophotometrically. Data were analyzed statistically by ANOVA test among the groups and unpaired Students "t" test between the groups by using SPSS. The mean serum MDA levels were (1.23+ 0.5, 3.64 + 0.12, 7.28 +1.05 mmol/ml) and vitamin E levels were (7.43 +1 40, 5.75 + 1.24, 2.69 +0.17 micro mole/L) in group A, B1, and B2 respectively. However, MDA levels were significantly ($p<0.001$) higher in preeclampsia than those of normal pregnant women. Again the serum MDA levels were significantly ($p<0.001$) higher in both the study groups than that of non-pregnant control group. But the serum vit-E level were significantly ($p<0.001$) lower in preeclampsia than those of normal pregnant women as well as control group. This results revealed that lipid peroxidation is an important factor in the pathogenesis of preeclampsia. In preeclamptic patients serum antioxidants are excessively utilized to counteract the cellular changes mediated by free radicals7.

Effects of vitamin E on antispermatogenic activity of alcohol in male albino rats

C.O. Akintayo[1,2] and O.T. Olaniyan[2,1]

[1]Physiology, Bingham University, Karu Nasarawa state, Nigeria, Karu, Nasarawa, Nigeria and [2]Physiology, University of Ibadan, Ibadan, Ibadan, Nigeria

Several factors affect fertility, ranging from environmental factor, nutritional factor, toxins and the way of life. However, Alcohol is often associated with fertility disturbances with low sperm count and impaired sperm motility. The sertoli cell seems to be the first testicular cell injured as a result of alcohol exposure. However, chronic alcohol administration to male animals is often associated with testicular atrophy and gonadal failure. This study was designed to investigate the effect of vitamin E, a known antioxidant, on alcohol induced antispermatogenic action in male rats. Mature wistar rats(200-250g) were divided into: Group I (control) received 0.2ml of 0.9% normal saline, group II (received alcohol 0.003ml/g b.w as 40%v/v orally), group III (received alcohol 0.003ml/g b.w as 20% v/v orally), group IV (received alcohol 0.003ml/g b.w as 40%v/v + Vitamin E 100mg/kg b.w orally), and group V (received alcohol 0.003ml/g b.w as 20%v/v + Vitamin E 100mg/kg b.w orally). All animals were treated for 30 days. At the end of each experimental period, animals were sacrificed via cervical dislocation and organ weights, sperm characteristics, serum testosterone levels, and fertility were assessed. There was a significant reduction ($p<0.05$) in sperm motility, viability and of alcohol treated groups (sperm motility: 69.12±2.6, 57.70±3.07)compared with the control group(89.06±1.07) However, there was a recovery/reversibility of sperm motility in groups treated with alcohol with co-administration of vitamin E showed that vitamin E was able to ameliorate the effect produced by alcohol on sperm characteristics . There was a significant increase in organ weights (testis, heart, kidney and liver) of alcohol treated rats. However, the study showed that Vitamin E (100mg/kg b.w) administration was able to prevent the antispermatogenic action of alcohol.

Trophoblast signalling of DNA damage and cell death to hES cells in response to oxidative stress

A. Rogers and C.P. Case

University of Bristol, Bristol, UK

A variety of toxicants that cause oxidative stress can cause DNA damage across a placental like trophoblast barrier1. This damage at a distance does not occur because the toxicants, including metal ions, pass through the barrier. Instead it is mediated by intercellular signalling, involving ATP release and Ca wave propagation, culminating in the secretion of as yet unidentified molecules, which cause DNA damage in the cells beneath and separate from the barrier2. Here we have examined whether this transbarrier signalling in response to Co and Cr ion exposure above the barrier could cause damage to human embryonic stem cells (hESCs). hESCs (H9 cell line) were exposed to Co and Cr6+ (50:40 ppb Co:Cr) for 24h across a confluent barrier of BeWo cells (a trophoblast cell line). Mass spectrometry analysis confirmed that Co and Cr did not pass through the BeWo barrier. Values are means ± standard deviations, compared by students T test. DNA damage was significantly higher in exposed cells (EC) compared to control cells (CC) when assessed by comet assay (mean tail moment CC 1±0.28 Vs 2.27±0.4, P≤0.05) and staining for γ-H2AX (% cells with ≥4 foci CC 8.76±3.37 Vs 21±2.19 EC, P≤0.05). Cells with >4 γ- H2AX foci appeared in small clusters of neighbouring cells (3-10 cells per cluster) throughout exposed colonies. Addition of connexin mimetic peptide Gap26 to H9 cells prior to exposure partially rescued EC from DNA damage (% cells with ≥4 foci C 9.78±1.70 Vs EC 20.22±1.95, P≤0.01; EC 20.22±1.95 Vs EC + Gap26 15±1.20, P≤0.05) and reduced clustering (% clustered cells CC 5.06±1.38 Vs EC 23±2.07, P≤0.01; EC 23±2.07 Vs EC + Gap26 13.9±1.38, P≤0.01). Cell counts detected a significant decrease in viable, adherent cells following exposure (number of cells recorded in 12 fields of vision at X20 magnification CC 1914.67±190.18 Vs EC 1126.22±264.96, P≤0.001) concomitant to vastly increased TUNEL staining (n=9 control and 9 exposed populations). A similar loss is not seen in cells directly exposed to Co and Cr (DEC), although DEC do have increased DNA damage compared to unexposed control cells (UEC) (comet assay mean tail moment UEC 1±0.29 Vs DEC 5.44±0.13, P≤0.001). This suggests that the loss of EC is not secondary to DNA damage but is caused by the release of a signalling molecule from the barrier in response to Co and Cr exposure. Investigation of barrier conditioned media by ELISA has established TNF α as a potential candidate for cell death effects (absorbance at 450nm CC 0.009±0.008 Vs EC 0.023±0.003, P≤0.05 in one tailed test). This investigation has shown that hESCs may be damaged by exposure to metal ions through a trophoblast barrier. In addition, it has highlighted an important potential biological mechanism, whereby the trophoblast barrier between mother and fetus may secrete an apoptosis inducing signal to the embryo in response to oxidative stress.

Reduction of human placental taurine transporter activity is associated with compromised syncytiotrophoblast renewal

C. Hirst, S.L. Greenwood and M. Desforges

The Maternal and Fetal Health Research Centre, The University of Manchester, Manchester, UK

Pre-eclampsia (PE) is a serious disease of pregnancy affecting 4 million women/year. The disease etiology is complex but its origin lies in abnormal placental development and function. PE is associated with increased nitrative stress and abnormal renewal of syncytiotrophoblast (STB), the transport epithelium of human placenta. STB is renewed by cytotrophoblast cells (CTB) that proliferate, differentiate, and fuse with the multinucleated STB and this is balanced by apoptosis and shedding of aged nuclei. In non-placental tissues the amino acid taurine regulates proliferation, differentiation, and apoptosis. Taurine is accumulated in STB by the taurine transporter (TauT) and we have shown that TauT activity is significantly lower in PE compared to normal pregnancy[1]. TauT activity can be downregulated by nitrative stress and in PE those placentas with a lower TauT activity also had elevated nitrotyrosine expression, a marker of nitrative stress. Furthermore, generation of STB nitrative stress in vitro with SIN-1 reduced TauT activity by 14%[2].

Here we test the hypothesis that reducing placental TauT activity by nitrative stress alters CTB proliferation and apoptosis.

Placental villous explants from normal pregnancy were cultured for 7 days. On day 5 explants were treated with 1mM SIN-1 for 48hrs to reduce TauT activity. Immunohistochemistry was used to assess proliferation (detected by Ki67) and apoptosis (detected by M30: caspase-cleaved cytokeratin). The apoptotic index was calculated as the area of M30-positive staining expressed as a percent of total villous area using image pro plus software. To quantify proliferation explants were dual stained for ki67 and the CTB marker E-cadherin. Proliferation index was calculated as the number of cells positive for both ki67 and E-cadherin (i.e. proliferating CTB) expressed as a percent of the total number of E-cadherin positive cells (i.e. CTB). For each experiment, 8 fields of view were assessed and a mean calculated.

There was no difference in villous area or number of CTB between control and SIN-1 treated placental explants. SIN-1 treatment significantly reduced CTB proliferative index (Fig1) and significantly increased apoptotic index compared to controls (Fig2). Inspection of stained tissue sections showed morphological integrity was maintained throughout culture and secretion of hCG, an indicator of endocrine viability, was unaffected by SIN-1 treatment.

Nitrative stress reduces placental TauT activity[2], inhibits CTB proliferation and increases apoptosis. Future work will determine whether this abnormal STB renewal is a direct effect of nitrative stress or a result of reduced TauT activity. We propose that in PE placental TauT activity is reduced by nitration,

leading to altered CTB proliferation and apoptosis, resulting in abnormal renewal of the STB.

Mathematically modelling the system L amino acid exchanger in human placenta

K.L. Widdows[1], N. Panitchob[2], I. Crocker[1], S. Brooks[3], C. Please[3], E. Johnstone[1], B. Sengers[2], J. Glazier[1] and R. Lewis[3]

[1]Maternal and Fetal Health Research Centre, University of Manchester, Manchester, UK, [2]Bioengineering Research Group, University of Southampton, Southampton, UK and [3]University of Southampton, Faculty of Medicine, Southampton, UK

System L is a heterodimeric Na+-independent amino acid (aa) membrane transporter that mediates the transport of essential aa's. System L activity has been demonstrated in the microvillous (MVM) and basal (BM) plasma membranes of the human placental epithelial exchange barrier, the syncytiotrophoblast. System L transporters are thought to act as obligatory 1:1 aa exchangers, transporting one aa in exchange for another. However, other modes of carrier-mediated transport are implicated; system L substrates can be transported across MVM and BM under zero-trans conditions, without exchangeable aa. This led to our hypothesis that system L-mediated transport may not occur solely via an obligatory exchange mechanism. To investigate this, we applied an integrated mathematical modelling approach to predict how transport of serine (Ser), a system L substrate, would behave under theoretical models of transport.

Mathematical predictive models of obligatory aa exchangers, along with facilitated transport, were developed based on assumptions of carrier-mediated transport. Exchanger transporters were assumed to bind aa to confer 1:1 transport across the plasma membrane, whilst facilitated transport was assumed to be driven by the transmembrane aa gradient. The model predicted that for an exchanger together with a facilitated (slower rate) transport component, an outwardly directed substrate gradient would lead to an overshoot of substrate accumulation above tracer equilibrium concentration (Fig 1A).To test the models, we measured uptake of 7.5μM ^{14}C-Ser (tracer) into MVM vesicles isolated from normal term placentas, in vesicles preloaded with 250μM (equal to extravesicular Ser concentration) or 1mM Ser (outwardly directed substrate gradient). Uptake of ^{14}C-Ser mediated by system L was taken to be that inhibitable by 20mM 2-amino-2-norbornanecarboxylic acid (BCH), a system L substrate.

In the presence of equal intravesicular and extravesicular Ser (250μM), ^{14}C-Ser accumulated in a time-dependent manner to reach tracer equilibrium concentration (7.5μM; assuming an intravesicular volume of 1 μl/mg protein) by 10min, indicating uptake of ^{14}C-Ser in the absence of a transmembrane substrate gradient. However, an outwardly directed substrate concentration gradient evoked a rapid overshoot of ^{14}C-Ser accumulation above tracer equilibrium concentration, which was abolished by BCH (Fig 1B). These observations suggest trans-stimulation of system L activity showed good correspondence to model predictions with both an exchanger and facilitated transport component, suggesting system L activity in MVM vesicles is mediated by both components, although their molecular identities remain to be determined. This study emphasizes the utility of mathematical modelling in predicting aa modes of transport, providing an improved quantitative understanding of placental aa transporter mechanisms.

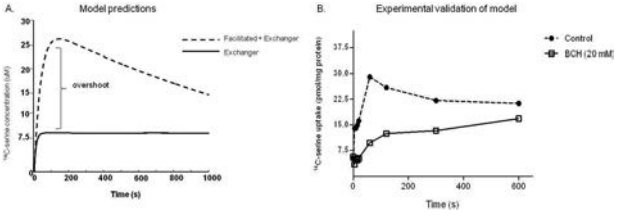

Figure 1. Experimental validation of model predictions for system L activity in MVM. (A) Modelling either exchanger activity (solid line) or exchanger with facilitated transporter (dashed line) predicts tracer accumulation to equilibrium (7.5μM) or overshoot above equilibrium, respectively. (B) Testing this model experimentally in MVM vesicles demonstrated good correspondence to the exchanger plus facilitated model with overshoot (dashed line), which was abolished by BCH (solid line). This suggests the presence of both an exchange plus facilitated transport component mediating serine transport across MVM in the human placenta

The expression of facilitated amino acid transporters in the human choriocarcinoma BeWo cell line

C. Simner[1], N.C. Harvey[2], K.A. Lillycrop[3], R.M. Lewis[1] and J.K. Cleal[1]

[1]Institute of Developmental Sciences, University of Southampton, Southampton, UK, [2]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, UK and [3]Centre for Biological Sciences, University of Southampton, Southampton, UK

Amino acids are vital for fetal growth, and must be supplied by the mother via the placenta. Previously we have shown that the facilitated amino acid transporters TAT1 (slc16a10), LAT3 (slc43a1) and LAT4(slc43a2) mediate efflux of specific amino acids from the placenta into the fetal circulation. TAT1 and LAT3 mRNA levels in human placentas are related to measures of fetal growth whereas LAT4 mRNA levels are affected by maternal nutritional status. It is now important to establish how these transporters are regulated. This study aimed to establish whether the human choriocarcinoma, BeWo, cell line is a suitable model for investigating the regulation of facilitated amino acid transporters.

BeWo cells were cultured in 35 mm diameter 6 well plates at 37C (5% CO2) in DMEM/Ham F-12K nutrient mix supplemented with 10% fetal bovine serum and 1% penicillin/streptomycin. At 70-80% confluence cells were harvested for RNA and protein extraction. Total RNA was extracted (Ambion mirVanaTM miRNA isolation kit) and reverse transcribed into cDNA. PCR was carried out on BeWo cDNA (n=3) with specific primers to detect the expression of TAT1, LAT3 and LAT4 transcripts. Western blotting was carried out to detect the protein expression of TAT1 and LAT4 (LAT3 not tested). BeWo preparations (45 μg protein, n=3) were run on SDS-PAGE gels and transferred to PVDF membranes. Blots were incubated with rabbit anti-TAT1 or anti-LAT4 primary antibody then goat anti-rabbit-HRP secondary antibody. Immunoreactive signals were visualized using enhanced chemiluminescence.

The presence of TAT1, LAT3 and LAT4mRNA in BeWo cells was confirmed by PCR. The presence of TAT1 and LAT4 proteins in BeWo cells was confirmed by Western blotting demonstrating antibody specific bands which were not present in the negative control. Immunoblotting for B-actin on each blot indicated similar protein loading in each lane.

BeWo cells are placental in origin and commonly used to study human placental function. BeWo cells express the facilitated amino acid transporters at both the mRNA and protein level as seen in human placental tissue. They may therefore provide a useful model for studying the regulation of the facilitated amino acid transporters TAT1, LAT3 and LAT4 in the placenta.

The effect of adenovirus-VEGF gene therapy on placental nutrient transport mechanisms in an ovine model of intrauterine growth restriction

J. Naftel[1], D.J. Carr[2], R.P. Aitken[3], J.S. Milne[3], J.M. Wallace[3], A.L. David[2], L.R. Green[1] and J.K. Cleal[1]

[1]Institute of Developmental Sciences, University of Southampton, Southampton, UK, [2]Institute of Woman's Health, University College London, London, UK and [3]The Rowett Institute of Nutrition and Health, University of Aberdeen, Aberdeen, UK

Intrauterine growth restriction is a major cause of perinatal mortality and morbidity. Injection of an adenovirus (Ad) vector containing the vascular endothelial growth factor-A165 (VEGF-A165) gene into the uterine arteries increased growth velocity and birth weight (trend) in growth restricted fetal sheep (1,2). Ad.VEGF-A165 treatment increased mRNA levels of the VEGF receptor FLT1/KDR in maternal but not fetal placental tissues and placental efficiency near term (trend) (1,2). We measured late gestation placental expression of genes regulating growth (insulin-like growth factor receptor 1, IGF-1R), lipid handling (lipoprotein lipase, LPL) and amino acid transport (TAT1) in normal and growth-restricted pregnancies with and without Ad.VEGF-A165 treatment. Single embryos (from superovulated single sire inseminated donor ewes) were transferred into adolescent recipient ewe uteri under general inhalational anaesthesia (isoflurane in O2/NO). Recipients were fed control (C n=12) or high (H n=45) intake of complete diet from 4-131 days' gestational age (dGA term=145dGA) to induce normal and restricted fetal growth, respectively (3). At 89dGA under general anaesthesia (induction with propofol IV then as above) both uterine arteries were injected with 5x1011 particles of Ad.VEGF-A165 (H-Ad.VEGF, n=18) or control vector Ad.LacZ/control saline (H-Ad.LacZ/saline, n=27; C-saline, n=12). At 131dGA ewes were killed (pentobarbitone overdose IV). RNA was extracted from separated fetal and maternal placental compartments (frozen at -80C) and real-time quantitative PCR was performed to measure mRNA levels of LPL, TAT1 and IGFR-1 (normalised to GAPDH and βactin geometric mean). Data are mean±SEM and were analysed by two-way ANOVA (placental compartment and group [C-saline; H-Ad.VEGF; H-Ad.LacZ/saline]) then Least Squares Difference correction. Regardless of placental side TAT1 and LPL mRNA levels were lower in H-Ad.VEGF compared to H-Ad.LacZ/saline (TAT1, 0.54±0.08 vs. 0.75±0.06, P=0.02; LPL, 0.77±0.09 vs. 0.97±0.07, P=0.06) and compared to C-saline (TAT1, 0.54±0.08 vs. 0.76±0.09, P=0.07; LPL, 0.77±0.09 vs. 1.03±0.10, P=0.06). Regardless of group LPL, IGFR-1 and TAT1 mRNA levels were greater in the fetal compared to maternal placental side (LPL: 1.22±0.07 vs. 0.66±0.07; IGFR-1: 1.19±0.07 vs. 0.99±0.07; TAT1: 1.24±0.07 vs. 0.13±0.06; P <0.05). These data suggest that increased fetal growth velocity following Ad.VEGF-A165 is independent of altered IGFR-1 gene expression. Decreased TAT1 and LPL gene expression following Ad.VEGF-A165 is unexpected but may reflect complex amino acid and lipid transport regulation in these animals which requires further molecular analysis. Higher expression of genes related to nutrient transfer in the fetal-facing placental portion may indicate membrane specific placental nutrient transport mechanisms.

Effects of avian influenza virus (H5N1) on cytokine and chemokine gene expression in human respiratory epithelium

N. Huipao[1], S. Hiranyachattada[1], S. Borwornpinyo[2], A. Thitithanyanont[3], C. Pholpramool[4], D. Cook[5] and A. Dinudom[5]

[1]Physiology, Prince of Songkla University, Hat Yai, Songkhla, Thailand, [2]Biotechnology, Mahidol University, Ratchathewi, Bangkok, Thailand, [3]Microbiology, Mahidol University, Ratchathewi, Bangkok, Thailand, [4]Physiology, Mahidol University, Ratchathewi, Bangkok, Thailand and [5]Physiology, University of Sydney, Camperdown, NSW, Australia

One important feature of influenza A/H5N1 immunopathogenesis is the appearance of hypercytokinemia (cytokine storm) which is characterized by the extreme production and secretion of large numbers and excessive levels of pro-inflammatory cytokines. H5N1 targets specific host cells, i.e., bronchiolar cells, macrophages and type 2 alveolar pneumocytes. These cells, but not those in the tracheal or the upper path of the respiratory tract, express the α2-3 sialic acid receptors, the binding site for H5-hemagglutinin. It has been reported that H5N1 infection induced the production of TNF-α, IP-10, IL-6 and IFN-β in human alveolar and bronchial cells. Recent data, however, suggest that H5N1 can also induce cytokine release via an infection-independent mechanism. This study aimed to investigate the mechanism by which H5N1 triggers expression of cytokines/ chemokines in the respiratory epithelium. Expression of the mRNAs of interest in 16HBE14o cells treated with inactivated-H5N1 was analyzed by quantitative RT-PCR. Our results showed that the inactivated-H5N1 increased mRNA expression of IL-6 and IL-8 but not of TNF-α, RANTES and IP-10. Since cytochalasin D treatment, which disrupts actin cytoskeleton and, hence, inhibits endocytotic uptake of the virus, had no effect on the effect of the inactivated-H5N1 on cytokines mRNA expression, this effect of H5N1 did not require the presence of the virus particles in the cytosol. Cytokines production can, therefore, be initiated by an interaction between H5N1 capsule and surface membrane of the respiratory epithelial cells. The underlying mechanism by which H5N1 generates this infection-independent effect on cytokine production is currently under investigation.

Characterisation of genetically disrupted strains of *Staphylococcus aureus* shows that sugar transport is important for apical growth in an airway-bacterial co-culture model

D. Braun[1], J.P. Garnett[1], A.J. McCarthy[2], J.A. Lindsay[2], E.H. Baker[1] and D.L. Baines[1]

[1]Biomedical Science, St Georges, University of London, London, UK and [2]Clinical Sciences, St Georges, University of London, London, UK

Glucose concentration in the airway surface liquid (ASL) is normally lower than blood (~0.4mM compared to ~5mM). We developed an in vitro model of airway glucose homeostasis and showed that, normally, glucose diffuses from blood/interstitial fluid across the respiratory epithelium into the ASL via paracellular pathways, and this is limited by epithelial permeability, glucose uptake and metabolism. In this model, increasing the diffusion gradient for glucose across the epithelium (e.g. hyperglycaemia) elevated glucose in ASL [1, 2].

Sugars (glucose and fructose) are known to promote the growth of *S. aureus* [3]. The growth of *S. aureus* on the apical surface of an in vitro model of human airway epithelium (H441) was significantly increased by elevating basolateral glucose concentration from 10mM to 20mM or 40 mM (colony forming units; cfu increased by 155±49% or 392±105%, $p<0.05$ and $p<0.001$, respectively, n=9). Furthermore, there were significantly more bacteria post infection in the airways of an in vivo mouse model of diabetes (db/db) (4611±995 bronchoalveolar lavage; BAL cfu) than wild type mice (950±293 BAL cfu, $p<0.001$, n=9).

To confirm that *S. aureus* utilised sugars that diffused across the epithelium into ASL, we obtained several *S. aureus* JE2 derived strains from the Nebraska Transporon Mutant Library which contained genetically disrupted genes associated with sugar transport. We firstly characterised the effect of these mutations on growth in the presence of sugars. Addition of either fructose (10 mM) or glucose (10 mM) significantly increased the growth of the parent strain (JE2) (measured as log10 OD600) at 8 hours ($p<0.001$, n=3, respectively). Glucose (10 mM) promoted the growth of all *S. aureus* strains, although two strains, NE1944 and NE172, with mutations in the glucose specific domain of the phosphoenolpyruvate-dependent sugar phosphotransferase system (PTS), exhibited mildly reduced growth at 8 hours ($p<0.05$, n=3). NE768 a strain in which the fructose specific permease had been disrupted, exhibited significant growth inhibition in the presence of fructose compared to glucose ($p<0.001$, n=3) consistent with an inability to utilise fructose to support its growth. Comparison of sugar induced JE2 and NE678 growth in bacterial epithelial co-culture showed that basolateral fructose increased apical JE2 but not NE678 growth at 7 hours ($p<0.05$, n=5).

These data provide new evidence that fructose in addition to glucose diffuses across the airway epithelium and is utilised by *S. aureus* as a substrate for growth. This provides a proof of concept for *S. aureus* utilisation of glucose in ASL. Our data also indicate that pathways for glucose uptake in *S. aureus* are more complex and may involve multiple mechanisms.

2,6-bis-4-(hydroxyl-3-methoxybenzylidine)-cyclohexanone (BHMC) prevents allergic airway inflammation in ovalbumin-sensitized mice

C. Tham[1], K. Lam[2], N. Md[3], M. Sulaiman[1] and D. Israf Ali[1]

[1]Biomedical Science, Universiti Putra Malaysia, UPM Serdang, Malaysia, [2]Faculty of Pharmacy, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia and [3]Scientific Chairs Unit, Taibah University, Madina, Saudi Arabia

Asthma is affecting approximately 300 million people worldwide with 250,000 annual deaths. The marked increase in the global prevalence of asthma is likely to continue over the next two decades. Over the years, corticosteroids remain the mainstay in the treatment of asthma despite recently raised issues regarding safety and lack of responsiveness in 5-10% of asthmatic individual. Therefore, there is an urgent need in the search of more effective and safer treatment for patients with allergic asthma which is associated with increased pulmonary inflammation and airway hyperresponsiveness. A novel curcuminoid derivative, 2,6-bis-4-(hydroxyl-3-methoxybenzylidine)-cyclohexanone (BHMC) has been designed and synthesized as a non-steroidal anti-inflammatory agent in our previous study. BHMC has been proven to inhibit the synthesis of pro-inflammatory mediators in macrophages, restores endothelium dysfunction and decreases mortality in septic mice through specific disruption on p38 MAPK enzymatic activity. Recent preliminary research findings further demonstrated potential anti-inflammatory effects of BHMC in both acute and chronic models of inflammation in rodents. The present study addressed the effects of BHMC on allergic airway inflammation in an acute murine model. Mice were sensitized with ovalbumin (OVA) and treated with various doses (0.1, 1 and 10 mg/kg) of BHMC intraperitoneally. Respiratory function was measured whereas bronchoalveolar lavage fluid (BALF), blood and lung tissue were collected. Treatment with BHMC significantly attenuated airway hyperresponsiveness, number of inflammatory cells in BALF and infiltration of inflammatory cells into the airways. These observations were further strengthened by the findings that BHMC inhibited production of Th2 cytokines and goblet cells hyperplasia without reducing the level of total IgE in peripheral blood serum. Collectively, the preventive effects of BHMC on acute allergic inflammation open further avenue of research and development of a synthetic non-steroidal small molecule, BHMC, as an additional option of currently available anti-asthma therapies.

Serum levels of antioxidants enzymes glutathione peroxidase (GPx) and cupper zinc superoxide dismutase (Cu Zn SOD) in Sudanese asthmatics and their relationship with the severity of asthma

M.M. Sherief[1], A.H. Yousif[2] and A.M. Saeed[2]

[1]Physiology, International University of Africa Faculty of Medicine and Health Sciences, Khartoum, Khartoum, Sudan and [2]University of Khartoum Faculty of Medicine, Khartoum, Sudan

Asthmatic patients tend to have increased oxidative stress caused by imbalance between oxidants and antioxidants. Changes in the level of antioxidant enzymes, Cu Zn SOD and GPx may play an important role in the development and progression of asthma. It was hypothesized that asthmatic individuals with higher level of oxidative stress may have greater loss of these enzymes, which would be reflected clinically by development of severe asthma. The abnormalities in redox are magnified in asthmatic airways in response to exacerbating factors (1). In this study we aimed to investigate the role of oxidative stress in asthma by determining serum levels of Cu Zn SOD and GPx in patients with asthma compared to healthy individuals. Furthermore, to find out whether the acute attack or severity of asthma would change the serum levels of these enzymes. Serum Cu Zn SOD and serum GPx concentrations were measured in 96 asthmatic adult patients and 55 healthy control subjects matched for age and sex. The patients were recruited from asthma clinics and wards of two tertiary referral hospitals: Al shaab and Omdurman teaching hospitals in Khartoum State. Guided by the GINA classification of asthma, patients were grouped according to asthma severity to mild and severe and according to existence of symptoms to symptomatic and asymptomatic(2). Serum Cu Zn SOD and serum GPx concentrations were measured in these patient groups. Concentrations of serum were measured using ELIZA kits assay according to instructions of manufacturers. Mean serum GPx was found significantly decreased in patients compared with controls (247.24μ/l in patients and 302.42μ/l in controls and P = 0.001). Mean serum Cu Zn SOD was found lower in cases than controls (86.5μg/l in patients and 87.6μg/l in controls). Mean serum Cu/Zn SOD of mild and severe stable cases was 80.64μg/ml and 98.21μg/ml respectively. Mean serum Cu/Zn SOD in symptomatic and asymptomatic was 84.95μg/ml and 102.78μg/ml respectively. Mean serum Gpx of mild and severe was242.14μg/ml and 258.43μg/ml respectively. Mean serum Gpx in symptomatic and asymptomatic was 213.μg/ml and307.73 μg/ml respectively. These findings revealed oxidative stress exists in asthmatic patients showed by deficiency of the antioxidant enzymes compared to controls. Also, their levels decreased during the acute attack compared to the steady state. Control of oxidative stress at the appropriate time with the proper methods is mandatory for effective management of asthma

Fig 2: Mean serum level of Superoxide dismutase (Cu Zn SOD) and Glutathione Peroxidase (Gpx1) in ug/ml in cases and controls

Elevated glucose flux across cystic fibrosis airway epithelium is an important factor for *Pseudomonas aeruginosa* growth in airway epithelial co-culture

J.P. Garnett[1], R. Tarran[2], M.A. Gray[3], M. Brodlie[3], E.H. Baker[1] and D.L. Baines[1]

[1]Division of Biomedical Sciences, St George's, University of London, London, UK, [2]Department of Cell Biology and Physiology, University of North Carolina, Chapel Hill, NC, USA and [3]Institute for Cell and Molecular Biosciences, Newcastle University, Newcastle, UK

The airway epithelium is covered by a thin layer of surface liquid (ASL), which is vital for maintaining the sterility of the respiratory tract. The glucose concentration of the ASL (~0.4mM) is much lower than that in blood and is tightly regulated by the airway epithelium (1). ASL glucose is elevated in patients with cystic fibrosis (CF; ~2mM) and is associated with increased incidence of respiratory bacterial infection (2). The aim of this study was to compare the effect of *P. aeruginosa* on the mechanisms governing airway glucose homeostasis in polarized monolayers of CF and non-CF primary human bronchial epithelial (HBE) cells. In addition, Calu-3 monolayers were used to evaluate the potential importance of glucose on *P. aeruginosa* growth, in comparison to other hallmarks of the CF ASL, namely mucus hyper-viscosity and reduced bicarbonate content/acidic pH (3).

The addition of *P. aeruginosa* filtrate to HBE monolayers reduced transepithelial resistance and was associated with an increase in paracellular permeability of glucose, as well as enhanced glucose-uptake. The increase in paracellular glucose flux was much greater across CF HBE monolayers (145±28%) compared to non-CF (56±23%, $p<0.05$, n=3) and was associated with elevated *P. aeruginosa* growth. No difference in glucose uptake was observed between non-CF and CF monolayers ($p>0.05$, n=4). Increasing the basolateral glucose concentration from 5 to 15mM resulted in a 54±12% increase in *P. aeruginosa* growth on the apical surface of HBE monolayers ($p<0.05$, n=3) and a 76±16% increase on Calu-3 monolayers ($p<0.01$, n=7), after 6 hours of co-culture. Removal of bicarbonate from the bathing solution (replaced with HEPES) led to elevated bacterial growth (by 109±7%, $p<0.01$, n=3) and the pH of the surface fluid was also more acidic (7.06±0.03 compared to 7.43±0.03 using bicarbonate; $p<0.01$, n=3). *P. aeruginosa* growth was significantly reduced by 57±18% following the addition of the cAMP-agonist forskolin (5μM, $p<0.05$, n=3) and this was associated with an alkalinisation in fluid pH to 7.51±0.01, (in bicarbonate-buffered solution; $p<0.05$). In both cases, elevating basolateral glucose increased apical bacterial growth. The presence of a thick mucus layer across Calu-3 monolayers also increased *P. aeruginosa* numbers by 84±13% ($p<0.05$, n=3). Similarly, under these conditions raising basolateral glucose enhanced the growth of the bacterium by 53±8% ($p<0.05$, n=3).

These results indicate that *P. aeruginosa* induced an elevated glucose leak across the CF epithelium compared to non-CF. In addition, elevating glucose increased *P. aeruginosa* growth over and above the effects of pH/bicarbonate and mucus. Together these studies highlight the potential importance of glucose in promoting *P. aeruginosa* growth and respiratory infection in CF and CF-related diabetes.

Oscillations in airway surface liquid pH and pCO2 enhance antimicrobial activity

D. Kim[1,3], J. Liao[1], N.B. Scales[1], M.L. Palmer[2], R. Robert[1], S.C. Fahrenkrug[2], S.M. O'Grady[2] and J.W. Hanrahan[1,3]

[1]Physiology, Mcgill University, Montreal, QC, Canada, [2]Physiology, Univeristy of Minnesota, St Paul, MN, USA and [3]Groupe d'étude des protéines membranaires, Montreal, QC, Canada

A microscopic layer of secreted fluid covers the airways and provides the first line of defense against inhaled pathogens. Depletion of this airway surface liquid (ASL) in cystic fibrosis (CF) disrupts mucociliary clearance and leads to chronic infections by Pseudomonas aeruginosa and other bacteria. Epithelial bicarbonate secretion is also reduced in CF, resulting in a decrease in pH that may promote infection in CF pig airways, although it remains uncertain whether the measured reduction from pH 7.14 to 6.96 inhibits antimicrobial activity significantly. We found that Pseudomonas is sensitive to alkaline pH in pure solutions when pH is elevated by a decrease in luminal pCO2 or increase in HCO3- concentration. Computer simulations suggested that CO2, which varies between 0.035% during inspiration and 5% during expiration, may equilibrate with ASL. To test this experimentally we studied thin layers of liquid placed on monolayers of fixed Calu-3 cells, a human airway epithelial cell line Calu-3. BCECF-dextran microfluorimetry was used to measure surface liquid pH, a computer-controlled gas mixing pump was used to generate pCO2 oscillations that simulate tidal breathing, and pCO2 was mon-

itored using a fast response CO2 analyzer. Physiological pCO2 oscillations caused the surface pH to vary by ~1.5 units, with pH reaching maximal values of pH 8.7 - 9.2 depending on HCO3- concentration. Similar values were observed under steady-state conditions when secretions were equilibrated with 5% CO2 (7.42± 0.11, mean ± s.d., n=8) or room air (9.2 ± 0.14; n=7). The antimicrobial effect of oscillating pH was assessed by comparing by counting colony forming units on agar plates after exposure to physiological CO2 oscillations or various (constant) pCO2 levels for 1, 3, or 6 hours at 37oC. The number of viable bacteria increased 3-fold after 6h exposure to 5% CO2 but not 2.5% CO2, presumably due to moderate elevation of the pH. Oscillations between 5% and 0.035% were also bacteriostatic when secretions were collected from unstimulated Calu-3 cells. Importantly, 90% killing was observed if fluid was collected from forskolin-stimulated control Calu-3 cells, but not if fluid was collected from CFTR knock-down cells. Similar results were obtained using other HCO3- secretagogues (VIP, cpt-cAMP) and with mucoid and non-mucoid strains of Pseudomonas. We conclude that HCO3- allows rapid, transient alkalinizations during physiological variations in pCO2. Bacteria are sensitive to alkaline pH, and this sensitivity is enhanced by pCO2 oscillations and by stimulated HCO3- secretion. These results provide the first evidence for dynamic alterations in airway surface pH and help clarify the role of CFTR and bicarbonate secretion in airways host defense.

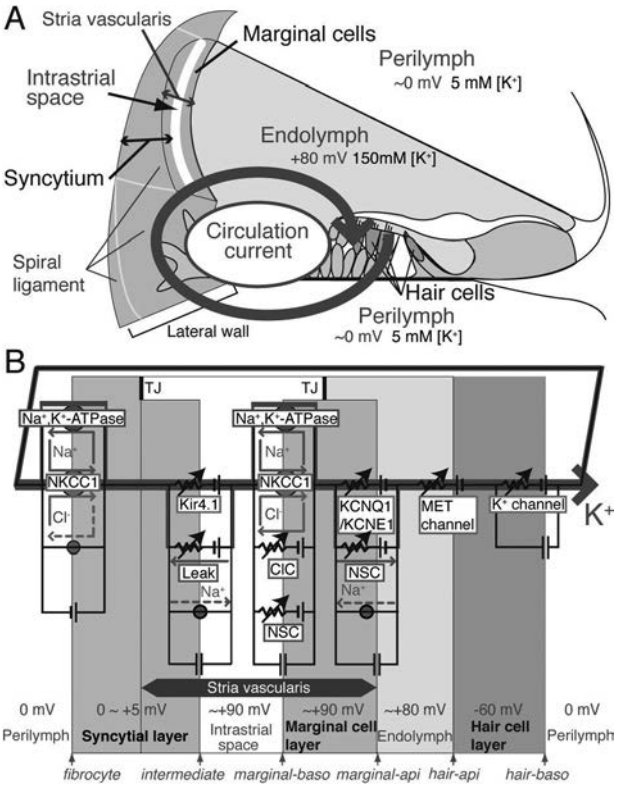
Computational model of a circulation current that controls electrochemical properties in the mammalian cochlea

F. Nin[1,2], H. Hibino[1], S. Murakami[2] and Y. Kurachi[2]

[1]Molecular physiology, Niigata university, Niigata, Japan and [2]Molecular and cellular pharmacology, Osaka university, Osaka, Japan

Sound-evoked mechanical stimuli permit endolymphatic K^+ to enter sensory hair cells. This transduction is sensitized by an endocochlear potential (EP) of +80 mV in endolymph. After depolarizing the cells, K^+ leaves hair cells in perilymph, and it is then circulated back to endolymph across the lateral cochlear wall. In theory, this process entails a continuous and unidirectional current carried by apical K^+ channels and basolateral K^+ uptake transporters in both the marginal cell and syncytial layers of the lateral wall. The transporters regulate intracellular and extracellular [K^+], allowing the channels to form K^+ diffusion potentials across each of the two layers. These diffusion potentials govern the EP. What remains uncertain is whether these transport mechanisms accumulating across diverse cell layers make up a continuous circulation current in the lateral wall and how this current might affect the characteristics of the endolymph. To address this question,we developed an electrophysiological model that incorporates channels and transporters of the lateral wall and channels of hair cells that derive a circulation current. The simulation replicated normal experimental EP values and reproduced experimentally measured changes in the EP and intra- and extracellular [K^+] in the lateral wall when different transporters and channels were blocked. The model predicts that, under these different conditions, the circulation current's contribution to the EP arises from different sources. Finally, our model also accurately simulated EP loss in a mouse model of a chloride channelopathy associated with deafness.



Key elements of the NHK(Nin-Hibino-Kurachi) model. (A) Structure of the cochlea and the concept underlying the circulation current. The circulation current (arrow) unidirectionally flows through a pathway comprising the endolymph, hair cells, perilymph, and lateral cochlear wall, and it flows back to the endolymph. In normal conditions, this flow would be carried by K^+. (B) The electrical circuit and its components used in the modeling. The channels and transporters that are involved in driving the circulation current as well as the potential in each compartment are described. The fibrocytes belong to the spiral ligament (A). The stria vascularis contains three cell types: basal cells, intermediate cells, and marginal cells. Basal cells, which are omitted in this scheme, are apposed to the fibrocytes and intermediate cells.

The role of interleukin-6 in gastrointestinal contractile activity in a mouse model of Duchenne Muscular Dystrophy

J. Manning and D. O'Malley

Physiology, University College Cork, Cork, Ireland

Introduction: Duchenne Muscular Dystrophy (DMD) is characterised by severe progressive wasting of skeletal muscle and a shortened life expectancy of between 20-30 years. Deficiency of the protein dystrophin, results in progressive necrosis, muscle fibre degeneration and a chronic inflammatory response. The pro-inflammatory myokine, interleukin-6 (IL-6), is elevated in patients with DMD. Dystrophin is absent from smooth muscle cells; and a little-reported symptom of DMD is altered gastrointestinal (GI) function. Patients suffer from bloating, constipation and in more severe cases, acute gastric dilation and intestinal pseudo-obstruction.

The aims of this study are to investigate IL-6 and the stress hormone, corticotropin-releasing factor (CRF) in mdx mice to determine if elevation of IL-6 and possible interactions with CRF are associated with changes in (GI) physiology.

Methods: Morphology was investigated in transverse sections (10μm) of colon stained with Haematoxylin & Eosin. Diameter and thickness of the mucosal and muscular layers were scored. Whole colon sections taken from wildtype (WT) and mdx (C57BL/10ScSn-Dmdmdx/J) mice (10 weeks old) were suspended in organ baths to compare contractile activity under basal conditions and following stimulation with IL-6 (200nM) and/or CRF (200nM).

Results: Histological investigations determined that mdx mice exhibit a thickened muscular layer (141±7.918μm, n=4) as compared to WT mice (95.26±7.494μm, n=4, $p<0.001$). The mucosal layer and colonic diameter was unchanged from WT mice.

To assess if the thickening of the muscle translated into changes in contractile activity, excised colon was suspended in organ baths and stimulated to evoke contractile response. Carbachol (500nM, 20 mins) was added to the bath to evoke a maximal response. No significant difference was observed between the strains (n=6). Thus, responses to IL-6 and/or CRF were normalised to the carbachol response. IL-6 stimulated a six-fold greater contractile response in mdx (172.6± 66.48%, n=6, $p<0.05$) as compared to WT (30.39± 6.512%, n=7) mice. Pre-incubation of the tissue with the Na+ channel blocker, tetrodotoxin (TTX, 250nM) attenuated this response in mdx mice (26.14±14.58%, n=5, $p=0.05$) but had no effect in the WT mice (24.68±3.078%, n=4, $p>0.05$). In both strains (n=6, $p>0.05$) the stimulation of contraction by IL-6 and/or CRF was similar. However, the neuronally-mediated effects of IL-6 in mdx mice was borne out by the inhibitory effects of TTX on IL-6 plus CRF in mdx mice only (1.681±0.6920%, n=6, $p<0.01$).

Discussion: These data begin to elucidate the physiological GI changes in the dystrophin-deficient mdx mice which may contribute to altered function. From these studies it appears that neuronally regulated IL-6-induced muscular contraction is important in GI pathophysiology in this strain.

Tear volume and tear stability across the phases of the menstrual cycle

A.D. Ighoroje[2,1] and J.A. Ebeigbe[1,2]

[1]Physiology Department, University of Benin, Benin City, Edo State, Nigeria and [2]Optometry Department, University of Benin, Benin City, Edo State, Nigeria

Dry eye is a very common condition among many women. Women are said to be twice likely to have dry eyes than men. Research suggests that dry eyes may be related to women's monthly cyclical changes in hormone levels, particularly estrogen levels. (Fresina and Campos, 2007). The menstrual cycle has been reported to affect many physiological processes. In addition to the effects of the menstrual cycle on the cardiovascular and nervous systems, it has also been reported to affect such ocular parameters like intraocular pressure, visual acuity, tear volume and tear stability (Tarlipinar et al, 2001). In Nigeria, there is a dearth of literature on effects of the menstrual cycle on tear volume and tear stability. This study was a cross sectional one to investigate the changes in tear volume (TV) and tear stability (TS) during the different phases of the menstrual cycle in Nigerian women. 100 healthy women aged 20 to 35years with regular cycles of 26 to 29 days were recruited for this study after informed consent was obtained from them. They were screened for systemic and ocular diseases. Exclusion criteria included irregular menstrual cycle, use of oral contraceptive pills, history of hypertension, cardiovascular abnormalities, diabetes mellitus and any ocular infections that could affect tear volume or stability. They were examined for changes in tear volume and tear stability during the follicular, ovulation and luteal phases. Ophthalmoscopy was done to rule out any posterior segment disease. Schirmer's test, which measures tear volume and the noninvasive tear break up time (NTBUT) which measures tear stability were carried out. (Schaumberg et al, 2001). Values are in means ± S.E.M, compared by ANOVA and student t test. Tear volume across the phases of menstrual cycle was statistically significant, $p < 0.0001$- Follicular 24.76±1.26, Ovulation 17.54±1.33, Luteal 21.14±1.50 (n=100). Reduction in TV (follicular vs ovulation was significant, $p<0.05$ and increase in TV (ovulation vs luteal was also significant, $p<0.05$.) However the difference in tear volume between the follicular phase and the luteal phase was not significant ($p>0.05$). Increase in tear stability during the menstrual cycle was also statistically significant, $p<0.05$. Follicular 13.70±1.10, Ovulation 16.32±1.42, Luteal 18.44±1.53 (n=100). Hormonal variation during the different phases of the menstrual cycle influence tear volume and tear stability in healthy young women of reproductive age. These changes may be clinically significant particularly in contact lens wearers where fluctuations in ocular parameter may alter the contact lens fit leading to a possible change in comfort and reduced visual acuity.

PCC231

Extrarenal potassium homeostasis after chronic potassium deficiency and after potassium repletion in rats

P. Napradit[1] and P. Piyachaturawat[2]

[1]Department of Physiology, Phramongkutklao College of Medicine, Bangkok, Thailand and [2]Department of Physiology, Faculty of Science, Mahidol University, Bangkok, Thailand

Potassium (K) plays an important role in several cellular homeostasis. K deficiency causes derangements of various tissue and organ functions. In order to study the effect of chronic K deficiency and subsequent to K repletion on extrarenal potassium homeostasis, adult male and female Sprague-Dawley rats were divided into 2 groups. K depletion was induced by feeding with a K-deficient diet and deionized water ad libitum for 120 days. The other group was paired-fed with normal rat chow at the same amount consumed by the former group serving as controls. During K depletion, rats had low food intake and their growths were retarded compared to control period. Polyuria, polydipsia, and a reduction in urinary K+ excretion were observed. Dietary K deprivation for 16-17 weeks resulted in a significant decreased in plasma K+ concentration to 1.5-2 mEq/L whereas plasma Na+ concentration was virtually not changed. In addition, K deficiency caused a metabolic alkalosis, a reduction in K+ but an accumulation in Na+ contents in soleus and extensor digitorum longus muscle. However, 2 weeks repletion of K by feeding normal rat chow resulted in marked increases in body weight, rapid restoration in water intake and urine output. Moreover, changes in plasma and muscles electrolyte and acid-base status were also reversible. To investigate extrarenal potassium homeostasis; K–depleted (n=7), K-supplemented (n=8), diet-restricted (n=11), and normal-untreated rats (n=11), were anesthetized with Inactin i.p.. Functional nephrectomy and adrenalectomy were performed and acute K-loading was challenged by intravenous infusion with KCl at a dose of 2 mEq/kg/hr for 1 hour. This resulted in elevations of plasma K+ concentration and muscle K+ content in all groups. The increment in plasma K+ concentration was significantly lower in K-depleted rats vs. normal rats (1.9±0.3 vs. 3.9±0.1 mEq/L, $p<0.001$), whereas the increases in muscle K+ content was higher than those in other groups. Values are means±S.E.M., compared by ANOVA. Furthermore, following KCl infusion blood pH was significantly decreased ($p<0.05$) and plasma Na+ concentration was increased ($p<0.05$) in K–depleted rat but those in the other groups were virtually not changed. These results were related to a greater K uptake in K–depleted rat indicating an alteration in extrarenal potassium disposal after chronic K deficiency. It is concluded that following KCl infusion the K+ ion may be an appropriate stimulus that leads to a marked activation of the residual Na+-K+ pump in K–depleted rats sufficient to lower plasma K+ concentration than in normal rats. This effect may be mediated by insulin as well as an accumulation of Na+ in muscle, increase in extracellular HCO3- and metabolic alkalosis developed after chronic K deficiency. However, alteration in extrarenal potassium disposal is completed reversed after K repletion.

PCC232

Interaction between Ang1-7 ('Mas') and AT1 receptors in regulating renal sodium and water excretion

J. O Neill, V. Healy and E.J. Johns

Physiology, University College Cork, Cork, Ireland

Intra- renal (IR) Ang (1-7) has diuretic and natriuretic actions that are proportional to the degree of activation of the Renin Angiotensin System (RAS). The question is why the magnitude of this diuresis and natriuresis is compromised in high sodium fed rats (HNa+)(suppressed) RAS and enhanced in low sodium fed rats (LNa+)(activated RAS)? Could the answer lie with changes in IR AT 1 or 'Mas' receptor expression?

IR Ang (1-7) increased sodium and water excretion in both LNa+ and normal sodium fed rats (NNa+), but the excretory responses were reduced in the presence of the AT1 receptor antagonist (Losartan) and completely blocked by the, 'Mas' receptor antagonist (A-779). These data suggest that both AT1 and 'Mas' receptors need to be functional in order to fully mediate the renal responses to IR Ang (1-7). The aim of this study was to determine whether there is a relationship between changes in the renal expression of AT1 and 'Mas' receptors and the altered responsiveness to IR Ang (1-7) during dietary sodium manipulation.

Male Wistar rats (250-300g)(n=4-5) were fed LNa+ (0.03%), NNa+ (0.3%) or HNa+ (3%) for 2weeks. Rats received 1ml Chloralose-Urethane anaesthetic (16.5 and 250 mg/ml, respectively) via the intraperitoneal (IP) route. The right femoral vein was cannulated to facilitate the administration of both sustaining (0.05ml/30mins) and terminal (1.5ml) anaesthesia. The latter was performed after removal of both kidneys. Kidneys were dissected and homogenized. AT1 and 'Mas' receptor expression in renal cortex tissue was evaluated using Western blotting and densitometry. Data ±SEM were subjected to a Students t-test and significance was set at ($P<0.05$).

AT 1 receptor expression was increased by 5 fold and reduced by 2 fold in renal cortex tissue of LNa+ and HNa+ rats respectively, (both $P<0.05$) when compared with rats fed a NNa+ diet. 'Mas' receptor expression was the same in all 3 groups. The Ang (1-7) levels in the cortex of LNa+ rats were significantly greater than those in the cortex of NNa+ and HNa+ rats ($P<0.05$).

The current data shows that there is a proportional relationship between AT1 receptor expression in the cortex and the magnitude of the renal actions of IR infused Ang (1-7), which is only partially dependent on the level of 'Mas' receptor expression. These data suggest that although the renal tubular responses to IR Ang (1-7), are mediated by the Mas receptor, their magnitude is dependant upon the level of AT1 receptor expression and more specifically Ang II/ AT1 receptor signalling. Thus, in LNa+ rats, IR infused Ang (1-7) acts via the 'Mas' receptor to inhibit Ang II/ AT 1 receptor signalling. In HNa+ fed rats the down regulated AT 1 receptor expression implies a reduction in Ang II/AT1 receptor signalling which renders the counter-regulatory effect s of IR infused Ang (1-7) redundant.

The acute effect of smoking on blood fluidity

T. Kimura[1], S. Taito[2,3], K. Sekikawa[3], M. Takahashi[3] and H. Hamada[3]

[1]Yasuda Women's College, Hiroshima, Japan, [2]Division of Clinical Support, Hiroshima University Hospital, Hiroshima, UK and [3]Department of Health and Sports Medical Sciences, Graduate School of Health Sciences, Hiroshima University, Hiroshima, UK

Introduction: Smoking is well known as a risk factor of arteriosclerotic disease and for effects on blood fluidity. The chronic effects of smoking on hematology are the increase of WBC and hematocrit. Chronic smoking causes a decrease of blood fluidity, but the acute effect of smoking on blood fluidity is not well known. In this study, we examined the changes of blood fluidity before and after smoking to estimate the acute effect of smoking on blood fluidity.
Subject: The subjects were 14 young men (7 controls; age 23.4±2.3 year, 7 smokers; age 23.3±2.2 year,) who don't have internal disease. We obtained informed consent from them.
Method: The blood collections were done before smoking, right after smoking and 5 minutes after smoking. The subjects quit smoking at least six hours before blood collection. The blood was drawn from the elbow nasal venules of retina. We used a microchannel array flow analyzer (MC-FAN). The MC-FAN utilizes 8736 micro channels fabricated in silicon, simulates capillary vessels in vivo and is also an imaging instrument to visualize the state of blood flow. The whole blood passage time of 100 micro liters was measured to evaluate blood fluidity. The platelet rich plasma passage time of 100 micro liters was measured to evaluate platelet function. An automatic cell counter (Beckmancoulter Co., Ltd.) was used to measure red blood cells, white blood cells, hemoglobin, hematocrit, and platelets.
Result: The whole blood passage time and the platelet rich plasma passage time did not show significant differences in the two groups. In the smokers, the whole blood passage time measured "right after smoking" (48.0±5.0 sec) was significantly longer than that of "before smoking" (45.5±4.4 sec) and "5 minutes after smoking" (44.4±3.5sec) almost returned "before smoking". In the smokers, the platelet rich plasma passage time did not show significant differences on the time course.
Discussion: There were no significant differences between smokers and non-smoker on the blood fluidity and blood cell counts. The whole blood passage time of "right after smoking" was significantly longer than that of "before smoking". The blood cell counts of "right after smoking" showed a tendency to increase.

Cardiovascular reactivity in response to othostatic challenge in healthy young individuals with family history for increased cardiovascular risk

N.Y. Belova

Physiology, Medical University of Sofia, Sofia, Bulgaria

Cardiovascular (CVS) diseases remain a leading cause for morbidity and mortality worldwide.
The aim of our study was to assess cardiovascular reactivity in healthy young adults with family history related increased CVS risk. 48 individuals aged 20-24 years were studied: 38 with family history for CVS diseases, obesity and/or diabetes type 2 - F+ group; 10 were their age matched controls without family history - F-. All subjects gave informed consent for their study participation. The orthostatic test, which consisted of three 5-minute periods – baseline supine (BAS), active standing (OT) and supine recovery (REC), was applied as a sympathetic challenge. Continuous electrocardiogram, non-invasive blood pressure and brachial-ankle pulse wave velocity (ba-PWV) were recorded using BiopacMP100 and Finapress device. Data were analyzed by means of the Acknowledge and MIS2000 software. Blood pressure variability (BPV) was assessed with fast Fourier analysis (FFT). The spectral α-index of spontaneous baroreflex sensitivity (BRS) was calculated (Pitzalis et al. 1998). Ba-PWV was measured for arterial stiffness evaluation (Sugawara et al. 2005). Results are presented in Table 1 as means ± SEM. Statistical significance was evidenced with the t-test.
CVS response to OT in F+ was more pronounced. Systolic arterial pressure (SAP) was significantly higher during the 3 studied periods; F+ responded to OT with a larger increase in SAP as compared to F-. BPV was considerably higher in F+ although statistical significance could not be shown due to the well known interindividual variance in this parameter. BRS decreased during OT (more markedly in F+). During REC BRS indices were significantly lower in F+ as compared to F-. Pulse pressure (PP) and ba-PWV data were higher in F+. Our data suggest the existence of subtle changes in the autonomic cardiovascular function with a sympathetic predominance in F+, which is in conjunction with our previous studies (Belova et al., 2007). An early and clinically non-manifested autonomic dysregulation might explain the higher CVS reactivity and the less sensitive baroreflex leading to greater BPV in F+. We might speculate that the increased sympathetic outflow to vascular smooth muscle cells causes functional increase of arterial stiffness and underlies the greater pulse pressure as well. We suggest that OT might be used as a screening tool for individuals at higher CVS risk and for primary prevention of CVS diseases.

Table 1

	SAP (mm Hg)	BPV (mmHg^2)	α-LF (ms/mm Hg)	α-HF (ms/mm Hg)	Heart rate (beats/min)	PP (mm Hg)	ba-PWV (m/s)

Effects of anaerobic threshold and respiratory compensation point on optimal fat utilisation in sedentary male subjects

S. Ugras[1], B. Yilmaz[2], I. Serhatlioglu[3] and O. Ozcelik[1]

[1]Physiology, Firat University, Medical School, Elazig, Turkey, [2]Physiology, Yeditepe University, Medical School, Istanbul, Turkey and [3]Biophysics, Firat University, Medical School, Elazig, Turkey

Fat and carbohydrates are the main substrates in the human skeletal muscle, both at rest and during exercise. Understanding the regulation of fuel selection in muscle is an important issue that needs to be clarified in clinical and sports sciences. It has been suggested that fat is the major substrate oxidised by muscle during low and moderate intensity exercise and it declines with increased exercise intensity. However, there is no specific exercise region that defines the optimal fat burning zone. During an incremental exercise test, anaerobic threshold (AT) and respiratory compensation point (RCP) reflects two important exercise intensities: onset of aerobic to anaerobic metabolic transition and onset of hyperventilation, respectively. In the present study, we have investigated the effects of exercise intensity corresponding to AT and RCP on fat and also carbohydrate utilisation. After obtaining an informed consent which was approved by the local ethics committee, nine sedentary male subjects (20.2±1.6 yr, 75.5±5.8 kg) performed an incremental exercise test (15 W/min) until the limit of tolerance using a cycle ergometer. During exercise, the ventilatory and pulmonary gas exchange indices were estimated breath-by-breath. V-slope method used to estimate AT (1) and increased VE/VCO2 and decreased PETCO2 used to estimate RCP (2). Then they participated five 30 min (or until exhaustion) stages of exercise at intensities of corresponding to 25% below AT (W1), AT (W2), RCP (W3), 25% above AT (W4) and %100 above AT (W5). The respiratory quotient (RQ) was used to evaluate substrate utilisation. Statistical analysis was done by using paired t test. Maximal exercise capacity (Wmax), AT and RCP were found to be 221±25 W, 134±21 W (60% of Wmax) and 160±24 W, (72% of Wmax) respectively. The RQ at the end of the exercise was found to be 0.925±0.05 for W1 and 0.931±0.04 for W2 (p>0.05), reflecting ~75% CHO and 25% fat utilisation. RQ decreased to 0.904±0.04 in W3 (p<0.05) reflecting ~65% CHO and 35% fat utilisation. The subjects were not able to complete 30 min of exercise duration in W4 and W5. The RQ was systematically higher than 1.00 in W4 (1.060±0.04) and W5 (1.374±0.1). The highest fat oxidation ratio (as seen a marked decrease in RQ) was observed in the work rate corresponding to the RCP. In conclusion, these findings suggest the region between AT and RCP can be used as an optimal fat burning zone. In addition, investigators should consider RCP instead of using low-moderate-high intensity criteria as determined % values of Wmax or maximal O2 uptake.

PCC236

Medium-intensity rhythmic exercise and high-intensity resistance exercise reduces fasting plasma cholesterol/HDL Ratio

J.R. Wells

University of Gloucestershire, Gloucester, UK

Different modes of exercise have been shown to reduce the health risks associated with elevated plasma Cholesterol (Tjonna, Lee et al. 2008) (Martins, Verissimo et al. 2010). However the results do not agree on the modes of exercise that are beneficial. Some recent research, the STRRIDE clinical study, has shown little Cholesterol reduction (Bateman, Slentz et al. 2011). The mode of high-intensity, short-duration, resistance exercise has not been compared with the Government recommendations of moderate-intensity exercise. PURPOSE: To compare changes in Total Cholesterol and in HDL over 3 months in moderate-intensity rhythmic exercisers and high-intensity resistance exercisers. METHODS: 63 participants in a health club setting gave voluntary informed consent and completed 3 months of supervised exercise, divided between 30-minute bouts of moderate-intensity rhythmic exercise 3 to 5 times a week (MI), 8 minute bouts of high-intensity resistance exercise only 1 to 2 times a week (HI) and a no additional physical activity control group (CON). Venous blood samples (12 hour prior fast) were taken before and after the 3 months. Total Cholesterol and HDL were determined using an automated photometric chemistry analyser. RESULTS: The mean reductions in the Total Cholesterol / HDL ratio (+/- standard error) over the 3 months for the groups were: MI (n=18) 0.11 +/- 0.16, HI (n=23) 0.26 +/- 0.11 and CON (n=22) –0.04 +/- 0.09. However, as can be seen in plots, the MI exercise was more beneficial than this data indicates. Although the Cholesterol/HDL ratios were balanced between the 3 starting groups, uneven attrition has distorted the results. CONCLUSION: These results show that, over a 3-month period, 30-minute bouts of moderate-intensity rhythmic exercise and short bouts of high-intensity resistance exercise both reduce the Cholesterol/HDL ratio. Further research, in which the total work done is controlled, is now required to see if it is the mode or intensity of

the exercise that has the greatest effect. Plus greater participant numbers are required for this reported research to strengthen the statistics.

Dietary nitrate supplementation improves cerebral haemodynamic function in males

J.V. Brugniaux, C.J. Marley, D. Hodson, K. Evans and D.M. Bailey

Neurovascular Research Laboratory, University of Glamorgan,, Pontypridd, UK

Background and aims
Beetroot juice (BJ) is a natural source of nitrate, which can be reduced into nitrite and ultimately nitric oxide (NO), leading to an increase in circulating NO (1). Because of its vasodilatory properties, NO can lower blood pressure even in normotensive subjects (2). Amongst other signalling pathways, it has also been suggested to modulate mitochondrial respiration, supporting recent observations of ergogenic effects of dietary nitrate supplementation, such as BJ, on aerobic performance (3). Following the aforementioned vascular pathway, one can speculate that the effects of an increase in NO are not limited to the systemic circulation and could extend to the brain, hence inducing an increase in cerebral perfusion and oxygenation. Therefore, the aim of this study was to determine the impact of dietary nitrate supplementation in the form of BJ on the resting cerebral hemodynamic function.
Methods:
10 healthy males (age: 26±1 years; height: 182±1 cm; weight: 80±2 kg) consented to this double-blind randomized placebo-controlled trial. Middle cerebral artery velocity (MCAv, Transcranial Doppler) and changes in frontal cortical oxygenation (cO2Hb, near-infrared spectroscopy) were recorded continuously during a 5-minute baseline period, followed by a 3-minute hypercapnea (5% CO2 in balanced O2 and N2), before and 3.5 hours after the ingestion of 500ml of either BJ (containing ≈5.2mmol of nitrate; Beet It, James White Drinks, Ipswich, UK) or a low-calorie blackcurrant juice cordial (negligible nitrate content). Trials were separated by a week and the participants' diet was monitored during a 3-day lead-in period. Exhaled NO (ozone-based chemiluminescence) was measured before and 2 hours post-ingestion. Haemodynamic data were averaged over the last 30 seconds of the respective stage. Data were analysed using a 2-way repeated measures ANOVA (time x drug) and paired samples t-tests. Significance was set at $P \leq 0.05$ and data are presented as mean±SD.
Results:
BJ raised the exhaled NO concentration 2h post ingestion (Figure 1A). The increase in cO2Hb in response to the hypercapnic challenge was greater post BJ ($P<0.05$) than placebo (Figure 1B). However, the hypercapnia-induced alteration in MCAv was not different post supplementation (BJ vs. Placebo). The alterations in NO and cO2Hb post-supplementation were positively correlated ($P=0.05$) (Figure 2).
Conclusion:
The present results demonstrate for the first time that dietary nitrate supplementation increases cerebral oxygenation but without altering perfusion during hypercapnea. While the underlying mechanisms remain to be fully unravelled, this observation has clear implications not only from a physical performance point of view, but also for the clinician. Indeed, increased oxygenation can be seen as being a neuroprotective mechanism possibly able to prevent the development of dementia in later life.

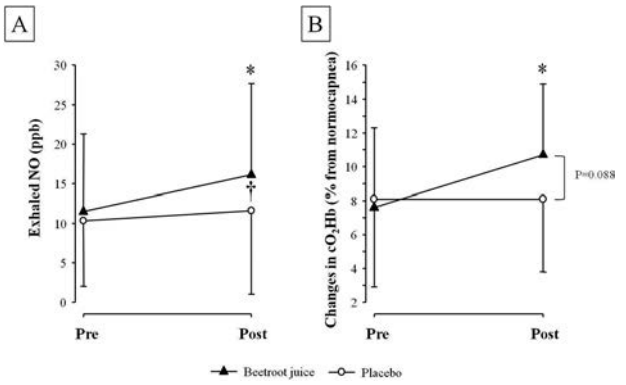

Figure 1: Changes in exhaled nitric oxide (NO, A) and cerebral oxygenation (cO2Hb, B) in response to 3 minutes of hypercapnea (5% CO2) following the ingestion of the nitrate supplement (Beetroot juice) or Placebo (n=10 in each group).

Values are mean + SD; *P<0.05 vs. Placebo; †P < 0.05 vs. Placebo.

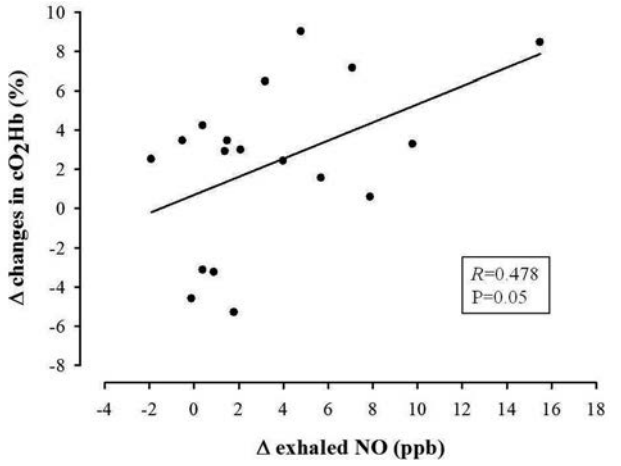

Figure 2: Relationship between the changes in exhaled NO and cO2Hb in response to 3 minutes of hypercapnea (5% CO2).

Cutaneous and muscular influences on beer- lambert and spatially-resolved indicators of blood volume in near infrared specroscopy

A. Messere and S. Roatta

University of Turin (Italy), Turin, Italy

Near-infrared spectroscopy (NIRS) is a non-invasive optical technique increasingly used to assess muscle oxygenation during exercise, although the possible interference by cutaneous circulation remains a major limitation of the technique (Davis et al. 2006). Spatially resolved spectroscopy (SRS) was proven to effectively reduce the influence of extracranial blood flow in cerebrovascular assessesments as compared to original Beer-Lambert (BL) NIRS but its potential effectiveness in muscle circulation is currently unexplored.

The aim of this study is to compare BL vs SRS indices of blood volume during selective cutaneous and muscle hyperemia.

To this purpose we performed the NIRS assessment with the NIRO 500 (Hamamatsu) which provides simultaneous BL and SRS indices of blood volume, tHb and THI, respectively. In 10 healthy subjects enrolled in the study NIRS optodes were placed along the belly of the flexor carpi radialis (left arm) and skin blood flow was measured with laser-Doppler flowmetry. Selective cutaneous vasodilatation was obtained by locally warming the left forearm with warm air flow and selective muscle dilatation was obtained by a 10-s lasting maximum voluntary wrist flexion, producing an exercise-hyperemia in the relevant muscles

In the two conditions changes in blood volume were computed as absolute changes for tHb (in uM*cm) and relative changes (%) for THI. In addition a warm/exercise ratio (WER) was computed as the ratio between changes observed during the warm- and exercise-hyperaemia (in %) This index quantifies and allows to compare the dependence on cutaneous circulation of THI and tHb: the higher the WER, the higher the dependence.

Warming (26.6± 0.9 to 33.2±1.3 °C) produced marked changes in cHB in all subjects (19.5±7.4 uM*cm) associated with the increase in skin blood flow while THI was unresponsive to warming in 5 out of 9 subjects and highly responsive in the others (average on all subjects11.8±18.6 %) Consequently, also the warm/exercise ratio exhibited a bimodal distribution for THI: 2.2 ±22.5% (indicating that the response to warming is 2% of exercise hyperemia) in 5 subjects and 531±261 % (n=4). WER for tHb was on average: 333±258 %.

The results confirm that changes in skin blood flow can markedly affect NIRS parameters. As observed for cerebrovascular monitoring (Canova et al. 2011) SRS spectroscopy appears to be less dependent on cutaneous circulation than the classical BL technique. The reason for high WER values in the THI of 4 subject may represent an additional problem for NIRS assesments whose excact nature remains to be ascertained.

Respiratory muscle power (RMP) in normal subjects, asthmatics, trained police officers and healthy obese adults in Sudan

O.A. Musa[1], O.A. Elbadri[2], S.E. Ibrahim[3], A.A. Magzoub[1], K.M. Awad[1], F.G. Abdalla[1] and B.A. Hussein[1]

[1]Physiology, National Ribat Uinversity, Khartoum, Sudan, [2]Physiology, Alshaikh Abdulla University, Barbar, Sudan and [3]Physiology, Gezira University, Madani, Sudan

Respiratory muscle power (RMP) is the main drive for respiration in health and disease. Negative correlation was found between age and RMP for both sexes. Height, obesity and physical training have been shown to increase RMP. The use of RMP in asthma as a tool of investigation and as a predictor of training has not been investigated. Asthma diagnosis when mild or intermittent is a clinical challenge in between attacks, and the

common pulmonary function tests (PFTs) are not very sensitive. An extensive study has been performed on the RMP in normal individuals, in asthmatics as a new diagnostic tool, in trained police officers, and in obesity.
Methods: A total of 653 subjects from Gezira and Khartoum states, Sudan were included. Two hundred and sixty normal adult volunteers both sexes, aged 16-60 years have performed RMP measurement (Maximum Expiratory and Inspiratory Pressures, MEP and MIP) by mouth pressure meter and pulmonary function (FVC, FEV1 & PEFR) by microplus spirometer. RMP and PFTs in 30 young adults aged 16 -23 years were compared with 30 old subjects aged 65-85 years. Respiratory muscle thickness at the end of quiet and maximum inspiration were measured using ultrasound device .Fifty asthmatic and 50 matching controls have performed reversibility test and spontaneous variability by RMP and PFTs. Fifty nine trained policemen and 28 policewomen were compared with 61 matching control. Diaphragmatic thickness and RMP was performed in 10 chronic asthmatics, matched with 10 controls. Obesity and RMP was studied in 52 obese individuals and 43 matching controls.
Results: Both RMP and PFTs in males were significantly higher than in females (mean MIP (cmH2O) and FEV1 (L) were 111±21 and 3.7 ± 0.5 in males compared to 75.8± 16.3 and 2.8 ± 0.3 in females .Both RMP and PFTs values decreased with age in both sexes (mean MIP and FVC (L) in young subjects were 114.3±28.4 and 4.1± 0.5 compared to 78±19 and 2.9±0.5 in old subjects. The sensitivity of MEP and MIP was better than FEV1 and PEFR in asthma diagnosis by reversibility test (49% & 71% for MEP & MIP, and 40% & 31% for FEV1 and PEFR) and in variability test (53% & 61% for MEP & MIP and 40% & 46% for FEV1 and PEFR). MEP and MIP significantly increased in obese subjects (p=0.01 and 0.00 respectively) and insignificant difference (p=0.73) was found in lung function between obese subjects and controls (Mean FVC (L), MEP and MIP (cmH2O) were 3.58 ±0.9, 109±29.8 and 78±17.2 respectively in obese subjects compared to 3.63±0.7, 94.6 ±27.7 and 67.8±18.7 respectively in non-obese controls). The diaphragm muscles thickness was significantly increased in chronic asthmatics compared to healthy controls (diaphragm thickness in quiet inspiration was 4 mm in asthmatics and 3.1 mm in controls). RMP and PFTs were found significantly higher in trainee polices officers compared to controls (mean MIP and FVC in policemen were 106.9 ±28.2 and 3.96 ± 0.5 compared to 88.1 ±31 and 3.58± 0.8 in controls).
In conclusions: RMP differences between males and females and in younger and old adults can explain the differences in their lung function values. RMP reversibility and variability is a new potential diagnostic tool for asthma. Obese and trained subjects have Higher RMP which could explain their lung function values.

Effects of Ginkgo biloba extract 50 on beta-amyloid-induced apoptosis and oxidative stress in hippocampal neurons

Z.Z. Xiong and X.C. Yi

Basic Medical Science College, Shanghai University of Traditional Chinese Medicine, Shanghai, China

Objective To study the effect of Ginkgo biloba Extract 50 (GBE50) on beta-amyloid(Aβ)-induced apoptosis and oxidative stress in hippocampal neurons in vitro. Methods The primary hippocampal neuron was cultured in vitro and reduced to apoptosis and oxidative stress by 20 μM Aβ25-35. The MTT, flow cytometry and fluorescent probes labeling were used to observe the effect of GBE50 with different concentrations on cell viability, apoptosis and generation of intracellular reactive oxygen species (ROS) in neurons. Results (1) 20 μM Aβ25-35 could reduce the cell vitality significantly ($P < 0.05$). There was statistical difference between GBE50 group with different concentrations (10 μg/ml except) and Aβ group ($P < 0.05$). GBE50 could improve cell vitality with certain concentration dependence. (2) The cell apoptosis rate and necrosis rate were obviously increased by 20 μM Aβ25-35 ($P < 0.01$) and higher about 14.5% and 8.6% respectively. However, 50 μg/ml GBE50 could significantly reduce the cell apoptosis and necrosis rate ($P < 0.05$) and lower about 47.7% and 59.5% respectively. (3) The result of intracellular reactive oxygen species generation detected by fluorescent probes DCFH-DA show that the statistical difference was observed between Aβ group and control group ($P < 0.05$), and 20 μM Aβ25-35 could enhance ROS. However, any difference wasn't detected between every concentration of GBE50 group and control group($P > 0.05$). Conclusions The 20 μM Aβ25-35 could induce hippocampal neuron apoptosis and generations of intracellular ROS, which were inhibited by GBE50 with different degrees. Through these effects and improving cell vitality, GBE50 could availably protect hippocampal neurons.

The role of SIRTI in Ginkgo biloba extract 50 delaying telomere shortening in the hippocampus of natural aging rats

Z.Z. Xiong and H. Li

Basic Medical Science College, Shanghai University of Traditional Chinese Medicine, Shanghai, China

Objective To investigate the role of SIRTI in Ginkgo Biloba Extract 50 (GBE50) delaying telomere shortening in the hippocampus of natural aging rats
Method Thirty Sprague-Dawley (SD) rats (male, 21 months, 700-1050g) were randomly divided into GBE50 treated group, Ginkgo biloba extract 761(EGB761) treated group and model group (n=10 each). Eight SD rats (male,1 months, 100-110g,) were control group. GBE50 group and EGB761 group were respectively administered intragastrically with GBE50 (100mg/kg/day) and EGB761 (100mg/kg/day) dissolved in 1% Carboxymethyl-cellulose Sodium (CMC-Na) for 60 days. The

control group and the model group were treated intragastrically with 1% CMC-Na for 60 days. Rats in each group were anaesthetised with 25 urethane(3ml kg-1, both i.p.) and sacrificed after 60 days, and hippocampus were taken out for analysis of RNA, DNA and protein. Telomere length and SIRTl mRNA in the hippocampus were determined by fluorescent quantitative real-time polymerase chain reaction (RT-PCR), Western blot was used to analyze the levels of Sirtl, p53 and p21 respectively. Expressions of p53 and p21 in hippocampal region CA1 were quantified by immunohistochemistry .
Results (1) Significant difference in telomere length was observed between model group and control group (P<0.05). The length of telomere was significantly longer in GBE50 group compared to model group (P<0.05). GBE50 could delay telomere shortening(24.2%). (2) SIRTl mRNA and protein levels were significantly lower in model group relative to control group (P<0.05). GBE50 could increase SIRTl mRNA and protein level compared to model group (P<0.05). (3) The protein level of p21 was increased in model group relative to control group (P<0.05). GBE50 could significantly decrease p21 compared to model samples (P<0.05). However, any difference wasn't detected in the expression of p53 among model group, control group and GBE50 group (P>0.05). (4) GBE50 could inhibit protein expressions of p21 in hippocampal region CA1 (P< 0.05).
Conclusion GBE50 might delay telomere shortening in the hippocampus of natural aging rats through up-regulated the SIRTl expression, and the expression of p21 were down-regulated.

Middle cerebral artery blood velocity in response to dynamic upright resistance exercise: effect of load and repetition

B. Perry[1], Z.J. Schlader[1], M.J. Barnes[1], D.J. Cochrane[1], S.J. Lucas[2] and T. Mündel[1]

[1]School of Sport and Exercise, Massey University, Palmerston North, New Zealand and [2]Depratment of Physiology, University of Otago, Dunedin, New Zealand

Weightlifting is a common mode of exercise because of its positive effects on a host of physiological outcomes. However, the transient and extreme nature of the mean arterial blood pressure (MAP) response during and following resistance exercise, particularly whilst upright, will likely translate into fluctuations in middle cerebral artery blood flow velocity (MCAv). We examined the effect of resistance load and number of repetitions on the dynamic responses of MCAv during and following upright squatting exercise. Healthy resistance trained males (n = 12; mean ± SD: 26 ± 5 y; 94 ± 13 kg) completed 30, 60 and 90% of a predetermined 6 repetition maximum (RM) load, in a randomised order. Participants completed 2 or 6 repetitions of their 6 RM during two separate visits (order randomised between participants). Beat-to-beat MCAv and blood pressure, continuous end-tidal PCO2 and heart rate were measured. Peak MCAv and MAP during exercise, and nadir, recovery and peak following exercise were compared to a pre-exercise standing baseline period (1 min). There was no difference in average peak MCAv during exercise between loads (P = 0.737) or repetitions (P = 0.892). MAP was greater during the 60% compared to the 30% set (P = 0.015), and with 6 repetitions (P = 0.02 vs. 2 repetitions); specifically, 122 ± 9 vs. 135 ± 11 mm Hg for 2 and 6 repetitions at 30%, respectively; and 128 ± 13 vs. 143 ± 14 mm Hg for 2 and 6 repetitions at 60%, respectively. Only 3 participants had a satisfactory blood pressure trace for both 90% sets; MAP at this load peaked at 150 ± 2 and 176 ± 6 mm Hg mm Hg for 2 and 6 repetitions, respectively. Participants only performed a Valsalva manoeuvre during both 90% repetition sets, with an average mouth pressure of 43 ± 6 and 44 ± 10 mm Hg for the 2 and 6 repetition sets, respectively. Post-exercise MCAv reductions occurred via a selective, load-dependent (P < 0.001) decrease in diastolic MCAv. The 90% load produced the lowest MCAv nadir (-19 ± 6 cm/s, P < 0.001) and MAP nadir (-36 ± 10 mm Hg, P < 0.001) following exercise. Greater reductions in MCAv were seen at 30 and 60% loads following 6 repetitions (both P <0.05 vs. 2 repetition sets), but not for MAP (P= 0.59). The MAP nadir occurred later (13.3 ± 7.6 s) than MCAvmean nadir (6.7 ± 5.2 s) for all loads and repetitions (all P ≤ 0.05). Higher loads increased the time to MAP nadir (P = 0.05) but not MCAvmean nadir (P > 0.10). In summary, the combination of heavier loads and the Valsalva manoeuvre challenge cerebral autoregulatory processes and produce a greater reduction in MAP and subsequently MCAv immediately following dynamic upright resistance exercise. However, dynamic cerebral autoregulation begins to restore MCAv within the same time frame regardless of the magnitude of the drop in MCAv, and the magnitude and time course of the reduction in MAP.

Power performance in swimmers- a physiological multiparametric analysis

C. Prabha and S. Prakash

Department of physiology, Meenakshi medical college& research institute enathur kanchipuram tamilnad india, Kanchipuram, Tamil Nadu, India

The athletic status is a composite multi-factorial output. Sprinting success can be pinned purely on nature and nurture. Along with societal factors investment in infrastructure, training system and powerful desire play an important role. The evolutionary advantage in the form of ACTN3, gene for speed, the physiological determinant of the sprinting ability has come into main focus recently. Most studies have demonstrated a relationship between the presence of Alpha actin3 and the ability of muscle to generate force. The aim of our study was to analyse the various physiological factors contributing to the power performance of adolescent swimmers. The study assessed their socio-economic status, anthropometric measurements, pulmonary function tests and ACTN3 genotype. This was a case control study. The cases being 35 in number and age matched controls, 70 in number. Human ethical committee clearance was obtained. The subjects were chosen from different swimming pools in Chennai, Tamilnadu, India. All members were briefed about the intent and conduct of tests. The volunteers were then chosen in strict adherence to the inclusion and exclusion criteria. Informed consent was obtained from the participant and Anthropometric measurements were recorded. After demonstration of proper technique Spirometry was done. ACTN3 gene testing was done from cheek swabs. The results were statistically analysed using Graph Pad Prism-version 5. The mid-arm circumferences of swimmers and con-

trols were compared. Unpaired 't' test was applied. The P value was 0.002. The means were significantly different, P<0.05. Fisher's test was performed and variances compared. The P value was 0.0224. The proportion test of ACTN3 genotype was done. It was inferred that RR type and RX type difference in proportion between cases and controls was not significant but XX type proportion was significant between groups. On analysis of results we concluded that swimmers had better anthropometric measurements. Their Spirometry revealed better values. The ACTN3 genotyping showed R allele was associated with elite swimming performance.

The effect of adiposity on skeletal muscle size and strength in untrained women

D.J. Tomlinson, R.M. Erskine, C. Morse, K. Winwood and G. Pearson

The Institute for Performance Research, Manchester Metroploitan University, Crewe, Cheshire, UK

Background: It is not known how elevated adiposity in obese individuals or abnormally low levels of adiposity in underweight people affects the size and strength of skeletal muscle. Resistance training is known to induce gains in both muscle size and strength (Erskine et al., 2010), while prolonged muscle disuse has been shown to cause a reduction in these variables (de Boer et al., 2007). Moreover, simulated hypergravity for a 3 week period has been shown to increase muscle strength (Bosco et al., 1984), while low-load, high volume resistance exercise has been shown to enhance muscle protein synthesis more than conventional high-intensity resistance exercise (Burd et al., 2010). Therefore, we hypothesised that chronic over-loading of skeletal muscle in obese individuals would lead to greater lower-limb lean mass and higher absolute strength values compared to under-weight and normal-weight individuals.

Method: Fifty untrained healthy women aged 19-49 yrs (mean ± SD: 25.1 ± 8.7 yrs) were recruited to take part in this study. Body fat and lean mass were assessed using dual-emission X-ray absorptiometry. Plantar flexion maximum voluntary isometric contraction (MVC) torque was assessed in the dominant limb using an isokinetic dynamometer at different ankle joint angles (-5 to +10 deg plantar flexion; 0 deg = neutral ankle position). MVC joint torque was corrected for voluntary muscle activation level (assessed using the interpolated twitch technique) and antagonist muscle co-activation (assessed via surface EMG).

Results: Body mass index was 26.0 ± 7.0 kg/m2 (range: 17.0 – 51.9 kg/m2. Body fat percentage was 35.4 ± 8.8% (range: 19.6 – 51.9%). There was a positive relationship between lower-limb lean mass and MVC plantar flexion torque ($r2 = 0.594$; $p<0.005$). Moreover, total body fat mass was positively correlated with lower-limb lean mass ($r2 = 0.500$; $p<0.005$) and MVC plantar flexion torque at optimum joint angle ($r2 = 0.332$; $p<0.005$). A superior positive correlation though existed between total body mass and optimum MVC plantar flexion torque ($r2 = 0.458$; $p<0.005$).

Conclusion: Our findings confirm that total body fat mass is associated with lower-limb fat-free mass and maximum strength in untrained women. This suggests that the anti-gravity muscles of the lower-limb may possibly adapt to chronically low and high levels of adiposity in a similar manner to chronic unloading or overloading of the muscles, as seen following prolonged periods of bed-rest or resistance training.

Sweat potassium concentration decreases with increased sweating in perimenopausal women

E. Amabebe[1], S.I. Omorodion[2] and J.O. Ozoene[2]

[1]Physiology, Niger Delta University, Amassoma, Bayelsa, Nigeria and [2]Physiology, University of Benin, Benin, Edo, Nigeria

Sweat rate is higher in perimenopausal women than in premenopausal and postmenopausal women (Minkin et. al., 1997) and excessive sweating during menopause depletes some of

the body's essential nutrients, especially potassium (Balch and Balch, 1999).

In this study, we assessed whether there is an association between sweat rate (SR), sweat volume (SV) and sweat potassium concentration (S[K+]) in premenopausal (preM), perimenopausal (periM) and postmenopausal (postM) women after a moderate exercise.

Thirty (30) healthy women comprising of preM (aged 22.5±0.8yrs, n=10), periM (aged 46.5±1.1yrs, n=10) and postM (aged 52.2±0.9yrs, n=10) participated in the study. Participants were adequately informed of the experimental procedures and they all consented to it. TP was rated using the Visual Analogue Scale, VAS. Sweat was obtained with the sweat suction apparatus from a 120cm2 circular area marked on the skin of the face and neck (Ugwu and Oyebola, 1996), after a moderate exercise (a 15min walk on the treadmill) at a speed of 4.2 km/h at 270C, with the start time noted and SV and [K+] measured. SR was determined using the formula: (volume of sweat collected)/(exercise time) .

The results show that periM women exhibited a significantly higher SR (0.12±0.01 ml/min vs preM - 0.07±0.02 ml/min vs postM - 0.06±0.01 ml/min) ($p<0.05$), but a significantly lower S[K+] (19.98±1.5 mmol/l vs preM – 23.37±1.3 mmol/l vs postM - 24.88±1.8 mmol/l) ($p<0.05$). However, there was no significant difference in the SV (periM – 1.7±0.2 ml vs preM – 1.3±0.4 ml vs postM – 0.9±0.1 ml). The linear regression plot showed a significant ($p<0.05$) inverse relationship (negative correlation) between S[K+] and SR, but the negative relationship between S[K+] and SV was not significant, i.e. increase in SR and/or SV produced a decrease in S[K+].

In conclusion, these data indicate that although excessive sweating can lead to depletion of the body's potassium concentration, the sweat potassium concentration decreases with increasing sweat rate and volume especially in perimenopausal women during moderate exercise.

Lipopolysaccharide infusion enhances dynamic cerebral autoregulation with no effects of acute isocapnic hypoxia in healthy volunteers

R.M. Berg[1,2], R.R. Plovsing[3], K.A. Evans[4], C.B. Christiansen[1], D.M. Bailey[4], N. Holstein-Rathlou[2] and K. Møller[1,5]

[1]Centre of Inflammation and Metabolism, Department of Infectious Diseases, University Hospital Rigshospitalet, Copenhagen Ø, Denmark, [2]Renal and Vascular Research Section, Department of Biomedical Sciences, Faculty of Health Sciences, University of Copenhagen, Copenhagen N, Denmark, [3]Intensive Care Unit 4131, University Hospital Rigshospitalet, Copenhagen Ø, Denmark, [4]Neurovascular Research Laboratory, Faculty of Health, Science and Sport, University of Glamorgan, Copenhagen Ø, UK and [5]Neurointensive Care Unit 2093, University Hospital Rigshospitalet, Copenhagen Ø, Denmark

Sepsis may be associated with disturbances in cerebral oxygen transport and cerebral haemodynamic function, thus rendering the brain particularly susceptible to hypoxia (Berg et al, 2011). The purpose of the present study was to assess the impact of isocapnic hypoxia on dynamic cerebral autoregulation in a human-experimental model of the systemic inflammatory response during the early stages of sepsis.

A total of ten healthy volunteers were exposed to normoxia (FIO2 = 21%) and acute isocapnic inspiratory hypoxia (FIO2 = 12%) before and after a 4-hour lipopolysaccharide (LPS) infusion (2 ng kg-1). Middle cerebral artery blood follow velocity was assessed using transcranial Doppler ultrasound, and dynamic autoregulation was evaluated by transfer function analysis.

Transfer function analysis revealed an increase in the phase difference between mean arterial blood pressure and middle cerebral artery blood flow velocity in the low frequency range (0.07–0.20 Hz) after LPS (Table). In contrast, there were no effects of isocapnic hypoxia on dynamic autoregulation.

The observed increase in phase suggests that the dynamic cerebral autoregulation is enhanced after LPS infusion and resistant to any effects of acute hypoxia; this may protect the brain from ischemia and/or blood-brain barrier damage during the early stages of sepsis.

Dynamic cerebral autoregulation during normoxia (FIO2 = 21%) and acute isocapnic hypoxia (FIO2 = 12%), before and after lipopolysaccharide (LPS) infusion in healthy volunteers (n=9).

	Baseline		LPS	
	Normoxia	Hypoxia	Normoxia	Hypoxia
MAPsp (mmHg2)	4.5 (3.4-6.3)	9.0 (4.7-13.8)	3.6 (1.9-9.2)	9.0 (2.2-11.0)
MCAvsp (cm2 sec-2)	7.7 (5.5-10.0)	12.6 (7.6-18.7)	5.6 (1.7-14.2)	13.1 (5.7-23.4)
Gain (cm mmHg-1 sec-1)	1.24 (1.04-1.36)	1.27 (1.18-1.34)	1.17 (1.04-1.24)	1.29 (1.17-1.33)
Phase (radians)	0.64 (0.49-0.76)	0.49 (0.45-0.60)	0.80† (0.77-0.83)	0.91† (0.76-1.01)
Coherence (units)	0.87 (0.82-0.88)	0.91 (0.86-0.93)	0.76 (0.70-0.84)	0.88 (0.69-0.94)

Data are presented as median (IQR). Values for the spectral power of mean arterial blood pressure (MAPsp) and middle cerebral artery blood flow velocity (MCAvsp), as well as transfer gain, the MAP-to-MCAv phase difference, and coherence are presented for the low frequency range (0.07–0.20 Hz). Only data for subjects with coherence ≥0.4 are presented. Different from the same intervention (normoxia/ hypoxia) at baseline, † $p < 0.01$.

Correlation of serum estradiol, IL-6 and IGF-1 with bone density in menopausal women with and without regular exercise

V. Tarawan[1], I. Akbar[1], A. Purba[1] and F. Tandjung[2]

[1]physiology, school of Medicine universitas Padjadjaran, Bandung, westjava, Indonesia and [2]Orthopedic, Faculty of Medicine Padjadjaran University, Bandung, West Java, Indonesia

Increase of medicine technology and health service will increase quality of life and will be followed with increasing the number of menopausal women. Thus make osteoporosis disease increase which will give impact in increasing morbidity and mortality caused by osteoporosis. This study is done to detect osteoporosis early in menopausal women. The objective of this study is to analyze differentiation, correlation, risk factor between serum estradiol, IL-6, IGF-1 level to bone density in menopausal women with and without regular exercise and to analyze role of regular exercise. The method used was cross sectional that conducted on 56 menopausal women first decade who chosen randomly and divided into two groups, with and without regular exercise. Data were analyzed with T-test for normal and Mann-Whitney test for abnormal data distribution, Pearson correlative test, multiple linier regression test, multiple logistic regression test, and count risk factor used RP (Prevalence Ratio) risk and 95% CI (Confident Interval). The results showed that menopausal women with regular exercise had increased estradiol level significantly (22.94 (6.09) vs 14.23 (3.54)) ($p<0.05$), decreased IL-6 level significantly (1.69 (0.95) vs 3.198 (2.82)) ($p<0.05$) and increased IGF-1 level non significantly (89.36 (39.33) vs 79.57 (32.37)) ($p=0.243$) compare with menopausal women without regular exercise, although non significantly, there was tendency increasing IGF-1. Menopausal women with regular exercise showed higher bone mass density significantly compare with menopausal women without regular exercise ($p<0.001$). Menopausal women with regular exercise had positive correlation between IGF-1 with bone mass density (BMD-T) significantly ($r=0.648$; $p<0.05$). Menopausal women with and without regular exercise had positive correlation between estradiol with IL-6 significantly ($p<0.05$). Base on multiple linier regression test in menopausal women with regular exercise, there was significant correlation ($p<0.001$) between IGF-1 and BMD-T, but there was no correlation between estradiol, IL-6 and BMD-T. Based on ROC curve, estradiol cut off point ≤16.38, IL-6 ≤ 1.661, IGF-1 ≤ 69. If estradiol level ≤16.38, IL-6 > 1.661, IGF-1 ≤ 69 possibility for osteoporosis 28.2% among menopausal women with regular exercise and 64.7% among menopausal women without regular exercise. In conclusion, menopausal women with regular exercise have estradiol level higher, IL-6 level lower, and IGF-1 level higher and bone mass density higher vs. menopausal woman without regular exercise. There are correlation between serum IGF-1 level and bone mass density among menopausal women with regular exercise. The value of serum estradiol, serum IL-6, and serum IGF-1 can become risk factors of osteoporosis and sensitive measurement for the diagnostic test.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

The role of local tissue temperature on resting and exercising skeletal muscle haemodynamics in the human leg

S.T. Chiesa, S.J. Trangmar, K.K. Kalsi and J. González-Alonso

Brunel University London, Uxbridge, UK

Introduction: The haemodynamic responses of skeletal muscle to localised changes in tissue temperature are still poorly understood, despite the widespread therapeutic use of heating and cooling. We aimed to systematically identify these responses both at rest and during one-legged exercise over a wide range of physiologically relevant temperatures. Methods: Leg tissue temperatures in 7 males (age 22±1 years) were altered at rest over 1hr through the use of frozen gel packs (cooling) or a water perfused suit (heating). Core, skin and deep muscle (T_m) temperatures were measured throughout. Haemodynamic alterations in 3 major arteries of the leg (common, superficial, and profunda femoral arteries: CFA, SFA, and PFA) were assessed using duplex Doppler ultrasound, with the contralateral leg providing control measures. Systemic haemodynamic responses were measured non-invasively using infrared plethysmography. Following each intervention, CFA flow was measured during incremental single-legged knee extensor exercise in the experimental or control leg (10±1, 16±1, 23±2, and 30±2W). All values are means ± SEM, with T_m and flows analysed using RM-ANOVA and conductance using linear regression. Results: At rest, 1hr of localised cooling (T_m 34.9±0.3°C to 29.5±0.6°C;$p<0.05$) led to small but significant decreases in blood flow to all three vessels (40-60ml.min^{-1} or 15-25%;$p<0.05$), with heating (T_m 34.5±0.5°C to 36.8±0.1°C;$p<0.05$) leading to significant increases (100-360ml.min^{-1} or 63-99%;$p<0.05$). Blood flow through the PFA (the major supply artery of the thigh skeletal muscle and therefore representative of muscle blood flow) showed significant alterations following both interventions (25% decrease and 63% increase respectively;$p<0.05$). PFA vascular conductance showed a strong linear relationship with muscle temperature during both interventions (R^2=0.95 and 0.96;$p<0.01$), with the sensitivity of the response increasing considerably at ~35 °C (i.e. normal resting muscle temperature; 0.11±0.03 to 0.70±0.07ml.min^{-1}.mmHg^{-1}.°C^{-1}). Systemic and control leg values remained unchanged. During exercise, prior cooling of the leg had no effect on CFA flows. In contrast, exercise following heating resulted in significantly higher CFA flows throughout the duration of the protocol (~500ml.min^{-1};$p<0.05$). Conclusions: These findings suggest that local temperature exerts significant effects on skeletal muscle haemodynamics both at rest and during exercise over a wide range of temperatures, but with significantly increased sensitivity observed at temperatures ≥ 35°C. The maintenance of an increased blood flow throughout exercise following heating suggests an independent role for temperature in the hyperaemic exercise response, potentially mediated through the rapid increases in local muscle and blood temperature experienced when undertaking dynamic muscular contractions.

Line dance class with their spouse increase participation on exercise and Improve physical fitness and health status among Palembang's traffic police officers

Y. Fediani, S. Andriyani and M. Irfannuddin

Biomedical Science, University of Sriwijaya, Palembang, South Sumatra, Indonesia

Lack of physical activity and increase risk of degenerative disease have become problems among traffic police officers. Demanding schedule and exposure of air pollutants are daily life cycle trough the years. A delightful line dance class has been organized in traffic police quarter. The officers were asked to join the course with their spouse to increase participation. Most of total 70 traffic police officers in Palembang were interested to join the class, but class only received 40 officers with their spouse due to limited room. Line dance training packet was transpired for 2 months, 3 times a week, and 45 minutes for each session. The class was opened flexible adjusted shift schedule. The couple could choose 1 of 2 time options in each their schedule day in the morning or afternoon. There are 37 officers aged 35-48 years old complete their class properly and participated in physical fitness test before and after the course. In 2 months, line dance training could significantly improve physical fitness capacity among officers. The VO2max increase from 33.6±2.1 to 36.3±2.2 ml/kg/min ($p<0.001$), BMI decrease from 26.7±2.8 to 26.5±2.7 ($p=0.01$), sit and reach flexibility test improve from 42.4±4.7 to 43.5±4.5 cm ($p<0.001$) and relative muscle strength increase from 4.7±0.9 to 4.9±9.8 ($p<0.001$). The training also improves resting mean arterial pressure from 106.2±9.7 to 102±8.8 mmHg ($p<0.001$).
A delightful line dance could improve physical activity and physical fitness among traffic police officers. Training with their spouse could increase their participation.

To Palembang's Traffic Police officers for their participation in this study.

To Palembang's Traffic Police Department for their permission to publish the result of this study

Effects of long-term exercise on norepinephrine transporter gene expression of cardiac sympathetic ganglion in SD rats

X. Li and L. Chen

Graduate Division, ShanDong Institute of Physical Education and Sports, Jinan, ShanDong Province, China

Backgroup: Norepinephrine transporter (NET) is synthesized in sympathetic ganglion and arrived to presynaptic membrane of sympathetic nerve ending by axoplasmic transport. The synaptic norepinephrine concentration is regulated through norepinephrine release and norepinephrine re-uptake by NET, thus maintaining cardiac function. Regular exercise training has been associated with improvement of the sympathetic nervous system in several animal models and in some human studies. Although these data are consistent with the hypothesis that exercise training reduces the incidence of cardiovascular diseases, ameliorates cardiac function and enhances exercise performance via reduced sympathoexcitation, the mechanisms are unknown. Objective: The present study was to observe the effects of long-term exercise on NET gene expression of cardiac sympathetic ganglion in SD rats and to investigate the possible mechanism of exercise-induced improvement of cardiac sympathetic nerve function. Methods: Ten SD rats performed 12-week aerobic treadmill running (exercise group, EG) and the other ten SD rats as control group (CG) maintained resting state. After experiment and coeliac anesthesia with 1% pentobarbital (30mg/kg), exhaust time (ET) was determined during incremental treadmill test; left ventricular end-systolic diameter (LVESD), left ventricular end-diastolic diameter (LVEDD), fractional shortening (FS), left ventricular ejection fraction (LVEF) and heart rate (HR) using echocardiography; myocardial and plasma norepinephrine (NE) by high pressure liquid chromatography-electrochemical detection; cardiac sympathetic ganglion and myocardial NET mRNA level were determined by real-time fluorescent quantitation PCR; cardiac sympathetic ganglion and myocardial NET protein and myocardial tyrosine hydroxylase (TH) protein by Western blot. Results: Compared with CG, ET (42.6±4.2 vs 27.4±3.8 min, $P<0.01$) increased; LVEDD (7.15±0.81 vs 8.82±0.91 mm, $P<0.05$), FS (57.8±4.6 vs 45.0±4.3 mm/s, $P<0.01$) and LVEF (67.6±5.8 vs 52.4±4.7%, $P<0.01$) raised but HR reduced (314±37 vs 395±39 b/min, $P<0.05$); both plasma NE (375.7±47.2 vs 464.6±42.9 pg/ml, $P<0.01$) and myocardial NE (528.2±54.4 vs 664.1±39.8ng/g, $P<0.01$) lowered; NET mRNA (1.75±0.20 vs 1.00±0.07, $P<0.01$) and protein (1.82±0.17 vs 1.00±0.09, $P<0.01$) of sympathetic ganglion elevated; NET mRNA of heart was not detected but NET protein step-up (1.69±0.18 vs 1.00±0.08, $P<0.01$); TH protein was not significantly different (1.15±0.22 vs 1.00±0.12, $P>0.05$). Conclusion: Long-term exercise training improved cardiac construction and sympathetic nerve function, as well as enhancing exercise capacity, the mechanism of which might be related to upregulation of NET gene expression of cardiac sympathetic ganglion.

Dehydration reduces blood flow to the human brain and increases oxygen extraction during prolonged exercise in humans

S.J. Trangmar[1], S.T. Chiesa[1], K.K. Kalsi[1], N.H. Secher[2] and J. González-Alonso[1]

[1]Centre for Sports Medicine and Human Performance, Brunel University, Uxbridge, UK and [2]The Copenhagen Muscle Research Centre, Department of Anaesthesia, Rigshospitalet, Faculty of Health Sciences, University of Copenhagen, Copenhagen, Denmark

Background: Dehydration accrued during prolonged exercise in the heat induces significant cardiovascular strain on the human body characterised by reductions in cardiac output, active muscle and skin blood flow, arterial blood pressure, vascular conductance and an overall impaired exercise capacity (1). However, it is presently unknown whether progressive dehydration during exercise in the heat reduces blood flow to the brain, thereby impairing aerobic metabolism. A hyperthermic-hyperventilation induced lowering of the $PaCO_2$ may reduce blood flow to the brain, assuming that reductions in middle cerebral artery velocity (MCA V_{mean}) reflect reductions in cerebral blood flow (CBF) (2,3,4,5). This study tested the hypothesis that progressive dehydration reduces CBF during prolonged exercise in the heat, in part through mechanisms associated with $PaCO_2$, but without impairing brain VO_2. **Methods:** We assessed blood flow in the internal carotid artery (CBF) using Doppler ultrasonography and middle cerebral artery velocity (MCA V_{mean}) in ten cyclists (VO_{2PEAK}: 59 ± 2 ml/kg/min), who performed two hours of prolonged cycling exercise in a warm environment (182 ± 6 W; 35°C), without fluids to induce moderate dehydration (DEH; 3.1 ± 0.3 % body mass loss). Subjects returned one week later to repeat the protocol, but with regular fluid ingestion to maintain hydration status (Control). Blood samples were obtained from the brachial artery and left internal jugular vein (DEH only) to measure a-vO_2 differences and for the calculation of brain VO_2. All data are mean ± SEM and were compared with ANOVA and Pearson correlation (SPSS). **Results:** During dehydration CBF and MCA V_{mean} increased by 13 ± 3 % from rest to 30 min (p<0.05). Thereafter CBF declined to resting values with flow at 120 min significantly lower than at 30, 60 and 90 min (p<0.001). During control, CBF and MCA V_{mean} increased from rest to 30 min and were subsequently maintained throughout exercise (Increase ≥ 25%, p<0.05). Reductions in CBF and MCA V_{mean} during DEH were accompanied with significant increases (p<0.05) in a-vO_2 diff resulting in an unchanged brain VO_2. $PaCO_2$ declined in accordance with flow and velocity (p<0.05) with changes in flow correlated to changes in $PaCO_2$ (R^2 = 0.75, p<0.001), supporting a role for $PaCO_2$ in cerebral vasoconstriction. **Discussion:** The present findings show that progressive dehydration during prolonged exercise results in a marked reduction in CBF, whereas in control CBF did not decline. Compensatory increases in cerebral oxygen extraction allow for the maintenance of brain VO_2 throughout exhaustive exercise. These findings suggest that a reduction in brain VO_2 is an unlikely mechanism underpinning exercise capacity during prolonged, exhaustive exercise with dehydration.

Reversing potential immobilisation induced deficits in muscle blood flow does not reverse immobilisation induced blunting of forearm glucose uptake in humans

S.L. Skirrow, E.J. Simpson, K. Tsintzas, I.A. Macdonald and P.L. Greenhaff

MRC-ARUK Centre for Musculoskeletal Ageing Research, University of Nottingham, Nottingham, UK

Physical inactivity has been proposed as a major contributor to the age-related loss of muscle mass and strength [1, 2]. Alongside these impairments are several metabolic adaptations, such as the development of insulin resistance [3], which may result from an age-related decline in muscle perfusion [4]. This study investigated the impact of forearm immobilisation on brachial artery blood flow and glucose uptake. We hypothesised that if inactivity induced decrements in muscle blood flow are responsible for blunting forearm glucose uptake, this would be ameliorated by the vasodilatory action of glyceryl trinitrate (GTN).

Sixteen healthy men (20.4 ± 0.4yrs, BMI 22.9 ± 0.6kg.m^{-2}) participated and were randomly assigned to placebo or GTN group. Measurements were made before and after 5wks immobilisation of the non-dominant forearm. Subjects underwent an oral glucose tolerance test (OGTT) and received either 400μg sublingual GTN or placebo mouth spray at t=0 and t=30. Brachial artery blood flow (BF) was measured during the OGTT using Doppler ultrasound, forearm glucose uptake (FGU) was calculated from the arterialised-venous and venous difference in blood glucose concentration, and total FGU over the 3hr OGTT was calculated from the incremental AUC. Forearm muscle volume was quantified with MRI and isometric strength was measured using handgrip dynamometry. The study was approved by the University of Nottingham Ethics Committee. Values represent mean ± SEM. Single measures were compared between groups using Student's t-test. Postprandial responses were analysed using two-way ANOVA with repeated measures. Statistical significance was set at P<0.05.

Before immobilisation, GTN did not affect FGU AUC during the OGTT (GTN 99.9 ± 25.7mmol/l/mm^2 vs. Placebo 74.8 ± 13.6 mmol/l/mm^2, P=0.42). Immobilisation reduced hand grip strength by 27.1 ± 7.3% and 21.0 ± 5.7% from baseline in the placebo and GTN group respectively (P<0.01), but had no effect on muscle volume in either group (placebo change 0.05 ± 1.83% vs. GTN change -0.7 ± 1.33%, P>0.05). Immobilisation reduced FGU AUC by 42.4 ± 14.2% (P<0.05) in the placebo group. GTN increased brachial artery diameter by 15.2 ± 0.7% (P<0.01) throughout the OGTT and increased BF by 17.3 ± 2.9%

during the first hour of the OGTT (P<0.05). However the immobilisation induced decrement in FGU AUC was no different from the placebo response (55.9 ± 21.2%, P=0.64).
Immobilisation reduced FGU in response to an OGTT. The administration of GTN increased brachial artery diameter and blood flow during the OGTT, but did not improve the immobilisation induced deficit in FGU. This suggests that an immobilisation induced deficit in muscle blood flow is not responsible for the decline in glucose disposal, but instead is a muscle centric phenomenon.

Nutritional status, physical activity and food habit of children of a selected government primary school of Bangladesh

M.U. Khan[1], M.M. Abedin[1] and M.A. Salam[2]

[1]Physiology, Noakhali Medical College, Noakhlai, Bangladesh and [2]Pharmacology, Noakhali Medical College, Noakhali, Bangladesh

Background: Increase in childhood overweight and obesity have become a major public health problem in industrialized nation (1). It is also increasing in developing countries (2). Bangladesh is a developing country. School going children of this country is suffering from malnutrition rather than obesity. The national nutrition survey (1995-96) report shows that about 62% of the children aged 6-9 years are malnourished (3). The nutritional status, physical activity and food habit of school going children of Bangladesh is not known. Objectives: To know the nutritional status, physical activity and food habit of children of a selected government-run primary school at a peripheral district town of Bangladesh. Method: We conducted this cross-sectional descriptive study in the Department of Physiology, Noakhali Medical College, Bangladesh during the period of April, 2012 –June, 2012. Two hundred and twenty students of a selected government-run primary school of a district town of Bangladesh were enrolled for the study by using convenient sampling. Data on diet, physical activity, height (cm) and weight (kg) were collected using a structured questionnaire. Permission was taken from concerned authorities consent from participants. BMI <5, 5-85, >85, and >95 percentile were considered under-weight, normal, overweight, and obese respectively. Data were analyzed by using SPSS (version 12) for windows and web-based "Excel BMI calculator". Result: There were 41.4 percent boys. The mean age was 9.3±1.6 years. The main diet was rice or bread made of wheat-flour (85.5%) in breakfast, rice with meat, fish, egg, or vegetables for lunch (95.45%) and same menu for dinner (98.64%). Forty-six percent students drank cow's milk and 22.7% soft drinks. Ninety-nine percent students participated in games for a mean period of 2.81±1.25 hours. The mean±SD period of playing outdoor-game, indoor-game and game-at-school was 1.35±0.58, 1.04±0.45, and 0.76±0.31 hours respectively. Eighty-three percent students did household work for a mean period of 1.03±0.65 hours. The mean±SD height, weight and BMI of the students were 126.6±9.9 cm, 22.01±5.07 kg and 13.56±1.60 respectively. Conclusion: Sixty-five percent students were underweight, 34.55% normal weight and 0.45% obese. The prevalence of under-weight was alarmingly high and that of overweight and obesity was extremely low among the students of a government-run primary school in a peripheral district town of Bangladesh. Ninety-nine percent students participated in physical activity. The menu of diet contained all kinds of food but the quantity of food was not measured.

Effects of age, gender and starting age on muscle and bone side differences in veteran tennis players

A. Ireland[1], T.M. Maden-Wilkinson[1], B. Ganse[2], H. Degens[1] and J. Rittweger[2,1]

[1]IRM, Manchester Metropolitan University, Manchester, UK and [2]Department of Space Physiology, German Aerospace Centre, Cologne, Germany

The effectiveness of regular exercise for bone strength into older age, or when begun after puberty is not fully understood. Comparisons of sedentary individuals and athletes may introduce a self-selection bias, whereas study of tennis players allows the non-racquet arm to act as a control for the exercising racquet arm.
Therefore, peripheral quantitative computed tomography (pQCT) scans were taken at radius, ulna and humerus mid-shaft, and distal radius in both arms of ninety veteran tennis players (mean age 63.7±11.8y). Large side differences in muscle and bone size and strength – in favour of the racquet arm – were found. The most pronounced findings were a 13±10% higher distal radius bone mass and 23±12% larger cortical area in the humerus (both $P < 0.001$). There was no age effect on bone mass (all $P > 0.2$; except humerus where $P = 0.055$ and $R^2 = 0.002$). Proximal radius and ulna strength in bending and torsion were positively associated with increasing age (all $P < 0.05$). Despite no age effect on training volume ($P = 0.201$) many side differences were less pronounced in older players – particularly in the humerus where side differences in bone mass, cortical thickness and stiffness in bending and torsion were 43-47% less in 80- than 40-year olds (all $P < 0.01$). Gender effects on side difference were found for a number of bone

parameters - in all cases differences were more pronounced in men than women. This was most apparent in the humerus where male side differences in most parameters (except cortical BMD and endocortical circumference) were 22-37% greater than in females despite similar training volumes for both genders. Bone strength side differences in players who began playing in adulthood were smaller than those who began during childhood – in particular in total bone CSA, and periosteal circumference at all sites (all $P < 0.05$).
In summary, whilst regular tennis participation in older age is associated with greater racquet arm muscle and bone size and strength these differences are lower at old age and in females. The age-associated decline is likely due – at least in part – to the reduced racquet arm advantage in muscle size and strength at older age. In addition, the effectiveness of exercise for bone when begun in adulthood (i.e. after epiphyseal closure) is less - mainly due to the lack of significant periosteal apposition.

A new equation to estimate oxygen consumption during exercise on the cycle ergometer

F. Formenti[1,2], J. Ives[2], E. Seminati[3], S. Sethi[2], N.J. Somerville[2], A.E. Minetti[3] and F. Borrani[4,2]

[1]Nuffield Division of Anaesthetics, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK, [2]Department of Sport and Exercise Science, University of Auckland, Auckland, New Zealand, [3]Institute of Human Physiology, University of Milan, Milan, Italy and [4]Department of Physiology, University of Lausanne, Lausanne, Switzerland

Direct measurement of human metabolism is recommended for accuracy in individuals' exercise testing; when direct measurement is not feasible, estimation of metabolism during exercise is acceptable. The American College of Sports Medicine (ACSM) suggests estimating oxygen consumption (VO2) during exercise on a cycle ergometer through a straightforward equation that considers an individual's body mass and work rate (ACSM, 2009). Despite avoiding complex calculations, this equation does not consider the effect of pedalling rate (PR) on VO2. However, when cycling at a given work rate, PR can be a strong determinant of VO2 (Seabury et al., 1977, Zoladz et al., 2000). We hypothesised that, for sub-maximal exercise on the cycle ergometer, including PR in the ACSM equation would allow more accurate VO2 prediction.
Seven healthy male participants (average ± standard deviation: age 26 ± 9 years, height 180 ± 6 cm, weight 76 ± 10 kg) took part in the study, which conformed to the Declaration of Helsinki and had been approved by the local Ethics Committee. Participants' VO2 was recorded during steady-state exercise on the cycle ergometer at four PR (50, 70, 90, 110 revolutions per minute); each PR was studied at four subsequent sub-maximal external work rates (0, 50, 100, 150 W). Participants rested for a period of at least 40 min between tests. Participants' VO2 was also predicted as a function of participant's body mass, work rate and PR (Minetti, 2011):
VO2 = 3.5 + 10.8 * WR/BM + 0.0000076 * PR (Equation 1)
Here, 3.5 is an assumed constant for resting VO2 (ml O2 kg-1 min-1), WR indicates work rate (W), and BM participant's body mass (kg); PR is pedalling rate (revolutions per minute), and represents the metabolic equivalent of the internal work. Participants' VO2 was also predicted through the ACSM equation as a means of comparison. Data were analysed by Student's paired t-test and linear regression analysis.
The recorded VO2 values ranged from 6 to 37 ml O2 kg-1 min-1. Figure 1 shows the VO2 values predicted by Eq. 1 and by the ACSM equation as a function of measured VO2 values. Both sets of predicted VO2 values showed a direct linear relationship with measured VO2 values. When plotted against the measured VO2 values, those predicted by Eq. 1 were closer to the identity line than values predicted by the ACSM equation. We conclude that PR is an important determinant of VO2, and that Eq. 1 improves the accuracy of the ACSM equation for exercise on the cycle ergometer. These preliminary findings need to be confirmed in a larger sample population.

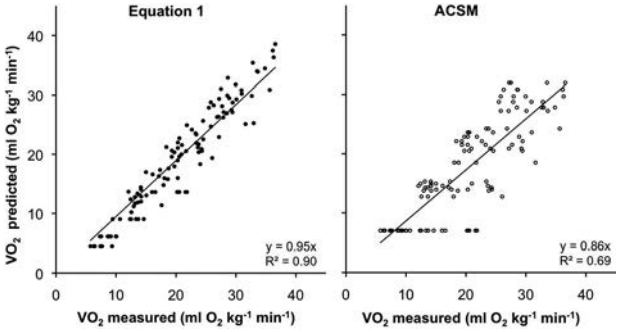

Figure 1. VO2 values predicted by (left) Eq. 1 and by (right) the ACSM equation are shown as a function of measured VO2 values. Each circle shows data recorded at steady state for 2 min in one participant, at a given combination of work rate and PR (n = 112). The straight lines illustrate the respective linear regression lines.

Remote ischemic preconditioning increases the time to task failure during rhythmic handgrip exercise in men: underlying hemodynamic mechanisms

T.C. Barbosa[1], A.C. Machado[1], I.D. Braz[1,3], I.A. Fernandes[1], L.C. Vianna[1], A.L. Nobrega[1] and B.M. Silva[1,2]

Ischemic preconditioning (IP) protects both the tissue where it is applied (Local IP) and others (Remote IP) against injury induced by prolonged ischemia. Local IP can increase maximal power output in an exercise test. However, it is not clear whether Remote IP could also increase physical performance and which mechanisms associates IP and physical performance. This study investigated the effects of Remote IP on physical performance during handgrip exercise and possible mech-

anisms associated. Thirteen men underwent randomly Remote IP or Sham intervention in 2 sessions. After that, they performed handgrip exercise until task failure. Time to task failure was measured as well as brachial blood flow and conductance, forearm normalized concentration of deoxygenated hemoglobin and myoglobin (Deoxy-Hb norm.), tissue oxigenation index (TOI norm.), heart rate (HR), stroke volume (SV), mean arterial pressure (MAP) and total peripheral resistance (TPR). Comparisons between conditions were made at equal exercise time (20%, 40%, 60%, 80% and 100% of shorter session exercise time) and at peak exercise of each session. Measurements of maximal voluntary contraction, exercise time and brachial artery diameter were reproducible (intraclass correlation coefficient >0.9) and mean coefficient of variation was between 5.1% to 13.5%. Time to task failure increased by 25.3%, from 191±21 s after Sham intervention to 244±37 s after Remote IP (Student's T test P=0,019). The increment of exercise time between Remote IP and Sham correlated positively to the increment of blood flow, conductance, TOI norm. and SV at 100% of total exercise time, and correlated negatively to the impairment of Deoxy-Hb norm., HR, MAP and TPR at 100% of total exercise time. At peak exercise, Remote IP led to a higher Deoxy-Hb norm. and lower TOI norm. Subjects who were responders to Remote IP (exercise time increment >13.5%; n=6) had lower MAP and TPR and higher VS at 100%, compared to Sham. At peak exercise, Remote IP increased blood flow. However, Deoxy-Hb norm. and TOI norm. were similar between conditions in these subjects. In conclusion, Remote IP increased exercise performance, possibly by improvement of blood flow and vascular conductance response to exercise. This improvement, in turn, could be due to a greater local vasodilation and an attenuation of sympathetic tone.

Age, but not osteoarthritis is related to a reduction in skeletal muscle Na^+,K^+ -ATPase content in older adults

B. Perry[1], P. Levinger[1,4], F.R. Serpiello[1], M.K. Caldow[2,5], D. Cameron-Smith[3], J.R. Bartlett[6], J.A. Feller[4], N.R. Bergman[6], I. Levinger[1] and M.J. McKenna[1]

[1]Institute of Sport, Exercise and Active Living, Victoria University, Melbourne, VIC, Australia, [2]School of Exercise and Nutrition Sciences, Deakin University, Melbourne, VIC, Australia, [3]Liggins Institute, University of Auckland, Auckland, New Zealand, [4]Musculoskeletal Research Centre, Faculty of Health Sciences, La Trobe University, Melbourne, VIC, Australia, [5]Basic and Clinical Myology Laboratory, Department of Physiology, University of Melbourne, Melbourne, VIC, Australia and [6]Warringal Medical Centre, Melbourne, VIC, Australia

Introduction: Knee osteoarthritis (OA) is a debilitating disorder that is accompanied by loss of muscle mass and strength and is prevalent in older populations (Lawrence *et al.*, 2008). In skeletal muscle the Na^+,K^+ -ATPase (NKA) regulates membrane potential and excitability and thereby directly influences skeletal muscle force generation (McKenna *et al.*, 2008). This study examined the effects of both OA and ageing on muscle NKA content in old participants. *Methods:* Thirty-six older adults participated (range: 55-81 years old); nineteen had OA (69.9 ± 6.5 yr, mean age ± SD) and 17 were asymptomatic age-matched controls (CON; 66.8 ± 6.4 yr). A vastus lateralis muscle biopsy was taken and analysed for NKA content ($[^3H]$ ouabain binding sites), NKA $\alpha_{1\text{-}3}$ and $\beta_{1\text{-}3}$ isoform protein abundance (immunoblotting) and NKA isoform mRNA content (real time RT-PCR). Participants also underwent knee extensor muscle strength testing and completed a physical activity questionnaire. Differences in NKA between OA and CON were assessed using independent t-tests, and association between age and NKA content was investigated using bivariate correlation in both the OA and CON group individually, and in the pooled data. *Results:* OA participants had 40.8% lower strength ($p = 0.005$), but 34% higher NKA α_2 ($p = 0.006$) and 1 fold greater NKA α_3 ($p = 0.016$) abundance compared to CON. OA participants performed more incidental physical activity ($p = 0.035$). No significant differences were found between groups for total NKA content, NKA $\alpha_{1\text{-}3}$ and $\beta_{1\text{-}3}$ isoform mRNA content, and NKA α_1, β_1, β_2, and β_3 isoform abundance. There was an inverse correlation between age and $[^3H]$ ouabain binding sites with both participant groups combined ($r = -0.467$, $p = 0.038$, Figure 1), and in the OA participants ($r = -0.626$, $p = 0.03$). *Conclusions:* NKA content was not decreased in OA compared to asymptomatic controls. We also reported that age is negatively correlated with $[^3H]$ ouabain content independent of disease state which may suggest that age but not knee OA is related to decreased muscle NKA content.

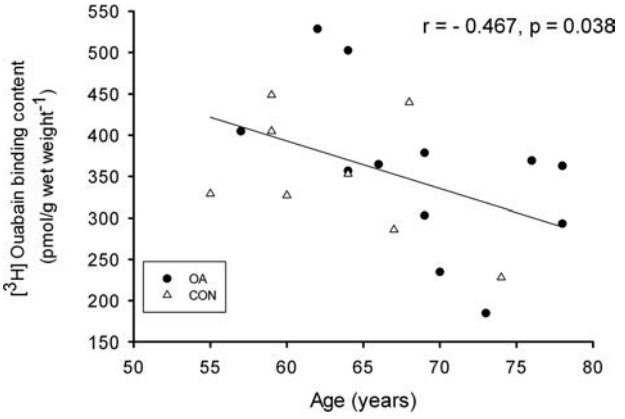

Figure 1: Spearman correlation coefficient: age and ouabain binding site content. Filled circles: OA, unfilled triangles: CON.

Fibre type specific differences and adaptability of the Na^+,K^+-ATPase α1-3 and β1-3 isoforms to intermittent training in human single skeletal muscle fibres

V.L. Wyckelsma[1], R.M. Murphy[2], F.R. Serpiello[1], C.R. Lamboley[1] and M.J. McKenna[1]

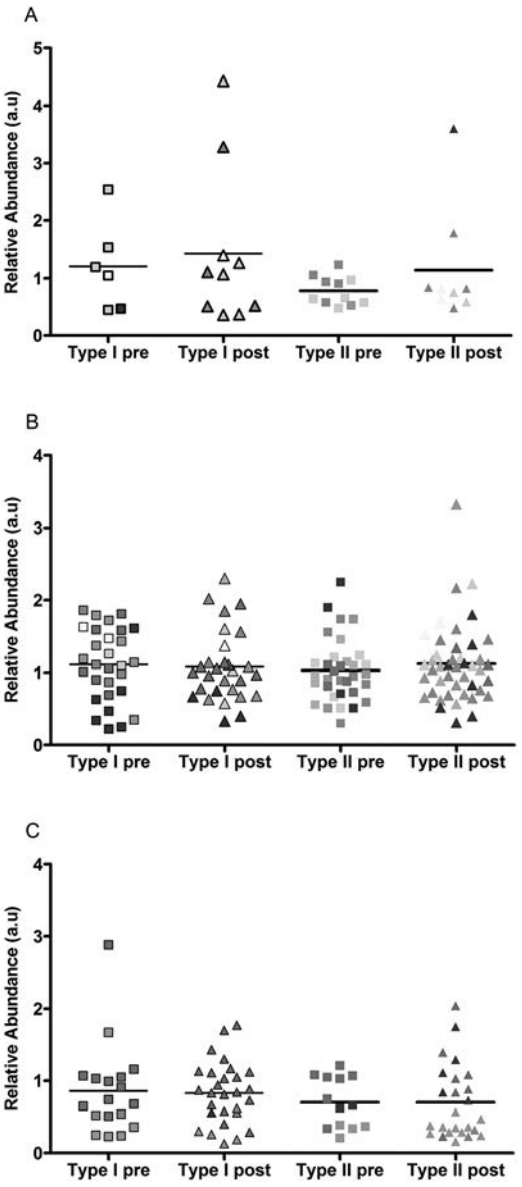
[1]ISEAL, College of Sport and Exercise Science, Victoria Univerisity, Melbourne, VIC, Australia and [2]Department of Zoology, La Trobe University, Melbourne, VIC, Australia

Introduction The Na^+-K^+-ATPase (NKA) plays a key role in skeletal muscle excitability but little is known on the fibre-specific NKA abundance in human skeletal muscle. Exercise training is a proven modality for upregulating NKA in skeletal muscle and enhancing exercise performance. Repeated-sprint exercise (RSE) training comprises multiple "all-out" efforts interspersed by brief recovery periods and might differentially upregulate NKA isoforms in different fibre types. Therefore we investigated the fibre-specific differences in the abundance of all six NKA isoforms expressed in single human muscle fibres and whether fibre-specific adaptations in NKA occurred in response to intense RSE training.

Methods Eight healthy participants trained three times per week for 4 weeks, each session comprising three sets of five, 4-s maximal sprints. A vastus lateralis biopsy was taken before and after training, single fibres were separated and fibre type (MHC I and IIa) and NKA isoform protein abundance (α1-3, β1-3) were determined by western blotting.

Results All six NKA isoforms were co-expressed in both Type I and IIa fibres. None of the three α isoforms were expressed in a fibre type specific manner; although there was a tendency for α1 protein to be more abundant in type I compared to type IIa fibres (Figure 1). The NKA β1 and β3 isoforms were also not expressed in a fibre type specific manner (Figure 2). The NKA β2 abundance was higher in type I than in Type IIA fibres (1.33±0.18 vs. 0.83±0.07, respectively, P=0.012). RSE training upregulated NKA β1 in both type I (Pre-train 0.91±0.08, vs. Post-Train1.22±0.08, P=0.035); and Type IIa fibres (Pre-train 0.81±0.06 vs. Post-Train 1.17±0.08, P=0.05). There was a tendency for upregulation of other NKA isoforms in MHC IIa fibres post training with moderate effect sizes detected for α1 (ES=0.6), β2 (ES=0.4) and β3 (ES=0.5).

Discussion The first important finding was that all six NKA isoforms were detected at the protein level in each human single muscle fibre; furthermore, these fibres showed homogeneity of NKA isoform expression across the type I and IIa fibre types. The only major exception was the greater abundance in β2 in Type I fibres. These findings contrast sharply with previous studies conducted on rat muscle. Four weeks of RSE training upregulated β1 in both fibre types, which may have implications for increasing NKA activity. However RSE training did not increase the NKA α isoform abundance in either fibre type; this may reflect insufficient physiological stress induced by 4-s sprints with RSE.



Individual and mean data of fibre type specificity of Na^+, K^+-ATPase α1-3 isoforms in single fibres pre-training and following four weeks of repeat sprint training. Individual fibres colour coded to participants which they belong to. Each isoform is normalised to the average of the type IIa fibres on each gel and expressed as relative abundance (a.u), (A) α1 (B) α2 (c) α3. Training changes measured by independent t-test. Data expressed as mean ± SEM

Arterial baroreceptor loading does not alleviated heat-induced hyperventilation

R.A. Lucas[1,2], J. Pearson[1,3], Z.J. Schlader[1] and C.G. Crandall[1]

[1]Institute for Exercise and Environmental Medicine, Texas Health Presbyterian Hospital, Dallas, TX and Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX, USA, [2]Centre for Global Health Research, Umea University, Umea, Sweden and [3]Cardiff Metropolitan University, Cardiff, UK

Introduction: Hyperthermic hyperventilation has been well documented in humans; however, the mechanisms and the physiological relevance of such a response remains unclear. Reductions in mean arterial pressure (MAP) often coincide with hyperthermia due to heat dissipation mechanisms. Given that reductions in MAP stimulate increases in ventilation this study tested the hypothesis that arterial baroreceptor loading would reverse heat-induced increases in ventilation and accompanying decreases in end-tidal carbon dioxide ($P_{ET}CO_2$).

Methods: Eleven individuals (26 ±5 y; 71 ±15 kg) underwent passive heat stress via a water perfused suit while lying supine with their lower legs resting off the end of the bed, their knees at an angle of ~80° and their feet supported. This was done to aid venous pooling and augment heat-related reductions in MAP. Intestinal temperature (HQ Inc.), mean skin temperature, MAP (Finometer Pro), central venous pressure (central venous catheter, n=4), minute ventilation, tidal volume, respiratory rate (Parvo-Medics) and $P_{ET}CO_2$ (capnograph) were monitored continuously. After intestinal temperature was elevated (P<0.05) 1.8 ±0.5°C, causing a sustained rise in ventilation (by 4.9 ±2.7 $L.min^{-1}$, P<0.01) and reductions in $P_{ET}CO_2$ (by 5 ±2 mm Hg, P<0.01) plus MAP (by 9 ±7 mm Hg, P<0.01), phenylephrine was infused over 5 min to restore MAP to normothermic values.

Results: Phenylephrine infusion increased MAP by 11 ±5 mm Hg (P<0.01), restoring it to normothermic values, but did not change (P>0.05) ventilation or $P_{ET}CO_2$. Intestinal and skin temperatures did not change (P>0.05) with phenylephrine infusion. See Table.

Conclusion: The absence of a reduction in ventilation upon returning arterial baroreceptor loading to pre-heat stress levels indicates that hyperthermic hyperventilation is not caused by arterial baroreceptor unloading coincident with the heat stress.

Table: Thermal, haemodynamic and respiratory measures during normothermia, hyperthermia and phenylephrine infusion.

	Normothermia	Hyperthermia	Phenylephrine infusion
Intestinal temperature (°C)	36.9 ±0.2	38.7 ±0.4 *	38.9 ±0.5 *
Mean skin temperature (°C)	33.9 ±0.5	39.9 ±0.5 *	39.8 ±0.5 *
MAP (mm Hg)	85 ±7	76 ±8 *	87 ±9 #
Ventilation ($L.min^{-1}$)	7.6 ±2.3	12.5 ±2.8 *	11.6 ±4.6 *
$P_{ET}CO_2$ (mm Hg)	41 ±2	36 ±3 *	36 ±3 *
Tidal volume (L)	0.51 ±0.14	1.01 ±0.43 *	0.99 ±0.49 *
Respiratory rate (breaths per min)	14.8 ±2.1	14.5 ±5.9	13.4 ±5.8

$P_{ET}CO_2$, end-tidal carbon dioxide; MAP, mean arterial pressure. * Significantly different from normothermia P<0.05, # Significantly different from hyperthermia P<0.05.

Aged garlic extract improves on metabolic parameters in exercise trained obese rats

D. Seo[1], H. Kwak[2], L. Dizon[1], Y. Baek[3], N. Kim[1], B. Rhee[1], K. Ko[1], S. Lee[1], B. Park[4] and J. Han[1]

[1]Cardiovascular and Metabolic Disease Center, College of Medicine, Inje University, Busan, Republic of Korea, [2]Department of Kinesiology, Inha University, Inchon, Republic of Korea, [3]Department of Physical Education, Pusan National University, Busan, Republic of Korea and [4]Division of Leisure & Sports Science, Dong Seo University, Busan, Republic of Korea

Aged garlic extract (AGE) is known to have a protective effect against immune system, endothelial function, oxidative stress

and inflammation. We examined the effects of exercise with and without aged garlic extract administration on body weight, lipid profiles, inflammatory cytokines, and oxidative stress marker in high-fat diet (HFD)-induced obese rats. Forty-five Sprague-Dawley rats were fed either a HFD (HFD, n = 40) or a normal diet (ND, n = 5) for 6 weeks and thereafter randomized into ND (n = 5), HFD (n = 10), HFD with AGE (n = 10), HFD with Exercise (n = 10), or HFD with Exercise+AGE (n = 10) for 4 weeks. AGE groups were administered at a dose of 2.86 g/kg/body weight, orally. Exercise consisted of running 15-60 min 5 days/week with gradually increasing intensity. AGE ($P < 0.01$), Exercise, and Exercise+AGE ($P < 0.001$) attenuated body weight gain and food efficiency ratio compared to HFD. Visceral fat and liver weight gain were attenuated ($P < 0.05$) with all three interventions with a greater effect on visceral fat in the Exercise+AGE than AGE ($P < 0.001$). In reducing visceral fat ($P < 0.001$), epididymal fat ($P < 0.01$) and liver weight ($P < 0.001$), Exercise+AGE was effective, but exercise showed a stronger suppressive effect than AGE. Exercise+AGE showed further additive effects on reducing visceral fat and liver weight ($P < 0.001$). AGE significantly attenuated the increase in total cholesterol and low-density lipoprotein-cholesterol compared with HFD ($P < 0.05$). Exercise+AGE attenuated the increase in triglycerides compared with HFD ($P < 0.05$). Exercise group significantly decrease in C-reactive protein ($P < 0.001$). These results suggest that AGE supplementation and exercise alone have anti-obesity, cholesterol lowering, and anti-inflammatory effects, but the combined intervention is more effective in reducing weight gain and triglycerides levels than either intervention alone.

Changes in body composition and rates of fat oxidation following 12 weeks high intensity exercise

L. Bagley, M. Slevin, N. Al-Shanti, M. Piasecki, G. Morrissey, H. Foulkes, M. Carroll, C. Murgatroyd, D. Liu, W.S. Gilmore and J.S. McPhee

Institute for Biomedical Research into Human Movement and Health, Manchester Metropolitan University, Manchester, England, UK

Intro:
A typical High Intensity Interval Training (HIIT) programme involves only around 4 min exercise per session, yet improves cardiorespiratory function and increases fatty acid oxidation. It remains unclear whether such short duration, high intensity exercise will lead to significant loss of fat mass over time.
Methods:
Men and women (n=42, 57% male, mean (SD) age: 33 (±5) yrs;) from the general Manchester population gave written informed consent to participate. Measurements of body composition by Dual energy X-ray absorptiometry (DXA), maximal oxygen uptake (VO2max) and maximal rates of fat oxidation (FATmax) were taken in the fasted state before and after 12 weeks HIIT. HIIT consisted of 4 x 20 sec sprints on a cycle ergometer at a workload of approximately two-times higher than VO2max; 3 times per week, totalling 4 mins exercise per week.
Results:
VO2max increased by 7%(pre-training: 2.9 ml/min-1(±0.9) vs post-training:3.1ml/min-1 (±0.88) p=0.0003). The maximal rate of fat oxidation during steady-state exercise increased by 19%, from 7.8 mg/kg/min-1 (±3.2) to 9.3 mg/kg/min-1 (±3.9) (p=0.02). There were no significant changes to total body lean mass, lean mass of the legs or of the arms. Total body fat mass decreased by 5.42% (pre-training: 18.25 kg (±6.10) vs post-training 17.24 kg (±5.96) P=0.0002). Trunk fat decreased by 3% (pre-training: 9.1 kg (±3.9) vs post-training 8.8 kg (±3.8) p=0.007) and leg fat decreased by 6% (pre-training: 6.8 kg (±1.1) vs post-training: 6.4 kg (±1.1) p=<0.0005).
Conclusion:
A total of 4 min exercise per week over 12 weeks significantly increased VO2max and fat oxidation. It also decreased total body, trunk and leg fat mass. These adaptations might improve health status and reduce risk of metabolic and cardiovascular disease.

Caveolin-1 negatively regulates TLR4 to activate MAPK pathway in LPS-challenged mammary epithelial cells

X. Wang[1], Z. Wu[1], H. Huang[1], C. Han[1], W. Zou[1,2] and J. Liu[3]

[1]Liaoning Normal University, Dalian, China, [2]Liaoning Key Laboratories of Biotechnology and Molecular Drug Research and Development, Dalian, China and [3]The First Affiliated Hospital, Dalian Medical University, Dalian, China

Mastitis is an inflammation of the mammary gland commonly caused by bacterial infection. Mammary epithelial cells mount defense against invading pathogens by detecting their respective danger signals or ligands and initiating appropriate immune responses. Caveolaes are a subset of lipid rafts that are rich in glyco-sphingolipids and cholesterol, mediate non-clathrin-dependent endocytosis, and regulate the internalization of particles such as bacteria. Caveolin-1, component of caveolae membranes, has been implicated as a modulator of innate immunity and inflammation. TLRs, Toll-like receptors, play central roles in the regulation of the host immune system and each TLR recognizes specific pathogen-associated molec-

ular patterns. TLR4 is one of the well characterized pathogen recognition receptors that recognizes the LPS of Gram-negative bacteria. To explore the role of caveolin-1 gene silencing on mitogen-activated protein kinase (MAPK) activation in lipopolysaccharide (LPS)-challenged human mammary epithelial cells, we established MCF-10ACE of caveolin-1 gene silencing from human mammary epithelial cell line MCF-10A by iRNA technology. DNA micro-assay was used to detect the expression file of inflammation-associated genes in MCF10ACE. Western blot analysis was used to examine the activation of mitogen-activated protein kinase (MAPK) in lipopolysaccharide (LPS)-challenged MCF-10A and MCF-10ACE. Moreover, immunofluorescence and Western blot analysis were performed to detect the co-localization of caveolin-1 and toll-like receptor 4 (TLR4) in human mammary epithelial cells. We found that MCF-10ACE exhibited significant increases in inflammation-associated genes expression, such as Prostaglandin-endoperoxide synthase 2 (PTGS2), B-cell lymphoma 2 (BCL2), Fas ligand (FAS) and Interleukin 2 receptor alpha (IL2Rα) were increased by >1.5-fold, even Interleukin 6 (IL-6) was increased by 7-fold and Interleukin 6 receptor (IL-6R) was increased by 17-fold.. In addition, LPS-induced p38 MAPK and JNK MAPK activation were significantly increased in MCF-10ACE ($p<0.01$). Furthermore, caveolin-1 colocalized with TLR4 and appeared a negative correlation trend. In conclusion, caveolin-1 gene silencing promotes MAPK activation via TLR4 signaling in human mammary epithelial cells response to LPS.

The relationship between brain cortical activity and brain oxygenation in the prefrontal cortex during hypergravity exposure

C. Smith[1,2], N. Goswami[2], R. Robinson[3], M. von der Wiesche[4] and S. Schneider[5]

[1]Sport and Exercise Sciences, University of Birmingham, Birmingham, UK, [2]Institute of Physiology, Medical University Graz, Graz, Austria, [3]Centre of Human & Aerospace Physiological Sciences, King's College London, London, UK, [4]Institute of Aerospace Medicine, German Aerospace Center (DLR), Cologne, Germany and [5]Institute of Movement and Neurosciences, German Sport University Cologne, Cologne, Germany

Artificial gravity has been proposed as a method to counteract the physiological de-conditioning of long duration spaceflight, however the effects of hypergravity on the central nervous system has had little study. The study aims to investigate whether there is a relationship between prefrontal cortex brain activity and prefrontal cortex oxygenation during exposure to hypergravity. Twelve healthy participants were selected to undergo hypergravity exposure aboard a Short Arm Human Centrifuge. Participants were exposed to hypergravity in the +Gz axis, starting from 0.6+Gz for females, and 0.8+Gz for males, gradually increasing by 0.1+Gz, until the participant showed signs of syncope. Brain cortical activity was measured using electroencephalography (EEG), and localized to the prefrontal cortex using standard low resolution brain electromagnetic tomography (LORETA). Prefrontal cortex oxygenation was measured using near-infrared spectroscopy (NIRS). Analysis of variance, including Fisher's least significant difference post hoc test were used to determine significant changes in prefrontal cortex cortical activity and oxygenation, and Pearson's test of correlation to determine any relationship between the two. A significant increase in prefrontal cortex activity ($p < 0.05$) was observed during hypergravity exposure compared to baseline. Prefrontal cortex oxygenation was significantly decreased during hypergravity exposure, with a decrease in oxyhemoglobin levels ($p < 0.05$) compared to baseline, and an increase in deoxyhemoglobin levels ($p < 0.05$) with increasing +Gz level. No significant correlation was found between prefrontal cortex activity and oxy/deoxyhemoglobin. It is concluded that the increase in prefrontal cortex activity observed during hypergravity was most likely not the result of increased +Gz values resulting in a decreased oxygenation produced through hypergravity exposure. No significant relationship between prefrontal cortex activity and oxygenation measured by NIRS, concludes brain activity during exposure to hypergravity may be difficult to measure using NIRS. Instead, the increased in prefrontal cortex activity might be attributable to psychological stress, which could pose a problem for the use of a SAHC as a countermeasure.

Diet related water seems to affect in vivo skin hydration and biomechanics

L. Palma[1], L. Tavares[1], C. Monteiro[1], M.J. Bujan[3] and L.M. Rodrigues[1,2]

[1]CBiOS, U Lusofona Fac Health Sc & Technol, Lisboa, Portugal, [2]Pharmacol Sc Departm, U Lisboa School PHarmacy, Lisboa, Portugal and [3]UAH, U Alcala Faculty Medicine, Madrid, Spain

The biomechanical behaviour of human skin has been studied in order to better understand this complex behaviour allowing all types of movements, within the physiological limits, without cracking. Water from diet allegedly affect skin hydration and both seems to play a role in this context. So, the aim of this study is to identify the relationship between ingested water, skin hydration and skin biomechanical properties. Forty

healthy volunteers, female, mean age 24,30±5,53 y.o. participated in the study, after informed written consent. All procedures respected Helsinki principles and respective amendments. Volunteers with different dietary water intakes were asked to drink 2L water/dayly during 1 month. Measurements of skin physiological variables were taken in day 0 (t0) and day 30 (t30) and focused several anatomical regions (zygomatic, forehead, ventral forearm, hand and, external leg). Representative variables were transepidermal water loss (TEWL, measured by Tewameter TM300, CK electronics), epidermal hydration (measured by MoistureMeter SC and MoistureMeter D, Delphin) and biomechanical descriptors (Cutometer CM575, CK electronics).. Statistics included a t-student paired sample, hypothesis testing Shapiro - Wilk, Spearman, and a Pearson and Spearman correlation with a confidence level of 95%
A significant positive correlation between hydration and total extensibility (Uf) and a negative correlation (p<0,05) with total elasticity (Ua/Uf) elasticity (Ur/Ue), visco-elastic index (Ue/Uv) and total deformation recovery at the end of stress-off period (Ua) was noted. Thus, a positive impact on skin physiology seems to result from higher water intakes, in particular in those individuals that regularly consume less water

Adipogenic transdifferentiation of fibroblasts, but not myogenic stem cells, from human skeletal muscle

C.C. Agley, A. Rowlerson, C.P. Velloso, N.R. Lazarus and S.D. Harridge

Centre of Human & Aerospace Physiological Sciences, King's College London, London, UK

Several pathologies of adult skeletal muscle are associated with increased intramuscular adipose tissue, but the cellular source of the adipocytes is disputed. In order to establish which cell types from human skeletal muscle might be responsible we undertook experiments *in vitro* on cells extracted from muscle biopsy samples. These were obtained (following local anesthesia, 2% Lignocaine), from the vastus lateralis of healthy male volunteers aged (25.6±3.5 years). We first optimised an immuno-magnetic method to separate human myogenic stem cells from non-myogenic cells (predominantly fibroblasts). This gave initial purities of 96.9±1.4 and 90.5±3.12 (mean ±SD, n=5 biopsies) for myogenic (CD56+ve/desmin+ve) and fibroblast (CD56-ve/TE-7+ve) populations respectively. We then tested if the purified cell populations could transdifferentiate into adipocytes in response to treatment with fatty acids (600μM palmitic and oleic acid) or Adipocyte Inducing Medium. This experimental approach was combined with quantitative analysis of Oil-Red O staining for lipid acummulation and immunostaining for lineage markers and transcription factors. Both treatments caused the fibroblasts to transdifferentiate into adipocytes, as evidenced by loss of the intracellular connective tissue protein TE-7 (from 94.6±3.6% to 5.0±2.% of cells, P<0.001), significant upregulation of the adipogenic transcription factors PPARγ and C/EBPα (P<0.001), and adoption of the typical Oil-Red O+ve lipid-laden adipocyte morphology. Lipid content per cell (Oil-Red O+ve area μm^2) was significantly greater (P<0.001) in fibroblasts compared to muscle cells both before (muscle cells 13.1±5.5 vs. fibroblasts 80.0±17.6) and after fatty acid treatment (muscle cells 149.5±75.9 vs. fibroblasts 556.0±224.0). Muscle cells did not transdifferentiate under any condition, but significantly upregulated PPARγ and C/EBPα in response to fatty acids (P<0.001). Contrastingly, PPARγ and C/EBPα were slightly, but significantly decreased (P<0.001) in muscle cells cultured in AIM medium, revealing differences in the regulation of these transcription factors between myogenic cells and fibroblasts. After 15 days of AIM treatment muscle cells, all of which were incapable of adipogenesis, contained on average ~500 fold less lipid per cell than the fibroblasts which had transdifferentiated into adipocytes. These data suggest that skeletal muscle fibroblasts and not myogenic cells, are the major cellular source of intramuscular adipose tissue. Our findings have clear implications for therapeutic approaches aimed at regulating adipogenesis in skeletal muscle.

Evidence for centrally-induced cholinergic vasodilatation in skeletal muscle at the start of voluntary one-legged cycling and during motor imagery in humans

K. Ishii[1], K. Matsukawa[1], N. Liang[1], K. Endo[1], M. Idesako[1], H. Hamada[2], K. Ueno[3] and T. Kataoka[3]

[1]Department of Integrative Physiology, Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan, [2]Department of Health and Sports Medical Sciences, Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan and [3]Department of Health Care for Adults, Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan

We have recently shown that neurogenic vasodilatation in non-contracting and contracting vastus lateralis (VL) muscles is induced by descending signal from higher brain centres (termed central command) at the start of voluntary one-legged cycling and during motor imagery of the exercise (Ishii et al. 2012). The centrally-induced vasodilatation may be mediated by a sympathetic cholinergic mechanism as our laboratory reported previously using voluntary static exercise in conscious cats (Komine et al. 2008). On the other hand, as another possibility, central command may activate sympathetic adrenergic nerve, which in turn causes β-adrenergic vasodilatation in skeletal muscle. We examined which of the two vasodilator mechanisms contributes to the centrally-induced vasodilatation in both non-contracting and contracting VL muscles at the start of voluntary one-legged cycling with the right leg and during motor imagery of the cycling. The blood flow responses in the VL muscles during the two interventions were compared before and after intravenous injection of atropine sulfate (10 μg/kg) or propranolol (0.1 mg/kg). The relative concentrations of oxygenated- and deoxygenated-hemoglobin (Oxy- and Deoxy-Hb) in the bilateral VL muscles were measured with near-infrared spectroscopy as an index of muscle tissue blood flow in nine subjects. The Oxy-Hb increased by 3.5 ± 1.2% (mean ± S.E.M.) in the non-contracting VL muscle and by 3.1 ± 2.0% in the contracting VL muscle at the start of the one-legged cycling, although the Deoxy-Hb was unchanged throughout the cycling. The results suggested the increased in tissue blood flow to both contracting and non-contracting VL muscles. Atropine abolished the initial increases in the Oxy-

Hb of both non-contracting and contracting VL muscles. In contrast, propranolol did not affect the initial hyperaemia in both VL muscles but tended to reduce the Oxy-Hb responses during the later period of one-legged cycling, suggesting that the initial hyperaemia cannot be explained by β-adrenergic vasodilatation. Motor imagery of the right one-legged cycling caused increases in the Oxy-Hb of bilateral VL muscles (right VL: 2.4 ± 0.5%; left VL: 3.1 ± 0.6%) without changing the Deoxy-Hb. The centrally-induced increases in Oxy-Hb were abolished by atropine, but they were not affected by propranolol. Taken together, it is concluded that central command transmits cholinergic, but not β-adrenergic, vasodilator signals to both non-contracting and contracting skeletal muscle at the start of voluntary exercise and during motor imagery.

Team sports are as effective as traditional aerobic exercise training at reducing risk factors associated with the development of type 2 diabetes mellitus

A.E. Mendham[1], R. Duffield[2], A.J. Coutts[2], F. Marino[1] and D.J. Bishop[3]

[1]School of Human Movement, Charles Sturt University, Bathurst, NSW, Australia, [2]Sport and Exercise Discipline Group, University of Technology Sydney, Sydney, NSW, Australia and [3]ISEAL, Victoria University, Melbourne, VIC, Australia

The majority of research on the benefits of physical activity to counter the occurrence of diabetes has employed continuous aerobic exercise, often performed at a low or moderate intensity. Recent research has identified intermittent exercise, as performed during team sports, as a promising alternative for those otherwise not inclined towards conventional aerobic exercise training, particularly given the associated greater enjoyment, motivation and social benefits. However, there is limited evidence for the efficacy of intermittent exercise for improving factors normally associated with the development of diabetes. In the present study, we investigated whether small-sided games (SSG) could be an effective alternative to traditional continuous exercise training. Thirty middle-aged, sedentary, men (48.6±6.6 y) were randomly assigned to a cycle ergometry (n=11), SSG (n=10), or control group (n=9). Participants in both exercise groups trained 3 d/wk for 8 wk, while control participants maintained normal activity and dietary patterns. All participants completed pre- and post-intervention testing, including: dual-energy x-ray absorptiometry scan, incremental exercise test, resting oral glucose tolerance test (OGTT) and a resting muscle biopsy. Plasma glucose and insulin concentrations were measured in a fasted state and throughout the 2 h OGTT. Total content of proteins associated with mitochondrial biogenesis, and glucose and insulin signaling, were analysed via western blotting. Two-way RM ANOVA with post hoc and effect sizes for difference between groups. Paired sample t-tests for within-group significance. Peak oxygen consumption improved by 19% in both exercise groups (P<0.05). In response to the OGTT, the control group exhibited no changes, while both the cycling and SSG groups showed a decline in the area under the curve (AUC) for glucose, and only SSG showed a decline in the AUC for insulin (P<0.05). There was a trend for an increase in PGC-1α (effect size (ES) ± confidence interval: 0.49±0.62), p53 (ES 0.47±0.55) and GLUT4 (ES 0.57±0.65) within the SSG group, and for mitochondrial complex I (P<0.05; ES 1.0±0.67) and IV (P<0.05; ES 1.1±0.77) within the cycling group. Participants in both exercise groups decreased total body fat mass (%) and intra-abdominal fat mass (kg; P<0.05). Collectively, SSG training in sedentary middle-aged populations was as effective as traditional cycle ergometry in reducing clinical risk factors normally associated with the development of diabetes. In addition, SSG training evoked skeletal muscle adaptations involving an increase in p53, PGC-1α and GLUT4 proteins, collectively important for mitochondrial biogenesis and glucose regulation. These changes show the potential relevance of intermittent exercise training via SSG as a chronic disease prevention strategy.

PCC272

Pattern of skeletal muscle deoxygenation during incremental exercise is associated with cardiorrespiratory fitness in subjects with metabolic syndrome

A.D. Machado[1], A.K. Sales[1], A.F. Campos[1], T.C. Barbosa[1], L.C. Vianna[1], A.L. Nobrega[1] and B.M. Silva[1,2]

[1]Department of Physiology and Pharmacology, Fluminense Federal University, Niterói, RJ, Brazil and [2]Department of Physiology, São Paulo Federal University, São Paulo, SP, Brazil

Motivation. The pattern of skeletal muscle deoxygenated hemoglobin and myoglobin (deoxy [Hb + Mb]) during incremental exercise is typically fitted by a sigmoid model and is a proxy of microvascular fractional O_2 extraction. Given previous studies showing that metabolic syndrome subjects (MetS) have an altered vascular function, which possibly contributes to an imbalance between O_2 supply and O_2 demand during exercise, we tested the hypothesis that their sigmoidal increase in deoxy [Hb + Mb] would show a leftward shift when compared to healthy (H) controls, and that the deoxygenation pattern would be associated with cardiorespiratory fitness. **Methods.** Twenty subjects with MetS (4 women) and 14 H controls (7 women) were recruited. All subjects were submitted to a maximal cardiopulmonary exercise test performed on a cycle ergometer. In addition, a subgroup of twelve subjects with MetS (3 women) and nine H controls (6 women) were submitted to dual energy X-ray absorptiometry (DEXA). Cardiorespiratory fitness was evaluated by the oxygen consumption at the ventilatory threshold (VO_2VT) and the peak pulmonary oxygen consumption (VO_2peak), which were measured by a metabolic analyzer. Deoxy [Hb + Mb] was measured by near-infrared spectroscopy in the Vastus Lateralis muscle. This signal was normalized to the total response amplitude and expressed in relation to power output (PO) by a sigmoid function [$f(x)=f0+A/[1+e^{-(-c+dx)}]$], which generated the variable *c/d* (PO at 50% of deoxy [Hb + Mb] response). **Results.** There was no difference between groups' age (MetS: 37±7 vs. H: 33±9 years, mean±SD, p=0.15), test duration (MetS: 535±90 vs. H: 540±101 s, p=0.88), and absolute VO_2peak (MetS: 2.2±0.6 vs. H: 1.9±0.5 L/min, p=0.24). Within the subgroup, there was no difference in VO_2peak corrected for lean body mass (MetS: 38.3±5.7 vs. H: 42.2±5.6 ml/kg/min, p=0.13). The deoxygenation pattern was adequately fitted by the sigmoid

model (r≥0.95 for all cases). There was no difference for *c/d* between groups (MetS: 109±25 vs. H: 110±32 W, p=0.88), however there was a significant correlation between *c/d* and absolute VO_2VT and absolute VO_2peak in the whole sample (VO_2VT r=0.67, p<0.0001; VO_2peak r=0.69, p<0.0001), and within groups [(MetS VO_2VT r=0.68, p=0.001; VO_2peak r=0.69, p=0.001) (H VO_2VT r=0.74, p=0.002; VO_2peak r=0.76, p=0.001)]. Moreover, within the subgroup submitted to DEXA, we observed a significant correlation between *c/d* and VO_2peak corrected for lean body mass r=0.56, p=0.008 in the whole group, and within groups (MetS: r=0.52, p=0.08; H: r=0.67, p=0.049). **Conclusions.** The pattern of skeletal muscle deoxygenation was similar between groups, probably due to similar cardiorespiratory fitness, as the deoxygenation pattern was significantly associated with cardiorespiratory fitness.

Benefits of aerobic fitness on cerebrovascular reactivity to carbon dioxide

C.J. Marley[1], D. Hodson[1], J.V. Brugniaux[1], K.J. New[1], P.N. Ainslie[2], K. Evans[1] and D.M. Bailey[1]

[1]Department of Sport and Exercise, University of Glamorgan, Treforrest, UK and [2]School of Health and Exercise Sciences, University of British Columbia, Kelowna, BC, Canada

Background and aims: Impaired cerebrovascular reactivity to carbon dioxide (CVR_{CO2}) is an established risk factor for stroke (1) and has been linked with cognitive dysfunction (2). Preliminary evidence suggests that CVR_{CO2} may be improved through increases in physical activity (3; 4). However, data are scarce and cross-sectional studies are lacking.
Methods: Ten *untrained* (25 ± 5 years; 86 ± 12 kg; < 150 minutes of aerobic exercise per week; maximal oxygen consumption (VO_{2MAX}), 37 ± 5 $ml.kg^{-1}.min^{-1}$) and 10 *trained* (23 ± 4 years; 79 ± 10 kg; > 150 minutes of aerobic exercise per week; VO_{2MAX}, 57 ± 8 $ml.kg^{-1}.min^{-1}$) healthy males participated in the study. CVR_{CO2} was assessed in response to a 3-minute exposure to hypercapnea (5% CO_2). Blood flow velocity in the middle cerebral artery (transcranial Doppler) and end-tidal CO_2 (capnography) were continuously recorded throughout the procedure as described previously (5). VO_{2MAX} was assessed via an incremental exercise test to volitional exhaustion (semi-recumbent cycle ergometer) and online expiratory gas exchange. Following confirmation of distribution of normality (Shapiro-*W*-Wilk Tests), CVR_{CO2} and VO_{2MAX} data were analysed using independent samples *t*-tests. The relationship between VO_{2MAX} and CVR_{CO2} was examined using a Pearson Product Moment correlation. Significance was established at $P < 0.05$ and data are expressed as mean ± SD.
Results: By design, the *trained* participants recorded a higher VO_{2MAX} ($P < 0.05$). The *trained* were able to elicit a greater CVR_{CO2} compared to their *untrained* counterparts (3.64 ± 1.1 *vs.* 1.87 ± 0.8 %/mmHg; $P < 0.05$) during the hypercapnic challenge (Figure 1). Figure 2 illustrates the positive correlation between VO_{2MAX} and CVR_{CO2} (r = 0.79; $P < 0.05$).
Conclusion: These findings highlight the cerebrovascular benefits of regular physical activity, which may act as a potential preventative mechanism against cerebrovascular diseases in later life.

Four legs good, two legs bad: Visual and tactile mechanisms underlying interpersonal control of postural sway

R. Reynolds, P. Watts and C.J. Osler

Sport & Exercise Sciences, University of Birmingham, Birmingham, UK

Fingertip contact with another person reduces sway(1). However, this represents a complex control loop, with both persons relying on a moving reference point. Here we attempt to understand this control loop with a combination of experiment and modelling. We also determine whether vision of another person drives sway, and if this interacts with touch. We studied 8 pairs of subjects standing next to each other on separate forceplates. We included 3 conditions of touch (no contact(NC), light touch(LT), shoulder contact (SC)) and 3 visual conditions (both eyes closed, both eyes open, asymmetric). Centre of pressure velocity (COPv) was the measure

of sway. Magnitude and timing of sway coupling was quantified by the COPv-COPv cross-correlation function (XCORR). Data was compared with a Simulink model(2) consisting of a two inverted pendulums and PID controllers coupled together. Physical contact (LT & SC) reduced sway, with a greater effect for shoulder contact (Fig 1A; F=193,21;p<0.01). Vision also reduced sway but less so with increasing tactile contact (p<0.01). When only light touch was available, XCORR's exhibited twin peaks at ~500 and -500ms (Fig 1B). Vision alone produced strikingly similar XCORR's. However, the effect of touch and vision did not summate with both available. During asymmetric vision, XCORR's showed only 1 peak at positive lag. In contrast to light touch, shoulder contact produced XCORR's with a single peak at ~0ms lag irrespective of visual condition. We modelled the interaction in simulink as follows. Firstly, we coupled both sensory feedback loops to each other, such that each (model) person's feedback error was summed with 20% of their partner's. This recreated the XCORR shape and timing observed during both visual and light touch conditions (Fig 1C). Secondly, we coupled the torque output, such that 20% of one person's ankle torque summed with the other (while maintaining the sensory coupling). This recreated the XCORR seen during shoulder contact.

Firstly we conclude that tactile sway coupling is a continuous bidirectional sensorimotor process with a delay in each direction of ~500ms. It is unnecessary to invoke 'switching' mechanisms to explain the interaction, whereby a sway leader and follower periodically swap roles; a continuous control model was sufficient to recreate the XCORR characteristics. Unlike light touch, effects of shoulder contact were explained by mechanical linkage. Secondly, we have shown that vision of another person produces sway coupling near identical to touch. This is despite only peripheral vision of one's partner, and abundant veridical feedback from the laboratory. The observation that the effects of touch and vision did not summate suggest sensory redundancy. Paradoxically, the visual coupling demonstrates that sometimes the partner with eyes closed lead the sighted partner.

Biochemical changes in patients before and after the different types of premedications

R. Rokyta[1], J. Fricova[2], M. Vejrazka[3] and P. Stopka[4]

[1]Normal, Pathological and Clibical Physiology, Charles University, 3 rd Faculty of Medicine, Prague, Czech Republic, [2]Anesthesiology, Resuscitation and Intensive Care, Pain Management, Charles University, First Faculty of Medicine, General University Hospital, Prague, Czech Republic, [3]Biochemistry and Toxicology, Charles University, First Faculty of Medicine,, Prague, Czech Republic and [4]Inorganic Chemistry, Academy of Scinces of the Czech Republic, Prague, Czech Republic

Introduction

The aim of our study was to assess the changes of free radicals and other biochemical parameters after nociceptive stimulation in patients. We detected whether preemptive analgesia had a positive effect on acute postoperative pain.

Patients and methods:diagnosis: hernia inquinalis,operation:herniotomia,group of patients (n=63), men (n=50), women (n=13),timing of the investigations from blood samples: immediatelly before operation,4 hours after operation,24 hours after operation. Patients were divided into three groups: without premedication, the premedication with pethidin,the premedication with morphine .We measured biochemical parametres: proteins, albumins, prealbumins, apolipoproteins A, B, CRP, glucose, lipids (LDL, HDL, total cholesterol, triacylglycerols) and uric acid.

Results

We found out that nitroxid and hydroxyl free radicals and singlet oxygen increased significantly after nociceptive stimulation. In particular, we measured the free hydroxyl radicals and singlet oxygen by EPR method. Our goal was to find the most effective combination for the effective analgesic treatment of acute postoperative pain. Free radicals increased in individual samples during the postoperative course in pethidine and without premedication. After application of morphine the free radicals were insignificantly reduced,especially in the third sampling. The increase in measured values of free radicals is statistically significant in patients without premedication.Beside finding an optimal preemptive and postoperative analgesia, we tried to understand the mechanisms of postoperative pain and oxidative stress. We were able to objectify the biochemical changes in acute postoperative pain on the basis of postoperative stress. This method is absolutely a priority and has never been used before. Earlier experimental results were partially clinically verified using different types of acute and chronic pain in humans. In all these pain syndromes are different biochemical changes.

Our next goal was to find the most effective combination for the effective analgesic treatment of acute postoperative pain.

Conclusions

We studied postoperative analgesia and the effects of various types of analgetics, including preoperative and postoperative medication and its objective evaluation. We focused on an objective assessment of pain using different biochemical parameters, especially the free radicals that are significantly changed during acute pain. It was shown that morphine is the best indication in preemptive analgesia prior to surgery with an expected moderate pain. Morphine in comparison with Pethidine and the group without premedication only significantly reduced levels of free radicals 24 hours after surgery. We tried to explain the relationship of postoperative pain and oxidative stress.

The role played by Nav1.8 channels in the somatic pressor chemoreflex

A.J. Stone, J. Kim and M.P. Kaufman

Heart and Vascular Institute, Penn State University College of Medicine, Hershey, PA, USA

Thin fiber muscle afferents (Aδ and C) are supplied by NaV 1.8 channels, whereas thick fiber afferents (spindles and tendon organs) are not. We determined the role played by NaV 1.8 channels on the thin fiber afferents evoking the reflex pressor response to femoral arterial injections of lactic acid (24mM; ~0.1mL) and capsaicin (0.1ug) in decerebrated Sprague Dawley rats with either patent or ligated femoral arteries. This was done both before and after femoral arterial injection of the A803467 (500μg, 1mg, and 2mg), a NaV 1.8 antagonist. We also recorded the responses of spindle afferents to succinylcholine (200μg) and stretch before and after injecting A803467. Rats were anesthetized with 2% isoflurane and 100% O2 until decerebration. In "freely perfused" rats (n=6), 1 mg of A803467 significantly reduced the pressor responses to lactic acid (16±5 to 4±4ΔmmHg) and capsaicin (47±7 to 26±8ΔmmHg). In "ligated" rats, 1 mg of A803467 significantly reduced the pressor response to lactic acid (32±13 to 3±3ΔmmHg, n=6), whereas 2 mg of A803467 was required to significantly reduce the pressor response to capsaicin (66±11 to 37±17ΔmmHg, n=4). Surprisingly, we found that A803467 (1mg) reduced the responses of 10 spindle afferents to succinylcholine (34±11 to 4±3 Δ imp/s p=0.04) and stretch (83±17 to 0.4±1 Δ imp/s; p<0.01). We conclude that A803467 reduces the chemoreflex response to lactic acid and capsaicin; however, it may be working on channels other than NaV 1.8 such as voltage-gated calcium channels.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Thirst perception and water intake in older males following exercise

V.U. Igbokwe[1] and L.F. Obika[2]

[1]Department of Physiology, Usmanu Danfodiyo University, Sokoto, Nigeria and [2]Department of Physiology, University of Benin, Benin City, EDo State, Nigeria

The oropharyngeal satiety mechanism of thirst in the elderly is a subject not resolved. However, since other oropharyngeal senses such as taste changes with age, it may be that oropharyngeal satiety mechanism of thirst is also diminished with age. This however remains to be proven experimentally. This work therefore investigates thirst perception (TP) and water intake in young males (n = 10, age = 19 – 25 years) and older males (n = 9, age = 44 – 58 years). All the subjects live a normal active life, that is they go about their daily business or work but none of them, was athletically trained as "defined by the absence of a regular exercise programme during the last six months before the experiment" (Kokkinos et al, 1995). Thirst perception (TP) and dryness of mouth (DM) before exercise were obtained using the visual analogue scale (Takamata et al, 1994). Thereafter subjects performed exercise at 30kmh-1 till exhaustion at a workload of 0.5kgm on a bicycle ergometer. After exercise TP, DM and water intake were assessed. Subjects did not drink any water during the exercise but were given clean tap water ad libitum at 16OC to drink at the end of the exercise (Boulze, et al, 1983). The results are presented as mean ± standard error of mean. The paired and unpaired student t-test was used to compare the difference between the means within a group and between the group means respectively. The basal TP and DM in the older males were 1.08 ± 0.40cm and 0.6 ± 0.29cm respectively, and that of the young males were 1.46 ± 0.47cm and 1.63 ± 0.55cm respectively. There was no significant difference in the basal TP and DM between the young and older male subjects. After exercise the changes in TP and DM in the young males (3.75 ± 0.93 and 3.23 ± 0.92) and in the older males (1.26 ± 0.57 and 1.48 ± 0.76) did not show any significant difference. However the time spent on exercise (43.2 ± 3.53mins for young males and 9.6 ± 1.28min for older males) and the water intake after exercise (405 ± 47.29ml and 160 ± 70.0ml for the young and older males respectively) were different (p<0.05).
It is concluded therefore that thirst following dehydration in older males is similar to that of young males. The difference in fluid intake between the young and older males might be due to the time spent on exercise. Thirst perception might not show a decrease with increase in age as does taste.

Plasma amino acid profile, redox state and nitric oxide synthesis in red blood cells from girls with anorexia nervosa

N.R. Pereira[2], T. Brunini[2], M.A. Siqueira[2], M. Moss[1], C. Assumpção[2] and A. Mendes-Ribeiro[2,1]

[1]Departamento de Ciências Fisiológicas, Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro, Brazil and [2]Departamento de Farmacologia e Psicobiologia, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, UK

Background: Anorexia nervosa is a debilitating eating disorder with profound biological and psychological consequences. Recent evidence implicates nitric oxide abnormalities in the pathogenesis of anorexia nervosa. Objective: To investigate nitric oxide bioavailability in red blood cells from adolescents with anorexia nervosa and its association with the arginase

pathway, redox state and systemic amino acid profile. Methodology: A case-control study of plasma amino acid levels, nitric oxide synthase and arginase activities, and oxidative stress markers (lipid peroxidation, protein oxidation, reactive oxygen species production and superoxide dismutase activity) in red blood cells from volunteer adolescents with anorexia nervosa (n=10) recruited at the Center for Studies on Adolescent Health - State University of Rio de Janeiro, and healthy controls (n=10), age-matched. The Ethical Committee of the State University of Rio de Janeiro approved this work (CEP -1485), and informed consent was obtained from each of the patients. The student t test was used for statistical analysis and statistic difference was considered when $p<0.05$. Results: Nitric oxide synthase activity was impaired in red blood cells (controls: 8.22 ± 1.45 vs patients: 3.88 ± 0.46 pmol/108 cells/min) in the presence of increased arginase activity in anorexia nervosa (controls: 0.02 ± 0.01 vs patients: 0.09 ± 0.03 pmol urea/mg protein/2h). Asymmetric dimethylarginine, an endogenous inhibitor of nitric oxide synthase, was not affected, whereas L-lysine (controls: 160 ± 10 vs patients: 130 ± 7 μM/L) and L-ornithine (controls: 93 ± 9 vs patients: 64 ± 6 μM/L) were reduced in plasma from patients with anorexia nervosa compared to controls. No oxidative damage or increased reactive oxygen species production was observed in anorexia nervosa. On the other hand, diminished anti-oxidant protection by superoxide dismutase was present in red blood cells from patients with anorexia nervosa (controls: 15260 ± 2803 vs patients: 4791 ± 678.4 U of SOD/g of haemoglobin). Conclusions: Our findings provide the first evidence of reduced nitric oxide synthesis associated with diminished antioxidant defence and arginase activation in red blood cells, which may contribute to impaired vascular nitric oxide bioavailability in anorexia nervosa.

The influenses of hand work and stand up on the function of autonomic nervous system during menstrual cycle in healthy female college students

Y. Itoi[1], M. Onozaki[1], T. Shimizu[2] and T. Okada[3]

[1]International University of Health and Welfare, Otawara, Japan, [2]Toin University of Yokohama, Yokohama, Japan and [3]Juntendo University Graduate School of Medicine, Bnkyouku, Japan

Purpose: The purpose of this study was to examine the correlation between functional modulation of the autonomic nervous system and the menstrual cycle.Methods: Subjects were comprised of 11 healthy female college students (19.5±0.5 years old) with regular menstrual cycles. The changes in emotional sweating induced by hand work (beans work and puzzle) and the modulation in autonomic nervous system(electrocardiograph and heartbeat) with active orthostatic load were compared among the follicular, luteal and menstrual phases. The Japanese version of the Profile of Mood State (POMS), healthy life habit (DIHAL.,2,junior high school student~adult) were also examined. Analysis: Effect size of the difference between group or correlation were evaluated. Results:Emotionalsweating(task is beans work) during the menstrual phase was significantly higher than those during follicular and luteal phases and it associated with the high score of "depression dejection" of POMS factors. Group with the highest T score (standardized score) of "depression dejection" emotional sweating was significantly higher during luteal phase. In addition, the group which complained subjective low healthy state, showed higher emotional sweating (beans work) during luteal phase.Fluctuations of heart rate at rest(the size of the activity),during menstrual phase was significantly higher than those during follicular phase, although it was a normal range.The balance of the autonomic nervous activity at rest (balance) was significantly higher during luteal phase compared to menstrual phase, indicating predominance of sympathetic nervous system. Active orthostatic load-induced fluctuations of heart beat(powers of the response)was significantly higher during follicular phase compared to those during menstrual and luteal phase, although it was a normal range. Fluctuations of balance of the active orthostatic load (powers of the change) was significantly higher during menstrual phase than that during follicular phase; the range which need special medical attention. In addition, there found an association between balance and "confusion". Group with the highest T score of "confusion" factors, showed predominant sympathetic nervous system during menstrual phase.Conclusion:These findings suggest that Stresses of beans work may influence the function of the autonomic nervous system to during menstrual phase . In addition, these findings suggest that powers of the change was higher during menstrual phase, the range which need special medical attention. Students with the high T score of "confusion" factors, showed the balance is sympathetic nerve predominance during menstrual phase.

Fixed dose combinations of bromocriptine, glibenclamide and metformin improve insulin resistance in hyperglycaemic rats

A.A. Adeneye[1] and J.A. Olagunju[2]

[1]Department of Pharmacology, Lagos State University College of Medicine, Ikeja, Lagos State, Nigeria and [2]Department of Medical Biochemsitry, Lagos State University College of Medicine, Ikeja, Lagos State, Nigeria

Background: In recent years, attention has been drawn to the therapeutic usefulness of bromocriptine in the effective management of insulin resistance diabetes mellitus. Materials and Methods: The present study evaluates the effects of the oral treatments with 10 mg/kg bromocriptine in fixed combinations with 1 mg/kg glibenclamide, 20 mg/kg metformin and glibenclamide/metformin combination on body weight, blood glucose, lipids and cardiovascular risk profile in dexamethasone-induced hyperglycemic male Wistar rats for 30 days. The effects of these drug combinations on OGTT of the treated rats were also evaluated. Results: Repeated daily dexamethasone injection for 30 days caused significant increases in the average body weight, blood glucose, triglycerides, total cholesterol, LDL-c, VLDL-c and cardiovascular risk indices in the treated male Albino Wistar rats. However, these increases were significantly attenuated in rats orally pretreated with bromocriptine and its various combinations. In addition, bromocriptine and its combinations significantly improved OGTT in the treated rats. Conclusions: Overall, results of this study suggest that the antihyperglycaemic, antihyperlipidaemic and cardio-

protective effects of the fixed-dose drug combinations were possibly mediated via improved glucose tolerance mechanism.

Table 2: Effects of bromocriptine, glibenclamide and metformin combinations on serum lipids and cardiovascular risk indices

Nicotine alters male reproductive hormones in male albino rats

I.P. Oyeyipo[1,2], Y. Raji[2] and A.F. Bolarinwa[2]

[1]Physiology, Osun State University, Osun, Osun State, Nigeria and [2]Physiology, University of Ibadan, Ibadan, Oyo State, Nigeria

The use of nicotine through smoking remains a serious health problem. It has been associated with reduced fertility (Oyeyipo et al, 2011), although the mechanism responsible is still unclear. The present study was designed to investigate the effects of nicotine administration on male reproductive hormones in male albino rats. Forty male rats weighing between 200-230g (8-10 weeks) were divided equally into five groups and treated orally for thirty days. Group I, which served as the control received 0.2ml / kg normal saline, Group II and III received 0.5mg/kg (low dose) and 1.0mg/kg (High dose) body weight of nicotine respectively. The fourth and fifth groups were gavaged with 0.5mg/kg and 1.0mg/kg body weight of nicotine but were left untreated for another 30 days. These groups served as the recovery groups. At the end of the experimental period, animals were anaesthetized with 1.9% ether and blood was collected through cardiac puncture. Serum was analysed for testosterone, luteinizing hormone (LH), follicle stimulating hormones (FSH) and prolactin using radioimmunoassay. Values were expressed as mean ± S.E.M compared by ANOVA. Results showed that nicotine administration significantly decreased ($p<0.05$) testosterone in the low and high treated groups (3.46 ±0.16 ng /ml; 2.16 ± 0.18 ng /ml) and FSH (0.97 ±0.06 mIU/ml) in the high dose treated group when compared with the control group (4.94 ± 0.18; 2.01 ± 0.14) respectively. There was a significant increase ($p<0.05$) in mean LH (3.49 ± 0.20 mIU/ml) and mean prolactin level (8.10 ±0.32 IU/ml) in the high dose treated group when compared with the control (1.68 ±0.08 mIU/ml; 4.23 ± 0.26 mIU/ml) respectively. However, the values of the recovery groups were comparable with the control. Thus, these findings suggest that nicotine administration is associated with distorted reproductive hormones in male rats although ameliorated by nicotine cessation. It is plausible that the decreased testosterone level is associated with testicular dysfunction rather than a pituitary disorder.

PCC285

Coffee attenuates induction of insulin resistance by high sucrose-diet in rats

A. Morakinyo, D.A. Adekunbi and O.A. Adegoke

Physiology, University of Lagos, Lagos, Nigeria

Numerous epidemiology reports suggested that consumption of coffee is associated with lower risk of diabetes mellitus (Natella & Scaccini, 2012). These epidemiological observations have not been evaluated experimentally. The present study therefore employs an animal model to examine the relationship between intake of coffee and risk of type 2 diabetes mellitus (in this case, insulin resistance). In the study, high-sucrose feeding (30% w/v) was used to induce insulin resistance (Riberio et al, 2005). Sprague-Dawley rats (male, 120-150g) were maintained for 12 weeks on a normal diet (ND, n=6), normal diet supplemented with coffee (ND+COF, 300 mg/kg BW, n=6), high sucrose-diet (HSD, n=6) and high sucrose-diet supplemented with coffee (HSD+COF, n=6). Glucose tolerance and insulin resistance were measured by performing the oral glucose tolerance test (OGTT) and insulin tolerance test (ITT) respectively; and for both tests, the area under curve (AUC) was determined. The serum insulin was estimated using ELISA while an automatic blood chemical analyzer was employed for the measurement of total cholesterol (TC), triglycerides (TG), high-density lipoprotein (HDL) and low-density lipoprotein (LDL). Malondialdehyde (MDA), glutathione reduced (GSH) and superoxide dismutase (SOD) were measured using previously described standard methods. Data were expressed as mean±SEM, compared by ANOVA. HSD rats showed reduced glucose tolerance (AUC: 2016.8±119.2 vs. 1017.5±59.9, $p<0.05$) and insulin sensitivity (AUC: 535.88±36.41 vs. 414.5±29.08, $p<0.05$) when compared with ND rats but intragastric administration of coffee prevented these metabolic abnormalities in HSD+COF (AUCOGTT: 1132.3±64.5; AUCITT: 388.75±26.27). In addition, insulin concentration was markedly increased in HSD rats compared with ND rats (12.25±0.51 vs. 7.69±0.22, $p<0.05$), but was suppressed in HSD+COF rat treated with coffee (9.21±0.66, $p<0.05$). Whereas compared with the HSD rats, the levels of TG and LDL (0.44±0.06 vs. 1.43±0.32; 0.75±0.03 vs. 0.91±0.06 respectively, $p<0.05$) decreased; HDL (1.10±0.06 vs. 0.69±0.02, $p<0.05$) increased significantly in HSD+COF rats. Additionally, MDA level was reduced (21.4±2.36 vs. 37.4±3.59, $p<0.05$), GSH (0.53±0.03 vs. 0.24±0.01, $p<0.05$) and SOD (4.38±0.47 vs. 1.63±0.01, $p<0.05$) activities were increased in HSD+COF when compared with HSD rats. Collectively, our data indicate that coffee consumption confers protection against the risk of contracting non-insulin dependent diabetes in rats and lends support to the idea that coffee consumption is associated with a lower risk of type 2 diabetes. Understanding some aspect of the relationship between coffee and diabetes is a desirable step in the context of healthy eating habits and disease control.

Mercury chloride-induced glucose intolerance in rats: role of oxidative stress

A.O. Morakinyo, B.O. Iranloye, G.O. Oludare, J.O. Oyedele and O.O. Ayeni

Physiology, University of Lagos, Lagos, Lagos State, Nigeria

Although mercury is recognized as a hazardous chemical, its commercial importance and applications has led to an increase in occupational and environmental exposures in many parts of the world. This study evaluated the impact of HgCl2 on glucose homeostasis and the possible involvement of oxidative stress. In addition, the potential protective effects of the antioxidant Alpha Lipoic Acid (ALA) were investigated. Thirty Sprague Dawley rats were divided into five equal groups of six animals: Group 1 (control) received 0.5 ml distilled water; Group 2 (ALA) received 100 μg/kg of ALA; Group 3 (LDM) and Group 4 (HDM) received 250 and 500 μg/kg body weight of HgCl2, respectively; and Group 5 (HDM-ALA) received 500 μg/kg of HgCl2 and 100 μg/kg of ALA. Both HgCl2 and ALA were administered orally for 14 days. Fasting blood glucose was measured and all groups were subjected to Oral Glucose Tolerance Test (OGTT) using One-Touch Ultra Easy Glucose Meter, Lifescan, U.K. The activities of reduced glutathione (reaction of Ellman's reagent to the thiol group of GSH), superoxide dismutase (auto oxidation of epinephrine), catalase (measuring the exponential disappearance of H2O2) as well as the level of lipid peroxidation (indexed by MDA as the presence of thiobarbituric acid reactive substances) were estimated. Values are means ± SEM, compared by one way ANOVA. The fasting blood glucose (mmol/L) for Control, ALA, LDM, HDM and HDM-ALA were as follows; 4.02 ± 0.35, 4.6 ± 0.26, 7.23 ± 0.48, 8.03 ± 0.64 and 4.45 ± 0.41 respectively. After thirty minutes of glucose load (2ug/kg body weight) blood glucose levels were 6.62 ± 0.85, 7.22 ± 0.64, 9.43 ± 1.07, 9.43 ± 1.05 and 7.03 ± 0.52 in the Control, ALA, LDM, HDM and HDM-ALA respectively. Subsequent values were obtained every 30 minutes and after 3 hours, the blood glucose values were 2.32 ± 0.43, 4.26 ± 0.23, 7.29 ± 0.29, 8.28 ± 0.33 and 3.97 ± 0.21 in the Control, ALA, LDM, HDM and HDM-ALA respectively. The results on MDA in the Control, ALA, LDM, HDM and HDM-ALA groups are; 0.0318 ± 0.005, 0.0242 ± 0.004, 0.069 ± 0.004, 0.104 ± 0.011 and 0.045 ± 0.006 respectively. Superoxide dismutase activity was; 46.74 ± 4.85, 43.16 ± 3.68, 24.42 ± 3.17, 19.62 ± 2.51, 35.32 ± 3.38. Reduced glutathione values were; 0.31 ± 0.04, 0.32 ± 0.04, 0.15 ± 0.02, 0.13 ± 0.03, 0.21 ± 0.02 and catalase activity were; 224.60 ± 15.03, 230.98 ± 14.98, 155.11 ± 17.63, 139.38 ± 16.44, 162.94 ± 15.62 in the Control, ALA, LDM, HDM and HDM-ALA respectively (values are in units/mg protein). The results showed changes in glucose tolerance and oxidative indices in rats exposed to HgCl2. However, treatment with ALA attenuated all HgCl2 triggered changes. This study shows the induction of glucose intolerance by HgCl2 and suggests the involvement of oxidative stress as an important regulator of glucose homeostasis during HgCl2 exposure.

Metabolic disorders and oxidative stress in type 1 diabetes mellitus; role of testosterone

A.O. Morakinyo, D.A. Adekunbi and O.A. Adegoke

Physiology, University of Lagos, Lagos, Nigeria

A bidirectional relationship has been established between testosterone deficiency (TD) and type 2 diabetes mellitus (T2DM). Low testosterone level has been reported to be a predisposing factor to T2DM (Selvin et al., 2007), while recent clinical studies have shown a high prevalence of low testosterone in diabetic individuals (Dhindsa et al., 2004). However, it is not known if any relationship exists between type 1 diabetes mellitus (T1DM) and testosterone level. This study was designed to investigate the effects of TD on T1DM. Sprague-Dawley rats (male, 140-160g) were randomly divided into four groups designated as control, diabetic, orchiectomized and orchiectomized-diabetic. Diabetes was induced with alloxan (100mg/Kg BW i.m.) and orchiectomy was performed under aseptic surgical conditions. Rats were anesthetized with Ketamine (90mg/kg BW) and Xylazine (10mg/kg BW) intramuscularly, for bilateral removal of the testes. After 3 weeks, glucose tolerance was assessed by oral glucosee tolerance test (OGTT) where each rat received an oral glucose of 2g/kg BW and blood sample drawn from tail vein afterwards at intervals of 30, 60, 120 and 180 min for measurement of glucose level. The area under the glucose (AUC glucose) was calculated using the trapezoidal rule. Serum insulin was analysed using ELISA system and lipid parameters were analysed enzymatically with kit obtained from Randox, UK. Oxidative analyses of the liver homogenate were carried out using previously described standard methods (Morakinyo et al., 2011). Values are means ± S.E.M., compared by ANOVA. The results shows that baseline glucose values in the orchiectomized-diabetic group was lower (217.5±18.81mg/dl $P<0.05$) compared to diabetic group (340.75±17.15), although this was higher than the baseline glucose for both control (99.67±3.23) and orchiectomized group (95.5±4.60). The AUC during OGTT showed that the orchiectomized-diabetic group expressed an enhanced ability to metabolize glucose than the diabetic group. (51139.65±1592.52 vs. 77961.00±2806.43, $P<0.05$ respectively). The MDA level in the diabetic group was increased (103.20±5.05, $P<0.05$) compared with control and orchiectomized group (87.12±4.18, 78.08±3.78 μmol/ml respectively). More so, there was a decrease in GSH activity and an increase in SOD activity in the diabetic group compared with control. (GSH: 1.09±0.13 vs. 1.77±0.15, SOD: 2.68 ±0.11 vs. 2.03 ± 0.20, μmol/ml $P<0.05$). Meanwhile, the activities of GSH and CAT were significantly reduced in the orchiectomized as well as orchiectomized-diabetic group (GSH: 0.17±0.03, 0.16±0.03, CAT: 5.39±0.22, 3.75±0.28, $P<0.05$, respectively) when compared with both control and diabetic group (GSH: 1.77±0.15, 1.10±0.12, CAT: 10.85±0.99, 10.95±0.77 respectively). These data indicates that testosterone promotes glucose intolerance and oxidative stress under type 1 diabetic condition.

In vivo and in vitro reproductive toxicity of Quassia amara extract and Quassin: action on sperm capacitation and acrosome reaction in male Wistar rats

O.O. Obembe[1,2] and Y. Raji[2]

[1]Physiology, Osun State University, Osogbo, Osun, Nigeria and [2]Physiology, University of Ibadan, Ibadan, Oyo, Nigeria

Quassia amara is a medicinal plant with several pharmacological properties [1-3]. There are preliminary reports implicating this plant in male reproductive toxicology. Its bioactive principle quassin has been reported as the antifertility agent. However, the mechanism of action remains to be elucidated, but the major site of action appears to be the epididymis. The action of Q. amara and quassin on epidydimal reproductive parameters was therefore investigated. Effect on sperm cells in vitro was also examined.

Q. amara extract (100mg kg-1 p.o.), quassin (0.1 and 2mg kg-1 p.o.) and distilled water (0.5ml p.o.) were administered daily for 6 weeks to male rats (180-200g, n=5), and thereafter sacrificed [4]. Organ weights, sperm, hormonal and biochemical analysis were conducted. Sperm capacitation and acrosome reaction were determined by Coomassie brilliant blue staining technique. Values are Mean ± SEM, compared by ANOVA. In vitro extender studies were conducted on graded doses of the crude extract (50-500 μg/ml).

The respective weight (g) of testes (0.78±0.14; 0.81±0.15; 0.99±0.14 vs 1.18±0.02), caudal epididymis (0.15±0.02; 0.12±0.02; 0.14±0.02 vs 0.30±0.01), seminal vesicle (0.9±0.18; 0.21±0.09; 0.28±0.09 vs 1.6±0.01) and prostate (0.15±0.02; 0.16±0.02; 0.16±0.01 vs 0.29±0.02); %sperm motility (42.0±10.2; 68.0±3.74; 68.0±3.74 vs 93.75±0.97), %viability (88.0±2.55; 88.6±3.39; 94.2±1.8 vs 97.25±0.75), count (58±4.24; 94±7.89; 88.8±5.61 vs 121.2±4.24) and volume (5.15±0.004; 5.14±0.02; 5.16±0.02 vs 5.20±0) were significantly reduced ($p<0.05$) in all treatment groups, except %viability for quassin high dose. No effect was observed on the weight, histology of visceral organs and liver function biomarkers. Lipid profile of the extract treated group were not affected, while quassin significantly reduced HDL (0.3±0.03; 0.2±0.02 vs 0.6±0.08, $p<0.05$) and increased LDL (0.9±0.04; 1±0.09 vs 0.7±0.07; $p<0.05$). Total epididymal protein were significantly reduced (0.67±0.11; 0.60±0.07; 0.70±0.17 vs 1.65±0.32, $p<0.05$). Q. amara extract significantly reduced ($p<0.01$) LH (0.6±0.14 vs 1.5±0.18) and testosterone level (0.03±0.01 vs 0.32±0.09), while quassin reduced FSH level (1.6±0.19; 2.2±0.2, $p<0.05$). In vitro extender study to verify these results showed that the action of the extract on sperm parameters is consistent, as progressive motility declined and abnormal morphology increased with dose. Also, after in vitro induction of sperm capacitation, the percentage of "acrosome reacted capacitated sperm cells" was significantly lower (27.2±1.98; 24.0±2.74; 37.8±10.72 vs 95.2±0.86, $p<0.01$) in all treated groups. Q. amara and quassin may have reproductive specific toxic effect and its deleterious effect on sperm cells affects capacitation and acrosome reaction.

Overexpression of GLUT2 protein in obesity mices with nonalcoholic steatohetatitis

A.D. Silva[1], R.R. Favaro[2], R.C. Petroni[3], D.T. Furuya[1], P.E. Silva[1], H.S. Freitas[1], A.C. Poletto[1], M.M. Okamoto[1], F. Barrence[2], T.M. Zorn[2] and U.F. Machado[1]

[1]Physiology and Biophysics, Institute of Biomedical Sciences - University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil, [2]Cell biology and development, Institute of Biomedical Sciences - University of Sao Paulo, Sao Paulo, Brazil and [3]Medical Sciences, Medical School - University of Sao Paulo, Sao Paulo, Brazil

Background and aims:
We believe that GLUT2 (Glucose transporter 2) can be involved in the development of nonalcoholic steatohepatitis (NASH). Considering the importance of knowing the glucose flux in liver of obesity animals with nonalcoholic steatohepatitis, we studied the expression of GLUT2 protein.
Materials and methods:
We studied obesity mices (MSG) and control mices (C). The obesity was induced by neonatal subcutaneous dose of monosodium glutamate (2mg/g) during 5 days and a higher dose (4mg/g) at the 7th day of life. After the weanig, the animals were fed with normal fat diet (ND) and high fat diet (HD - 60% of fat) by 12 weeks. We obtain four groups: MSG-ND, MSG-HD, C-ND and C-HD. The obesity it not always related with the high weigh, thus measures of adiposity, Lee index and weigh of periepididymal adipose should be used. The GLUT2 protein was analysed by western blot. Paraffin-embedded liver were stained by regular hematoxylin-eosin (HE) methot for evaluation of liver histology.
Results:
The histological analyses demonstrated that nonalcoholic steatohepatitis is present in MSG-HD mices. In comparison to C-ND ($P<0,05$) and MSG-ND ($P<0,01$) animals, the MSG-HD showed higher weigh. The MSG-HD mices also showed higher Lee index when compared with the other groups ($P<0,01$). The weight of periepididymal adipose was higher in MSG-HD group when compared to C-HD group ($P<0,01$). The histological analyses shows nonalcoholic steatohepatitis in MSG-HD mices. In comparison to C-DN and C-DH animals, MSG-DN and MSG-DH mices showed increased GLUT2 protein content in and liver ($P<0,05$).
Conclusions: We demonstrated a new data in the literature: the treatment of monosodium glutamate associated with high fat diet, leads to NASH. NASH is related to insulin resistance where there is a higher output of fatty acids and glucose to the liver. This glucose can be converted into triglycerides by the de novo lipogenesis, contributing for the hepatic steatosis. Thus, the GLUT2 can collaborate to NASH, by falicilitate the glucose input to hepatocyte

Repeated acute restraint-induced stress: Effects on body weight, cortisol and reproductive hormones in female Wistar rats

S.O. Sulaiman, L.A. Olayaki and M.T. Salman

Physiology, University of Ilorin, Nigeria, Ilorin, Kwara, Nigeria

Stress through its response, be it chronic or acute, produces behavioural and chemical deficits that affect most body functions especially reproduction (Selye, 1936; Khodaei-Motlagh et al., 2011). Although chronic exposure to stress has been reported to affect reproduction in an adverse manner (Krulich et al., 1974; Blake, 1975; Hillier and Tetsuka, 1998), effects of acute exposure to stress on reproduction have been controversial. To study the effects of repeated acute restraint-induced stress on reproductive hormones in female rats, fifteen female Wistar rats were divided into three groups of five rats each. Groups I and II rats were restrained for 10 minutes and 20 minutes respectively for seven days while group III rats served as control. All the rats were weighed everyday before the restraint throughout the duration of the experiment. On the 7th day, immediately after the restraint, the rats were anaesthetized using chloroform and killed, then their blood samples collected into heparinized tubes and centrifuged. The supernatant plasma from each blood sample was then used to analyse reproductive hormones and cortisol. Statistical analysis was done with one-way ANOVA and the results were expressed using mean ± SEM. The results showed that there were increases in weights and hormonal levels of the restrained rats compared to the control. The weight increase was significant only in 10 minute restrained rats when weights of days 1 and 7 were compared (180 ± 9.08g vs. 188 ± 8.60g). In 10 minute restrained rats, levels of oestradiol (240 ± 17.55pg/ml), progesterone (41.25 ± 1.94ng/ml) and FSH (1.33 ± 0.06mIu/ml) significantly increased when compared to their corresponding control values of (174.00 ± 8.28pg/ml), (13.13 ± 1.40ng/ml) and (0.3 ± 0.3mIu/ml) respectively. Levels of cortisol (7.63 ± 0.76μg/ml), LH (4.80 ± 0.49mIu/ml) and prolactin (4.25 ± 0.32ng/ml) also increased in the 10 minute restrained rats compared to their control values of (3.90 ± 1.10μg/ml), (4.42 ± 0.28mIu/ml) and (3.50 ± 0.20ng/ml) respectively but the increases were not significant. Thus, it was concluded that acute stress such as 10-minute and 20-minute restraint used in this study could lead to increases in body weight and reproductive hormones.

Identification and characterisation of progesterone-induced microRNAs in mouse endometrial epithelial cells

D. Yuan, Q. Xu, L. Yu, T. Qu, S. Zhang, Y. Zhao, Y. He, J. Zhang and L. Yue

Department of Physiology, West China School of Preclinical and Forensic Medicine, Sichuan University, Chengdu, Sichuan, China

It is essential for progesterone to inhibit estrogen-induced proliferation of endometrial epithelial cells (EECs) and make endometrial epithelium to convert into the secretory epithelium for the preparation of embryo implatation. But the mechanism of progesterone effect on EECs remains unclear. Recent studies have indicated that some reproductive hormones can regulate the expression of some special genes in post-transcriptional level. MicroRNAs are important post-transcriptional regulators in target mRNA, thus they are involved in many physiological and pathological processes. We speculate that there should be progesterone-induced microRNAs which mediate the physiological effect of progesterone on EECs.

In this study, 20 six-week-old ovariectomized female Kunming mice were randomly divided into 2 groups, 10 mice for each. One group (P4 group) was treated both estrogen (100ng / daily for 2 days) and progenstrone(2 mg). The other one (control group) was treated with only estrogen and sesame oil. All mice were sacrificed and their uteri were collected. The EECs were enzymatically isolated and the total RNA was respectively extracted from each group. Small RNA molecules were purified by PAGE, ligated a pair of Solexa adaptors and amplified by PCR, thus 90 bp of DNA were isolated with agarose gel. The purified DNA was used for cluster generation and sequencing analysis using the Illumina's Solexa Sequencer. Then we evaluated sequencing quality, calculated length distribution of small RNA reads and filtrated impure reads. Finally, clean reads were identified and analyzed based on the known mice miRNA of miRBase database 19.

The miRNA expression of two groups was compared to find out the differentially expressed miRNA. The results showed that there were 149 up-regulated miRNAs of which the differences is more than twice of control group. Afterwards, the target genes of these miRNAs were predicted using the following algorithms: miRanda, PicTar, and TargetScan.

22 miRNAs were selected from the 149 up-regulated miRNAs, of which the target gene proteins are involved in significant biological functions, such as cell adhesion, transmembrane transport, cell cycle and metabolism (table). To data, 9 microRNAs (miR-23a-3p, mmu-miR-26a-5p, mmu-miR-1a-3p, mmu-miR-133a-3p, mmu-miR-195a-5p, mmu-miR-3473b, mmu-miR-204-5p, mmu-miR-145a-5p, mmu-miR-143-3p) have been verified by real time PCR. The results proved that their expression is progesterone-dependent on the EECs.

In our conclusion, progesterone can specifically regulate the expression of some miRNAs in EECs, which possibly mediate the effect of progesterone on the structure and function of endometrial epithelium for preparing for implantation through influencing some functinal proteins. This project will be helpful for further exploring the molecular mechanism of progesterone's effect on EECs.

The inducible nitric oxide synthase and proinflammatory cytokines expression are decreased by thyroid hormone treatment in skeletal muscle of diabetic rats

A.P. Costa, S.S. Teixeira, L.L. Poyares and M. Nunes

Physiology and Biophysics, University of São Paulo, São Paulo, Brazil

In vitro (Bérdad et al., 1997) and in vivo (Carvalho-Filho et al., 2005) studies have shown that cytokines decrease glucose uptake in skeletal muscle in response to insulin by increasing the expression of inducible nitric oxide synthase (iNOS). Thyroid hormone treatment was shown to increase the insulin sensitivity and decrease the glycemic levels in db/db mice (Lin and Sun, 2011). In this context, this study aimed to evaluate whether thyroid hormone treatment could affect insulin sensitivity in diabetic rats by altering TNF-α, IL-6 and/or iNOS expression in oxidative skeletal muscle. Methods: Male Wistar rats were assorted in control (C), diabetic (D) and T3-treated diabetic group

(D T1,5) – 15. 10-3 μg. g-1 b.w.. The diabetes was induced by aloxan injection (150 mg. Kg-1 b.w.) and after 15 days, the glycemia was measured. The animals which presented glycemia levels higher than 250 mg/dL were included in the diabetic groups. A subset of diabetic rats was treated with T3 for a 28 day-period (D T1,5). After this period, the skeletal muscle (soleus) was removed and TNF-α, IL-6 and iNOS content was analyzed through western blotting. Results: T3 treatment decreased the amount of TNF-α, IL-6 and iNOS protein and improved insulin sensitivity in oxidative skeletal muscle tissue (soleus), as shown by the increased Akt kinase phospho-

rilation in response to insulin administration. Conclusion: The present data provide evidence that at least part of the benefits of T3 treatment in insulin sensitivity of diabetic rats occurs by its negative modulation of cytokines and iNOS expression.

GPR30 mediates the fast effect of estrogen on mouse blastocyst and its role in implantation

L. Yu, T. Qu, S. Zhang, D. Yuan, Q. Xu, J. Zhang, Y. He and L. Yue

Department of Physiology, Sichuan University, Chengdu, Sichuan, China

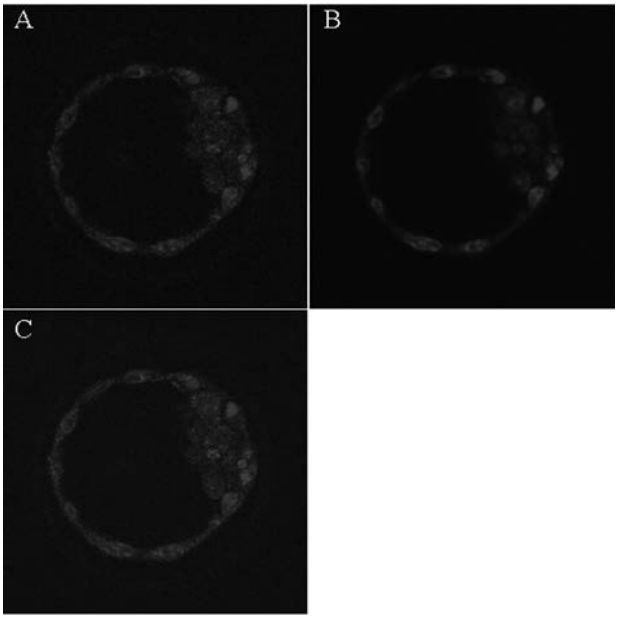
It was reported that that there was a fast action of estrogen on the target cells. Recent researches on some kinds of cells have suggested that G protein-coupled receptor 30 (GPR30) is involved in the rapid effects of estrogen as its membrane receptor. The aim of this research is to reveal whether GPR30 mediates the fast action of estrogen on mouse blastocyst and its role in embryo implantation.

We firstly used RT-PCR to detect the expression of GPR30 mRNA, immunocytochemistry to detect the expression of GPR30 protein and FITC- E2-BSA to detect the binding sites of estrogen in the mouse blastocyst cells further to be compared with the GPR30's location. We found that the mRNAs and proteins expressed on the mouse blastocyst cells and their location was mostly consistent with the binding sites of estrogen on the plasma membrane (Figure 1).

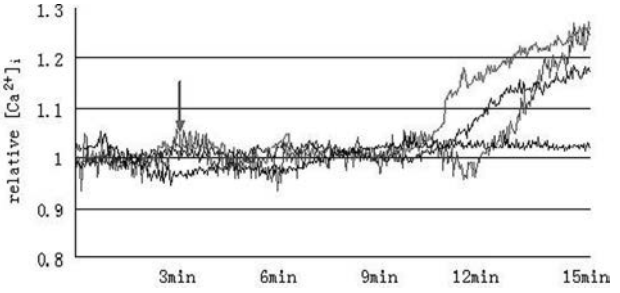
To study GPR30 mediating the fast action of estrogen on mouse blastocyst, we used Fluo-3/AM (3μmol/L) to label intracellular calcium and confocal laser scanning microscopy to detect the dynamic change of [Ca2+]i in different groups of mouse blastocysts, which were treated respectively with 1μmol/L E2, 1μmol/L E2-BSA, 1μmol/L G1, a GPR30-specific agonist and 1μmol/L G15, a GPR30-specific antagonist, followed by 1μmol/L E2-BSA. The results showed that E2, E2-BSA as well as G1 could induce their rapid increase of Cai2+, while G15 could inhibit the fast effect of E2-BSA (Figure 2).

To study the role of GPR30 mediating the effect of estrogen on mouse blastocyst in implantation, total 53 blastocysts from donor mice were divided into two groups, one is G15 group (n=26) in which blastocysts were pretreated with 1μmol/L G15 for 30 minutes, the other one is for control (n=27) in which blastocysts were pretreated with the same amount of vehicle, and then both groups of blastocysts were separately transplanted into the bilateral uterine horns of five day 4 pseudopregnant recipient mice and the implantation rates on day 10 between two groups were compared. The results indicated that the implantation rate of G15 group was 19.2%, significantly lower than 55.5% of control group ($P<0.05$).

Recent studies have implicated GPR30 as a mediator of the rapid effects of estrogens in some kinds of cells. We provided the first evidence that GPR30 expressed on the mouse blastocysts, and their locations were mostly consistent with the binding sites of estrogen on the blastocyst cells. Furthermore, both estrogen and GPR30-selective agonist could induce the rapid increase of Cai2+ of blastocyst cells, while GPR30-selective antagonist could specifically block the fast effect of estrogen. Moreover, the pretreatment of G15 on blastocysts lead to a lower implantation rate, compared with that of control. Thus, it can be inferred that GPR30 can mediate the fast effect of estrogen on blastocysts and play important role in embryo implantation.



The expression and locations of GPR30 protein on mouse blastocyst cells. A: The green indicates that the binding of E2-BSA-FITC on the plasma membrane B: The red indicates that GPR30 is localized in the mouse blastocyst cells, C: merged image indicates GPR30 proteins were mostly consistent with the binding sites of E2.



The mobilizations of Cai2+ which induced by different factors in blastocyst cells. Arrow: To add E2/E2-BSA/G1, Red line: E2 group, Blue line: E2-BSA group, Green line: G1 group, Black line: G15+E2-BSA group.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC297

Integrins are involved in GPR30 mediating the fast effect of estrogen on mouse blastocysts in implantation

T. Qu, L. Yu, S. Zhang, D. Yuan, Q. Xu, J. Zhang, Y. He and L. Yue

Department of Physiology, Sichuan University, Chengdu, China

It is necessary for estrogen to rapidly activate mouse blastocysts, so that they may attach to endometrial epithelium in implantation. Our previous and recent work has shown that estrogen induces the fast effect on mouse blastocysts in implantation which is mediated by G protein-coupled receptor 30 (GPR30). There also were evidences that integrins and their ligands are involved in embryo–endometrium interaction. Thus, we infer integrins may be involved in GPR30 medi-

ating the fast effect of estrogen on mouse blastocysts in implantation.

Firstly, blastocysts were collected from day 4 pregnant Kunming mice and divided into 5 groups, 3 embryos for each, which were treated respectively with the same amount of vehicle, 1μmol/L estradiol (E2), 1μmol/L E2 conjugated with bovine serum album (E2-BSA), 1μmol/L G1, a GPR30-specific agonist, and 1μmol/L E2-BSA with pretreatment of 1μmol/L G15, a GPR30-specific antagonist. Immunocytochemistry staining and confocal microscopy were used to examine the expression of integrins. The experiment was repeated three times. The result showed that E2, E2-BSA and G1 could induce their clustering, while G15 may block the clustering induced by E2-BSA (Fig 1).

To explore GPR30 mediating the fast effect of estrogen on the affinity of integrins in mouse blastocysts. The collected some other blastocysts were pretreated as the above experiment, followed by the treatment of 50μg/L fibronectin labled with FITC (FN-120-FITC), one kind of integrin ligands, The fluorescence intensity was examined which represented the affinity of integrins with their ligand. The result indicated that E2, E2-BSA and G1 could increase the FN binding activity of integrins in blastocyst cells, while G15 may block this effect of E2-BSA on it (Fig 2).

In order to study integrins are involved in the effect of estrogen on mouse blastocysts in implantation, blastocysts (n=38) were pretreated with 1μmol/L E2, and then divided into two groups. One group was cultured in M2 medium containing RGD, (Arg-Ala-Asp) peptide (1mmol/L) for 30 minutes, which can specifically block the binding of integrins with their ligands, the other group was cultured in non-specific RGE peptide (1mmol/L) as control. Two groups of blastocysts were separately transplanted into the bilateral uterine horns of recipient mice on the pseudopregnant day 4 and the implantation rate between two groups were compared in 10 days. We found that the implantation rate in RGD group (3/19, 16%) was significantly lower than that in RGE group (13/19, 68%), $P<0.05$.

In conclusion, GPR30 mediating the fast effect of estrogen may induce the clustering of integrins and increase the affinity of integrins with their ligand in mouse blastocysts, which play important roles in the process of implantation.

Acute vs chronic caffeine: Are the effects on insulin sensitivity mediated by altered insulin/AMPK signaling pathway?

J.F. Sacramento, M.J. Ribeiro, M.P. Guarino and S.V. Conde

Pharmacology, CEDOC, Faculdade de Ciências Médicas, Universidade NOVA, Lisboa, Portugal

Caffeine is the most widely behaviorally active substance consumed in the world. We have recently showed that chronic caffeine intake prevents the development of insulin resistance (IR) in diet-induced IR rats (Conde et al. 2012). In contrast, acute caffeine administration decreases insulin sensitivity in a dose dependent manner (Sacramento et al. 2012). However, the mechanism behind the distinct effects of acute and chronic caffeine administration on insulin sensitivity is not clarified. Herein we have investigated if the mechanism that contributes to the differences between acute and chronic caffeine effects on insulin sensitivity is mediated by altered insulin/AMPK signaling pathway in skeletal muscle.

Experiments were performed in 3 months Wistar rats anaesthetized with pentobarbitone (60mg/Kg, ip). Six groups of animals were used to evaluate if the effects of chronic caffeine intake on insulin sensitivity are mediated by altered insulin/AMPK pathway. A control group (fed with a sham diet), an high sucrose (HSu; 35% sucrose in drinking water, 28 days) and an high fat (HF; lipid rich diet with 45% fat, 21days) groups were randomly divided into two subgroups, treated and not treated with 1g/l caffeine during 15 days. Insulin sensitivity was measured by an insulin tolerance test (ITT). Acute caffeine administration effects on insulin/AMPK signaling pathway were evaluated in animals submitted to an i.v. administration of different doses of caffeine (0.001-5 μM) 15 minutes before the ITT. Blood was collected by heart puncture and skeletal muscle was removed for Western-blot detection and quantification of insulin receptor, insulin receptor phosphor-Tyr1322, AMPKα1, AMPKα1 Thr172 and Glut4 transporters.

Glut4 expression decreased by 59.35% in HSu animals, an effect not modified by chronic caffeine. In contrast, acute caffeine administration decreased significantly Glut4 expression at 0.5μM of caffeine ($p<0.01$). HSu and HF diets decreased significantly AMPKα1 expression by 70.45% and 33.93%, respec-

tively. Chronic caffeine intake increased significantly AMPKα1 in HSu animals (42.54%) and in HF group AMPK α1 expression was restored to control levels. AMPK α1 activity decreased significantly in HF animals (44.74%), however chronic caffeine intake did modify those values. In opposite, acute caffeine intake did not alter AMPK α1 expression. Insulin receptor decreased significantly in HF animals (59.43%) but chronic caffeine intake did not alter this value. Acute and chronic caffeine did not altered insulin receptor phosphor-Tyr1322 expression. In conclusion, the effect of chronic caffeine intake on insulin sensitivity is not mediated by altered insulin and/or AMPK signaling pathway. In contrast, the effect of acute caffeine administration on insulin sensitivity seems to involve a decrease in Glut4 transporters.

Vascular endothelial growth factor (VEGF)-mediated microvascular remodeling in the pituitary gland

J. Castle-Miller[1,2], H. Poole[1], C. Sullivan[1], D. Bates[2] and D. Tortonese[1]

[1]Centre of comparative and clinical anatomy, University of Bristol, Bristol, UK and [2]Microvascular research labatories, University of Bristol, Bristol, UK

The pituitary gland contains a complex portal system that transfers signals from the pars tuberalis (PT) and infundibulum to the pars distalis (PD). Vascular loops arising from the PT, traverse to the infundibulum, an area encompassing glial cells and endothelium in close proximity, before descending towards the PD as long portal vessels. Vascular endothelial growth factor (VEGF), originally isolated from the pituitary gland, has been identified as a key regulator of endothelial function, controlling angiogenesis and vascular permeability, the latter via regulation of fenestrations. We hypothesised that VEGF-mediated remodeling of pituitary microvasculature may therefore play a role in the control of reproductive function by acting to either maintain, remodel or signal through this vasculature. If this was the case, one would expect the functional remodeling of this microvasculature to be under seasonal regulation in photoperiodic species as a key mechanism underlying the control of temporal changes in seasonal fertility. To test this hypothesis, pituitary glands from adult ewes were collected during the breeding season (BS; n=5) and non-breeding season (NBS; n=5). The expression of pro- (VEGFxxx) and anti- (VEGFxxxb) angiogenic isoforms was revealed in PT cells co-expressing the melatonin receptor MT1-R, endothelial cells of the vascular loops, and both glial and endothelial cells of the infundibulum. Seasonal variation in VEGF isoform expression was observed in the PD, with a significantly higher content of the anti-angiogenic VEGFxxxb during the BS ($p<0.01$), and an increase in the expression of angiogenic VEGFxxxa ($p<0.01$) during the NBS. Consistent with these findings, total cell proliferation and endothelial cell proliferation were both significantly increased in the PD during the NBS ($p<0.01$). In contrast, no such seasonal changes of VEGF expression or cell proliferation were detected in the PT ($p>0.05$). The expression of S-100, a marker of folliculo-stellate cells (FSC) known to produce VEGF, was significantly increased during the NBS in the PD ($p<0.01$), where expression of VEGFR2 by lactotrophs, endothelial cells, FSC and other endocrine cells was also observed. Critically, seasonal alterations to the intrinsic morphology of the vascular loops of the infundibulum were also identified. The number and area of these loops were significantly increased during the NBS ($p<0.05$). These findings support a role for VEGF-mediated pituitary vascular remodeling in the mechanisms underlying the pituitary control of temporal changes in fertility.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Antioxidative and anti-immflammatory activity of Croatian propolis preparations in alloxan induced diabetes in mice

S. Novak[1], D. Sirovina[2], I. Ivic[3] and N. Oršolić[2]

[1]Department of Physiology and Immunology, Medical Faculty Osijek, J.J. Strosmayer University Osijek, Osijek, Croatia, [2]Department of Animal Physiology, Faculty of Science, University of Zagreb, Zagreb, Croatia and [3]Department of Pathophysiology and Gerontology, Medical School, University of Pécs, Pécs, Hungary

Introduction: Diabetes mellitus is metabolic disease and its consequences are seen in many different tissues. Hyperglycemia results in developing reactive oxygen species which induce inflammatory process. The antioxidant capacity of propolis could protect organism from oxidative stress, diminished hyperglycemia effect and could reduce inflammation.
Hypothesis: Antioxidant and anti-inflammatory effect of propolis improve life quality and lifespan in alloxan-induced diabetic mice.
Methods: Diabetes was induced in Swiss albino mice with a single intravenous injection of alloxan (75 mg kg-1). Two days after alloxan injection, water soluble derivative of propolis (WSDP) or ethanol extract of propolis (EEP) (50 mg kg-1 per day) were intraperitoneally injected for 7 days in diabetic mice. We have measured in vivo lipid peroxidation of liver, spleen, and brain in mice treated with WSDP or EEP. Functional activity of macrophages was also examined and effect of WSDP or EEP on body weight and survival of alloxan-induced diabetic mice.
Results: The lipid peroxidation in liver tissue was improved in animals treated by EEP and WSDP ($p <0.001$). In addition, WSDP was able to lower the extent of lipid peroxidation of kidney and spleen ($p <0.05$). In our study, we couldn't observe a difference in malondialdehyde (MDA) levels of diabetic and healthy brain, but in WSDP-treated diabetic animals a significant reduction in MDA levels could be noted. The results showed a statistically significant increase in the number of activated macrophages in untreated diabetic mice and in mice treated with WSDP or EEP ($p <0.001$) versus healthy animals. Diabetic animals treated with WSDP showed a significantly increased number of functional activated macrophages as compared to untreated diabetic mice ($p <0.001$). Increased life span was observed in diabetic mice treated with either aqueous or

ethanol propolis preparations for 30.43% (WSDP) and 20.67% (EEP), respectively, in relation to control diabetic mice.
Conclusions: Our results have shown that propolis preparations have a promising role in the protection against oxidative stress damage in diabetic mice, which may be mainly attributed to its antioxidant and anti-inflammatory potential. The mechanism of polyphenol/flavonoid action on mice with diabetes mellitus is yet to be determined.

Calcium oscillations and waves in beta cells from acute mouse pancreas tissue slices

A. Stozer[1,2], J. Dolenšek[1], M.S. Klemen[1] and M.S. Rupnik[1,2]

[1]Institute of Physiology, University of Maribor, Faculty of Medicine, Maribor, Slovenia and [2]Centre for Open Innovations and Research, University of Maribor, Maribor, Slovenia

In beta cells from Langerhans islets, cell stimulation is coupled to insulin secretion. Upon stimulation with glucose, the concentration of intracellular calcium ions ([Ca2+]i) oscillates in phase with accompanying oscillatory changes in membrane potential and insulin secretion. The calcium oscillations in different cells within a single islet of Langerhans are well synchronized, with phase differences between oscillations in individual cells of up to a few seconds (1, 2). Furthermore, some studies have reported the presence of calcium waves in islets of Langerhans, with a speed of 20-200 μm/s (3).
However, many different types of calcium oscillations have been reported in isolated islets which are the most widely used experimental model. It has been suggested that the duration and conditions of islet culture influence the types of responses and that calcium waves occur only in cultured islets (4-6). Additionally, due to limited diffusion of fluorescent calcium indicators, calcium imaging experiments performed on isolated islets enable insight only into the most peripheral parts of islets, where beta cells are least abundant in mice and where other types of cells are present (7).
To enable access to all cellular layers of an islet and clarify the existing controversy regarding types of oscillations present in islets and the existence of calcium waves, we combined the recently introduced acute pancreas tissue slice method (8) with confocal laser scanning calcium imaging, using the Oregon green® 488 BAPTA-1 fluorescent calcium indicator. The study was conducted in accordance with all national and European recommendations pertaining to work with isolated tissue and our protocol was approved by the Veterinary Administration of the Republic of Slovenia. The tissue slices were prepared from agarose-injected pancreata of 10-20 week old NMRI mice of either sex, upon sacrifice by cervical dislocation as described in detail previously (8). Taking advantage of previous reports that islet cell types can be identified by their characteristic responses to glucose (7), this enabled simultaneous recording of [Ca2+]i in a large number of cells from all layers of an islet. We showed that fast [Ca2+]i oscillations (4-6 /min) superimposed on a sustained increase in [Ca2+]i are the predominant type of response to 12 mM glucose in beta cells in mice. Additionally, we were able to detect other types of responses, characteristic of alpha and delta cells, predominantly at the periphery of islets. The changes in [Ca2+]i were well synchronized exclusively between coupled beta cells (Figure 1).
Finally, employing high speed calcium imaging (20 frames/s) we detected calcium waves spreading in an orderly manner across the beta cell syncitium at a velocity of 80-90 μm/s as the mechanistic substrate of synchronicity between beta cells in uncultured acute pancreas tissue slices (Figure 2).
A detailed quantification of activation and deactivation phases before and after the sustained plateau with superimposed oscillations revealed that large amplitude changes in [Ca2+]i are insufficient to ensure intercellular synchronization during stimulation with glucose and that metabolic activation is necessary to align the activity of a heterogeneous population of beta cells.

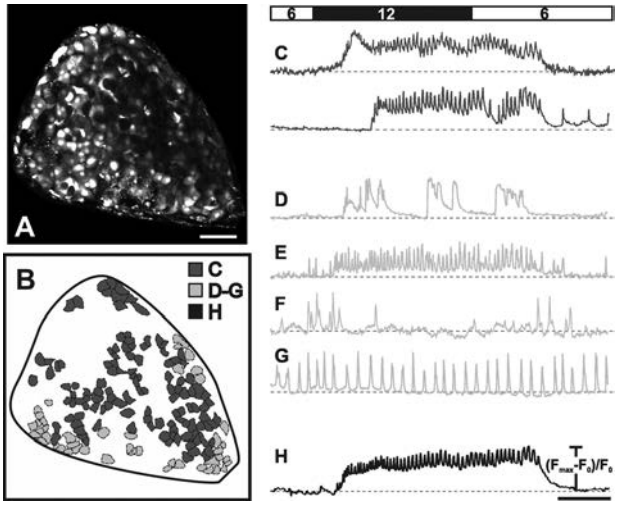

Figure 1. Types of responses. A Oregon green 488 BAPTA-1 labeled most of the cells in the focal plane. Scale bar indicates 50 μm. B A grayscale-coded representation of cells from A, responding to stimulation with 12 mM glucose as represented in C-G (N=177 cells). C A sustained increase with superimposed fast oscillations was the predominant type of response and is characteristic of beta cells (N=124 cells, 70 %). D Slow [Ca2+]i oscillations with superimposed fast oscillations, indicative of poorly coupled or cAMP-depleted beta cells (N=6 cells, 3 %). E Responses characteristic of delta cells (N=30 cells, 17 %). F Responses characteristic of alpha cells (N=5 cells, 3 %). G Some cells displayed [Ca2+]i oscillations not responsive to higher glucose, most probably indicative of already maximally activated delta cells. H The average signal confirming the synchronicity of fast oscillations superimposed on the sustained increase in individual cells. Scale bar indicates 200 s.

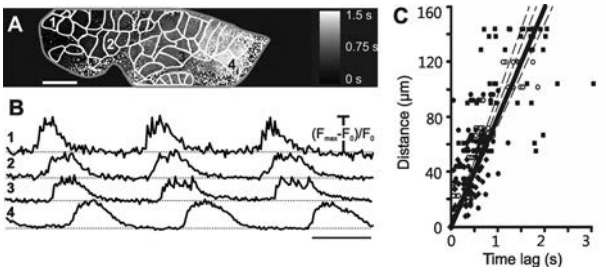

Figure 2. [Ca2+]i waves are the mechanistic substrate of synchronization between individual beta cells. A Cross-correlation determined grayscale-coded time delays for each pixel demonstrating the average direction of spreading of [Ca2+]i waves for 6 subsequent oscillations in 45 cells indicated as regions of interest in white. Scale bar indicates 20 μm. B 3 consecutive [Ca2+]i oscillations in 4 cells indicated in A. Scale bar indicates 2 s. C In 4 different islets, for 6 consecutive oscillations in 10 cells from each islet, the average speed of waves was 80 μm/s (R2 = 0.62, p<0.001), solid line. The respective values obtained in 4 islets were 98 μm/s (R2 = 0.83, p<0.001), 88 μm/s (R2 = 0.34, p<0.001), 80 μm/s (R2=0.40, p<0.001), and μm/s (R2 = 0.46, p<0.001), dashed lines.

Effects of estrogen replacement on high-fat diet-induced insulin resistance in ovariectomized rats

N. Yokota, S. Omoto, S. Tazumi, M. Kawakami and K. Morimoto

Dept. Environm. Health, Facult. Human Life & Environm. Sci., Nara Women's University, Nara, Nara, Japan

Menopause is associated with obesity and insulin resistance. However, the effects of estrogen on insulin sensitivity in ovariectomized rats fed on high-fat diet (HFD) remains unclear. In this study, we examined in vivo effects of estrogen on energy intake, body weight, fat accumulation, insulin sensitivity and insulin signaling in ovariectomized (OVX) rats fed on HFD or standard chow diet (SD). Female Wistar rats aged 9 week were ovariectomized. After 4 week, the rats were assigned either to a placebo-treated (Placebo; n=26) group or a group treated with 17β-estradiol (Estrogen; n=26) subcutaneously implanted with either placebo- or 17β-estradiol (1.5 mg/60-day release) pellets. Simultaneously, rats in either group were divided into two groups and given either SD (13% of calories from fat) or HFD (60% of calories from fat). Four weeks after the replacement and HFD treatment, intravenous glucose tolerance test (IGTT, 1g/kg) was performed for assessment of insulin sensitivity. Blood samples were taken at 0, 5, 10, 30 and 60 min from the catheter implanted into the right jugular vein of rat. Plasma glucose and insulin were measured by the glucose oxidase method using a glucose assay kit and by ELISA assay kit, respectively. Two days after the IGTT, 10^{-5} mol/l insulin was injected into the portal vein in each group of rats, and the liver, hind-limb muscle and mesenteric adipose tissue were dissected for insulin signaling analysis. The Akt and phosphorylated Akt in these organs were assayed by Western blotting. In the Placebo group, HFD increased energy intake compared with SD for 3 weeks after the diet started, while in the Estrogen group it decreased energy intake remarkably for 2 weeks. Four weeks after replacement and HFD, the accumulation of intra-abdominal fats was enhanced in the Placebo group, but was suppressed in either diet group of the estrogen-treated rats. The basal levels of plasma glucose and insulin concentrations were higher in the Placebo group than in the Estrogen group. IGTT revealed that insulin sensitivity was decreased in the Placebo group than that in the Estrogen group of rats fed on SD. Furthermore, HFD reduced insulin sensitivity in the Placebo group, but had little effects on the sensitivity in the Estrogen group. In addition, insulin injection increased Akt phosphorylation in the liver of the Estrogen group, but not in the Placebo group. These results suggest that HFD induces insulin resistance in the OVX rat by impairing insulin-stimulated Akt activations in insulin target organs, which are ameliorated by estrogen replacement.

The interstitial GABA concentration and pharmacology of GABAA channels in human pancreatic islets

Y. Jin, S. Korol, Z. Jin and B. Birnir

Department of Neuroscience, Uppsala University, Uppsala, Sweden

Gamma-aminobutyric acid (GABA) is known as the inhibitory neurotransmitter in the adult mammalian central nervous system (CNS). It is also produced in the islets of Langerhans in pancreas where it serves as an paracrine and autocrine signaling molecule regulating the hormone secretion of pancreatic cells through GABAA channels (1). The GABAA channel is a ligand-gated ion channel permeable to chloride and bicarbonate. When the GABAA channels are activated, they depolarize the β-cells and hyperpolarize the α-cells in the human islets, due to different intracellular chloride concentrations (2). In pancreatic islets, GABA is synthesized in the β-cells, and released by both vesicular and nonvesicular processes (3). We have recently shown GABA modulates hormone release in islets from type 2 diabetic and normoglycaemic individuals. Moreover, both phasic and tonic GABAA channels activation were recorded in intact islet cells (4). Whereas the normal range of interstitial GABA concentration is not known, and information regarding the islets GABAA channel pharmacology is not available either. We, therefore, did whole-cell patch-clamp recordings on cells in intact human islets to further investigate the pharmacological characteristics of the native GABAA channels expressed in the islets. The results show that in 16 out of 23 cells, the GABAA channels conductance in human pancreatic islets are enhanced maximally (82 + 23 pS), when 100 nM or 1 μM GABA is applied, as compared to the channel conductance (39 + 17 pS) activated by the interstitial GABA. Among the 16 cells, channels in 9 cells desensitize in 1 μM GABA. These results support the notion that GABAA channels with very high affinity are present in the islet cells. Furthermore, the endogenous interstitial GABA concentration is in the range between 10 nM and 1 μM in islets when 20 mM glucose is present. We further examined several known GABAA channel modulators: pentobarbital, diazepam, zolpidem and propofol. The results demonstrated that 100 μM pentobarbital (15 cells), 1 μM diazepam (12 cells) and 50 μM propofol (13 cells) consistently potentiated the GABAA channels, whereas 100 nM zolpidem (10 out of 11 cells) did not. The results identify the pancreatic islet cells' GABA channels are high-affinity, high-conducting, extrasynaptic GABAA channels.

The effects of sodium acetate availability on phosphorylation of hormone sensitive lipase in 3T3-L1 cells

N. Aberdein[1], M. Schweizer[2] and D. Ball[1]

[1]Health and Exercise Research Group, Heriot-Watt University, Edinburgh, UK and [2]Biological Sciences Research Group, Heriot-Watt University, Edinburgh, UK

We recently reported that exposing white adipose cells to 4mM sodium acetate reduces the rate and total release of non-esterified fatty acids (NEFA) [1]. It was unclear from this study whether NEFA release was suppressed or whether acetate inhibited lipolysis. The aim of the current study was to examine whether acetate administration reduces the phosphorylation of hormone sensitive lipase (pHSL) in 3T3-L1 cells that were stimulated with the β-adrenergic receptor agonist, isoproterenol (ISO). The 3T3-L1 cell line was used throughout this study at day 9 post-differentiation. Cells were treated with a combination of the following: ISO (5μM), insulin (1μg/ml) and sodium acetate (4mM) for 3 hours. Under sodium acetate conditions cells were pre-treated (4mM) for 30 minutes. Samples of media were collected every 60 minute for a total duration of 180 minutes and analysed for NEFA and glycerol concentration. Cells for western blot analysis were lysed after 120 minutes. All samples were normalised to total protein content and statistical analysis was by non-parametric Friedman and Mann-Whitney tests. Over the 3 hour period, ISO stimulation of the cells resulted in a >2 fold increase in both NEFA (Fig. 1) and glycerol release and the greatest relative volume of pHSL (Fig. 2) at 120 minutes. Insulin with ISO resulted in a reduction in NEFA release at 120 and 180 minutes (P=0.010; (P=0.016, respectively) (Fig. 1). Incubation with acetate and ISO also reduced NEFA release at 120 and 180 minutes, compared with ISO ((P=0.004; (P=0.004, respectively). Glycerol release was found not to differ between treatment groups (data not shown). Under ISO stimulated lipolysis, the relative quantity of pHSL at serine residue 563 was lower in the presence of acetate, insulin and acetate plus insulin compared with ISO treatment alone (Fig. 2). These data support our previous findings that acetate reduces the appearance of NEFA under ISO stimulated lipolysis. The reduced accumulation of NEFA appears to be due to a down regulation of pHSL and thus lipolysis. The acute metabolic effects of increased acetate availability on lipolysis closely resemble those of insulin however; it is unlikely that the mechanism of reducing pHSL under these two conditions is the same. Future studies to identify the effects of an increase in acetate availability on other lipolytic proteins and secondary messengers upstream of pHSL are warranted.

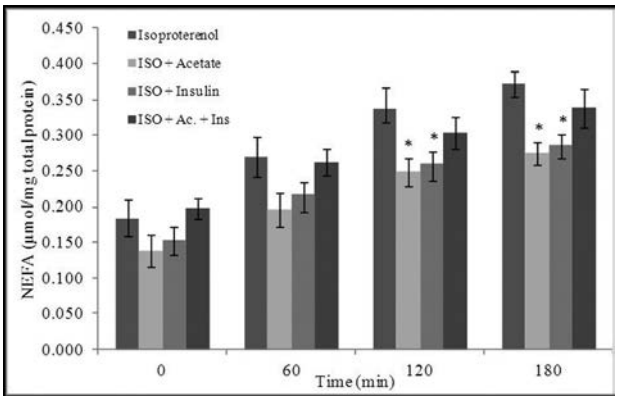

Fig. 1 NEFA release over 180 minutes under conditions of ISO stimulation alone and with insulin, acetate and insulin + acetate. Values are mean±SE (n=3-6) *P<0.05 vs. Isoproterenol.

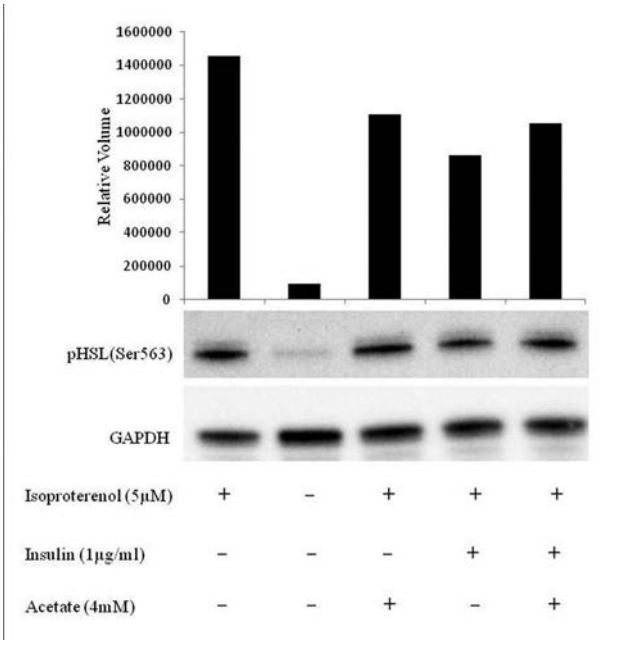

Fig. 2. Sodium acetate, insulin and sodium acetate plus insulin all reduce the phosphorylation of HSL(Ser563) during ISO stimulation. Cell lysates were analysed using western blot with relative volume calculated and normalised to GAPDH. (n=1)

Hypothalamic Apolipoprotein E Effects on Plasma Lipids in obese rats with metabolic syndrome

M. Bunea[1], C. Scheau[1], R. Moldovan[2], C. Ciornei[1], R. Papacocea[1], S. Tache[2] and A. Badarau[1]

[1]Physiology I, University Of Medicine and Pharmacy "Carol Davila", Bucharest, Bucharest, Romania and [2]Physiology, "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, Cluj-Napoca, Romania

The metabolic syndrome is defined by raised values of plasma cholesterol, raised plasma triglycerides and elevated waist circumference (1), among other parameters. Nevertheless, the role of apolipoprotein E (ApoE) in the on set of obesity in the metabolic syndrome remains unclear, although apolipoprotein E is a key surface component of triglyceride-rich lipoproteins, low density lipoproteins (VLDL) chylomicrons remnants and high density lipoprotein (HDL). Also, traces of it are found in the hypothalamic area of the hunger center (2).
Objective: This study searches for the possible cause for obesity in metabolic syndrome due to a hypothalamic ApoE deficiency, associated with an increased level of combined ApoE in the systemic circulation, using a metabolic syndrome model in rats.
Methods: Wistar rats (male, 179-240 g, n=10), on a high caloric, high fat diet (20 g/day/rat of combined fodder grain + pork lard as fat supplement 2ml/day/rat) for 60 days, had measurements of their plasma levels of triglycerides, cholesterol and glycaemia taken every 30 days. Also weight and arterial pressure were measured. A group (n=10) of male Wistar rats (148g-220 g) on a normal caloric diet (20 g/day/rat ad libidum of combined fodder grain) was used as control. After showing raised blood lipids and obesity, according to the diagnostic criteria (cholesterol level ranging from 158 – 170 mg/dl, triglycerides levels 201- 558 mg/dl) the rats were injected with 8 μl liquid ApoE (Millipore apolipoprotein E, Merck) in the hypothalamic area, following the coordinates of 2.2 mm posterior to bregma and 7.4 mm ventral to dura (3). The procedure was performed under anesthesia with a mixture of ketamine 10% and Xilazine 2%. Blood samples were taken by non traumatic tail incision and arterial pressure was measured using the tail-cuff method.
Results: After the intracerebroventricular administration of apolipoprotein E the two parameters of plasma lipids have fallen to lower values (cholesterol) or even to normal values (triglycerides values ranging between 94-113 mg/dl) and a decrease in the food appetite of the rats was noticed. Daily food intake was noted to fall to 63%. Further measurements of the plasma leptin values, before and after administration of ApoE will take place.
Conclusion: Preliminary data shows that apolipoprotein E has hypothalamic effects that concern metabolic disorders and raised plasma lipid values. Although further study is highly necessary we can conclude that deficient ApoE in the hypothalamic area can lead to a greater food intake and have possible consequences in raised plasma lipid values.

L-cysteine reduces food intake and suppresses plasma ghrelin levels in rats

A.K. McGavigan[1], H.C. Greenwood[1], C. Wong[1], A. Lehmann[2], M.A. Ghatei[1], S.R. Bloom[1] and K.G. Murphy[1]

[1]Section of Investigative Medicine, Imperial College London, London, UK and [2]Research and Development, AstraZeneca, Mölndal, Sweden

Protein is the macronutrient that induces the strongest feeling of satiety. Protein-induced satiety may be mediated by the specific amino acids generated by protein digestion. We have identified L-cysteine as an amino acid with anorexigenic properties.
Food intake was measured in overnight fasted male Wistar rats, following oral gavage of water, 1, 2 or 4mmol/kg L-cysteine and a conditioned taste aversion protocol employed to investigate the possibility of treatment associated consequences. Subsequently, rats received an oral gavage of water or 4mmol/kg L-cysteine and 30 minutes post administration were culled by decapitation and trunk blood collected. Plasma levels of insulin and the anorexigenic hormones glucagon-like peptide-1 (GLP-1) and peptide YY (PYY) were measured by radioimmunoassay, and plasma levels of the orexigenic hormone acyl-ghrelin were measured by an enzyme immunoassay. The effect of repeated administration of L-cysteine on food intake was also investigated. All data are expressed as mean ± sem.
Oral gavage of 2 and 4mmol/kg L-cysteine significantly reduced food intake compared to water control in the 0-1 hour period following administration (water: 6.8 ±0.6g vs. 2mmol/kg L-cysteine: 4.3 ± 0.6g, $p<0.05$; vs. 4mmol/kg L-cysteine: 2.7 ± 0.3g, $p<0.001$, one-way ANOVA, n=7-8). Doses of L-cysteine that reduced food intake did not induce any aversive behaviour suggesting the reduction in food intake was not secondary to unpleasant post-ingestive consequences. L-cysteine significantly reduced plasma acyl-ghrelin levels 30 minutes post administration compared to water control (water: 8.8 ± 1.6pmol/l vs. L-cysteine: 3.6 ± 0.9pmol/l, p=0.019, t-test, n=7-8) and significantly increased plasma insulin levels compared to water control (water: 68.0 ± 7.7pmol/l vs. L-cysteine: 125.7 ± 20.7pmol/l, p=0.020, t-test, n=8). However, there was no effect on plasma GLP-1 or PYY levels. Repeated administration of L-cysteine over 5 days significantly reduced cumulative food intake compared to water and glycine (negative control) treated controls (day 5, water: 144.7 ± 3.5g, glycine: 145.7 ± 3.0g, vs. L-cysteine: 130.1 ± 2.5g, $p<0.001$, two-way ANOVA, n=6-9).
L-cysteine may therefore contribute towards protein induced satiety by suppressing the release of the orexigenic hormone

ghrelin. Altering the amino acid content of foods may represent a possible intervention to manipulate appetite.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Effect of Cassava (Manihot Esculenta) Feed Formulations on Tetra-iodothyronine (T4), Tri-iodothyronine (T3) and Thyroid stimulating hormone (TSH) of Adult Wister Rats

A.O. Oyabambi

Physiology, university of Ilorin, Ilorin, Kwara, Nigeria

Cassava meals are common in many tropical countries and are processed into different forms of human delicacies and animal feeds (Adekunle et al.2011) .It is fast becoming the major ingredient of many diets in Nigeria especially in the bakery, brewery and pharmaceutical industries. . A study was conducted to determine the effect of cassava feed formulations on thyroid functions and their relevance in clinical diagnosis. Thirty wister rats mean weight of 238±25.6g were acclimatized for one week and fed the different cassava feed formulations and water ad libitum. Thereafter, the rats were sorted out into 5 groups of six each. Group 1,2,3,4 and 5(control) were fed on 30g each of garri, cassava flour, tapioca, fresh cassava and grower's mash (local rat diet) respectively. After 4 weeks, each animal was exposed to 5mls of chloroform in cotton wool and anaesthetized by inhalation. Blood samples were collected by cardiac puncture and then assay for tetra-iodothyronine (T4), tri-iodothyronine (T3) and thyroid stimulating hormone (TSH). The data obtained were presented in tables and the significance determined at $p<0.5$ using paired samples t-test. In comparison with the control, group1 shows a significant decrease in T3 and T4 and group 2 shows a significant increase in T4 and TSH $p<0.05$. Group 3 shows a significant decrease in level of TSH $p<0.05$ while in group 4, the increase in T3 and T4 and the decrease in TSH had no statistical significant difference $p>0.05$.It was concluded that garri and cassava flours lower thyroid functions (goitrogens) while Tapioca and fresh cassava increase serum T3 and T4 activities and could worsen cases of hyperthyroidism.

Assessment of correlation of microcirculation parameters and secretion of c-peptide in diabetic patients

O.V. Suchkova(Makeeva)

Scientific clinical center JSC "Russian Railways", Moscow, Russian Federation

The growing incidence of the overweight has an enormous impact on increasing the risk of impaired glycemic control or insulin resistance and peripheral vascular disease. Often the problem of diagnosing errors lies in the development of contrinsular reactions in response to hyperinsulinism. The assessment of this condition is extremely complicated in the laboratory-instrumental level. Due to the rapid hormone destruction in blood serum the definition of insulin secretion is difficult.

Purpose of the study: To assess correlation between microcirculation parameters and secretion of c-peptide in diabetic patients.

Material and methods: A population of 72 diabetic patients was divided into 2 groups: group 1 included 31 normotensive patients with diabetes type 2 (49,7±10,9 years) with normal secretion of c-peptide (697,2±284,4 pmoll), group 2 consisted of 40 patients with diabetes (49,9±9.1 years) and c-peptide hypersecretion (1317,3±502,9 pmoll). In both groups there were the patients with the early stage of arterial hypertension. The level of glycated hemoglobin was similar in both groups: 8,37±1,9% in the 1st one and 8,2±1,7% in the 2nd one. The control group (n=43) consisted of nondiabetic normotensive individuals (50,1±9,9 years).

We performed a non-invasive vital capillaroscopy (Center for Analyses of Substances) to evaluate the density of vascular network, degree of coiled capillaries, diameters of capillary parts, perivascular zone size, average capillary blood velocity (aCBV) and blood aggregation.

Results: In the second diabetic group with C-peptide hypersecretion high value of BMI (Body Mass Index) was revealed, compared to the 1st group that confirmed the relationship of obesity and insulin resistance hypersecretion of c-peptide on the back of metabolic syndrome. Most important difference in microcirculation parameters was a significant expansion of the diameters of all parts of capillaries, especially of arterial one ($p<0,05$) that confirmed the anabolic effect of c-peptide on microcirculation system on the background of the decrease of the aCBV, which was significantly lower ($p<0,03$) in diabetic patients, than in the controls. Coiled capillaries quantity in both groups was significantly lower in comparison with the controls ($p<0,05$). There was no significant difference in the density of vascular network between the diabetic group and the controls.

Conclusion: C-peptide hyper secretion resulted in microcirculation abnormalities more than diabetes with c-peptide normal secretion, especially regarding expansion of diameters of all parts of capillaries. We suppose it is possible to assess abnormal c-peptide secretion with the help of the non-invasive vital capillaroscopy. Microcirculation parameters are already changed in the first weeks of administration of drugs that affect hyperinsulinism.

The prevalence of type 2 Diabetes mellitus (T2DM) has increased over the last decade and is expected to continue to increase in Sri Lanka. Most Sri Lankan diabetics are in the working age and debility amongst them adds to the economic burden of the country. Diabetics are advised on appropriate medical therapy, dietary and life style modifications free of charge in health care institutions, but most patients' compliance to the advice is poor. This study attempts to determine these effects using quantitative data from patients. The objective of the study was to determine the glycemic control and behavioral factors influencing glycemic control among adults with T2DM. A descriptive cross sectional study was done on consenting T2DM patients (n=50) attending diabetic clinics. Data were obtained by interviewer administered questionnaire and medical records. The data were analysed using SPSS version 16 statistical software. The mean age of the males and females were similar and the gender ratio was 1:1. The fasting blood glucose (FBS) was normal in only 14.3% subjects. The mean FBS was 172.9 ± 62.2 (SD) and 177.7 ±72.9 mg/dL (SD) respectively for females and males ($p > 0.05$). There was a significant negative correlation between the BMI and the diet control/exercise pattern among the subjects in this study (Pearsons correlation coefficient - 0.286, $p < 0.04$). There was a positive association between FBS and BMI ($p< 0.05$). Diet control behavior ($p > .05$), and duration of diabetes ($p > 0.05$) were not associated with the FBS in this study. HbA1C is not routinely assessed amongst Sri Lankan patients attending free health care facilities in Sri Lanka. 27% patients were engaged in some physical activity. The study reveals that dietary control and regular exercise are aspects poorly addressed by T2DM patients in Sri Lanka. Although glycaemic control is considered a priority most patients were not motivated to actively control their glycaemic levels by dietary control, and regular exercise and compliance to medication.

The effect of cAMP on cytosolic calcium oscillations in beta cells within mouse pancreatic slices

M. Skelin Klemen[1], J. Dolensek[1], A. Stozer[1,2], S. Seino[4] and M. Slak Rupnik[3,2]

[1]Institute of Physiology, University of Maribor, Faculty of Medicine, Maribor, Slovenia, [2]Centre for Open Innovations and Research, University of Maribor, Maribor, Slovenia, [3]Institute of Physiology/CIPKEBIP, University of Maribor, Maribor, Slovenia and [4]Division of Cellular and Molecular Medicine, Department of Physiology and Cell Biology, Kobe University Graduate School of Medicine, Kobe, Japan

Insulin is secreted from pancreatic beta cells in response to glucose stimulation via regulated exocytosis. The exocytosis of insulin granules is triggered upon increase in cytosolic calcium concentration and can be further amplified by cAMP [1]. How does cAMP amplify glucose-induced insulin secretion? General consensus is that cAMP augments insulin secretion by acting through PKA- and Epac2-dependent pathways, but precise mechanism is not fully understood [2, 3]. It was previously suggested that one of the many roles of cAMP is the enhancement of calcium signals either by voltage-dependent calcium entry or intracellular calcium mobilization [4]. To determine the role of cAMP in calcium dynamics we used forskolin which increases the cytosolic cAMP concentration through the activation of adenylate cyclase. Oregon Green 488 BAPTA-1 AM (OGB-1) calcium dye was used to record oscillatory changes in cytosolic calcium concentration in mouse pancreas tissue slices using confocal laser scanning fluorescence imaging. In the absence of forskolin the sub-stimulatory glucose concentration failed to increase cytosolic calcium concentration in beta cells while the stimulatory glucose concentration caused stable fast calcium oscillations (3-6/min) on a sustained plateau phase. Addition of 10 μM forskolin in the extracellular solution triggered high frequency calcium oscillations (3-6/min) even at otherwise sub-stimulatory glucose concentration. The effect on calcium oscillations was belated, triggered several minutes after the addition of forskolin. When the same concentration of forskolin was added to the extracellular solution together with the stimulatory glucose concentration, the frequency of calcium oscillations almost doubled (6-12/min) compared to glucose stimulus only. Again, the effect of forskolin was observed after several minutes. To determine which of the two cAMP dependent pathways was responsible for augmented calcium oscillations in pancreatic beta cells, we performed the same sets of experiments on the pancreatic slices from mice lacking the Epac2 protein. Most probably Epac2 is not crucial for cAMP-augmented cytosolic calcium oscillations in mouse pancreatic beta cells since forskolin triggered calcium oscillations at sub-stimulatory glucose concentration also in the Epac2 KO mice. Furthermore, at stimulatory glucose concentration the frequency of calcium oscillations was increased after addition of forskolin. These results corroborate previously published data describing that phosphorylation of several targets by PKA is responsible for cAMP augmented calcium oscillations in pancreatic beta cells [5].

Vitamin D levels in type 2 diabetic individuals

M.A. Kanpurwala[1] and K. Afzal[2]

[1]Physiology, University of Karachi, Karachi, Sindh, Pakistan and [2]Dow University of Health Sciences, Karachi, Pakistan

Type 2 diabetes Mellitus (T2DM) is a chronic disease which has an increased risk for hip and vertebral fracture. Diabetic bone is showed to be more fragile than non-diabetic bone [1] and is another possible cause of disability in these patients after a trauma or fall [2]. Diabetes may affect the bone in multiple ways including change in bone mass density especially when there is deficiency of vitamin D which worsens the condition. It has been seen that vitamin D and calcium are required for good skeletal health. Adequate vitamin D levels prevent autoimmune diseases, hypertension, and diabetes and there is reduced risk of cancer and falls or fractures [3]. Many studies have shown some association between impaired glucose mediated insulin release and decrease levels of serum vitamin D [4]. Thus, the present study is conducted to assess the serum Vitamin D levels in T2DM patients. Despite good exposure to sunlight in this part of the world, the vitamin D deficiency has become more prevalent and the basis of risk of diabetes and its related falls and fractures.

We conducted a cross sectional study in which 210 T2DM patients who visited the diabetic Out Patient Department of National Institute of Diabetes and Endocrinology were enrolled in the study after an informed consent. Patients with Tuberculosis, Patients with known renal or liver or thyroid diseases were excluded from the study. Demographic profile and anthropometric measurements of these patients were noted and blood sample was collected from each subject to assess glycosylated haemoglobin (HbA1c) levels, serum calcium and Vitamin D levels.

It was observed that majority of patients (n=113; 53.8%) had diabetes for 5-10 years, followed by 25.7% in those with less than 5 years, 16.2% in those with 11-15 years whereas only 4.3% had diabetes for more than 15 years. Though the mean vitamin D of the sample was 10.04 +6.65ng/dl, the levels greatly varied across the sample, minimum being 3.99 and the maximum being 48ng/dl. Mean serum calcium was 8.98 +0.64 mg/dl. The mean HbA1c of sample was 8.47 +3.79gm%. Only 0.5% of the total sample have sufficient Vitamin D levels, while 37.1% of sample have insufficient levels of Vitamin D. Majority of the subjects i.e. 62.4% have vitamin D deficiency.

This study confirms the association between serum vitamin D levels and diabetes mellitus. This uncovers the fact that diabetics individuals in our population are suffering from significant vitamin D deficiency. It is suggested that future studies should be carried out to address the efficacy of vitamin D supplementation in preventing frequency of falls and fractures in diabetic patients.

CATEGORIZATION OF VITAMIN D LEVELS (n=210)

Levels	Frequency (n=210)	Percentages (%)
Deficiency	131	62.4
Insufficiency	78	37.1
Sufficiency	01	0.5

Regulation of insulin and glucagon secretion in a mouse model of neonatal diabetes

M.F. Brereton[1], M. Iberl[1], A. Clark[2], P. Rorsman[2] and F.M. Ashcroft[1]

[1]Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, UK and [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, UK

Neonatal diabetes, diagnosed as severe hyperglycaemia within the first 6 months of life, is often caused by gain-of-function mutations in the K_{ATP} channel subunit, Kir6.2. Using a conditional transgenic mouse model selectively expressing the Kir6.2-V59M mutation exclusively in pancreatic β-cells (iβ-V59M), we investigated the effect of hyperglycaemia on pancreatic function.

Gene expression was induced at 12 weeks of age and resulted in severe hyperglycaemia within 2 days (control: 6.0±0.1mM vs. iβ-V59M: 23.7±1.0mM). After 4 weeks, blood glucose was 26.2±0.5mM and postprandial serum insulin had decreased (control: 0.6±0.3pM vs. iβ-V59M: 0.1±0.03pM) but no changes in serum glucagon levels were detected (73.5±2.4pM vs. 80.8±21.5pM). Glucose tolerance was impaired and glucagon sensitivity increased in iβ-V59M mice as assessed using an intraperitoneal glucose and glucagon tolerance test, respectively. Four-week exposure to hyperglycaemia resulted in a ~3-fold reduction in total pancreatic islet area from 17.5±2.6μm2x10-5 (controls) to 5.3±0.8μm2x10-5 (iβ-V59M). The remaining islets were predominantly composed of glucagon-positive cells; the percentage of islet area composed of glucagon-positive cells increased from 16.6±0.9% (controls) to 73.5±2.1% (iβ-V59M). This was accompanied by a marked reduction in insulin-positive cells (control 86.5±0.3% vs. iβ-V59M 27.8±1.7%).

iβ-V59M mice were implanted subcutaneously with a high-dose, slow-release pellet (17mg/kg/day) of the sulphonylurea glibenclamide, which closes K_{ATP} channels. Within 2 days of implantation, blood glucose had returned to control levels

(6.1±0.1mM) and remained stable for 4 weeks. Glibenclamide therapy improved glucose tolerance, but did not restore it to that of control mice. However, it prevented the reduction in islet area and changes in insulin/glucagon-positive cell number.
Gain-of function mutations in β-cell Kir6.2 subunits result in hyperglycaemia, hypoinsulinemia and alterations in glucose tolerance, glucagon sensitivity and islet cell morphology. These effects can be prevented, in part, by glibenclamide therapy. Therefore, iβ-V59M provides a good model to study the effects of hyperglycaemia on pancreatic function.

Alterations in metabolic relations and adiposity during and after cigarette smoke exposition, in young female and male mice

R.P. Gaspar-Reis, C.C. Silva, T.S. Magdalena, E.G. Aguiar, K.P. Albuquerque, S.S. Alves, A.S. Santos, Y.A. VIllaça, E.P. Garcia-Souza and C.A. Nascimento-Saba

Physiological Sciences, University of Rio de Janeiro State, Rio de Janeiro, Rio de Janeiro, Brazil

Cigarette smoking is worrisome in adults and also in adolescents. Actually, smoking rates have grown and little is known about the damages caused in these organisms still young and the consequences in adulthood (1, 2). This study aims evaluate the influence of smoking in puberty and the consequences of withdrawal in body composition of female and male mice. At 35 days, Swiss mice reproduced and maintained at the animal house of Phisiological Sciences department were exposed to 3R4F cigarette smoke (Tobacco and Health Research Institute), 8 h/day for 15 days (S, n = 24).Then, half of animals were evaluated and the other half was maintained and evaluated thirty days after stop exposure (30d AS). An unexposed group accompanied the events (NS, n = 24). Body mass, food intake, body composition (by Dual-energy X-ray Absorptiometry, DEXA), serum levels of insulin, lipids and glucose (ipGTT), subcutaneous and intra-abdominal adipose tissue mass were evaluated. During all experimental period food intake was similar in all groups (5.06±0.35g), however, S groups showed lower body mass gain. 30dAS, female S group presented similar body mass (36.39±0.56g) while male S group presented lower body mass (NS: 46.64±1.05g; S: 45.06±1.05g). In females was observed a significant increase in total body (NS: 11.86±0.07g; S: 15.17±0.87g) and trunk fat (NS: 9.17±1.16g; S:13.00±0.68g) during exposure and in lean mass 30dAS (NS: 13.60±1.89g; S:17.25±1.49g), while no alterations were developed in male's body composition. In males none region of fat differs during exposure: retroperitoneal (NS:0.411±0.030; S:0.475±0.079), mesenteric (NS:0.344±0.036; S:0.349±0.051) and subcutaneous (NS: 0.243±0.066; S:0.290±0.062). While in females the retroperitoneal was increased (NS: 0.360±0.039; S:0.575±0.079), the mesenteric decreased (NS:1.077±0.08; S:0.917±0.242) and subcutaneous did not alters (NS: 0.217±0.021; S:0.287±0.026). In regard to serum analyses during exposure, females had higher insulinemia and glycemia at 30min but no alterations were observed in males. On the other hand, withdrawal induced in male high insulinemia and low glycemia but in female, normal insulinemia and low glycemia. The set of results indicates different response to cigarette smoke in young that seem to start in females and lead malefic metabolic alterations in adulthood.

Altered agonist sensitivity of the N321K mutation of type-2 vasopressin receptor in a patient with nephrogenic diabetes insipidus

L.S. Erdélyi[1], A. Balla[1], M. Tóth[2] and L. Hunyady[1]

[1]Department of Physiology, Semmelweis University, Budapest, Hungary and [2]2nd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Loss of function mutations of the type-2 vasopressin receptor (V2R) in kidney lead to nephrogenic diabetes insipidus (NDI). The function of misfolded mutant receptors can be rescued using pharmacochaperons, which promote plasma membrane localization of V2Rs. We identified with genetic analysis a previously described, but not characterized, mutation in a NDI patient. In order to determine personalized therapy for the individual, properties of the mutant receptor were characterized. Based on the findings we could propose a therapeutical strategy.
The N321K mutation was identified with sequencing of the PCR product of genomic DNA isolated from peripheral blood. We constructed a highly sensitive Epac based BRET (bioluminescence resonance energy transfer) biosensor to perform real-time cAMP measurments. The β-arrestin binding of the receptors was examined with luciferase-tagged β-arrestin and mVenus-tagged V2Rs using BRET technique. The BRET measurements were performed on transiently transfected HEK293 cells using 96-well plates and Berthold Mithras LB 940 multilabel reader. Cell surface expression was determined with flow cytometry using anti-HA-Alexa488 antibodies. Localization examinations were implemented with fluorescent tagged receptors visualized with Zeiss LSM510 confocal laser-scanning microscope. The effect of agonists on V1R was tested on mouse arteries by wire myography.
Previous studies have identified the pathogenic N321K mutation is in the 7th transmembrane helix of the V2R. Flow cytometry and confocal microscopy revealed that cell surface expression of the mutant receptor is similar to that of the wild type receptor. Determination of the ligand induced cAMP generation of the mutant receptor showed increased EC50 in arginine-vasopressin (AVP) stimulation and lack of signal in desmopressin (DDAVP) stimulation. BRET experiments revealed

decreased β-arrestin binding of N321K-V2R. The mutant receptor also showed different sensitivity for V2R agonists. Valine-desmopressin (DVDAVP) relatively efficiently stimulated N321K-V2R, whereas even high doses of DVDAVP did not have effect on mouse arterioles, which are sensitive to AVP-induced vasoconstriction.
N321K mutant V2R showed cell surface expression, the physiologically essential cAMP generation of the receptor can be activated with elevated dose of AVP, while with clinically used DDAVP was not efficient. Different internalization of the receptor may occur through altered β-arrestin binding. Function of the mutant receptor can be rescued with administration of V2R receptor agonist DVDAVP, which had no detectable side effects on V1R in the effective concentration. Our in vivo experiments suggest that DVDAVP can rescuse the function of the N321K-V2R in a NDI patient with no significant side effect on V1R.
Supported by TÁMOP (4.2.1.B-09/1/KMR-2010-0001), OTKA 100883.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC320

High-fat diet intake suggests changes in reproductive function of young male rats

C.C. Silva, R.P. Gaspar-Reis, E.O. Guedes de Aguiar, A.S. Santos, S.S. Alves, K.P. Albuquerque and C.A. Nascimento-Saba

Physiological Sciences, State University of Rio de Janeiro, Rio de Janeiro, Brazil

Obesity seems affect reproductive function, lowering sex hormones and reducing sperm concentration. Excess of lipids on diet influences metabolism and testis reproductive function. Among physiological determinants of weight and appetite are Leptin and insulin, hormones secreted in proportion to fat mass and glucose levels regulating peripherally the metabolism, moreover in hypothalamus interact with receptors, favoring satiety (1). Obese people may have higher serum concentrations of this hormones and exhibit resistance to its action. The relationship between obesity, reproductive changes and metabolic syndrome is not yet fully clarified (2). Thus, the aim of the study was evaluate the effect of high fat diet, containing soybean oil, on body composition and reproductive system of young male rats.
Wistar rats, at 21days (after weaning) were fed with diet containing 7% (control diet, C) or 19% (high fat diet, HF) of soybean oil, manufactured according to AIN-93 G, until 30 and 60 days of age. At the end of each experimental period, body composition was evaluated by Dual-energy X-ray Absorptiometry (DEXA) and liver, adipose tissue, testis, epididymis and blood were collected. Serum analysis of glucose, lipids, insulin, leptin and testosterone were measured. During all experimental period food intake and body mass were monitored but no difference was observed between groups.
After feeding animals with a high-fat diet for nine days showed a higher testosterone concentration (C:1.36±1.1; HF:24.9±6.4ng/dl), while surprisingly lean mass (C:60.0±3,03; HF: 42,6 ±3,47g) and triglycerides (C:60.0±9.6; HF:32.7±6.9mg/dl) decreased, in spite of the protein content control and the high percentage of soybean oil in the diet. At 60 days, testosterone (C: 0.95±0.26; HF:30.4±3.5ng/dl), epididimal mass (C:0.3±0.01; HF:0.41±0.026g), mesenteric adipose tissue mass (C:2.15±0.18; HF:3.09±0.32g), liver mass (C:8.25±0,2; HF: 10.5±0,55g) and glucose (C:167.5±10.8; HF: 269.8±20.0mg/dl) increased in HF group. The other evaluated parameters, total fat mass (C:24.8±2,0/HF:28.0±2.17g;C:64,0±1,54/HF:59,67±6,108g); leptin (C: 0.98±0.17/ HF:1.34±0,17;C: 1,50±0,08/HF:2,04±0,35 ng/ml) and insulin (C: 21.9±29/HF: 21.4±3.9; C:25.8±4.6/HF:27.8±4.6 ng/ml) did not differ between the groups at 30 and 60 days, respectively.
Since nine days of high-fat diet intake, the excess of lipids reflects negatively on testis function with high levels of testosterone. Moreover, after thirty nine days of high-fat diet intake the effects on adiposity, glycemia and reproductive function are more evidents. It could predict some adult reproductive dysfunction, once the changes started early and were increasing in these young animals.

A role for large conductance calcium-voltage activated potassium channels in inflammatory mediator release in murine 3T3-L1 adipocytes

T. Scullion and S. Dolan

School of Life Sciences, Glasgow Caledonian University, Glasgow, UK

Large conductance calcium-voltage activated potassium (BKca) channels are important modulators in an extensive number of cellular functions, including hormone release from endocrine cells. White adipose tissue is increasingly regarded as the largest endocrine organ in the body, and adipocytes as key regulators of inflammation through the synthesis and secretion of a battery of pro- or anti-inflammatory cytokines. This study set out to characterise the expression of BKca channel and a "gain of function" splice variant STREX in adipocytes, and investigate BKca channels as potential modulators of cytokine release from these cells.
Mouse fibroblast 3T3-L1 pre-adipocyte cells were cultured in DMEM with 10% foetal bovine serum (FBS), and differentiated into mature adipocytes by replacing cell growth media with 10% FBS DMEM supplemented with 0.5 mM 3-isobutyl-1-methylated, 0.25 μm dexamethasone and 1 μg/ml insulin and incubated for 48 hours. Thereafter, cells were treated with media with 10% FBS, 1 μg/ml insulin complemented DMEM for up to 10 days. Total RNA was extracted on day 0, 4, 8, 10 and 10+ (n = 5 per group), reverse transcribed and levels of BKca and STREX mRNA, and the pro-inflammatory cytokines tumour necrosis factor (TNF)-α, interleukin (IL)-6 and IL-1β mRNA, and the anti-inflammatory cytokine IL-10 mRNA measured using real-time PCR. The effects of treating mature adipocytes (day 10+) for 24 hours with the BKca channel agonist NS 1619 (20 μg), or channel blocker iberiotoxin (IBX; 10

ng), or drug-vehicle on gene expression were also analysed. Values are means ± S.E.M., compared by ANOVA.
BKca and STREX mRNA and all four cytokines examined were found to be constitutively expressed in both pre- and mature adipocytes. In mature day 10 adipocytes, a 2 fold up-regulation in BKca and 32 fold STREX mRNA expression was observed. TNF-α, IL-6 and IL-1β mRNA were induced in mature day 10 adipocytes (all $P < 0.01$ vs. day 0); IL-10 mRNA levels were unchanged. Following treatment with IBX, futher up-regulation in expression of TNF-α (4 fold), IL-6 (2.7 fold) and IL-1β (6 fold), but not IL-10 mRNA were detected ($P < 0.01$ vs. vehicle and NS 1619 treated cells).
These data show that BKca channel and splice variant STREX are expressed in adipocytes. Furthermore, adipocyte derived pro-inflammatory cytokines were induced by blockade of BKca channel activity. These findings suggest that BKca channels may play a role in regulating the inflammatory response associated with obesity

Plasma TNF-α in obese type II diabetic patients: Is it a cause or a result of hyperglycemia?

T.H. Merghani and A.O. Alawad

Physiology, Tabuk University, Tabuk, Saudi Arabia

Hyperglycemia is a known cause of inflammation (1,2) followed by increased production of acute phase proteins and pro-inflammatory cytokines, including TNF-α.(1-3) Monocytes taken from diabetic patients produce higher levels of TNF-α in comparison with control monocytes taken from healthy subjects.(4) On the other hand, TNF- α is a known cause of hyperglycemia secondary to insulin resistance. Hypoglycemia was reported as one of the complications of treatment with TNF-α inhibitors.(5) This study was conducted to evaluate plasma TNF-α in obese diabetic patients and to determine its relation to glycemic control. A random sample of 40 obese type II diabetic patients (cases) and 40 obese non-diabetic subjects (controls) were interviewed and examined clinically to exclude presence of acute or chronic medical illness. The two groups were matched according to age, sex, body mass index and area of residence. Hemoglobin A1c was measured for each participant using the "NycoCard Hemoglobin A1c test" (Axis -Shield/ Norway). Fasting blood sugar was measured using one touch® glucometer (LifeScan Canada Ltd). Plasma TNF-α was measured using commercially available ELISA kits from ADIPO Bioscience/ USA. The research conforms to the ethical principles of medical research developed by the World Medical Association Declaration of Helsinki. The chi square test was used to test distribution of categorical variables. The difference in mean between the test and the control groups was assessed with the independent student's t test. The majority of obese diabetic patients had high plasma TNF-α values (≥ 5pg/ml) with "mean ± SEM" = "11.09 ± 3.03" whereas the majority of obese non-diabetic subjects had lower values with "mean ± SEM" = "4.68 ± 2.31"; P= 0.003. More than half (58%) of those with high TNF-α values had abnormal hemoglobin A1c (≥ 6.5%, P= 0.037). The relation between plasma TNF-α and fasting blood sugar in all participants was statistically insignificant (P= 0.515). These data suggest that the higher plasma TNF-α in obese diabetic patients compared to the non-diabetics cannot be explained by obesity alone since both groups were obese. A significant relation was found between high plasma TNF-α and poorly controlled diabetes mellitus, indicating that hyperglycemia might be responsible for the rise in TNF-α. The relation between plasma TNF-α and fasting blood sugar was statistically insignificant. This indicates that TNF-α production is most probably associated with a long term, rather than a short term effect of hyperglycemia.

Plasma TNF-α among obese diabetic and obese non-diabetic subjects in the study group

Group	< 5 pg/ml n (%)	≥ 5 pg/ml n (%)	Total
Obese Diabetic	18 (45%)	22 (55%)	40 (100%)
Obese Non-diabetic	31 (77%)	9 (33%)	40 (100%)
Total	49 (61%)	31 (39%)	80 (100%)

P= 0.003

Plasma TNF-α in relation to hemoglobin A1c among all participants

Hemoglobin A1c	< 5pg/ml n (%)	≥ 5pg/ml n (%)	Total
< 6.5%	33 (67%)	13 (42%)	46 (57%)
≥ 6.5%	16 (33%)	18 (58%)	34 (43%)
Total	49 (100%)	31 (100%)	80 (100%)

P=0.037

Measured versus predicted resting metabolic rate in obese diabetic and obese non-diabetic subjects

T.H. Merghani[1,2] and A.O. Alawad[1,3]

[1]Physiology, Tabuk University, Tabuk, Saudi Arabia, [2]Physiology, Khartoum University, Khartoum, Sudan and [3]Physiology, Al-Neelain University, Khartoum, Sudan

In clinical practice, predictive equations provide valuable information about energy expenditure that is used in estimation of metabolic needs for different individuals; however, accuracy of these equations is questioned in the tropical countries. The aim of this study was to determine which predictive equation is similar to indirect calorimetry in estimation of resting metabolic rate in obese diabetic and obese non-diabetic subjects. A random sample of 40 obese diabetic patients (cases) and 40 obese non-diabetic subjects (controls), 35 to 50 years of age, were selected from patients attending Gabir Abu-Eliz centre in Khartoum- Sudan. The PowerLab 8/35 with a gas analyzer (AD Instruments, Castle Hill Australia) was used for measurement of VO2, VCO2 and RER for each participant. Resting metabolic rate was derived from these parameters using Weir's formula.(1,2) Three predictive equations (Harris-Benedict (3), Mifflin (4) and Food and Agriculture Organization/ World Health Organization/ United Nations University (FAO/WHO/UNU) equations (5) were assessed for their accuracy in predicting resting metabolic rate for the two groups. Using Weir's derivation, resting metabolic rate ("mean±SD" kcal/day) was significantly higher among diabetic patients "1480.7 ± 274.2" compared to non-diabetics "1362.4 ± 184.8"; P= 0.027. The three predictive equations showed insignificant difference between the two groups; P>0.05. Resting metabolic rate measured with indirect calorimetry was significantly different from that measured with Harris-Benedict or FAO/WHO/UNU equations, P<0.05; whereas difference from Mifflin equation was statistically insignificant, P= 0.164. Resting metabolic rate, whether calculated or predicted, was significantly higher among males compared to females; P< 0.05. It was concluded that Mifflin equation is more reliable than Harris-Benedict and FAO/WHO/UNU equations in estimating resting metabolic rate in obese diabetic patients. Predictive equations are unlikely to detect difference in resting metabolic rate between obese diabetic and obese non-diabetic subjects.

Comparison in resting energy expenditure between obese diabetic and obese non-diabetic participants

Measurement method	Study group	Resting metabolic rate (mean ± SD) kcal/day	Confidence intervals kcal/day	P value
Indirect calorimetry	Diabetics (n=40)	1480.7 ± 274.2	1393.0-1568.4	0.027
	Non-diabetics (n=40)	1362.4 ± 184.8	1303.3-1421.5	
Harris-Benedict's equation	Diabetics (n=40)	1646.6 ±176.4	1590.1-1703.0	0.308
	Non-diabetics (n=40)	1689.3±195.7	1627.0-1751.9	
Mifflin's equation	Diabetics (n=40)	1547.6 ± 170.3	1493.2-1602.1	0.198
	Non-diabetics (n=40)	1598.1 ± 177.0	1541.5-1654.6	
FAO/WHO/UNU equation	Diabetics (n=40)	1691.6 ± 194.6	1629.3-1753.8	0.528

Bronchodilator reversibility among patients with non-obstructive spirometric patterns

T.H. Merghani[1,2] and M.E. Alamin[3]

[1]Physiology, Tabuk University, Tabuk, Saudi Arabia, [2]Physiology, Khartoum University, Khartoum, Sudan and [3]Medicine, National Ribat University, Khartoum, Sudan

Reversibility testing is typically positive in asthmatic patients showing obstructive pattern on spirometry; however, few studies evaluated this test among overweight and obese patients presenting with non-obstructive patterns. A sample of 218 overweight and obese adult asthmatic patients who satisfactorily completed spirometry and bronchodilator reversibility testing were selected for analysis. A portable spirometer (All flow, Clement Clarke International, UK) was used for measurement of lung ventilator function for each patient before and after inhalation of four separate doses of 100μg salbutamol given by a metered dose inhaler and using a spacer. Female to male ratio was 1.9:1. BMI (mean (SD)) was 31.6 (4.7). About one third of patients showed positive reversibility testing. Among these, more than one third (38%) had restrictive pattern, one third (33%) had combined pattern, 22% had obstructive pattern and only 7% had normal pattern (P= 0.000). Statistical differences between males and females in both spirometric patterns and reversibility testing were insignificant (P= 0.822 & 0.082 respectively). Reversibility testing was found to be positive in a significant proportion of overweight and obese asthmatic patients presenting with non-obstructive patterns on spirometry. The diagnosis of asthma can be confirmed with positive reversibility testing irrespective of spirometric pattern.

		Normal n (%)	Obstructive n (%)	Restrictive n (%)	Combined n (%)	Total	P value
Gender	Male	13 (18%)	11 (15%)	37 (50%)	13(18%)	074 (100%)	0.822
	Female	27 (19%)	27 (19%)	63 (44%)	27 (19%)	144 (100%)	
	Total	40 (18%)	38 (17%)	100 (46%)	40 (18%)	218 (100%)	
Reversibility	Positive	5 (7%)	17 (22%)	29 (38%)	25 (33%)	076 (100%)	0.000
	Negative	35 (25%)	21 (15%)	71 (50%)	15 (10%)	142 (100%)	
	Total	40 (18%)	38 (17%)	100 (46%)	40 (18%)	218 (100%)	

Parameter		Reversibility Testing			P value
		Positive n (%)	Negative n (%)	Total n (%)	
Gender	Male	20 (27%)	54 (73%)	074 (100%)	0.082
	Female	56 (39%)	88 (61%)	144 (100%)	
Age (years)	< 40	28 (30%)	64 (70%)	92 (100%)	0.362
	40-59	28 (35%)	51 (65%)	79 (100%)	
	≥ 60	20 (43%)	27 (57%)	47 (100%)	
Height (cm)	< 160	62 (38%)	101 (62%)	163 (100%)	0.090
	≥ 160	14 (25%)	41 (75%)	55 (100%)	
BMI	25-29.9	29 (30%)	67 (70%)	96 (100%)	0.201
	≥ 30	47 (39%)	75 (61%)	122 (100%)	

Restrictive pattern is the most dominant spirometric pattern among overweight and obese asthmatic patients. Positive reversibility testing is found in a significant proportion of patients with restrictive pattern.

Reversibility testing is not related to gender, age, height or BMI of patients in the study group (P > 0.05)

We would like to express our appreciation and special thanks to the participants for their understanding and cooperation.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Investigation of hypoglycaemic effect of the methanolic leaf extract of *A.lindleyana* on rats

B. Samanmali[1], M. Gunatilake[2], R.D. Guneratne[1] and T. Perera[3]

[1]Chemistry, University of Colombo, Colombo 3, Western, Sri Lanka, [2]Physiology, University of Colombo, Colombo 8, Western, Sri Lanka and [3]University of Colombo, Colombo 8, Western, Sri Lanka

Diabetes mellitus is considered as a major public health problem and one of the leading causes of deaths in the world today. There are many herbal preparations used in ayurvedic and other traditional systems of medicine which are claimed to have hypoglycaemic potential with fewer side effects. This study investigated the hypoglycaemic effect of tender leaves of the medicinal plant named *Aporusa lindleyana*.[1] The hypoglycaemic effect of the methanolic leaf extract of *A. lindleyana* on fasting blood glucose level, random blood glucose level and the effect on oral glucose load were tested using three oral doses of the extract (100, 400, 800 mg/kg body weight) in normoglycaemic adult male Sprague-Dawley rats weighing 200-250 g (n=6 for each dose, control and reference drug). In determining the effect of fasting and random blood glucose level, glucose concentration was measured prior to the treatment and hourly for four hours.[2] For the evaluation of glucose tolerance, blood was collected prior to the treatment and hourly for four hours after the administration of glucose load.[2] Blood (0.25 ml) was collected from the tail vein of the rats under light ether anesthesia (about 1ml by inhalation route) using aseptic precautions, serum was separated and the glucose concentration was determined spectrophotometrically using Randox glucose oxidase assay kit. Ethics approval was obtained from the Ethics Review Committee of Faculty of Medicine, University of Colombo for animal experimentation. Results were statistically analyzed by ANOVA followed by Dunnett's multiple comparison test and expressed as mean ± S.E.M. using Minitab 15 software. The results exhibit a dose dependent hypoglycaemic effect with lowest blood glucose level observed at 4 h after the treatment. All the three doses significantly reduce the fasting blood glucose level of rats at 4h after the treatment (Control vs. 100 mg/kg: 94.6±0.807 vs. 81.2±2.95 mg/dl, p<0.05; Control vs. 400 mg/kg: 94.6±0.807 vs. 77.8±2.80 mg/dl, p<0.05; Control vs. 800 mg/kg: 94.6±0.807 vs. 69.4±1.53 mg/dl, p< 0.05). Only intermediate and high doses show significant reduction in serum glucose level in normoglycaemic non fasted rats (Control vs. 400mg/kg: 129±3.00 vs. 114±2.63 mg/dl at 4h, p<0.05; Control vs. 800mg/kg: 129±3.00 vs. 113±3.03 mg/dl at 4h, p<0.05) and significant glucose tolerance when tested on oral glucose load (Control vs. 400mg/kg: 98.9±2.79 vs. 87.7±1.76 mg/dl at 4h, p<0.05; Control vs. 800 mg/kg: 98.9±2.79 vs. 85.2±1.18 mg/dl at 4h, p<0.05). According to the above results, it can be concluded that *A.lindleyana* leaves have hypoglycaemic activity since it significantly (p<0.05) reduces the blood glucose level in normoglycaemic rats and significantly (p<0.05) enhances the glucose tolerance.

PCC327

CFTR is an essential component in cAMP-dependent granular priming in human and mouse β-cells insulin secretion

A. Edlund[1], J.L. Esguerra[1], M. Flodstrom-Tulberg[2] and L. Eliasson[1]

[1]Clinical sciences in malmö, Lund University Diabetes Centre, Malmö, Sweden and [2]CIM, Karolinska Institute, Stockholm, Sweden

Aim: Cystic fibrosis transmembrane conductance regulator (CFTR) is an anion channel and regulator of proteins[1]. Mutations in CFTR cause cystic fibrosis (CF) and a major complication of CF is diabetes[2]. It is largely unknown why these patients develop diabetes but there is increasing evidence that CFTR is involved in islet hormone release[3]. The aim of this project is to investigate presence of CFTR in mouse and human pancreatic islets and role of CFTR in mechanisms controlling β-cell insulin release. **Method**: Experiments where performed on islets and single β-cells from human donors and NMRI-mice. Detection of CFTR was investigated using PCR and confocal microscopy. Insulin secretion was measured with RIA. Patch-clamp measurements of currents and exocytosis were performed. Statistical significance was calculated using t-test. **Results**: Human- and mouse islets express CFTR mRNA and CFTR protein was detected in β-cells. The whole-cell configuration of the patch-clamp technique was used and a ramp from -100 mV to +100 mV was applied to single human and mouse β-cells to measure cAMP-activated currents. Forskolin (10 μM) evoked an increase in current that was inhibited by CFTR antagonists, CFTRinh-172 (10 μM) or GlyH-101 (25 μM, GlyH; P<0.001, n_{human}=21, n_{mouse}=17). A major part of the cAMP-activated current was also reduced by the chloride channel blocker DIDS (200 μM), where the remaining part was inhibited by GlyH-101 (P<0.05, n_{human}=6, $_{mouse}$=10). The calculated CFTR conductance was small and we propose that CFTR act as a regulator of the DIDS-sensitive chloride channel Outward Rectifier Chloride Channel (ORCC) as suggested in other cell-types[4]. This was further confirmed by insulin secretion measurements. Glucose- and cAMP-stimulated insulin secretion was reduced by 43±5% (p<0.001, n=11 donors) and 40±12% (p<0.05, n=5) in the presence of GlyH (50 μM) in human and mouse islets, respectively. When DIDS was added, GlyH had no further inhibitory effect on insulin secretion in mouse islets, confirming that CFTR controls ORCC. However, in human islets,

addition of GlyH caused a further reduction ($p<0.05$, n=5 donors), suggesting that CFTR interact with additional proteins. Moreover, cAMP-amplified exocytosis elicited by a train of ten depolarizations from -70 mV to 0 mV and measured as an increase in membrane capacitance in single human and mouse β-cells was significantly reduced by >40% after pre-incubation with CFTR antagonists ($P<0.05$, $n_{human}=5$; $n_{mouse}=7$). The reduction was most prominent during the first two pulses representative of release of primed granules and first phase insulin secretion[5]. **Conclusion**: Based on our results we postulate that CFTR is an essential component in cAMP-dependent insulin secretion and exocytosis in human and mouse β-cells and hypothesize CFTR to be vital for granular priming and first phase insulin secretion.

C-C chemokine receptor type 5 knockout mice protects against obesity induced inflammation and insulin resistance by high-fat diet in gender difference

D. Li and L. Hung

Biomedical Sciences, Chang Gung University, Tao-Yuan, Taiwan

Obesity is a high risk factor in the development of insulin resistance and type 2 diabetes. Obesity increases macrophage infiltration into adipocyte and overproduction proinflammatory cytokines that leads to development of insulin resistance. T cell also plays an important role link between obesity and insulin resistance. CC-chemokine ligand 5 (RANTES) is a chemokine secret by T cells, eosinophils, and basophils, and plays an active role in recruiting leukocytes thus trigger sever inflammation. The CC-chemokine receptor 5 (CCR5) interactions with RANTES and mediates activation of T lymphocytes and macrophages by chemokines. It has been demonstrated high-fat diet-induced obesity, adipose inflammation, and insulin resistant could be attenuated in CCR5 knockout mice. Since the level of inflammation is also influenced by the difference of gender. Thus, the present study was aimed to investigate whether CCR5 knockout mice protect against high-fat diet (HFD)-induced obesity and insulin resistance has gender difference. C57Bl/6 male and female mice were fed with HFD for 24 weeks to induction of obesity and insulin resistance. The HFD mice developed insulin resistant syndrome characterized by elevated body weight, hyperglycemia, hyperinsulinemia, and hyperlipidemia. In addition, HFD mice exhibited impairment of oral glucose tolerance test (OGTT), increasing of glucose-stimulated insulin secretion, and decreasing of insulin sensitivity during insulin tolerance test (ITT). CCR5-/- attenuated diet induced obesity and glucose stimulate insulin secretion especially in female mice. The insulin sensitivity is improved only on CCR5-/- female mice during insulin tolerance test. Deficiency of CCR5 also attenuated obesity-induced fatty liver. The weights of fat pads were significantly decreased in CCR5-/-male and dramatic reduced in female mice. In addition, our results show that the insulin receptor protein level was reduced in liver of HF mice. CCR5-/- female mice increased protein expression of insulin receptor and Akt threonine phosphorylation. These results indicate that CCR5 deficiency protect against high-fat diet-induced obesity and insulin resistance especially in female mice.

Role of Li-permeable Na/Ca exchangers, NCLX, in the Exocytosis of Pancreatic β Cells

Y. Han, S. Park, S. Lee, S. Ryu and W. Ho

Department of Physiology and Biomembrane Plasticity Research Center, Seoul National University College of Medicine, Seoul, Republic of Korea

The Na+/Ca2+ exchangers are key regulators for Ca2+ homeostasis in pancreatic β cells, but their exact role in insulin secretion is not fully understood. In the present study, we investigated the role of Na+/Ca2+ exchangers on cytosolic Ca2+ dynamics and exocytosis in INS-1 cells. We newly discovered that the Li-permeable Na+/Ca2+ exchangers (NCLX), which are known as mitochondrial Na+/Ca2+ exchangers, contribute to plasma membrane Na+-dependent Ca2+ transport, and confirmed the presence of NCLX in the plasma membrane using immunocytochemistry and cell surface biotinylation experiments. We further investigated the role of NCLX on exocytosis function by measuring depolarization-induced capacitance increase in siNCLX-transfected INS-1 cells. Downregulation of NCLX significantly suppressed the second phase capacitance increase without affecting the first phase, but inhibition of mitochondrial Na+/Ca2+ exchange alone by removing intracellular Na+ did not cause a significant effect. These results suggest that normal surface NCLX activity is required for vesicle recruitment in the second phase. In addition, we discovered that oligomycin inhibited the second phase capacitance increase in the presence of intracellular ATP, suggesting that local metabolic control by mitochondria is critical for this phase. Our data indicate that the activity of surface NCLX may regulate local Ca2+ to optimize mitochondrial local metabolic control and thus contributes to vesicle recruitment for the normal secretory function in pancreatic β cells.

Regulation of inflammatory cytokines by nitric oxide in the kidney

D.S. Majid, P. Singh, R. Stephenson and A. Castillo

Physiology, Tulane University Health Sciences Center, New Orleans, LA, USA

Previous studies performed in our laboratory using dogs, rats and mice have demonstrated that inhibition of nitric oxide (NO) increases superoxide activity in the kidney and this imbalance enhances tubular sodium reabsorption leading to salt retention and the development of salt sensitive hypertension. However, recent findings in our laboratory also show that systemic NO inhibition results in an increase in tumor necrosis factor-alpha (TNF-α; a pro-inflammatory cytokine) and a decrease in interleukin-10 (IL-10; an anti-inflammatory cytokine) levels in plasma and in renal tissue which are associated with marked infiltration of macrophages in the kidneys. As these cytokines are suggested to be involved in the pathophysiology of salt-sensitive hypertension, we examined the hypothesis that high salt (HS) intake in NO deficient condition enhances the production of pro-inflammatory cytokines in the kidney. Using appropriate ELISA kits, the levels of different cytokines (pro-inflammatory, TNF-α, and IL-6 and anti-inflammatory, IL-10) were measured in plasma and renal tissues collected from wild type (WT; C57BL6) and eNOS enzyme knockout (eNOS-KO) mice (~8 wks old) which were fed either normal (NS) or HS (4% NaCl) containing diet for 2 weeks. Mean systemic blood pressure (measured by tail-cuff plethysmography) was significantly increased in eNOS KO (111±4 to 136±8 mmHg) but not in WT (99±5 to107±4 mmHg) due to HS intake. The changes in cytokines levels are summarized in the Table 1. The plasma level of TNF-α remains undetected in both WT & eNOS KO mice during NS intake but showed a slight increased during HS intake. During NS intake, the plasma level of IL-6 was higher and that of IL-10 was lower in eNOS KO mice compared to WT mice. However, compared to the values during NS intake, all the renal levels of cytokines were lower in the kidney during HS intake both in WT as well as eNOS KO mice. These findings indicate that HS intake generally suppresses the levels of both anti- as well as pro-inflammatory cytokines, particularly in the kidney. These data suggest that NO inhibition induced by deficient activity of eNOS enzyme generally responsible for upregulation of inflammatory cytokines in the kidney.

Table 1

Cytokines		WT		eNOS-KO

Sex hormones differentially modulate angiotensin-converting enzyme 2 (ACE2) activity in kidney of spontaneously hypertensive rats

P.M. Dalpiaz[1], A.S. de Medeiros Garcia[2], A.Z. Lamas[1], I.F. Caliman[1], G.R. Abreu[1], T.U. Andrade[3], M.F. Alves[4], A.K. Carmona[4], S.G. Figueiredo[1] and N.S. Bissoli[1]

[1]Department of Physiological Sciences, Federal University of Espirito Santo, Vitoria, Espírito Santo, Brazil, [2]Biological and Health Sciences, Federal Institute of Education, Science and Technology, Vila Velha, Espírito Santo, Brazil, [3]Department of Pharmacy, University Vila Velha, São Paulo, Espírito Santo, Brazil and [4]Department of Biophysics, Federal University of São Paulo, São Paulo, São Paulo, Brazil

Male spontaneously hypertensive rats (SHR) had a higher systolic blood pressure than female SHR. Previous studies have shown that castration lowered the blood pressure of male rats and can increase in female SHR. Differences between males and females have been found in components of the renin-angiotensin system (RAS) and these differences can be associate to sexual dimorphism in hypertension development. However, the activity of angiotensin-converting enzyme (ACE) and ACE2 in male and female SHR remain unclear. Therefore, this study was designed to investigate whether: 1) there are sex differences in ACE and ACE2 in the kidney in spontaneous hypertension; 2) sex hormones play a role in these sex differences. The procedures were carried out in compliance with the guidelines for the ethical use of animals in scientific research and were approved by the Ethical Committee of the Federal University of Espírito Santo (023/2009). Female and male SHR rats were divided into 4 experimental groups: sham and castrated. After 51 days of the castration, the rats were anesthetized with ketamine (70 mg/kg i.p.) and xylazine (10 mg/kg i.p.) and their kidneys were immediately excised and the ACE and ACE2 activity were evaluated by fluorimetry. Female rats exhibited a higher ACE (25±1 AFU, $p<0.05$) and ACE2 (0.15±0.002 AFU, $p<0.05$) activity than the male rats (ACE 17±3 AFU and ACE2 0.02±0.002 AFU), but female rats have more favorable ACE2/ACE ratio (0.006±0.001, $p<0.05$) than male (0.001±0.0001) rats. Castration did not affect the ACE activity in both sex (female 23±3 and male 16±2 AFU) but decreased ACE2 in the female rats (0.03±0.002 AFU, $p<0.05$), while increased in the male rats (0.14±0.001 AFU, $p<0.05$). The castration change the ACE2/ACE ratio in both sex, male rats (0.009±0.001, $p<0.05$) replaced by more favorable ratio than female (0.0012±0.0002). In conclusion, this study identified sexual dimorphisms among the ACE and ACE2 activity in SHR; sex hormones differentially modulate ACE2 activity. The higher ratio of the renal RAS (ACE2/ACE) in females observed in the present study may contribute to sex differences in the regulation of arterial pressure in SHR and can affect on the severity and the progression of renal disease, that is more rapid in men compared with women.

Evaluation of serum Cystatin C as an indicator of glomerular filtration rate in pre-eclamptic, in comparison to normal pregnant and non-pregnant Sudanese women

H.M. Beheiry[1,2], D.A. Rayis[3] and A.M. Saeed[4]

[1]Physioigy, International University of Africa, Khartoum, Sudan, [2]Physiology, Ahfad University /School of Medicine, Khartoum, Sudan, [3]Head Department of Obstetrics and Gynaecology, University of Khartoum, Khartoum, Sudan and [4]Physiology, University of Khartoum, Khartoum, Sudan

The glomerular filtration rate (GFR) is the best global indicator of renal function in health and illness. It decreases early in renal disease before onset of renal failure (1). Serum cystatin C has been introduced as a superior and sensitive endogenous marker of GFR. However, there are conflicting reports regarding its use in pregnancy and pre-eclampsia. Sudanese women who develop pre-eclampsia and subsequently eclampsia is still high and a genuine concern. The main target organ is the kidney as glomerular endotheliosis (2). The aim of this study was to assess GFR changes and evaluate the use of serum cystatin C in pre-eclampsia. This is a cross-sectional, case-control and hospital-based study performed in the period from December 2008 to December 2010 in Omdurman Maternity Hospital. The study group was 81 pre-eclamptic compared to100 second half normal pregnant and 65 non-pregnant Sudanese women. A blood sample and a 24-hour urine were collected. Serum cystatin C was determined using latex particle-enhanced immunoturbidimetry with Dako cystatin C PET Kit (3), serum creatinine by Jaffe method and uric acid by Fossati enzymatic reaction at St. Helier Hospital London. Kruskal Wallis test was used for comparisons of means. The mean ± S.E of serum cystatin C for the pre-eclamptic, normal pregnant and non-pregnant were 1.31 mg/L ±0.04, 1.0 mg/L ±0.03 and 0.80 mg/L± 0.01 respectively (P=0.0001). GFR of the pre-eclamptic 66.71 ml/min/1.73 m2 ± 3/09 was significantly lower than that of normal pregnant 89.54 ml/min/1.73 m2 ±2.74 and that of the non-pregnant 86.85 ml/min/1.73 m2 ± 3.31 (P=0.0001). There was no significant correlation of mean GFR of pre-eclamptic cases neither with serum cystatin C (r= -0.16, P=0.25) nor with serum uric acid (r=-0.19, P =0.16), but negatively significant with serum creatinine (r= -0.37, P=0.004) using Spearman's correlation. The correlation of mean GFR of normal pregnant group was negatively significant with serum cystatin C (r= -0.26, P=0.02), serum creatinine (r= -0.31, P=0.003) and serum uric acid (r= -0.35, P=0.001). The correlation of mean GFR of the non-pregnant group did not correlate neither with serum cystatin C (r= -0.19, P=0.17) nor with serum creatinine (r= -0.05, P=0.73) or serum uric acid (r= -0.10, P=0.45). The diagnostic accuracy of serum cystatin C level showed it to be sensitive to detect pre-eclampsia at cut-off value equals 1.0 mg/L and specific for pre-eclampsia at cut-off value above 1.0 mg/L for cystatin C. The diagnostic accuracy of serum cystatin C tested using ROC-plot at different cut-off values of GFR found to be not a reliable test for GFR changes in pre-eclampsia. Serum cystatin C may be a useful indicator of pre-eclampsia but not a reliable marker of GFR changes in pre-eclampsia.

Figure 1: Correlations between Serum Cystatin C, Serum Creatinine, Serum Uric Acid levels and GFR in Non-pregnant ■, Pregnant ■ and Pre-eclamptic ■ Subjects

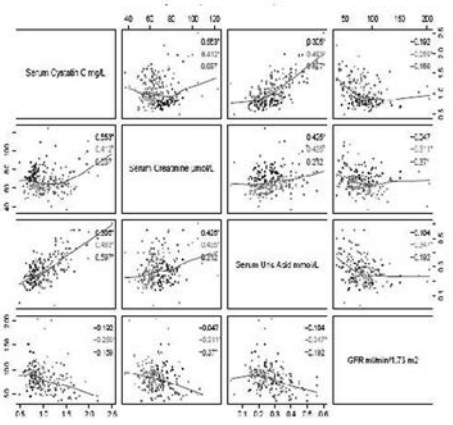

Figure 2: The Diagnostic Values of Serum Cystatin C at Different Cut off Levels for Detection of Pre-eclampsia and at ROC-60 Plot in comparison to serum creatinine and serum uric at cut off GFR (60ml/min/1.73m2) in pre-eclamptic subjects

Proteomic analysis of protein expression in lipid droplet of rat RMICs

W. Su, Q. Han, J. Yang and Y. Guan

Department of Physiology and Pathophysiology, Peking University Health Science Center, Peking, China

Basically, renomedullary interstitial cells (RMICs) are full of lipid droplets (LDs), which have been thought to be the source of vasodilators. Previous studies have indicated that the renomedullary interstitial cells of the renal papilla can secrete medullipin, which is a vasodilator that suppresses sympathetic tone, causes diuresis and natriuresis and apparently has a suppressive effect on the central nervous system. However, the chemical characteristic of medullipin is still unknown. Aim of this study was the identification of LD proteins based on purification of rat RMICs' lipid droplet followed by proteomic analysis using 2D-LC-MS/MS technics. To enhance the validity of the data, only proteins with at least two unique peptides were accepted. We found over 300 RMICs' LD associated proteins. Among these proteins, 92 proteins have been reported to be LD proteins in previous studies, 17% were associated with lipid metabolism and 15% were associated with mitochondria, suggesting close interactions of LDs with mitochondria, and that LDs were involved in metabolism of triglycerides, fatty acids, phospholipids, and sterol esters. We also found enzymes involved in arachidonic metabolism including CYP4F5, CYP4F6, CYP2E1 and CYP2A3, previous study report that LDs are specific sites of novo formation of LTC4 and PGE 2 in leukocytes, suggesting LDs in RMICs may also involved in regulating eicosanoid formation. The difference in the morphology and protein profile of LDs in renal medulla of SHR (spontaneously hypertensive rat) and Wistar-Kyoto(WKY) rats were further analyzed. Electron microscopy revealed more LDs in renal medulla of SHR than in that of WKY rats. Proteomic analysis revealed 15 differently expressed proteins in renal medulla of SHR when compared with WKY rats. Western blot further confirmed that the expression of clathrin and CYP4A3 were upregulated, whereas the expression of UBXD8 was downregulated in renal medulla LDs of SHR. In conclusion, these preliminary results have suggested that LDs in RMICs are rich in many enzymes involving lipid metabolism and blood pressure regulation. To further study the biological function of these proteins in LDs will shed light on the understanding of the mechanisms of high blood pressure.

Undernourished children have increased microalbuminuria

V.B. Martins[1], R. Sesso[2], A.P. Neves[1], A.G. Clemente[1] and A.L. Sawaya[1]

[1]Physiology, UNIFESP, Santo André, São Paulo, Brazil and [2]Medicine, UNIFESP, São Paulo, Brazil

Increased cardiovascular and renal disease has been described in humans with intrauterine or early life undernutrition. Microalbuminuria (MA) is a marker of renal and endothelial dysfunction, and a predictor of cardiovascular and renal disease. We hypothesized that undernourished children have increased MA, and after nutritional recovery, the MA concentrations would decrease to normal values. We evaluated the concentration of MA in three groups of children (mean age: 10.75 ± 2.45; range: 5.62 to 15.94): treated in a day-hospital and recovered from previous undernutrition (R group (n=32) height/age (HAZ) (mean±SD) -0.58 ± 0.68, BMI/age (BAZ) -0.46 ± 0.74); undernourished group (U group (n=48); HAZ -1.40 ± 1.10; BAZ -1.76 ± 1.06) and control group (C group (n=50); HAZ -0.37 ± 0.91; BAZ -0.27 ± 0.86). All families of participants signed the Free and Informed Consent form. The study was approved by Research Ethics Committee of the Federal University of São Paulo (number 1302/09).
Children underwent preliminary tests to detect urinary infection, anemia and thyroid axis alterations. Those with positive results were treated and afterwards included in the study; and if not possible, excluded. A morning spot urine sample was collected by the mother after waking up of the child. The mothers were instructed at least in two occasions about the procedure and reminded by phone call the day before the collection. Albuminuria was measured by an immunoturbidimetric assay and the results were expressed as the ratio of urinary albumin/creatinine (mg/g). The U group showed lower anthropometric values than the other two groups (HAZ: U= -1.4 ± 1.1, C= -0.37 ± 0.91 and R= -0.58 ± 0.68; BAZ: U=-1.76 ± 1.06, C=-0.27 ± 0.86 R= -0.46 ± 0.74, both ANOVA $p<0.001$); and greater mean values of MA than the R and the C groups (U= 10.4 ± 16.1 mg/g, C= 6.3 ± 8.2 mg/g and R= 4.6 ± 4.3 mg/g, $p=0.040$, ANOVA). Eight percent of the U group showed MA (defined as > 20 mg/g). None of controls had MA. When evaluating the difference in prevalence between the type of undernutrition (stunting or underweight), 12.5% of children with stunting had MA, while the underweight group had 4.2%, while the R group had a prevalence of 6.3%. Using a MA lower cut-off > 10 mg/g was used to identify children at risk, we found that 16.7% of the R group, 31.2% of the U group and 8.5% of C group showed elevated albuminuria (Pearson chi-square = 0.018). Our results showed the presence of microalbuminuria in undernourished children which may be a marker of higher risk for cardiovascular and renal disease in future life. On the other hand, after treatment for undernutrition, recovered children showed results similar to controls.

PCC336

The renal functional responses to Angiotensin 1-7 in the DOCA salt hypertensive rat

E. Barry and E.J. Johns

Department of Physiology, University College Cork, Cork, Ireland

Angiotensin 1-7 (Ang1-7) has diuretic/natriuretic properties at the kidney. There is evidence that this response is due to a counter-regulation of the anti-diuretic/anti-natriuretic actions

of Angiotensin II and is therefore dependant on the level of activation or suppression of the endogenous renin-angiotensin system (RAS). This study investigated whether the excretory responses to intrarenal Ang1-7 are altered in Deoxycorticosterone Acetate (DOCA) salt hypertensive rats where the RAS is known to be depressed.

Male Wistar rats received two s.c. injections weekly of DOCA(15mg/kg) in arachis oil (2ml/kg) and 9% NaCl/2% KCl drinking water for four weeks, one week following unilateral nephrectomy performed under 5% isoflurane (0.5L/min O_2) induction/2% (0.2L/min O_2) maintenance. Prior to the terminal experiments animals were placed in metabolic cages to determine baseline excretory function. Anaesthesia was induced using 1ml/kg body weight sodium pentobarbital i.p. The femoral artery was cannulated, to monitor mean arterial pressure (MAP), and vein, for infusion of saline at 3ml/h containing inulin. The left ureter was cannulated for urine collection and a small cannula inserted into the cortico-medullary border for the infusion of saline and Ang1-7 ($6x10^{-6}$M) at 1 ml/h. After 1.5h, 20 min clearances were taken, two before and two 50 mins after the start of the Ang1-7 infusion. The rats were killed at the end of the experiment by anaesthetic overdose. Data, means±SEM were subjected to t-tests and significance taken at $P<0.05$.

DOCA treated group (n=6) had a higher GFR than the control group (n=7), at 3.3±0.2 *vs.* 1.1±0.06ml/min/kg respectively, and a higher urine volume (UV), at 131.5±11.1 *vs.* 29.5±3.6μl/min respectively. Sodium excretion values were also higher for the DOCA treated group compared to the control group, with absolute sodium excretion (UVNa) values of 29.0±2.1 *vs.* 1.42±0.09 μmol/min respectively, and fractional sodium excretion values(FENa) of 5.4±0.4 *vs.* 0.9±0.05% respectively. Ang1-7 had no effect on blood pressure, at 111±5 mmHg for control rats and 162±4 mmHg for DOCA rats, or GFR, at 4.4±0.4ml/min/kg and following Ang1-7 infusion 5.2±0.5ml/min/kg for control rats and for DOCA rats 9.1±2.2ml/min/kg and 10.9±2.8ml/min/kg before and after infusion respectively. In control rats, UV significantly increased ($P<0.05$) from 100.9±6.9 to 139.1±4.5 μl/min, UVNa, from 16.0±1.3 to 24.3±1.0 μmol/min and FENa by 2.3±0.5 to 2.9±0.5%. In the DOCA model these responses to Ang1-7 were completely blunted, with UV, 163.5±35.7μl/min, UVNa, 39±11μmol/min and FeNa, 2.4±0.07% and following Ang1-7 infusion UV, 145.4±47.7μl/min, UVNa, 29.4±8.5μmol/min, and FENa, 1.5±0.2%.

These findings suggest that the suppression of the RAS in the DOCA model of hypertension interferes with the diuretic/natriuretic response seen in normal animals to intra renal Ang1-7 infusion.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Preservation of retinal glycocalyx integrity by a slow release hydrogen sulfide (H_2S) donor

J. Whatmore[1], K.I. Wolanska[1], A. Perry[2], M. Wood[2] and M. Whiteman[1]

[1]University of Exeter Medical School, University of Exeter, Exeter, UK and [2]Biosciences, University of Exeter, Exeter, UK

Background: Leukocyte adhesion to the vascular endothelium is mediated by endothelial adhesion molecules binding to their leukocyte ligands. The endothelial adhesion molecules are embedded in the glycocalyx, a dense network of membrane-bound proteoglycans and glycoproteins. In health, the glycocalyx contributes to the anti-inflammatory regulation of the vascular wall, effectively 'hiding' the adhesion molecules from the circulating leukocytes. However, in pathological conditions associated with glycocalyx loss such as diabetes this protective mechanism is lost, possibly contributing to the associated microangiopathies e.g. diabetic retinopathy. Indeed, the early stages of retinopathy are characterised by increased leukocyte adhesion, contributing to inflammation and vessel blockage. Thus, strategies to maintain glycocalyx integrity may be beneficial in the treatment of diabetic retinopathy.

It is possible that diabetes-associated glycocalyx loss is due to reduced bioavailability of H_2S. We have shown that plasma H_2S levels are significantly lower in individuals with type 2 diabetes compared with sex/age/BMI matched controls, and that reduced H_2S levels correlate with microvascular dysfunction. However, the direct effects of H_2S on the glycocalyx are unknown.

Aim: To investigate (a) the effects of the slow release H_2S donor GYY4137 on hyperglycaemia-induced changes to the glycocalyx and leukocyte adhesion and (b) potential mechanisms of action of GYY4137, specifically endothelial K_{ATP} channel activation.

Methods: Bovine retinal endothelial cells (BREC) were exposed to 5.6mM glucose (NG) and 25mM glucose (HG) ± GYY4137 for 24h. A cell based fluorescence assay was used to study glycocalyx changes. Glibenclamide (Glib), gliclazide (Glic) and cromakalim (Crm) were used to test involvement of endothelial K_{ATP} channels. Leukocyte adhesion to BREC was measured at a shear stress of 1dyn/cm^2. Data are presented as mean±SD.

Results: HG-induced glycocalyx degradation was reversed by GYY4137 [HG 93±5% vs HG + GYY 107±8%, $p<0.001$, n=12; control,100%)]. Crm, Glib or Glic had no effect on glycocalyx changes. HG enhanced leukocyte adhesion and this was attenuated by H_2S [HG 348±110% vs HG GYY 124±47%; p=0.028, n=4; NG control,100%]. The H_2S mediated decrease in adhesion was not inhibited by Glib or Glic suggesting no involvement of endothelial K_{ATP} channel activation. H_2S added simultaneously with HG to BREC pre-treated with Crm did not affect leukostasis.

Conclusions: Glycocalyx degradation and increased leukocyte adhesion induced by HG were reversed by GYY4137, highlighting the therapeutic potential for H_2S donors in hyperglycaemic conditions.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC338

Aging reduces the vasodilatory response of mesenteric resistance arteries to calcium channel blockers

S. Albarwani[1], A. Al-Kaabi[1], A. A-Busaidi[1], S. Al-Hadhrami[1], I. Al-Husseini[1], I. Al-Lawatiya[1] and M.O. Tanira[2]

[1]Physiology, Sultan Qaboos Uinversity, Muscat, Oman and [2]Pharmacology, Sultan Qaboos University, Muscat, Oman

Calcium channel blockers are widely used to treat cardiovascular disease (CVD) including hypertension. Aging is an independent risk factor for CVD and the use of these blockers increases with aging. The aim of this study was to evaluate the response of resistance mesenteric arteries to nifedipine, verapamil and diltiazem which are chemically unrelated calcium channel blockers. Male F344 rats, aging 2.5-3 months (young)

and 22-26 months (old) were used. Animals were sacrificed with an overdose of a mixture of ketamine (140 mg kg–1 I.P.) and xylazine (40 mg kg–1 I.M.). Third order mesenteric arteries were mounted on wire myograph and tension was measured in isometric recording in the presence and absence of different blockers. In all experiments, the viability of arteries was assessed by a contractile response to KCl (60 mM) and the integrity of the endothelium was assessed by a dilator response to acetylcholine (1μM). Arteries were sub-maximally pre-contracted with phenylepherine (PE; 4μM) and then relaxed in a cumulative dose-response manner with nifedipine (0.1-10uM), verapamil or diltiazem (0.1-5 μM) or sodium nitroprusside (SNP; 0.1-10 μM). Values (mean ± s.e.m..; statistically significant difference was calculated using unpaired Student t-test; $p < 0.05$). Contractions induced by KCl were 10.8±0.6 vs. 10.7±0.7 mN and PE 13±0.5 vs. 12±0.8 mN (young vs. old) were not significantly different. Concentration-response curves to the three calcium channel blockers were shifted to the right in arteries isolated from old rats with statistically significant IC50s. In arteries isolated from old rats compared to young rats, IC50 increased from 3.6 to 11 nM (nifedipine n= 8), 94 to 187 nM (verapamil n=7) and 250 to 400nM (diltiazem, n=12). To investigate that this response was particularly associated with calcium channel blocking, arteries relaxed with SNP in a cumulative dose response (0.1 nM to10 μM) showed no significant difference between young and old groups (n=8). In conclusion, our results suggest that aging reduces the response of mesenteric arteries to the vasodilatory effect of these calcium channel blockers.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC339

Exercise training could ameliorate age-induced changes in cerebral blood flow and capillary vascularity by up-regulated VEGF and eNOS levels

S. Patumraj and S. Viboolvorakul

Physiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Aging has been reported to increase the risk of developing cerebrovascular disease. Exercise training is well known to have beneficial effects to brain health, including promoted blood flow, angiogenesis and enhanced vascularization. The present study aims to investigate effect of exercise training on age-induced brain microvascular alterations in associated with VEGF and eNOS protein levels.
Male Wistar rats were divided into 4 groups: sedentary-young (aged 4-6 months) (SE-Young, n=5), sedentary-aged (aged 23-24 months) (SE-Aged, n= 8), immersed-aged (IM-Aged, n=5) and exercise trained-aged (ET-Aged, n= 8) rats. The study was approved by Ethics Committee on Care and Use of Laboratory Animals, Faculty of Medicine, Chulalongkorn University. ET-Aged rats were individually swum in cylindrical tanks for 60 minutes/day, 5 days/week for 8 weeks. Regional cerebral blood flow (rCBF) was measured by a laser Doppler Flowmeter. Laser-scanning confocal fluorescence microscopy provided high-quality visualization of microvascular network from surface through superficial intraparenchyma. Fluorescent images were recorded and then off-line analyzed for capillary vascularity (CV) by using image analysis software. VEGF and eNOS protein levels in isolated brain microvessels were determined using immunoassay technique.
ET-Aged rat was significantly reduced in MAP compared to the IM-Aged group ($P<0.05$). The rCBF was significantly diminished in SE-Aged (134.99±14.74 PU), IM-Aged (131.09±17.53 PU), and ET-Aged (255.83±13.17 PU) groups when compared to SE-Young group (334.27±35.00 PU). However, the rCBF in the ET-Aged group was significantly higher than that in the IM-Aged group ($P<0.05$). CV was significantly reduced ($P<0.05$) in SE-Aged (15.85±1.25%), IM-Aged (16.46±1.59%) and ET-Aged (29.81±1.64%) groups when compared to SE-Young group (39.25±2.18%). The capillary vascularity of ET-Aged group was significantly greater when compared to that of IM-Aged group ($P<0.05$). The VEGF level was significantly lower ($P<0.05$) in SE-Aged (20.51±1.75 pg/mg protein) and IM-Aged (19.07±1.27 pg/mg protein) groups compared to SE-Young group (32.27±0.93 pg/mg protein). Swimming training could significant increase ($P<0.05$) of VEGF level in ET-Aged (28.35±1.53 pg/mg protein) group when compared to that of IM-Aged group. Both SE-Aged and IM-Aged groups have significantly lower ($P<0.05$) eNOS levels (575.62±70.14 and 459.94±98.02 pg/mg protein, respectively) when compared to SE-Young group (994.39±88.49 pg/mg protein). Regular swimming significantly elevated ($P<0.05$) eNOS level in ET-Aged group (926.75±65.08 pg/mg protein) when compared with that of IM-Aged group.

This study was supported by Ratchadaphiseksompot Endowment Fund and Chulalongkorn University Dutsadiphiphat Grant.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC341

Aging - induced structural changes in arteries. Role of collagen and laminin isoforms

I. Ivic

Pathophysiology and Gerontology, University of Pecs, Pecs, Hungary

Introduction: Aging greatly affects the structure of the blood vessels in order to adapt to - among other things - the changes in the hemodynamic environment. Thus, we investigated rat carotid arteries from young and old rats regarding changes in their structural components.
Hypothesis: That aging induces substantial changes in the morphology and components of the arterial wall.
Methods: Carotid arteries were isolated from young (1 month: 1m), adult (12 months: 12m) and senescent (29 months: 29m) Wistar rats. Cryosections were taken from different age groups and immunofluorescence staining for cellular and extracellular matrix components of the vessel wall was employed to determine the structural characteristics of vessels. Measurements were divided in two groups: biomechanical and morphological measurements (measurements of intensity). All measurements and analyses were performed using the Volocity image analysis program.
Results: Changes in the biomechanical characteristics of carotid arteries from young to old: wall thickness, number of nuclei per section, artery inner volume, and artery wall surface increased significantly with age ($p<0.05$). Changes in the intensity of extracellular matrix components of carotid arteries from young to old: smooth muscle actin, elastin, endothelium marker MECA-32, nuclei, laminin Pan, laminin γ1, laminin α2, laminin α5, laminin β2, collagen I, collagen III, collagen IV,

increased significantly with age (p<0.05). The most substantial change was found in collagen type I and III, laminin γ1 and smooth muscle actin.
Conclusions: The data suggest that aging results in substantial structural changes in the vascular wall. Vessels size increases with age and it is associated with increases in extracellular matrix components, especially the fibrillar collagen content (collagen type III), which is several times higher than that of the laminins which increase evenly with age.

Fluid shear stress modulates redox signalling in bovine aortic endothelial cells

S.R. Mc Sweeney[1], M. Fowler[2], G.E. Mann[1] and R.C. Siow[1]

[1]BHF Centre of Research Excellence, Cardiovascular Division, King`s College London, London, UK and [2]Unilever Discover - R&D, Unilever, Bedford, UK

Fluid shear stress (FSS) exerted by blood flow on the endothelium is critical for the maintenance of vascular redox homeostasis. Regions in the vasculature where FSS is low (LS), oscillatory (OS) or turbulent tend to be associated with atherosclerotic lesion development and an impaired redox balance[1]. High unidirectional, laminar shear stress (HS) maintains endothelial cells (EC) in an "atheroprotective" phenotype by inducing the expression of cytoprotective antioxidant enzymes, such as heme oxygenase-1 (HO-1), which are regulated by the transcription factor nuclear factor (erythroid-derived 2)-like 2 (Nrf2)[2]. LS and OS are associated with an increase in vascular oxidative stress and expression of "pro-inflammatory" genes[3]. In the current study we have investigated whether FSS alters the expression of Nrf2 and antioxidant defence genes in EC.
Bovine aortic endothelial cells (BAEC) were isolated from unwanted aortas obtained from an abattoir and cultured in DMEM containing 10% fetal calf serum. BAEC were seeded into micro channel slides and after 24 h, a fluidic unit air pump system (Ibidi) was used to expose cell monolayers to HS (15 dynes/cm^2) or OS (±15 dynes/cm^2, 1 Hz) for 2-24 h. Expression of antioxidant proteins Nrf2, HO-1, peroxiredoxin-1 (Prx-1) and glutamate-cysteine ligase catalytic subunit (GCLC) were assessed by western blot analyses and immunofluorescence.
Nuclear translocation of Nrf2 elicited by HS was increased after 2h and 24 h compared to static cultures. Western blot analysis revealed that exposure of BAEC to HS caused a significant two-fold increase in Nrf2 protein expression after 24 h vs. static cultures (p<0.05, n=4). HS and OS (24h) significantly increased HO-1 protein levels >17 fold and Prx-1 levels >2.5fold (p<0.05, n=5). Finally HS and OS significantly increased GCLC levels >1.9 fold in comparison to static cultures (p<0.05, n=5).
We have demonstrated that HS caused a significant induction of Nrf2 protein expression and an increase in Nrf2 nuclear translocation in BAEC. In addition FSS differentially increased the expression of HO-1, Prx-1 and GCLC. These results suggest that high laminar FSS may protect EC through the enhanced expression of endogenous antioxidant genes.

Catechin prevents rat cerebrovascular damage due to hypoperfusion and reperfusion

D. Lapi, T. Mastantuono, D. Sapio, M. Fantozzi and A. Colantuoni

University, Naples, Italy

Catechin is an antioxidant polyphenol abundant in green tea and exhibits biological and pharmacological properties. Several studies have demonstrated the long term consumption of catechin prevents dyslipidemia, improves the cerebral blood flow and reduces the inflammatory response and the neuronal damage during cerebral ischemia.
The aim of the present study was to assess the in vivo dose-dependent effects of catechin on rat pial microcirculation during hypoperfusion and reperfusion injury.
Male Wistar rats were anesthetized with alpha-chloralose (50 mg/Kg b.w. intraperitoneally administered), tracheotomized and intubated.
Pial microcirculation of male Wistar rats was observed by fluorescence microscopy through a closed cranial window. Hypoperfusion was induced by bilateral common carotid artery occlusion (BCCAo) for 30 min; thereafter, pial microcirculation was observed for 60 min.
Arterioles were classified according to Strahler's ordering scheme. Arteriolar diameter was determined by computer assisted-method as well as permeability increase, leukocyte adhesion, perfused capillary length (PCL) and capillary red blood cell velocity (VRBC). Neuronal damage was evaluated by TTC staining.
Catechin (2 – 4 mg/kg b.w.) or L-N5-(1-Iminoethyl) Ornithine Hydrochloride (L-NIO: 15 mg/Kg b.w.) prior to catechin were intravenously administered before BCCAo and at beginning of reperfusion.
In ischemic rats, BCCAo caused decrease in order 2 arteriole diameter, reduced by 13.7 ± 2.0 % of baseline at the end of reperfusion (RE). Microvascular permeability and leukocyte adhesion were marked. PCL and VRBC decreased at RE.
At the end of BCCAo, catechin dose-dependently reverted order 2 arteriolar diameter decrease, causing vasodilation at RE. Microvascular leakage and leukocyte adhesion were prevented as well as the cortex and striatum neuronal loss in both hemispheres at RE. L-NIO prior to catechin abolished the catechin-induced effects. Western blotting showed that endothelial nitric oxide synthase (eNOS) protein concentration significantly increased in rats treated with cathechin at RE.
In conclusion, catechin administration prevents pial microvascular damage induced by hypoperfusion and reperfusion reduc-

ing vasoconstriction, microvascular permeability, leukocyte adhesion, capillary blockade and neuronal loss. It is reasonable to suggest that catechin's effects are mainly due to nitric oxide release and to free radical scavenger activity.

PCC345

A pilot study investigating whether dipeptidyl peptidase-IV inhibition alters vascular function in obese men

K.M. Gooding, A. Shore, D. Mawson, C. Ball, A. Pitt, K. Aizawa and W. Strain

Diabetes and Vascular Medicine, University of Exeter Medical School, Exeter, Devon, UK

There is increasing interest in whether incretin based medications have favourable vascular actions, including improving endothelial function and reducing ischaemia-reperfusion insult, in humans. Previous research has predominantly used in vitro or animal based models.
Aim: This pilot study examines whether dipeptidyl peptidase-IV (DPP-IV) inhibition, slowing the breakdown of endogenous incretins, alters vascular function in obese men.
Study design: Crossover, randomised double-blind placebo-controlled study.
Method: 15 obese men were recruited (age range:28-72years). Following recruitment participants were randomised to Vildagliptin (100mg/day) or placebo for 12 weeks. At end of the treatment vascular assessments were performed (maximum hyperaemia; endothelial (in)dependent microvascular function; microvascular filtration capacity; capillary density; peak reactive hyperaemia; fovea thickness and applanation tonometry). Following a 4 week washout period the participant received the alternative treatment for 12 weeks. Vascular assessments were repeated within the last 2 weeks of treatment.
Results: 14 participants completed the study. Active treatment resulted in a small but significant reduction in HbA1c (Active mean±standard deviation: 38.1±4.8 vs 39.1±4.1mmol/mol, p=0.003 paired T-test). Capillary density was increased with DPP-IV inhibition (n=7, active median(25th,75th centiles) 126 (118,144)mm2 vs placebo 117 (109,142)mm2, p=0.028 Wilcoxon Signed Rank test). There was no significant change in other vascular assessments or fovea thickness
Discussion: In this pilot study DPP-IV inhibition successfully reduced HbA1c in obese men. Capillary density significantly increased with Vildagliptin. However, as there were no significant changes in parameters associated with capillary density, namely microvascular filtration capacity, this observation needs to be confirmed with further research.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC346

Mechanosensitive TRP channel expression in rat retinal microvessels

M. McGahon, A.V. Zholos, G.J. McGeown and T.M. Curtis

Centre for Vision and Vascular Sciences, Queen's University, Belfast, Northern Ireland, UK

The pressure-induced vasoconstriction or "myogenic response" of small arteries and arterioles is thought to be a primary mechanism contributing to blood flow autoregulation in many vascular beds. In cerebral arteries, activation of TRPC6 (1) and TRPM4 (2) channels has been shown to contribute to pressure-induced smooth muscle cell depolarisation and myogenic vasoconstriction. To date, no studies have addressed the role of TRP channels in mediating arteriolar myogenic responses. In the present study, we have begun to define the molecular and functional expression of mechanosensitive TRP channels in retinal arteriolar smooth muscle cells.
Using mechanical dissociation, arteriolar enriched samples of rat retinae were screened (using RT-PCR) for expression of mRNA encoding a number of known mechanosensitive TRP channels. mRNA transcripts for TRPC1, TRPM7, TRPV1, TRPV2, TRPV4 and TRPP1 channels were detected. In contrast to larger resistance arteries, retinal arterioles do not appear to express TRPC6 or TRPM4 channels. Immunohistochemical staining of whole flat mounts of rat retinae revealed cytosolic and membrane expression of TRPV1, TRPV2, TRPP1 and TRPM7 in arteriolar smooth muscle cells surrounding arterioles, while TRPV1, TRPV2, TRPV4 and TRPM7 were also detected in the endothelial cells lining arterioles, capillaries and venules. These expression patterns were confirmed using multiple antibodies to different epitopes within the respective channels.
Whole-cell patch-clamp recordings were subsequently made from rat retinal arteriolar smooth muscle cells embedded within isolated arteriolar segments, using Cs+ based internal and external solutions containing 10 μM nimodipine, and 2 s voltage ramps from -80 to +80 mV. Application of the TRPV2 agonist, delta-9-tetrahydrocannabinol (Δ9THC; 10 μM), elicited an increase in inward current at negative voltages, from -43.9 ± 16.7 pA/pF at -80 mV in absence of Δ9THC to 61.9 ± 22.9 pA/pF in the presence of Δ9THC (mean ± SEM, n=9, P=0.03, paired Student's t-test) and in the outward current at positive voltages (88.6 ± 40.6 pA/pF in the absence of Δ9THC compared to 125.8 ± 55.5 pA/pF at +80 mV in the presence of Δ9THC; P=0.04). The current activated by Δ9THC was outwardly rectifying and reversed at -9.7 ± 4.0 mV. Both the inward and outward portions of the current elicited by Δ9THC were inhibited by pre-incubation of the vessel with the TRPV2 inhibitor, tranilast (10 μM; n=5). Our results suggest that retinal arteriolar smooth muscle cells express a range of mechanosensitive TRP channels and that TRPV2 channels may be strong molecular candidates underpinning the myogenic response in this vascular bed.

L-NAME alters sub-cellular distribution of eNOS and caveolin-1 in the perfused human placental microvascular bed

L. Leach, V. Ghori, A.J. Fox, H. Noori and P. Santidamrongkul

School of Biomedical Sciences, University of Nottingham, Nottingham, UK

Endothelial nitric oxide synthase (eNOS) is expressed in the endothelium of placental vessels and also surprisingly in the syncytiotrophoblast lining of these vessels in the human placenta. eNOS is thought to play an important role in basal nitric oxide release to maintain maximal vasodilatation of fetal capillaries. Caveolin-1 is known to bind eNOS and inhibit it by compartmentalisation within caveolae. The aim of this study was to investigate the effects of L-NAME, the non-selective competitive inhibitor of eNOS, on the spatial localization of eNOS and caveolin-1 in the human placental vascular tree. Using a well-established dual perfusion system, placental lobules of normal term placentae (n=6) were perfused for 30 min with/without 5 mM L-NAME added to the fetal circulation, with continual monitoring of fetal perfusion pressure. Following perfusion fixation, tissue biopsies were frozen, cryosectioned and immunostained for eNOS and caveolin-1. Chorionic villi and vascular profiles within were visualized by fluorescence microscopy and quantitative analysis (blinded) of villous/vascular profiles was performed. In control perfused placenta eNOS was located predominantly in the endothelium of larger stem and intermediate villous vessels at the expense of terminal villous capillaries. A similar differential expression was seen for caveolin-1. Both eNOS and Cavelolin-1 was also localised to the syncytiotrophoblast. In L-NAME perfused placentae there was an altered pattern of eNOS staining in the syncytiotrophoblast: from a mixed punctate (caveolar/vesicular) and diffuse (cytosolic) localization to a predominantly punctate staining pattern ($p \leq 0.05$). An increase in caveolin -1 positive puncta (frequency and intensity) was also seen in the L-NAME group. The induced alteration in expression profiles of both proteins suggest that L-NAME inhibits release of eNOS from the caveolae in the syncytiotrophoblast and this also allows a greater visualisation of caveolin-1. This study also highlights the role of the syncytiotrophoblast in regulating vascular tone of fetal capillaries in the human placenta.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC348

Thromboxane vasoconstrictor response of chorionic vessels from pregnancies complicated with gestational diabetes

A.A. Razak, L. Leach and V. Ralevic

School of Biomedical Sciences, University of Nottingham, Nottingham, UK

In human placenta, lack of autonomic innervation suggests that vascular tone is controlled by humoral factors such as thromboxane. A recent study on vasoconstriction to a thromboxane mimetic, U46619, in chorionic plate arteries from pregnancies with maternal obesity, showed that responses were unaltered[1]. The effect of gestational diabetes (GDM) on the contractile response of chorionic vessels to U46619 is not known. Since functional studies on fresh placental tissue can be challenging because of the unpredictability of placenta availability, responses were investigated in both fresh vessels and after overnight storage. Human placentas from normal (n=7) and GDM (n=3) pregnancies were collected following elective caesarean sections at term. Segments of chorionic arteries and veins were dissected and divided into two: (a) fresh and (b) overnight-stored (physiologic salt solution[2] with 2% Ficoll and 5% CO_2 in air gassing, 4°C). Responses of the vessel segments to U46619 were investigated by isometric tension recording[3]. Cumulative responses to U46619 were expressed as a percentage of the contractile response to KCl (60 mM). Data were analysed using two-way ANOVA. U46619 (1 nM - 30 μM) elicited concentration-dependent contractions in the chorionic arteries and veins. Contractile responses to U46619 were similar between GDM and normal groups in both arteries and veins ($P>0.05$). After overnight storage, contractile responses to U46619 were also similar between GDM and normal groups, in both arteries and veins ($P>0.05$), suggesting a stable agonist response that can be studied after overnight storage. Contractile responses to U46619 are unchanged in chorionic arteries and veins from GDM pregnancies, as in chorionic arteries from pregnancies with maternal obesity.

Novel Vascular Morphology in Human Glomeruli

C.R. Neal[1], P. Winlove[2], J. Bell[2] and S.J. Harper[1]

[1]School of Physiology and Pharmacology, Bristol University, Bristol, UK and [2]Physics and Astronomy, University of Exeter, Exeter, Devon, UK

Human glomeruli have a larger ratio of perfused volume to afferent arteriole conductance than mice or rats. These differences are likely to influence glomerular haemodynamics and blood pressure this study uses reconstructions of the human vascular tree to build upon previous work which revealed vascular chambers at the human glomerular vascular pole (Betteridge 2011).

Seven human kidneys not required for transplantation were perfused with Soltran solution (Baxter Healthcare, UK), and transported on ice. Fresh tissue wedges were removed for multiphoton microscopy (3 kidneys) and the sample site clamped off from the rest of the kidney. The remaining kidney tissue was perfused (100mmHg pressure) with mammalian HEPES Ringer containing Ficoll 400 (25mmHg colloid osmotic pressure), followed by glutaraldehyde (2.5%) fixative at the same pressures. Tissues were dehydrated, embedded in resin and Toluidine Blue stained 1μm serial sections used to reconstruct 3D images of the glomerular vasculature. In two fresh and two fixed unstained kidneys the vasculature was imaged in 0.5-1mm thick tissue slices using multiphoton microscopy as described previously (Arkill 2010). Fibrous collagen was visualised using second harmonic generation and elastin from its

intrinsic two photon autofluorescence in a multiphoton microscope.
Reconstructed human glomeruli (n=14) from resin sections show both afferent arterioles (22±1μm diam. mean±SEM) and efferent arterioles (16±1μm diam.) leading into ellipsoidal vascular chambers (VCs). Afferent VCs (49±3 x 48±4 x 32±2μm diam.) are larger than efferent VCs (46±9 x 43±4 x 26±1μm diam.) and lead into (on average) 7 unbranched wide vessels (Conduit vessels; 16±1μm diam.) with a paucity of podocytes that convey blood to the peripheral glomerulus. The smaller efferent VCs have (on average) 13 highly branched vessels (10±0.4μm diam.) draining into them. VCs scale with glomerular volume and could be absent from glomeruli smaller than 160μm diameter.
Multiphoton microscopy confirmed this morphology in two fresh and two fixed kidneys but also demonstrated coherent emission in Second Harmonic Generation consistent with Collagen I or III in a position matching the Vascular Chamber wall. Fibrous elastin was not detected, however the entire structure exhibited background autofluorescence.
VCs and Conduit vessels are not apparent in classical biopsy sections but they are revealed by perfusion fixation at in vivo matching pressures reinflating the glomerular vascular tree to in vivo diameters. Collagen III is observed in the mesangium of collagen glomerulopathies but this report is the first to find banded collagen (I or III) in normal glomeruli. VCs and Conduit vessels are likely to be important in the distribution of blood flow among the human glomerular lobes and are implicated in glomerular disease where complications originate at the vascular pole where these structures are located.

The functional role of acid-sensing channel 3 in the urinary bladder

L. Adjei[1], G. Sui[2], M. Roberts[1], W. Rong[3], J. Li[1] and C. Wu[1]

[1]University of Surrey, Guildford, UK, [2]St Thomas Hospital, London, UK and [3]Shanghai Jiaotong Univeristy, Shanghai, China

Acid-sensing ion channels (ASIC) are a class of ion-channels that are classically expressed in the neurones to sense extracellular acidification and pain. These molecules are also found in a variety of peripheral tissues as a sensory molecule. Recently several subtypes of ASICs have been identified in the urinary bladders, in particular ASIC3 which is preferentially expressed in the urothelium and has been suggested to have important pathological implications(1). However, the functional role of these channels in the bladder is poorly understood, in particular in native tissue. This study used a recently identified ASIC3-specific activator 2-guanidine-4-methylquinazoline (2GMQ) (2;3) to examine the role of ASIC3 channels in urothelium-mediated smooth muscle contraction and ATP release.
Guinea-pigs (male Dunkin-Hartley 450-600g) were sacrificed with schedule-1 procedure and urothelium-intact smooth muscle strips and urothelium sheets were isolated from the urinary bladders. The preparation was superfused in a HEPES-buffered Tyrode's solution and isometric tension was recorded with a tension-transducer via a bridge-amplifier. ATP was measured by sampling the superfusate adjacent to the urothelium and using a luciferin-luciferase assay.
Spontaneous contractions were consistently observed in urothelium-intact smooth muscle strips (μN/mg tissue, median (25%-75% range): 734 (272-1966), n=10) which were absent in urothelium-denuded smooth muscle strips. 2GMQ (100μM-500μM) augmented the peak contractile force in urothelium-attached muscle strips (net increase, μN/mg tissue, median (25%-75% range): 100μM 2GMQ: 707 (414 – 1981), n=5, p<0.05, paired Wilcoxon signed-rank test); 500μM 2GMQ: 320 (91-3601), n=5, p<0.05). ATP release was detected from the urothelium attached muscle strips (pmoles/g tissuse/min, median (25%-75% range): 15 (7-90), n=20) and a greater ATP release was generated from the urothelium sheets (182 (23-286), n=20, p<0.05). Application of 2GMQ (10μM-500μM) enhanced ATP release in the urothelium-intact smooth muscle (% control, median (25%-75% range); 10μM 2GMQ: 173 (116 – 276); n=8, p<0.05); 100μM 2GMQ: 250 (177 – 739); n=7, p<0.05; 500μM 2GMQ: 178 (131-270); n=8, p<0.05). Consistently, 2GMQ also increased ATP release from the urothelium sheets (10μM 2GMQ:163 (116-246), n=8, p<0.05); 100μM 2GMQ: 173 (140-296), n=7, p<0.05); 500μM 2GMQ: 165 (135-294), n=5, p<0.05).
These data provide the first evidence that ASIC3 channels enhance urothelium-mediated smooth muscle contractions and stimulate ATP release in the bladder wall, mainly attributed to a release from the urothelium. The latter may exert an autocrine/paracrine effect on both motor and sensory function in the urinary bladder.

Vascular endothelial growth factor (VEGF)C; a protective glomerular mediator?

S.L. Baker[1], N.R. Buckner[1], C.R. Neal[2], G.I. Welsh[1], D.O. Bates[2], S.C. Satchell[1] and R.R. Foster[1]

[1]Academic Renal Unit, University of Bristol, Bristol, UK and [2]MicroVascular Research Laboratories, University of Bristol, Bristol, UK

Introduction
In diabetic nephropathy, increased VEGFA expression is associated with proteinuria [1], however blocking VEGFA therapeutically also blocks its beneficial effects [2]. Previously we have shown that, in contrast to VEGFA, VEGFC decreases protein passage in human glomerular endothelial cells (GEnC) and tyrosine phosphorylates the same receptor as VEGFA, VEGFR2 [3]. Our aims were to determine how VEGFC induces differential signaling effects to VEGFA in GEnC in culture and in a

transgenic mouse model, and the impacts of this on GEnC health.

Methods

A podocyte-specific, inducible VEGFC overexpressing mouse (podVEGFC) was developed by crossing PodrtTA mice with TetO-VEGFC mice. Mice were either terminally anaesthetised (Dormitor 1.6mg/kg, Narkitan 100mg/kg, H2O (1:1:1) i.m.) or killed by schedule 1. Glomeruli were isolated from podVEGFC mice using dynabeads as previously [4], RNA extracted, reverse transcribed and QPCR performed for VEGFC, VEGFR2, VEGFA and GAPDH. PodVEGFC kidneys were wax embedded, sectioned and stained with Periodic Acid Schiff, or snap frozen and sectioned. Kidneys were also fixed using cardiac perfusion with gluteradehyde, processed and imaged by electron microscopy (EM). VEGFR2/R3 heterodimerisation was analysed in fresh frozen kidney using a proximity ligation assay (PLA). Cultured GEnC were stimulated with vehicle, 1nM VEGFA or 10nM mature VEGFC for varying times and either stained with trypan blue and counted or protein/RNA extracted. Protein was Western blotted and probed for specific phospho-/pan VEGFR2 or phospho-/total Akt antibodies. QPCR was performed for VEGFR2 and GAPDH.

Results

VEGFC treatment did not phosphorylate VEGFR2 at tyrosine residues 1175, 1214 or 951 in GEnC (min. n=7). QPCR demonstrated that glomerular VEGFR2 (0.39±0.155 fold decrease) and VEGFA (0.62± 0.1 fold decrease, $p<0.05$, n=3) expression was decreased in podVEGFC mice and VEGFR2 was also decreased in GEnC stimulated with rhVEGFC (0.19±0.01 fold decrease compared to vehicle). A PLA demonstrated increased VEGFR2/3 heterodimerisation in podVEGFC mouse glomeruli ($p<0.01$, n=3). VEGFC promoted decreased trypan blue positive GEnC over 24h ($p<0.05$, n=5), increased Akt phosphorylation (n=3) and there were no morphological changes by light (min. n= 5) or EM (n=4) in podVEGFC glomeruli.

Conclusions

Although VEGFA and VEGFC both induce VEGFR2 phosphorylation in GEnC, VEGFC affects VEGFR2 and VEGFA expression and activates VEGFR2/R3 heterodimerisation in glomeruli ex vivo. Both VEGFC and VEGFA promote GEnC cell survival, and glomerular VEGFC overexpression has no detrimental effects on glomerular filtration barrier structure or function. Since VEGFC can reduce protein passage through GEnC monolayers, these results indicate potential therapeutic benefits of glomerular VEGFC on proteinuric kidney disease.

Guinea pig preterm birth is affected by the lysine deacetylase inhibitor tichostatin A

W. Tong[1], M. Karolczak-Bayatti[1], B.F. Mitchell[2], G.N. Europe-Finner[1] and M.J. Taggart[1]

[1]Institute of Cellular Medicine, Newcastle University, Necastle upon Tyne, UK and [2]Department of Obstetrics & Gynecology, University of Alberta, Edmonton, AB, Canada

There is increasing interest in investigating the roles of protein lysine acetylation in mediating cell function. Recently, evidence was presented for a role of lysine deacetylase inhibitors (KDACi) in regulating human uterine function by epigenetic and non-epigenetic actions that highlighted a possibility of utilising such substances to target pathways involved in preterm labour [1]. The pregnant guinea pig, unlike rat or mouse, has a similar endocrine physiology to that of human and is therefore a useful model of human parturition [2]. We therefore sought to determine whether trichostatin A (TSA), a broad KDACi, could affect the timing, or duration, of parturition in a guinea pig model of experimentally-induced preterm labour [3,4].

All animal experimentation was performed under Home Office License. Preterm birth was induced in time-mated pregnant guinea pigs with RU486 (3 mg/kg body weight) on gestation day d55 and d56 (analogous to ~32 weeks human gestation) and oxytocin (2 U/kg) on d57. Animals in the treatment group received additional daily doses of TSA (1.03 mg/kg) from d54 to d57. All pregnancies were monitored to determine the exact timing of birth. Effects of TSA were quantified by the following assessments: LS, time between last injection to 1st pup's appearance; LE - time between last injection to last pup's appearance; LD - labour duration between 1st and last pups appearance; and litter survival rate (SR). Mean ± SEM data in preterm (PTL) and TSA- treatment groups were compared using two-tailed unpaired t-test with Welsh's correction.

Term delivery occurred at d67.9 ± 0.1 (n=11). LD was 0.37 ± 0.02 hr. Of 37 pups, 30 appeared healthy and 7 were either stillborn or died shortly after birth (SR = 80.5 ± 5.0 %). In PTL group (n=4), delivery occurred in all animals on d57. LS was 2.83 ± 0.18 hr, LE was 5.53 ± 0.63 hr and LD was 2.53 ± 0.63 hr. No pups survived. In the TSA-treated group (n=7), 4 animals progressed to term (completed delivery > d67) and 3 delivered on d57-d58. Remarkably, one animal that had begun delivery on d57 (with one stillborn pup) also delivered two more pups on d69 that appeared normal and healthy. Overall, delivery was completed on d64.7 ± 0.4 ($n=6$, $p<0.05$), LS was 114.63 ± 1.65 hr, LE was 176.43 ± 1.93 hr ($n=6$, $p<0.05$) and LD was 45.43 ± 1.73 hr (n=6). Of the 19 pups, 10 appeared healthy but 9 did not survive (SR = 52.4 ± 10.1 %, $n=6$, $p<0.05$). In conclusion, TSA inhibits the onset of parturition, and/or increases the length of gestation in ~50% of cases of a guinea pig model of preterm birth with improved neonatal survival. KDACi are thus promising tools for elucidating the basis of preterm and term parturition. Further work to establish the mechanism(s) of action and optimise the efficacy of KDACi may also result in the development of new tocolytic agents.

BK_{Ca} channels are functionally coupled to L-Type Ca^{2+} channels but not IP_3R-mediated Ca^{2+} waves in hamster cremaster arterioles

W.F. Jackson and E.B. Westcott

Pharmacology & Toxicology, Michigan State University, East Lansing, MI, USA

Large conductance, Ca^{2+}-activated K^+ channels (BKCa) appear to be activated by Ca^{2+} influx through L-Type, voltage-gated Ca^{2+} channels (VGCC) in arteriolar smooth muscle cells. In these same cells, Ca^{2+} influx through VGCC also stimulates IP_3R-dependent Ca^{2+} waves. However, the contribution of these IP_3R-dependent events to the regulation of BKCa in arterioles is not known. To test the hypothesis that VGCC-triggered, IP_3R-dependent Ca^{2+} signals contribute to the functional activity of BKCa, we studied isolated, cannulated hamster cremasteric arterioles by pressure myography in the absence and presence of the VGCC-agonist, Bay K 8644 (BayK, 5 nM) and the IP_3R antagonist 2-aminoethoxydiphenyl borate (2-APB, 100 μM). In arterioles pressurized to 20 cm H2O (to obviate pressure-dependent activation of VGCC), the BKCa blocker tetraethylammonium (TEA, 1 mM), had no significant effect on diameter (44 ± 4 vs. 42 ± 2 μm; n = 3, p > 0.05), consistent with low activity of VGCC and BKCa. Exposure to BayK (5 nM), constricted the arterioles from 44 ± 4 to 28 ± 3 μm (p < 0.05), and in the presence of BayK, TEA (1 mM) now produced robust constriction from 28 ± 3 to 18 ± 1 μm (p < 0.05). Identical results were obtained in the presence of 2-APB (100 μM): 2-APB had no effect on resting diameter (44 ± 4 vs. 43 ± 3 μm; p > 0.05) and did not affect the subsequent responses to BayK (29 ± 2 μm; p > 0.05 vs. BayK alone) and TEA (19 ± 2 μm; p > 0.05 vs. BayK + TEA alone). Efficacy of this concentration of 2-APB was verified by complete block of phenylephrine-induced constriction and abolition of Ca^{2+} waves in Fluo-4 loaded preparations. Before 2-APB, phenylephrine (20 nmols) constricted arterioles by 22 ± 4 μm, in the presence of 2-APB phenylephrine-induced constriction = 0.3 ± 0.2 μm (n = 3, p < 0.05). Before 2-APB, Ca^{2+} wave frequency = 0.21 ± 0.06 Hz, after 2-APB Ca^{2+} wave frequency = 0.04 ± 0.02 Hz (n = 6, p < 0.05). These data indicate that BKCa are activated by Ca^{2+} influx through VGCC, and that this occurs independent from IP_3R-dependent Ca^{2+} waves.

Optical mapping of action potential spatiotemporal waveforms in isolated guinea pig heart and uterus

W. Tong and M.J. Taggart

Institute of Cellular Medicine, Necastle upon Tyne, UK

Elucidation of the electrophysiological characteristics of uterine smooth muscle is important for understanding the electrical events that regulate parturition at the end of pregnancy [1]. Similarly, this may be informative in developing tocolytic drugs directed against ion channel targets for the treatment of premature labour. Two steps are important in this regard. First, it would be informative to determine the spatiotemporal characteristics of action potential (AP) propagation in the uterus in order to identify how electrical excitation-contraction coupling may be co-ordinated at a tissue and organ level. Second, consideration should be given to possible off-site actions of drugs targeting electrogenic events. In this regard, it is important to also understand the actions of electrogenic modulators on cardiac AP waveforms. The guinea pig is a useful model of human cardiac [2] and uterine [3] function. We, therefore, have undertaken pilot experiments using high frequency optical mapping to examine the spatiotemporal characteristics of AP propagation in hearts and uteri isolated from adult female guinea pigs. Fluorescence was excited by light-emitting diodes (at 488 nm) and the filtered emission images (590 nm long pass) were acquired by a high speed camera (up to 2.5 kHz) with a viewing area of 128x128 pixels, resulting in spatial resolutions of 200 x 200 μm^2. Following well-established methods [4], the optical mapping system was validated by recording epifluorescence images from perfused ex vivo intact hearts loaded with voltage-sensitive dye di-4-ANEPPS and mechanical uncoupler blebbistatin (Fig 1). Uterine tissues were mounted on a silicone support and superfused with MOPS-based Krebs solution at 37 °C. After a period of stabilization, the tissues were loaded with di-4-ANEPPS (5-10 μM), contraction was minimised with wortmannin (17-25 μM) and the fluorescent images were acquired at 0.5 kHz (Fig 2). In summary, our optical mapping procedure enables recordings of up to 0.4 msec and 200 μm resolution in 2.5 x 2.5 cm^2 areas of isolated hearts and uteri from guinea pigs. To our knowledge, these are the first reported visualisations of AP spatiotemporal patterns in uterine smooth muscle and offer much promise to add to our knowledge gathered thus far from spatially distributed surface electrode recordings [5]. In addition, the ability to visualise AP characteristics in both uterine and cardiac tissues will assist with (i) elucidating tissue-specific mechanisms of electrogenesis and (ii) investigating putative tissue-specific actions of ion channel modulators in both tissue types from one animal.

PCC355

The role of ER stress in vascular calcification

M. Furmanik and C.M. Shanahan

Department of Cardiology, King's College London, London, UK

Vascular calcification is a pathological process of deposition of calcium and phosphate crystals in the form of hydroxyapatite (HAp) in the blood vessel wall. Its presence in the vessel wall causes stiffness and leads to left ventricular hypertrophy and increases cardiovascular morbidity and mortality. It is a serious health problem common in ageing populations and widely prevalent in pathological conditions such as diabetes and chronic kidney disease.

Vascular calcification is a regulated, cell-mediated process, similar to bone formation that involves osteogenic transdifferention of vascular smooth muscle cells (VSMCs) characterized by expression of bone-specific genes in the calcified vessel. However, the exact mechanisms responsible for triggering this process are unknown.

The endoplasmic reticulum (ER) is involved in the production, correct folding and secretion of newly synthesized proteins in cells. ER stress occurs as a result of unfolded protein accumulation or an increased demand for protein secretion. It results in activation of a signalling pathway called the unfolded protein response (UPR), mediated by three main ER stress transducers IRE1, PERK and ATF6. Importantly, ER stress has recently been implicated in bone development. Therefore, we hypothesized that phenotypic conversion and calcification of VSMCs can be regulated by ER stress.

Human primary VSMCs were treated with tunicamycin and thapsigargin and expression of bone markers in response to ER stress was examined by Western blotting and quantitative real-time PCR. ER stress was shown to regulate expression of BMP2, a key bone morphogen and Osterix, an obligate bone specific transcription factor, as well as its downstream targets bone sialoprotein, alkaline phosphatase and osteoprotegerin in VSMCs. However no effects on Runx2 were observed. In addition, the two different ER stress inducers were found to have differential effects on activation of these bone markers. Using siRNA knock-down it was established that two branches of the UPR represented by ATF6 and ATF4 (downstream of PERK) play a role in mediating these effects on bone gene expression. Further analysis of Osterix, the osteogenic transcription factor shown to be regulated by ER stress, demonstrated that it localised predominantly in cytoplasmic foci and was present in matrix vesicles secreted by VSMCs suggesting it may play a novel role in mediating the VSMC response to ER stress.

The protein kinase C alpha and delta isozymes gene silencing restores vascular function in diabetic rats

K. Klymenko[1], T. Novokhatska[1], I. Kizub[1], V. Dosenko[2] and A. Soloviev[1]

[1]Institute of Pharmacology and Toxicology of National Academy of Medical Sciences, Kiev, Ukraine and [2]Bogomoletz Institute of Physiology of National Academy of Sciense, Kiev, Ukraine

Cardiovascular diseases are currently the principal causes of morbidity and mortality in patients with diabetes mellitus and current therapy is still ineffective. Protein kinase C (PKC) is a key enzyme involved in endothelial dysfunction and decrease of vascular tissues potassium (K^+) channels activity. Endothelium and K^+ channels, in turn, are the main factors for maintenance of normal vasodilator potential at different pathological conditions, including diabetes.

The aim of this study was to evaluate the effect of silencing of PKC-α and -δ genes using siRNA on endothelial dysfunction and potassium channelopathy in vascular smooth muscle cells (SMCs) at diabetes.

Experimental design of the study comprised isolated rat aorta contractile recordings and whole-cell patch-clamp technique in isolated aortic SMCs. Dilator responses of vascular rings to acetylcholine (ACh, 10^{-9} - 10^{-5} M) were expressed as a percentage of the maximum contractile response produced by norepinephrine (10^{-6} M).

Diabetes was induced by streptozotocin intraperitoneal injection to male Wistar rats (STZ, 65 mg/kg) and then verified by the presence of hyperglycaemia (glucose level was 30.05±0.51 mM, n=12, P<0.05) in 3d month after STZ injection and at the day of experiment.

Diabetic rats were injected intravenously with siRNA targeted to PKC-α or -δ. Animals were killed on the 7th day by cervical dislocation following ketamine (45 mg/kg, i.p.) and xylazine (10 mg/kg, i.p.) anesthesia.

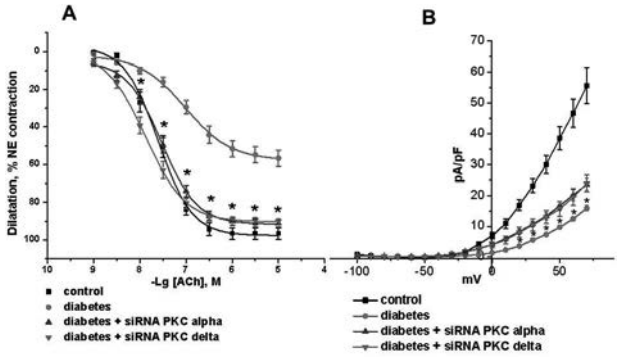
The concentration-response curve to ACh in diabetic aortas precontracted with norepinephrine (10^{-6} M) was significantly shifted to the right (EC_{50} = 6.93±0.11, n=12, P<0.05 *vs.* 7.59±0.08, n=7 in control). Maximum dilatation to ACh in diabetic tissues was depressed (56.7±4.26%, n=12, P<0.05 *vs.* 96.5±3.05%, n=7 in control)

PKC-α and -δ gene silencing led to significant restoration of ACh-induced dilatation in diabetic aortas with the maximum

of 91± 2.11%, n=17; P>0.05 (EC_{50} = 7.58±0.07) for siRNA PKC-α, and 90.1±1.34 %, n=15, P<0.05 (EC_{50} = 7.9±0.1) for siRNA PKC-δ.

In isolated diabetic aorta SMCs total outward K^+ current was reduced (peak current density was 15.9 ± 0.9 pA/pF (n=13, P<0.05) as compared to control (55.6 ± 5.8 pA/pF, n=8). Aortic SMCs from animals treated with siRNA PKC-α showed significant increase in total K^+ current in comparison to non-treated diabetic rats with peak density 23.5±1.9 pA/pF (n=12, P<0.05). The similar results were obtained in SMCs from animals treated with siRNA PKC-δ (23.9±2.7 pA/pF, n=7, P<0.05).

In conclusion, the silencing of both PKC-α and -δ gene expression using siRNA led to increasing of total K^+ outward current in vascular SMCs and restoring of endothelium-dependent vasodilatation in rats with diabetes mellitus. It is likely that siRNA technique can be a good therapeutic tool to normalize diabetic angiopathies.



A: Dose-response curve for ACh in isolated rat aortic rings precontracted with norepinephrine (NE, 10^{-6} M) obtained from control (n=7), diabetic animals (n=12) and diabetic animals treated with siRNA PKC-α (n=17) or siRNA PKC-δ (n=15). B: Steady-state current-voltage relationships for whole-cell outward K^+ current density in isolated rat aorta SMC from control (n=8), diabetic animals (n=13), and diabetic animals treated with siRNA PKC-α (n=12) or siRNA PKC-δ (n=7). Data are shown as means + S.E.M. *P < 0.05 versus control.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Serum proteins fetuin-A and albumin alter the cytotoxic effects of calcium phosphate nanocrystals on human vascular smooth muscle cells

Y. Dautova[1], D. Kozlova[2], M. Epple[2], M. Bootman[3,1] and D. Proudfoot[1]

[1]Signalling Laboratory, Babraham Institute, Cambridge, UK, [2]Institute of Inorganic Chemistry and Center for Nanointegration Duisburg-Essen (CeNIDE), University of Duisburg-Essen, Essen, Germany and [3]Department of Life, Health and Chemical Science, The Open University, Milton Keynes, UK

Controlled deposition of calcium phosphate (CaP) in bone matrix is essential for stability and strength of bones and teeth, but such deposits are also found within other tissues in association with several diseases including atherosclerosis. CaP can interact with host proteins *in vivo*, including albumin and fetuin-A, which may modulate crystal interactions with cells (1).

We recently demonstrated that CaP nanoparticles induced rapid rises in intracellular calcium ($(Ca^{2+})_i$) in vascular smooth muscle cells (VSMCs) and subsequent cell death (2). Incubation of CaP crystals with serum prior to addition to VSMCs abolished elevation of $(Ca^{2+})_i$ suggesting that serum may offset the detrimental effects of CaP crystals. Compared to synthetic CaP, crystals isolated from calcified atherosclerotic tissue had little effect on $(Ca^{2+})_i$ and were less potent in inducing cell death, possibly due to their association with endogenous serum proteins such as fetuin-A, which has been previously shown to inhibit VSMC calcification and apoptosis (3).

Due to the important role of VSMC in stabilising atherosclerotic plaques, we determined whether fetuin-A and albumin can prevent CaP-induced VSMC death. In parallel, we also investigated changes in $(Ca^{2+})_i$ in response to CaP crystal stimulation in the presence and absence of a range of physiological and sub-physiological concentrations of fetuin-A and albumin. Cytotoxicity assessment (MTT) revealed that the crystals reduced cell viability in a dose-dependent manner. Pre-incubation with albumin or fetuin-A (10, 3 and 1 μM but not 0.1 μM) in serum-free medium blocked the cytotoxic effects of the CaP crystals (25 μg/ml) (P < 0.0001). Furthermore, functionalised particles (fetuin-A or albumin attached to CaP) were less toxic than naked CaP. CaP-fetuin particles were less potent at evoking cell death compared to CaP-albumin.

The initial $(Ca^{2+})_i$ oscillations appeared after 14.6 ± 1.3 min (n=16) and cells that died exhibited a large, unrecoverable $(Ca^{2+})_i$ peak just prior to cell death which occurred at 31.3 ± 1.76 min (n=17) after CaP addition. Only those cells where $(Ca^{2+})_i$ levels increased to a particular threshold died (peak amplitude (PA) 0.93 ± 0.03; n=17). In surviving cells, the $(Ca^{2+})_i$ oscillations were maintained or dampened over time, and were of much smaller amplitudes (PA 0.58 ± 0.04 (n=8)) compared to cells that died (P < 0.0001). Pre-incubation with 1 μM but not 0.1 μM fetuin-A or albumin silenced $(Ca^{2+})_i$ activity resulting in protection from cell death. The results suggest that CaP-induced cytotoxicity in VSMCs depends on $(Ca^{2+})_i$, and that presence of fetuin-A or albumin can provide protection against CaP-induced cell death. The cellular mechanisms underlying this protection are currently under investigation.

Neuropilins and vascular remodeling

C. Pellet-Many, V. Mehta, I. Evans, J. Ruivo and I. Zachary

Medicine, University College London, London, UK

Aim: Neuropilin 1 (NRP1) and the structurally-related molecule, neuropilin 2 (NRP2), are co-receptors both for class 3 semaphorins, a family of secreted polypeptides with key roles in axonal guidance, and for various members of the VEGF family. Neuropilins were also identified to be key players in other physiological and pathological settings such as the primary immune response and cancer. Our group identified Neuropilins (NRPs) as regulators of vascular smooth muscle cell (VSMC) migration 1. In this study, we explored the role of NRP1 in abnormal VSMC accumulation in vivo in the rat carotid artery model of neointimal hyperplasia following balloon injury, in which VSMC migration and proliferation play important roles.

Methods: Male Sprague-Dawley rats were subjected to balloon angioplasty and left to recover for 7, 14 or 28 days. Quantitative PCR and Western blotting were used to look at endoge-

nous levels of NRPs expression in carotid arteries at the different recovery times. At the time of surgery, we applied 30% pluronic gel containing 10E10 adenoviral (Ad) particles expressing control LacZ, NRP1 Wild-Type (WT) or a truncated form, devoid of intracytoplasmic domain (NRP1ΔC), to the adventitia. Morphometric analysis was used to quantify the intima/media ratios in adenovirus-transduced arteries; Western blot and absolute RT-qPCR were used to detect changes in protein expression and mRNA levels respectively.
Results: Endogenous NRP1 and NRP2 mRNA and protein levels are upregulated after carotid injury with a maximum protein expression 7 days after injury, expression remaining elevated thereafter. Morphometric analysis of the vessels revealed that the over-expression of NRP1-WT did not alter the extent of neotinima formation but the NRP1ΔC mutant decreased the formation of neointimal hyperplasia.
Conclusions: These results strongly suggest a role for NRPs in the development of neointima in the rat carotid artery model of restenosis. Insights into NRP function in the aberrant migration and proliferation of VSMC in this model could be crucial to understand the mechanism of VSMC accumulation occurring in vascular remodeling.

PCC361

Spatial and temporal expression of Nrf2-inducible antioxidant defences in the gliovascular complex after stroke

A. Alfieri[1], S. Srivastava[1], R. Siow[1], M. Modo[2], M. Duchen[3], P. Fraser[1] and G. Mann[1]

[1]Cardiovascular Division, King's College London, London, UK, [2]Institute of Psychiatry, King's College London, London, UK and [3]Department of Cell and Developmental Biology, University College London, London, UK

Astrocytes are closely associated with cerebrovascular endothelium, providing functional and metabolic support. The relationship between these two cell-types has been defined as gliovascular complex. Activation of the redox sensitive transcription factor Nrf2 in the brain is a key mechanism underlying endogenous protection against oxidative stress. In the present study, we have investigated expression of Nrf2, constitutive antioxidant enzyme heme-oxygenase-2 (HO-2) and Nrf2-inducible HO-1 in cerebral microvessels after experimental stroke. Male Sprague-Dawley rats (250-300g) were subjected to 70 min right middle cerebral artery occlusion (MCAo) under isoflurane anaesthesia and followed by 4, 24 or 72 h reperfusion. HO-2, HO-1 and Nrf2 were detected by immunofluorescence and immunohistochemistry in brain coronal sections along with brain injury and cell markers. Cerebral ischaemia-reperfusion did not change constitutive HO-2 expression, however levels were significantly higher in perivascular astrocytes than endothelial cells. HO-1 expression was induced in microvessels of the peri-infarct region after 4-72 h, where it was mainly expressed by perivascular astrocytes. Nrf2 expression was significantly increased in microvessels after stroke between 4-24 h, peaking after 4h and remaining elevated after 72 h in perivascular astrocytes. In the endothelium, Nrf2 peaked after 24 h and declined by 72 h. In conclusion, astrocytes play a central role in protecting the gliovascular complex by expressing antioxidant enzymes. As Nrf2 and HO-1 expression are increased in cerebral microvessels following stroke, the Nrf2 defence pathway may be a therapeutic target to protect the brain against stroke.

Acute inhibition of hERG K^+ channel by the antipsychotic drug fluphenazine

B. Lee, S. Jo and M. Park

Department of Physiology, School of Medicine, Kangwon National University, Chuncheon, Gangwon-do, Republic of Korea

Fluphenazine is a potent antipsychotic drug that can increase action potential duration and induce QT prolongation in several animal models. Since block of cardiac human *ether-a-go-go*-related gene (hERG) channels is one of leading causes of acquired long QT syndrome, we investigated the acute effects of fluphenazine on hERG channels to determine the electrophysiological basis for its proarrhythmic potential. We examined the effects of fluphenazine on the hERG channels expressed in *Xenopus* oocytes using two-microelectrode voltage-clamp techniques. Fluphenazine induced a concentration-dependent decrease of the current amplitude at the end of the voltage steps and hERG tail currents. The IC_{50} of fluphenazine-dependent hERG block in *Xenopus* oocytes increased progressively relative to the degree of depolarization. Fluphenazine affected the channels in the activated and inactivated states but not in the closed states. The S6 domain mutation Y652A attenuated the hERG current block. The IC_{50} value of fluphenazine-dependent hERG block increased from 13.3 μM to 89.0 μM by the mutation from tyrosine to alanine at 652 amino acid of the channel. These results suggest that the antipsychotic drug, fluphenazine is a blocker of the hERG channels, providing a molecular mechanism for the drug-induced arrhythmogenic side effects.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Reversal of murine plaque hypoxia prevents apoptosis and necrotic core expansion

T. Theelen[1], E. Marsch[1], M. van Gink[1], S. Meex[1], M. Gijbels[1], E. Biessen[1], B. Janssen[1], M. Daemen[2] and J. Sluimer[1]

[1]Maastricht University medical center, Maastricht, Netherlands and [2]Amsterdam medical center, Amsterdam, Netherlands

Murine and human plaque macrophages are hypoxic. We hypothesized that hypoxia stimulates pro-atherogenic processes, including inflammation, and that reversal of plaque

hypoxia by hyperoxic gas breathing will consequently alleviate plaque progression.
To study whether hyperoxic carbogen gas (95% O2, 5% CO2) could increase arterial pO2, blood was samples from canulated femoral arteries of LDLR-/- mice (n=4 males, chow) subjected to a single 30 min exposure of carbogen (5L/min, normobaric). Carbogen significantly increased arterial pO2 from 97±3mmHg at baseline to 498±50mmHg after exposure (p<0.0001). Next, the effect of the carbogen-enhanced arterial pO2 on plaque hypoxia was studied. LDLR-/- mice with advanced, hypoxic plaques (11-wk-old males, n=5/group, 12 weeks of diet) were subjected to a single 90 minute exposure of carbogen or compressed air (21% O2), injected with pimonidazole to detect hypoxia and sacrificed directly after exposure. Single carbogen treatment of advanced plaques led to a dramatic 80% reduction of plaque hypoxia in the aortic arch (p=0.029) compared to control. Therefore, the effect of chronic carbogen exposure on atherogenesis was studied. LDLR-/- mice (20-wk-old males, n=15/group) were placed on a high cholesterol (0.25 %) diet for an initial 4 weeks, followed by 4 weeks of high fat diet and carbogen gas or compressed air (21% oxygen) 5 days/week for 90 min/day. Twenty-four hours after the last exposure, mice were sacrificed and plaque hypoxia and atherogenesis were studied in the aortic arch and root. Even 24 hours after the last exposure, chronic carbogen exposure resulted in a 42% decrease of plaque hypoxia in the aortic root (p=0.028) compared to control. Chronic carbogen exposure did not alter plaque size or macrophage content in aortic root or arch, but reduced necrotic core size by 37% in advanced plaques of the aortic root compared to control (p=0.0003). In parallel, carbogen treatment reduced plaque apoptosis (TUNEL+cells/total cell) (-50%, p=0.03) compared to compressed air, likely due to improved efferocytosis of apoptotic cells by MAC3+ macrophages (+36%, p=0.03). These plaque-stabilizing effects were independent of serum cholesterol, hematological parameters (Hb, Ht, erythrocyte counts), hematopoiesis and systemic inflammation (blood, spleen, lymph nodes, and bone marrow). Mechanistically, hypoxia reduced efferocytosis in vitro in bone marrow-derived macrophages and decreased gene expression of efferocytosis receptors (-52% MerTK, -56% CD36). Also, M2 gene expression was reduced (MRC1 -60%, IL10 -51%), whereas M1 genes were up-regulated (IL6 +250 fold, iNOS +178 fold), suggesting a hypoxia-mediated shift away from M2 pro-phagocytic macrophages.
Thus, we conclude that carbogen exposure successfully enhanced plaque oxygenation and prevented necrotic core expansion, most likely by enhancing efferocytosis.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC366

Crosstalk between mesenchymal stem cells and endothelial cells inhibits inflammatory leukocyte recruitment

N. Luu, H.M. McGettrick, C.D. Buckley, P. Newsome, G. Rainger, J. Frampton and G.B. Nash

University of Birmingham, Birmingham, UK

Mesenchymal stem cells (MSC) have immuno-modulatory capacity, but their effects on endothelial cells (EC) and recruitment of leukocytes are unknown. We cocultured human bone marrow-derived MSC and EC, and found that MSC could down-regulate adhesion of flowing human neutrophils or lymphocytes, and their subsequent transendothelial migration. This applied for EC treated with tumour necrosis factor-alpha (TNF), interleukin-1beta (IL-1) or TNF and interferon-gamma combined. Supernatant from cocultures added to EC also had an inhibitory effect on recruitment. This supernatant had much higher levels of IL-6 than supernatant from cultures of the individual cells, and the individual supernatants had no inhibitory functions. Addition of neutralising antibody against IL-6 removed the bioactivity of the coculture supernatant and also the immunomodulatory effects of coculture. Studies using siRNA to reduce IL-6 production in each cell type showed that it came mainly from the MSC in coculture, and reduction in production in these cells alone was sufficient to lose the inhibitory effects of coculture. Interestingly, studies using siRNA to reduce IL-6-receptor expression also showed that expression in MSC contributed to the effects of coculture. This was explained when we detected soluble IL-6R in supernatants and showed that receptor removal greatly reduced the potency of supernatant. Thus, crosstalk between MSC and EC caused up regulation of production of IL-6 by MSC which in turn down regulated the response of EC to inflammatory cytokines, an effect potentiated by release of soluble IL-6R. These studies establish a novel mechanism by which MSC delivered from the blood might have protective effects against inflammatory pathology and cardiovascular disease.

Sphingosine 1-phosphate inhibits angiogenesis in *ex vivo* human aortic valves

K.S. Mascall, G. Small, G. Gibson and G.F. Nixon

School of Medical Sciences, University of Aberdeen, Aberdeen, UK

Aortic valve stenosis (AVS) is closely associated with increased valve inflammation leading to calcification and ultimately results in cardiac failure if untreated. Currently the only therapeutic option is surgical valve replacement. Recent studies have indicated that increased angiogenesis within the valve may facilitate access of inflammatory cells and this plays an important role in the pathogenesis of AVS. Preventing angiogenesis in aortic valves is therefore a novel therapeutic target in this disease. Sphingosine 1-phosphate (S1P) is a lipid mediator present in plasma and produces intracellular effects via specific S1P receptors. We have previously shown that S1P can inhibit angiogenesis in human arteries (Mascall *et al*, 2012). The aim of the current study was to determine the effect of S1P on angiogenesis in human aortic valves. Valves from patients undergoing valve replacement surgery for AVS (diseased) or aortic regurgitation (non-diseased) were cut 2mm^2 pieces and embedded in Matrigel. Valve pieces were incubated for up to 14 days in growth factor-supplemented medium and angiogenic sprouts were quantified. Sprouts consisting of endothelial cells (confirmed by uptake of acetylated-LDL) increased in number from day 5 until day 14 and this was significantly greater in diseased compared to non-diseased valves (number of sprouts observed at day 14, non-diseased 60 ± 8 versus diseased 110 ± 12, n=4 per group, mean ± s.e.m., ANOVA, p<0.05). Treatment of either diseased or non-diseased valve tissue with 1μM S1P resulted in a significant decrease in

endothelial sprout formation compared to non-treated valves (number of sprouts observed at day 14, non-diseased valves - untreated 71 ± 5 versus S1P-treated 18 ± 3, n=3 per group; diseased valves - untreated 116 ± 9 versus S1P-treated 38 ± 5, n=3 per group, $p<0.05$). To examine this further, we assessed the activity of matrix metalloprotineases (MMPs) which are associated with angiogenesis. Activity of MMP-2 was significantly greater in diseased compared to control valves as assessed by *in vitro* gelatinolytic activity. Incubation with 1μM S1P decreased MMP activity in diseased valves (gelatinolytic activity observed at day 14, 94 ± 11% decrease in untreated valves compared to treated, n=3 per group, $p<0.05$). To determine the potential mechanisms involved we examined expression of the angiostatic protein, soluble fms-like tyrosine kinase-1 (sflt-1). Immunoblotting of valve homogenates demonstrated that sflt-1 expression is significantly decreased in diseased valves compared to control valves. Homogenates from diseased valves incubated with 1μM S1P for 14 days had a significantly increased expression of sflt-1 (n=3 per group). In conclusion, S1P can inhibit angiogenesis in human aortic valves, possibly via increasing expression of the angiostatic protein sflt-1. This mechanism may provide a therapeutic target in AVS.

The AMPKα2 subunit is crucial for myeloid cell-mediated post-ischemic revascularization

B. Fisslthaler, R. Abdel Malik, P. Seifert, N. Zippel and I. Fleming

Institute for Vascular Signalling, University Frankfurt, Frankfurt, Germany

Infiltrating immune cells play a key role in regulating angiogenesis through the production and release of a wide range of pro-angiogenic mediators and cytokines. As the AMP-activated protein kinase (AMPK) has been shown to positively regulate angiogenesis, we investigated the effect of deleting the AMPKα2 subunit in myeloid cells (LysM-AMPKα2) on macrophage and neutrophil function as well as on vascular repair.
Wild-type and LysM-AMPKα2 mice were subjected to hindlimb ischemia by femoral artery ligation. The recovery of blood flow (laser Doppler), capillary density (immunohistochemistry) and immune cell infiltration (flow cytometry) were determined. To assess the functional role of AMPKα2 in myeloid cells, bone marrow monocytes were differentiated (in M-CSF) and polarized to M1 (IFN-γ and LPS) or M2 (IL-4 and IL-13) macrophages. Polymorphonuclear cells (PMN) from the murine bone marrow were stimulated with LPS (2 hours). Expression levels of cytokines and growth factors were analyzed using quantitative real time PCR.
Recovery of blood flow after hindlimb ischemia was significantly impaired (80%) in LysM-AMPKα2 versus the wild-type littermates. In addition, LysM-AMPKα2 mice showed significantly reduced capillary density and decreased myeloid cell infiltration into the ischemic limb. The deletion of the AMPKα2 subunit had no significant effect on the mRNA expression levels of the M1 markers (TNF-α, IL-1β and inducible nitric oxide synthase) in macrophages. The M2 markers (FIZZ-1, arginase and YM-1) as well as VEGF were under basal decreased in macrophages from LysM-AMPKα2 mice. In PMNs deletion of the AMPKα2 resulted after stimulation with LPS in a significant increase in inflammatory markers whereas the expression of stromal cell-derived factor-1 and the metalloproteinase-9 was significantly reduced compared to cells from wild-type littermates.
Deletion of the AMPKα2 in the cells of the myeloid lineage almost abolished vascular repair after hindlimb ischemia. These results indicate that the AMPKα2 subunit plays a crucial role in regulating the inflammatory state and angiogenic potential of myeloid cells.

Aortic vasodilatation capacity of the glycosaminoglycan sulodexide is mediated by nitric oxide

Y. Mathison[1,3], G. Vásquez[2], J. Vásquez[1], A. Israel[3] and E. Romero[1]

[1]School of Medicine José María Vargas, Pharmacolgy Department, Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of, [2]PEEI School of Medicine, Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of and [3]School of Pharmacy, Laboratory of Neuropeptides, Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of

Diabetes mellitus (DM) is a chronic metabolic disorder considered to be a major risk factor for cardiovascular diseases. DM-induced endothelial dysfunction is associated with cardiovascular risk. In human and diabetic animals models, decrease levels of glycosaminoglycans (GAGs) have been associated with a generalized vascular dysfunction (Deckert y col. 1989), and recent studies has demonstrated a beneficial effect of sulodexide (SUL) (glycosaminoglycan composed from heparin-like and dermatan fractions) in experimental models of endothelial damage (Kristová et al. 2000; 2008).Since NO plays a key role in vascular function, we assessed the possible endothelium-protective effect of SUL (15mg/kg, s.c) on vascular relaxation and nitric oxide synthase (NOS) activity in aortic rings of diabetic rats. Diabetes type 1 was induced in male Sprague-Dawley rats (200-250, n=8-10/group) by administration of streptozotocin (STZ), 60 mg, i.v. Animals were randomly allocated in four groups: C=control, STZ=diabetic, SUL=control+SUL and STZ+SUL= diabetic+SUL. After three months of treatment, the animals were euthanized in thiopenthal anesthesia (30 mg/Kg i.p.) and the aorta was microdissected. Basal and SUL-stimulated NOS activity was assayed by monitoring the conversion of [3H]-L-arginine to [3H]-L-citruline. Phenilephrine precontracted aortic rings were used to evaluated acetylcholine (ACh: 1x10-7, 3x10-7, 1x10-6, 3x10-6) and nitroprusiate (NPS:10-8,10-7,10-6) relaxation capacity. Values are means ± E.E.M, compared by ANOVA. Basal NOS activity was lower in STZ-diabetic rats than in control group (57.2±4.02 vs. 90.58±4.6 $p< 0.01$), and this activity was restored by SUL treatment (100.83±12). In diabetic rats ACh relaxation was 28.8-35.1% lower than in control rats, but relaxation in SUL y SUL+STZ groups was similar to control. No significative statistical differences were found in endothelium-independent NPS relaxation, between the different groups. Our results demonstrated that pretreatment with SUL prevents loss of the relaxing capacity induced by diabetes in aorta of diabetic rats, by a mechanism involving the production of nitric oxide, and suggest a potential use of this drug to improve endothelial dysfunction in diabetes.

Asiatic acid alleviates metabolic and hemodynamic alterations in high-fat, high-carbohydrate diet-induced metabolic syndrome rats

P. Pakdeechote[1], S. Bunbupha[1], U. Kukongviriyapan[1], P. Prachaney[2], A. Timinkul[1] and V. Kukongviriyapan[3]

[1]Physiology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand, [2]Anatomy, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand and [3]Pharmacology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand

Consumption of high-fat, high-carbohydrate diet mainly contributed in the development of metabolic syndrome, which is associated with obesity, insulin resistance, dyslipidemia, and high blood pressure. It is well established that asiatic acid, a natural triterpenoid compound derived from Centella asiatica, exhibited biological effects including, antiinflammation, antioxidant and antihyperglycemia. In the presen study, we examined the metabolic, cardiovascular responses as well as antioxidant properties of asiatic acid in rats with metabolic syndrome (MS) induced by high-fat, high-carbohydrate (HFHC) diet. Male Sprague-Dawley rats (160-180 g) were fed with HFHC diet with 15% fructose in drinking water for 12 weeks to induce MS. Then, MS rats and normal rats received asiatic acid (10 mg/kg) or vehicle for further 3 weeks. Fasting serum insulin, fasting blood glucose (FBG), oral glucose tolerance test (OGTT) and systolic blood pressure (SBP) were measured once a month. At the end of treatment, rats were anaesthetized with peritoneal injection of pentobarbital-sodium (60 mg/kg) and hemodynamic status, lipid profiles and oxidative stress markers were evaluated. All procedures are complied with the standards for the care and use of experimental animals and approved by Animal Ethics Committee of Khon Kaen University, Khon Kaen, Thailand (AEKKU 36/2555). Data are expressed as the mean ± S.E.M., compared by ANOVA. Results showed that rats fed with HFHC diet had an impairment of OGTT, high homeostasis model assessment of insulin (HOMA-IR), high cholesterol, and high SBP, indicating metabolic syndrome (MS) in these rats ($p<0.05$). Moreover, mean arterial blood pressure (MAP) (MS: 114.61 ± 3.7 vs. 90.58 ± 1.7 mmHg control, $p<0.05$), hindlimb vascular resistance (HVR) (MS: 30.64 ± 2.5 vs. 11.46 ± 0.6 mmHg/min/100 g/ml control, $p<0.05$) were significantly increased, relating to the augmentation of vascular superoxide production (MS: 114.9 ± 15.1 vs. 56.9 ± 4.3 counts/min/mg dry weight control, $p<0.05$) and plasma MDA levels (MS: 5.8 ± 0.5 vs. 2.9 ± 0.2 μM control, $p<0.05$) in MS group. Treatment with asiatic acid significantly attenuated dyslipidemia and improved insulin sensitivity as shown by the decreased HOMA-IR ($p<0.05$). We found reductions in MAP (about 11.4%) and HVR (about 36%) in MS rats received asiatic acid ($p<0.05$). Moreover, asiatic acid exhibited antioxidant properties by markedly reducing oxidative stress markers in vascular tissues and plasma in MS rats ($p<0.05$). In conclusion, asiatic acid improved metabolic and hemodynamic changes as well as oxidative stress in HFHC diet induced MS rats.

K^+ and Cl^- channels modulate retinal blood flow *In Vivo*

M.A. Needham, T.A. Gardiner, M.K. McGahon, P. Bankhead, N. Scholfield, T.C. Curtis and G. McGeown

Centre for Vision and Vascular Science, Queen's University Belfast, Belfast, UK

Regulation of tissue blood flow is an important arteriolar function. Membrane potential in vascular smooth muscle regulates vascular tone and resistance, and is modulated by ion channel activity. This study directly tested the roles of K^+ and Cl^- channels in determmining retinal blood flow in vivo, using Hooded Lister (HL) rats (male, 320-450g). Channel blocker specificity was first established *in vitro* using electrophysiological recordings from isolated arterioles(1). Correolide (10μm), a KV1 inhibitor, blocked an A-type current and penitrem A (100nM) blocked a large conductance (BK) Ca^{2+}-activated K^+-current. Inhibition of K^+-currents using Cs^+-pipette solution and 10mM 4-aminopyridine, revealed a Ca^{2+}-activated Cl^- current (I_{ClCa}), which was blocked by 1mM disodium 4,4'-diisothiocyanatostilbene-2,2'-disulfonate (DIDS). This inhibition showed little voltage dependence, and DIDS had no effect on L-type Ca^{2+}-currents, Kv or BK currents(2). The effects of these inhibitors on retinal blood flow were then investigated *in vivo*. Rats were anaesthetised with an intraperitoneal injection of ketamine (130 mg/kg) and xylazine (17.5 mg/kg). Volumetric blood flow was assessed in arterioles in the superior retina using a confocal scanning laser ophthalmoscope (Heidelberg Engineering, Germany). Intraperitoneal injection of acridine orange was used to label leukocyte DNA and the velocity of leukocyte transit through retinal arterioles determined from sequential confocal images (8.8 frames/s). Fluorescein angiography was then used to estimate the diameter of these arterioles, allowing velocity to be converted to flow. Drug effects were assessed from recordings 15 min after intravitreal drug injection (10μl). Data was summarised (mean ± SEM; n=number of animals) and analysed using nonparametric ANOVA (Kruskal Wallis) and Dunn's *post hoc* test. In non-injected eyes, mean flow in single arterioles was 12.3 ± 0.2 nL/s (n=9). This was unchanged following injection of Hanks' solution (12.8 ± 0.3 nL/s, n=9, $P>0.05$). Injection of DIDS (estimated intraocular concentration=10mM) increased volumetric flow (15.7±0.4 nL/s, n=9, $P<0.001$), while penitrem A (1μM) and correolide (40μM), reduced flow rates (11.2±0.4 nL/s, n=11, $P<0.01$; and 11.3±0.3 nL/s, n=10, $P<0.05$, respectively). Et-1 (104nM) induced vasoconstriction and dramatically reduced flow (4.6±0.2 nL/s, n=8, $p<0.001$). This response was not affected by K^+ channel blockers ($p>0.05$ vs Et-1 alone), but was reversed by DIDS (14.71±0.272 nL/s, n=7, $p<0.001$ vs Et-

1). These results suggest that K^+ and Cl^- channels in vascular smooth modulate basal blood flow in the retina and activation of I_{ClCa} appears to be an important mechanism underpinning the vasoconstrictor actions of Et-1.

PCC375

ANG 1-7 restores no mediated dilation in response to flow in human microvessels from subjects with CAD

A.M. Beyer[1,2] and D.D. Gutterman[1]

[1]Medicine, MCW, Milwaukee, WI, USA and [2]Physiology, MCW, Milwaukee, WI, UK

Reactive oxygen species (ROS) are important modulators of vascular reactivity. Coronary artery disease (CAD) changes the mechanism of human arteriolar flow-mediated dilation (FMD) from NO to hydrogen peroxide (H2O2), a signaling ROS. Evidence suggests that mitochondrial ROS (mtROS) production and the longevity of a cell or organism are inversely related. Nuclear telomerase activity (TA), prevents cellular senescence and tissue aging, and shows a reciprocal relationship with mtROS production. Recently telomerase activity has been identified in the mitochondria where its ability to regulate. mtROS production could increase NO bioavailability, restoring vascular function.

Pro-atherosclerotic factors have been shown to inactivate telomerase [1]. Two antagonistic components of the renin angiotensin system, ANG II (pro) and ANG 1-7 (anti), have long been implicated in atherosclerosis. ANG II down-regulates telomerase activity in the endothelium, through accumulation of ROS [2]. This could explain the elevation in blood pressure seen in telomerase-deficient mice. ANG 1-7, a counter regulator to the actions of ANG II, increases NO bioavailability [3], decreases production of ROS [4], is anti-atherosclerotic and causes vasodilation [5].

Therefore, we hypothesize that ANG 1-7 operates through a mechanism involving stimulation of telomerase activity to reduce mitoROS production and restore the NO-mediated mechanism of dilation to shear in patients with CAD.

Human coronary arterioles (~200 μm) from discarded atrial and visceral adipose tissue were cannulated for videomicroscopy. Dilation to graded degrees of shear was measured in vessels constricted with endothelin-1. Pharmacological inhibition of TA (BIBR 1532; 10 μM 15-20 h) in vessels from healthy individuals shifted the mechanism of FMD from NO to H2O2 (Figure 1). In arterioles from patients with CAD, ANG 1-7 (1 nM 15-20 h) shifted the mechanism of FMD from H2O2 to NO. This effect was prevented by BIBR 1532 (Figure 2).

To evaluate if ANG 1-7 enhances telomerase expression by increasing expression, we used cultured endothelial cells (HUVECs) treated with either vehicle or ANG 1-7 (1 nM). Western blot analysis (Figure 2, right) suggests an increase in telomerase expression after ANG 1-7 treatment.

We conclude that ANG 1-7 increases telomerase activity in the vasculature, which plays a critical and acute role in modulating microvascular function.

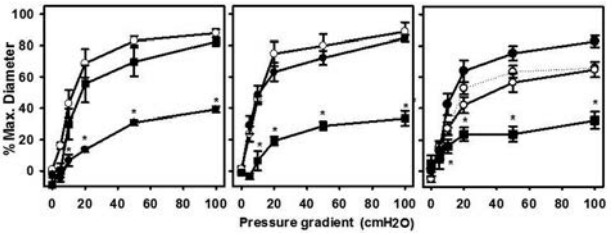

Fig 1. Inhibition of teloemrase in microvessels from healthy human subjects changes the mechanism of FMD from NO to H2O2.

Beta adrenergic overstimulation modulated vascular contractility via disorganization of actin-cytoskeleton in rabbit cerebral artery

H. Kim, K. Ko, B. Rhee, S. Lee, N. Kim, J. Youm and J. Han

National Research Laboratory for Mitochondrial Signaling, Department of Physiology, College of Medicine, Cardiovascular and Metabolic Disease Center, Inje University, Busan, Republic of Korea

Background and Purpose
Beta adrenergic overstimulation may increase the vascular damage and stroke. However, the underlying mechanisms of beta adrenergic overstimulation in cerebrovascular dysfunctions are not well known. We investigated the possible cerebrovascular dysfunction response to isoproterenol induced beta-adrenergic overstimulation (ISO) in rabbit cerebral arteries (CAs).
Methods
ISO was induced in six weeks aged male New Zealand white rabbit (0.8-1.0 kg) by 7-days isoproterenol injection (300 μg/kg/day). We investigated the alteration of protein expression in ISO treated CAs using 2DE proteomics and western blot analysis. Systemic properties of 2DE proteomics result were analyzed using bioinformatics software. ROS generation and following DNA damage were assessed to evaluate deteriorative effect of ISO on CAs. Intracellular Ca2+ level change and vascular contractile response to vasoactive drug, angiotensin II (Ang II), were assessed to evaluate functional alteration of ISO treated CAs. Ang II-induced ROS generation was assessed to evaluated involvement of ROS generation in CA contractility.
Results
Proteomic analysis revealed remarkably decreased expression of cytoskeleton organizing proteins (e.g. actin related protein 1A and 2, α-actin, capping protein Z beta, and vimentin) and anti-oxidative stress proteins (e.g. heat shock protein 9A and stress-induced-phosphoprotein 1) in ISO-CAs. As a cause of dysregulation of actin-cytoskeleton organization, we found decreased level of RhoA and ROCK1, which are major regulators of actin-cytoskeleton organization. As functional consequences of proteomic alteration, we found the decreased transient Ca2+ efflux and constriction response to angiotensin II and high K+ in ISO-CAs. ISO also increased basal ROS generation and induced oxidative damage in CA; however, it decreased the Ang II-induced ROS generation rate.
These results indicate that ISO disrupted actin cytoskeleton proteome network through down-regulation of RhoA/ROCK1 proteins and increased oxidative damage, which consequently led to contractile dysfunction in CA.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Atherosclerosis differentially affects Ca^{2+} signalling in endothelial cells from aortic arch and thoracic aorta in Apolipoprotein E knockout mice

C. Prendergast, J. Quayle, T. Burdyga and S. Wray

Cellular & Molecular Physiology, University of Liverpool, Liverpool, UK

Apolipoprotein-E knockout ($ApoE^{-/-}$) mice develop hypercholesterolemia and are a good model of atherosclerosis. Changes in Ca^{2+} are vital to the function of endothelial cells within vessels, but understanding of how atherosclerosis changes these signals, especially early in the disease, is limited. We have examined the effect of hypercholesterolemia on carbachol-mediated Ca^{2+} signals in aortic endothelial cells from wild-type (WT) and $ApoE^{-/-}$ mice of different ages; 10 weeks, before overt plaques are present and 24 weeks, where plaques are well established. The extent of plaque development was confirmed using en face staining with Sudan IV. Using confocal microscopy (Fluo-4-AM loading) allowed us to distinguish clearly the Ca^{2+} signals emanating from the endothelial cells alone, with the endothelium:smooth muscle interface intact. In addition, we compared the CCh response in thoracic aorta and in the more plaque-prone aortic arch. Three parameters of the Ca^{2+} responses were measured; the size of the initial Ca^{2+} peak, the size of the secondary plateau phase and area under the curve (AUC). Significance was assessed using the Students t-test.
All aortae from older $ApoE^{-/-}$ mice exhibited clear atherosclerotic plaques (n=9), whereas aortae from 10 week old $ApoE^{-/-}$ mice showed either no plaque or barely visible tiny areas indicating where plaques would later form (n=10). No WT mice exhibited atherosclerotic plaques in the aorta (n=5-10). In all tissues, CCh produced a concentration-dependent increase in all 3 parameters of the intracellular Ca^{2+} response. The aortic arch is more prone to development of atherosclerotic plaques than the thoracic aorta and it is this region in $ApoE^{-/-}$ mice that demonstrated the greatest alteration in CCh-mediated Ca^{2+} signalling. Thus, in aortic arch from 24 week old $ApoE^{-/-}$ mice, a significantly increased Ca^{2+} response was seen to all CCh concentrations (0.3-10μM) compared to WT, measured as peak, plateau or AUC responses (n=4-6 mice). In aortic arch from 10 week olds, the dose-response curves for peak Ca^{2+} were identical in WT and $ApoE^{-/-}$, however for the plateau and AUC responses, again a larger Ca^{2+} response was observed in the $ApoE^{-/-}$ mice, though this time the difference was seen at lower concentrations (1 & 3μM, n=4-5 mice). In thoracic aorta from young and older mice, a significant difference was only seen between WT and $ApoE^{-/-}$ responses at the highest concentrations of CCh, with the $ApoE^{-/-}$ mice showing a greater peak, plateau and AUC response to 10μM CCh. Therefore there was no age-dependent alteration in response in thoracic aorta.
It appears that hypercholesterolemia alone is enough to modify the CCh response in both thoracic and arch sections of $ApoE^{-/-}$ aortae, though the presence of atherosclerotic plaques causes a much more significant change in Ca^{2+} signalling.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

GABAergic regulation of arteriolar tone in the rat retina

K. Hinds[1], K.P. Monaghan[1], B. Frølund[2], G. McGeown[1] and T. Curtis[1]

[1]Centre for Vision and Vascular Science, Queen's University of Belfast, Belfast, UK and [2]Department of Medicinal Chemistry, University of Copenhagen, Copenhagen, Denmark

Although the neurophysiological and neurotrophic actions of GABA in the retina are well-recognised, less is known about the role of GABA in the regulation of the retinal microcirculation. In the present study, we have examined the actions of GABA on retinal arterioles of the rat retina using *ex vivo* retinal whole mount preparations and isolated vessel segments. All animal experiments conformed to the UK Animals (Scientific Procedures) Act (1986). We began by examining the effects of GABA on arterioles pre-constricted with Et-1 (10nM) in retinal whole mounts. Application of 100μM GABA evoked vasodilation in 39% of vessels, vasoconstriction in 8%, and no response in the remaining 53% of vessels. When the concentration of GABA was increased to 1mM, a larger percentage of vessels responded, with 59% displaying vasodilation, 18% vasoconstriction and 23% no response. 1mM GABA was found to have no effect on the diameter of isolated vessels pre constricted with 10nM Et-1. In whole-mounts, muscimol (10μM), a $GABA_A$ receptor agonist, caused vasodilation in 6% of vessels, vasoconstriction in 6% and no response in the remaining 88% of vessels. In contrast, arteriolar responses to $GABA_B$ receptor agonists more closely resembled those observed with 1mM GABA. Baclofen (100μM) elicited vasodilation in 50% of vessels, while the remaining 50% exhibited no response. Application of SKF97541 (100μM) induced vasodilation in 39% of vessels, vasoconstriction in 8%, and no response in the remaining 53%. The selective $GABA_C$ receptor agonist, 5-methyl-imidazole-4-acetate (100μM), failed to evoke a vasomotor response in any vessels tested. Following pre-incubation of the whole-mount preparations with the $GABA_A$ receptor inhibitor, bicuculline (100μM), 70% of vessels that had previously exhibited a vasodilator reaction to 1mM GABA displayed a second, similar-sized response. In the presence of the $GABA_B$ receptor antagonist, 2-hydroxysaclofen (100μM), all vessels that had previously been responsive to GABA failed to exhibit a vasodilator response. Bicuculline or 2-hydroxysaclofen was subsequently applied to retinal whole-mount preparations where the arterioles had not been pre-constricted with Et-1. Bicuculline caused vasoconstriction in 1 out 20 arterioles, whilst 2-hydroxysaclofen induced vasoconstriction in 4 out 31 arterioles. Our data demonstrate that GABA can exert a dual effect on arteriolar tone in the rat retina, inducing either vasoconstriction or vasodilation. These reactions are entirely dependent upon the presence of the adjacent retinal neuropile and appear largely dependent upon the activation of $GABA_B$ receptors. Despite these findings, we find little evidence to suggest that endogenous GABA makes a significant contribution to the regulation of basal vascular tone in the rat retina at least under the *ex vivo* conditions used in our experiments.

3D imaging of renal glycocalyx by scanning electron microscopy with focused ion beam milling

K.P. Arkill[1], C.R. Neal[2], D.O. Bates[2], J.M. Squire[2] and K. Qvortrup[3]

[1]Physics and Astronomy, University of Birmingham, Birmingham, UK, [2]MVRL, Physiology and Pharmacology, University of Bristol, Birmingham, UK and [3]CFIM, Medical Sciences, University of Copenhagen, Copenhagen, Denmark

The glomerulus is the primary filtration unit of the kidney. It is a bundle of capillaries approximately 130μm in the Rat. The filtration barrier is a specialised capillary wall of which it is believed the glycocalyx layer forms a molecular filter for large proteins. The permeability and hydraulic conductivity of the glycocalyx depends on many factors including thickness, fibre spacing, fibre organisation, and completeness of coverage. Robust structural imaging of the glycocalyx has proved non-trivial, in part due to pairing physiological variables with micrographs.

Presented here is the use of Scanning Electron Microscopy paired with Focused Ion Beam Milling (FIB-SEM) to image glomerular and peritubular glycocalyx. The tissue was harvested from a left-ventricle, oncotically balanced, perfusion fixed rat (after an injected lethal dose of 0.7 mL/kg sodium pentobarbitone). In addition to standard fixation, Lanthanum Dysprosium Glycosaminoglycan adhesion (LaDy GAGa), was added to show the endothelial glycocalyx. Sections of tissue were prepared as blocks for standard transmission electron microscopy (TEM). A section was cut from a block and imaged with TEM (Phillips 100) to use as a map. The remaining block was trimmed and coated with gold for FIB-SEM. FIB-SEM imaging was performed with a Quanta 3D (FEI) with a backscatter detector (vC-BS-ED, FEI) using an accelerating voltage of 2kV. Once an area of interest is identified then the block is tilted to 52 degrees and trenches milled with a focued ion beam (Ga) either side, a 1μm layer of Pt is put on along the expected cutting depth. Serial sections were then imaged by SEM after a 10nm layer is removed by the Ga Beam.

The FIB-SEM showed the capillary wall effectively over a 4μm*4μm*3μm sample volume. Estimated imaging resolution was 25nm. The serial sections were aligned and corrected for tilt angle (FIJI,NIH). Within the XYZ volume, slit diaphragms, foot processes and fenestrations were clearly visible. The glycocalyx thickness and location could be measured but not fibre spacing. The glycocalyx appeared similar in the peritubular capillaries and in the glomerulus, though it was not stained in all vessels. The peritubular capillaries had more glycocalyx contrast. The glycocalyx was not evenly stained, there were tufts of taller regions, as well as areas of little or no coverage, including the appearance of gaps, possibly related to the underlying fenestrations.

In conclusion though compared to electron tomography the resolution is not as high, FIB-SEM has a much greater sample volume, giving it a useful niche in the technical armory to investigate physiological understanding of glycocalyx.

Analysis of the expression of myosin phosphatase targeting subunit splice variants in human smooth muscles

J. Lartey, M. Sweeney, J. Taggart, S.C. Robson, H. Wessel and M.J. Taggart

Institute of Cellular Medicine, Newcastle University, Newcastle Upon Tyne, UK

Myosin phosphatase is a trimeric protein that regulates vascular tone by inducing dephosphorylation of smooth muscle regulatory myosin light chains. The 110-130 kDa myosin phosphatase targeting subunit (MPYT) is essential for this process. Nitric oxide- mediated arterial relaxation has been suggested to occur partly via PKG interactions with a leucine zipper (LZ) region of MYPT1 that is generated by alternative exon splicing of the 3' end of the gene [1]. The relative expression of MYPT1 LZ+ to LZ- isovariants may thus influence arterial sensitivity to endothelial-mediated vasodilators and/or NO donors. Interestingly, the sensitivity of isolated human myometrial arteries to endothelial-mediated vasodilators is greater than that of placental arteries from pregnant women (2). In addition, non-vascular uterine smooth muscle shows variable responsiveness to NO donors. We propose that tissue-specific differences in human MYPT1LZ+ to LZ- isovariant expression, not previously assessed in human tissues, may offer an explanation for these findings.

Human tissue samples were obtained, following written informed consent, from normal pregnant women undergoing elective Caesarean section at term. Myometrium, myometrial arteries (MA) and placental arteries (PA) were microdissected free of all surrounding tissue. The human MYPT1LZ+ sequence (NM_002480.1) was aligned with chicken (NM_205123) and mouse (NM_027892) MYPT1LZ- sequences to detect a shift in the reading frame that generates the putative human MYPT1LZ- sequence. RNA was isolated (Qiagen RNeasy fibrous kit) and reverse transcribed (Stratagene AffinityScript cDNA synthesis Kit) from the human tissues and qPCR, with isovariant-specific primers and PerfectProbe amplification (Primer Design, UK), used to measure MYPT1LZ+ and MYPT1LZ- isovariant expression. Human smooth muscle RNA (Clonetech, USA) was used as an internal calibrator.

MYPT1LZ+ expression was less in the myometrium (fold-change relative to calibrator RNA of 0.33+0.04) than MA (1.33+0.12) and PA (2.07+0.17; $p<0.01$, n=10, mean+SEM, ANOVA). A similar pattern was seen for MYPT1LZ- expression wherein changes relative to calibrator were 0.06+0.17 (myometrium), 0.45+0.05 (MA) and 0.65+0.07 (PA). This reveals differences in MYPT1LZ+ and MYPT1LZ- expression between human myometrium, MA and PA. Of note, the ratio of MYPT1LZ+ to LZ- expression in MA was not greater than in PA. As the former is more sensitive to endothelial-dependent relaxant agonists, this suggests that a correlation between MYPT1LZ+ expression and physiological sensitivity to PKG and/or NO stimulation in these human tissues may be an over-simplification. Further research is required, however, to determine such a relationship in relevant clinical conditions of heightened smooth muscle tone.

Ex-vivo expansion of human endothelial progenitor cells leads to cellular senescence

R. Medina[1], C. O'Neill[1], S. Chambers[1], J. Guduric-Fuchs[1], E. Reid[1], J. Neisen[2], D. Waugh[2], D. Simpson[1] and A. Stitt[1]

Endothelial progenitor cells (EPCs) play a reparative role during vascular regeneration in ischemic pathologies such as myocardial infarction, stroke, peripheral vascular disease, and ischemic retinopathies. For autologous therapy, EPCs need to be expanded in vitro in order to obtain sufficient numbers for therapy. Many EPC sub-classes have been described and this creates confusion surrounding EPC nomenclature. For this study, we have concentrated on the subpopulation known as Outgrowth endothelial cells (OECs) because these EPCs have unequivocal endothelial phenotype and significant proliferative potential. Here, we examined implications that this long term in vitro expansion step has on human OEC biology.

OECs were isolated from human peripheral and umbilical cord blood and expanded in culture until they reached their Hayflick limit. Cellular senescence was characterised by growth curves, cell cycle analysis, senescence-associated beta-galactosidase evaluation and DNA damage quantification. Furthermore, changes in gene/protein expression associated with OEC senescence were assessed by transcriptome, proteome and secretome analysis. OEC function was evaluated in vitro by migration and tubulogenesis assays. The therapeutic potential of

senescent OECs was evaluated in vivo using a mouse model of ischaemic retinopathy.
Proliferation capacity in late passage-OEC diminished significantly, with more than 70% of cells arrested in G0/G1 phase of the cell cycle. These late passage-OECs displayed a significant increase in cytoplasmic volume, increased β-galactosidase activity and accumulated γ-H2AX foci ($p<0.001$). There was also a significant decrease in telomerase activity coupled with telomere shortening. Senescent OECs demonstrated impaired migratory and tubulogenic capacity compared to early-passage OECs ($p<0.001$). Inflammatory signalling pathways were identified as major components of the OEC senescence programme by transcriptome analysis. IL8 was found significantly upregulated on the secretome of senescent OECs. shRNA mediated knock-down of IL8 in OECs significantly extended ex-vivo lifespan, delayed senescence and enhanced cellular function. Using the in-vivo animal model of ischaemic retinopathy, both early and late-passage OECs significantly reduced retinal avascular area compared to vehicle treated eyes ($p<0.001$). However, senescent OECs showed reduced ability to integrate into the retinal vasculature compared to early-passage OECs. Furthermore, only early-passage OECs significantly reduced the area of pathological pre-retinal neovascularisation ($p<0.001$).
Ex-vivo expansion of human OECs ultimately leads to replicative senescence linked to cellular dysfunction in vitro and in vivo. Modulation of OEC senescence is an important strategy to improve reparative potential and usage as an autologous cell therapy.

Endothelial progenitor cell-derived extracellular vesicles as a vehicle for microRNA delivery to endothelial cells

J. Guduric-Fuchs, A. O'Connor, R.J. Medina, C.L. O'Neill, A.W. Stitt and D.A. Simpson

Centre for Vision and Vascular Science, Queen's University Belfast, Belfast, UK

Extracellular vesicles (EVs) released from various cell types can mediate paracrine signalling and control important pathophysiological responses. MicroRNAs transferred within EVs represent one of the main mechanisms by which they influence the recipient cells. Circulating endothelial progenitor cells (EPCs) release EVs that are readily taken up by endothelial cells. We hypothesized that EPC derived EVs can be manipulated to deliver specific microRNAs to endothelial cells and thereby modulate their angiogenic response.
Human EPCs isolated from the umbilical cord blood displayed endothelial imunophenotype, being positive for CD31, CD146 and CD105 and negative for haemathopoetic markers CD45 and CD14. EVs were collected by ultracentrifugation of the EPC conditioned media. To identify microRNAs exported from EPCs, the small RNA contents of EPCs and their EVs were analyzed by deep sequencing. Several miRNAs were highly enriched in EVs compared to their expression levels in EPCs and there was remarkable consistency in miRNA expression in the cultures from different donors. EVs were then isolated from EPCs transfected with several vectors driving the expression of microRNAs, including miR-146a, and miR-451. Enrichment of these microRNAs in EPC EVs was demonstrated by RT-qPCR. Following direct transfection of human microvascular endothelilal cells (HMEC) with plasmid vectors driving the expression of miR-146a, downregulation of specific miR-146a predicted target genes such as CCND2, ELAVL1 and CRIM1, was revealed by microarray. When HMECs were incubated with miR-146a enriched EPC derived EVs, these EVs were taken up by HMECs, resulting in the reduced mRNA expression of the same miR-146a targets.
We show that the content of EPC released EVs can be manipulated to include significant amounts of exogenous miRNAs, which can be taken up by endothelial cells. The ability of EVs to carry anti- or pro-angiogenic microRNAs can be exploited to modulate angiogenesis in various models and may have therapeutic applications in multiple disease conditions associated with abnormal angiogenesis.

M13 filamentous phage as a potential system for improved wall shear stress measurement

K.P. Arkill[1], R. Pacheco-Gomez[2], F. Gower[2], T.J. Proctor[2], I. Hands-Portman[3], M.R. Hicks[2], S.K. Sandhu[2], M.J. Simmons[4] and T.R. Dafforn[2]

[1]Physics and Astronomy, University of Birmingham, Birmingham, UK, [2]Biosciences, University of Birmingham, Birmingham, UK, [3]Life Sciences, University of Warwick, Coventry, UK and [4]Chemical Engineering, University of Birmingham, Birmingham, UK

Suitable wall shear stress (WSS) measurements are important due to the wall being the point of many chemical interactions. This applies particularly to the vascular system where WSS is known to affect endothelial surface reactions. Measuring the near WSS is particularly difficult in the circulation, even with bulk flow approximations, due to the particulate nature of blood and the 3-dimensional nature of the system.
Here a novel methodology using the M13 filamentous bacteriophage virus (BPV) is presented as a possible solution to this problem. The BPV is a 1μm long cylinder but with a diameter of around 7nm. In this case, the BPVs are cultured by incubation with *E. coli* and separated with polyethylene glycol, then purified using a caesium chloride gradient, has been fluorescently tagged along its length using fluorescein Isothiocyanate (FITC) or tetramethylrhodamine-6-isothiocyanate (TRITC, Invitrogen). The BPV has 2700 possible binding sites for FITC or TRITC and so is trivial to detect in a fluorescent wide-field microscope even with as little as 5% binding efficiently. Free dye was removed with a salt trap (PD10, GE Healthcare) or dialysis. Linear dichroism was used to determine alignment with shear rate in bulk solution.
Additionally anti-collagen IV antibody was attached using a maleimide-cysteine reaction to one end of the BPVs prior to TRITC binding. This would enable the BPV to bind from one end to collagen coated glass flow sides and the other to align along the flow direction. Preliminary analysis and results are presented.
Optical and Electron microscopy were used to observe the additional affect of the TRITC- BPVs to form longer nano-rope,

assemblies more suited to low resolution visualisation techniques (Figure 1).
In conclusion suitably bound fluorescent BPVs has the potential to detect wall shear direction suitable for microfluidic devices and the circulation including 3D capillary beds such as the glomerulus.

The influence of tumour aldehyde dehydrogenase activity on prostate cancer cell metastatic potential and interaction with the bone endothelium *in vivo*

K.J. Reeves[1], G. van der Pluijm[3], M.G. Cecchini[4], C.L. Eaton[2], F.C. Hamdy[5] and N.J. Brown[1]

[1]Oncology, University of Sheffield, Sheffield, UK, [2]Human Metabolism, University of Sheffield, Sheffield, S Yorks, UK, [3]Urology, Leiden University Medical Centre, Leiden, Netherlands, [4]Urology Research Laboratory, University of Bern, Bern, Switzerland and [5]Urology and Oncology, University of Oxford, Oxford, UK

Cancer metastasis to the skeleton is the cause of significant morbity and mortality in prostate cancer patients. Despite its prevalence, the mechanisms involved in the development of bone metastases remain unclear. A metastatic initiating cell (MIC) phenotype CD44+/CD24- has been identified in prostate cancer, but a complementary approach to aid MIC cell recognition, involves detection of aldehyde dehydrogenase (ALDH) activity. This study characterises the proliferative and invasive functional behaviour of prostate cancer (PC-3) cell ALDH subpopulations *in vitro*. We also used a new *in vivo* model developed by our laboratory, to study bone micrometastasis and interaction with the bone marrow endothelial cells.
A metatarsal from a newborn mouse (1-3 day old) was engrafted into a Dorsal Skinfold Chamber (DSC) implanted on a severe combined immunodeficient (SCID) mouse (5-6 weeks old) under systemic ketamine/xylazine anaesthesia. PC3 labelled with red fluorescent protein (RFP) cells were sorted into $ALDH^{high}$ (7%) and $ALDH^{low}$ (20%) cell-subpopulations using the ALDEFLUORkit and flow cytometry. The subpopulations ($1x10^5$ cells) were administered via intra-cardiac injection into groups of animals (n=10). An additional group was used to evaluate the homing response of $ALDH^{high}$ cells treated with weekly zoledronic acid for 4 weeks (zol; intraperitoneal, 25μg/kg/injection; 100μg/kg total). Microscopy recordings of the chamber tissue and bone-graft were made at 48hr intervals for up to 4 weeks. At the end of the study, tissue was harvested and processed for microCT, multi-photon analysis, histology and immunohistochemistry. ALDH subpopulation cell proliferation, migration and invasion were investigated via functional in vitro assays.
$ALDH^{high}$ cells home to bone and interact with the bone microvascular endothelium in significantly higher numbers than $ALDH^{low}$ cells (Day 15: mean ± SEM; $ALDH^{high}$ 12.3±1.8 cells vs. $ALDH^{low}$ 1.9±0.5 cells; $p<0.05$). Treatment with zol does not influence $ALDH^{high}$ PC3 cells homing to bone and intereacting with the microvascular endothelium and bone microenvironment *in vivo*. PC3-$ALDH^{high}$ cells display increased proliferation, migration and invasion ability *in vitro*.
In summary PC3-$ALDH^{high}$ exhibit functional characteristics associated with enhanced metastatic potential i*n vitro*, with increased homing to and interaction with the bone microvasculature and metastatic-niche *in vivo*, which appear resistant to a standard current treatment regime.

$VEGF_{165}b$ confers protection in early diabetic nephropathy

Y. Qiu[1], S. Oltean[1], J.K. Ferguson[1], C. Neal[1], K. Harris[1], K.P. Arkill[1], C.F. Symonds[1], A. Russell[1], M. Stevens[1], C. Alsop[1], S.C. Satchell[2], S.J. Harper[1], D.O. Bates[1] and A.H. Salmon[1,2]

[1]MicroVascular Research Laboratories, University of Bristol, Bristol, UK and [2]Academic Renal Unit, University of Bristol, Bristol, UK

Diabetic nephropathy is the UK's leading cause of end-stage renal failure. Levels of Vascular Endothelial Growth Factor (VEGF), produced by podocytes and required for normal glomerular function, are frequently abnormal in diabetic nephropathy. Multiple splice variants of VEGF, including the traditional "$VEGF_{165}$" and opposing "$VEGF_{165}b$" forms, exist in the kidney. $VEGF_{165}$ overexpression accelerates diabetic nephropathy. We therefore investigated whether $VEGF_{165}b$ reduces albuminuria in rodent diabetic nephropathy models and modifies glomerular permeability in human kidneys. C57Bl/6 mice overexpressing human $VEGF_{165}b$ in podocytes (nephrin promoter: *neph*$VEGF_{165}b$), or wild-type littermates (WT), were rendered diabetic with 100mg/kg Streptozocin (STZ) i.p. daily for 3 days. As compared with diabetic-WT mice, diabetic *neph*$VEGF_{165}b$ mice had less albuminuria (68% reduction). Diabetes was also induced in DBA2J mice with 5 days of STZ (50mg/kg i.p.). After 2 weeks of hyperglycemia (>20mmol/L), mice received saline or 1μg $VEGF_{165}b$ injections i.p. bi-weekly for 6 weeks. Albumin-creatinine ratio (ACR) increased to 4.6-fold above baseline at 6 weeks in the sham-treated group, but only to 1.2-fold in the $VEGF_{165}b$-treated group. In db/db mice, bi-weekly intraperitoneal injections of $VEGF_{165}b$ for 8 weeks decreased albuminuria ($p<0.05$, two-way ANOVA), but did not alter GFR ($p>0.05$, one-way ANOVA). In diabetic mice, substantial upregulation of total and phosphorylated forms of VEGF receptor 2 (VEGFR2) (both 5.1-fold increase) was noted in glomeruli in response to systemic injections of $VEGF_{165}b$. To test whether diabetic glomerular func-

tion can be improved through direct modulation of the capillary wall, single glomeruli were isolated from untransplantable kidneys from diabetic and non-diabetic donors and corrected ultrafiltration coefficient (*LpA/Vi*, $min^{-1}.mmHg^{-1}$) was measured. *LpA/Vi* of human glomeruli from diabetic donors {2.3±0.4 (16/3)} was higher than *LpA/Vi* from non-diabetic donors {1.0±0.1 (25/3)} ($p<0.001$, unpaired t-test). Treatment with 1nM $VEGF_{165}b$ (1hr) restored *LpA/Vi* to normal in diabetic human glomeruli {1.0±0.2 (13/3)} ($p<0.001$, one-way ANOVA). $VEGF_{165}b$ appears to modify *LpA/Vi* of diabetic glomeruli via activation of VEGFR2, since the actions of $VEGF_{165}b$ on STZ-diabetic rat glomeruli were prevented by the VEGFR2-blocker ZM323881 (diabetes: 1.4±0.1; diabetes+$VEGF_{165}b$: 0.8±0.1*; diabetes+$VEGF_{165}b$+ZM323881: 1.3±0.2; *$p<0.05$, one-way ANOVA}. We have demonstrated that increasing $VEGF_{165}b$ levels locally (through podocyte-specific overexpression) and systemically (via repeated intraperitoneal injections), in both type 1 and type 2 diabetes, effectively reduces the functional features of early diabetic nephropathy and $VEGF_{165}b$ effect is through activation of VEGFR2. Our study suggests the potential of using $VEGF_{165}b$ as a therapeutic agent to slow the progression of diabetic nephropathy.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC387

Senescence-induced remodelling in large and small arteries of mice: impact of high-fat diet

F. Jiménez-Altayó[1], A.P. Dantas[2], Y. Onetti[1], M.A. Oliveira[3], M.H. Carvalho[3] and E. Vila[1]

[1]Departament de Farmacologia, Terapèutica i Toxicologia, Universitat Autònoma de Barcelona, Bellaterra (Cerdanyola del Vallès), Spain, [2]Institut Clínic del Tòrax, Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain and [3]Department of Pharmacology, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil

Aging and weight gain are independent cardiovascular risk factors, which have shown to be increasingly associated. We hypothesize that high-fat intake could lead to arterial remodelling similar to that promoted by vascular aging and worsen the remodelling exerted by senescence. For this purpose we analysed structure of large (aorta) and small (mesenteric artery, MA) arteries from senescence accelerated mice (SAM) following a Western-type diet (WD; 21 % fat). Five-month-old SAM prone (SAMP8) and resistant (SAMR1) female mice were fed a WD for 8 weeks. At 7 months of age, aortas and MAs were dissected. In aorta, vascular structure and mature or newly synthesized collagen was analysed by morphometric analysis of haematoxylin and eosin-stained cross sections and picrosirius red, respectively. In MA, vascular structure, collagen I/III protein and mRNA expression, and nuclei distribution was evaluated by pressure myography, immunofluorescence, RT-qPCR and confocal microscopy, respectively. Values are means ± S.E.M. compared by two way ANOVA with Bonferroni's post-test. On normal chow, weight gain, abdominal fat and cholesterol levels were comparable between strains and similarly increased after WD (Jiménez-Altayó *et al.*, 2012). In aorta, wall thickness (WT), but not cross sectional area (CSA), was increased by senescence (SAMR1: 171.3±4.8 μm, n=7; SAMP8: 194.6±6.1 μm, n=8, $p<0.05$). WD only modified aortic structure in SAMR1 (control: 171.3±4.8 μm, n=7; WD: 209.8±10.0 μm, n=7, $p<0.01$) paralleled by an increase in mature (n=11) and newly synthesized (n=9) collagen. In MAs, senescence did not alter the wall/lumen ratio but diminished ($p<0.05$) the CSA and WT in association with reduced number of adventitial (SAMR1: 2339±194, n=6; SAMP8: 1145±81, n=3, $p<0.01$) and smooth muscle (SAMR1: 3535±213, n=6; SAMP8l: 2613±68, n=3, $p<0.05$) cells per mm^3. WD decreased MA CSA ($p<0.01$), WT ($p<0.001$) and wall/lumen ratio ($p<0.05$) in SAMR1 paralleled by diminished adventitial (control: 2339±194, n=6; WD: 1393±269, n=6, $p<0.05$) and smooth muscle (control: 3535±213, n=6; WD: 2314±230, n=6, $p<0.01$) cells per mm^3. Nevertheless, WD intake in SAMP8 did not further modify MA structure. Collagen I/III protein (n=4-6) and mRNA expression (n=4-6) was unaltered by senescence or diet. Therefore, senescence induces qualitatively different remodelling in large and small arteries of mice. High-fat intake promotes remodelling in non-senescent mice consistent with accelerated senescence, whereas the vasculature of senescent mice does not display any further alteration. In both cases, arterial remodelling may exacerbate vascular injury.

Vascular activity and endothelial cell toxicity of metal organic frameworks

C.J. Kelsall[1], L.J. McCormick[3], M.K. Doherty[2], P.D. Whitfield[2], R.E. Morris[3] and I.L. Megson[1]

[1]Diabetes and Cardiovascular Science, University of Highlands & Islands, Inverness, UK, [2]Lipidomics, University of Highlands and Islands, Inverness, UK and [3]School of Chemistry, University of St Andrews, St Andrews, UK

Nitric oxide (NO) donors are agents that release NO by chemical reaction, either spontaneously or under specific biophysical conditions. NO donors have been widely used in a variety of clinical situations, with mixed success [1]. Alternatively, metal organic frameworks (MOFs) have potential to provide targeted, flexible applications in gasotransmitter delivery. Here, we describe bioactive properties of two designs of MOF loaded with NO.

MOFs derived from 2,5-dihydroxyterephthalic acid and nickel (Ni_2(dhtp)) or magnesium (Mg_2(dhtp)) were prepared and pressed into 20 mg discs containing 10wt% Teflon. The discs were dehydrated under vacuum at high temperature, cooled and exposed to an atmosphere of NO. Once loaded, MOF discs were stored individually under argon until use. Unloaded discs were also prepared to act as controls. . Previous studies revealed the gas is rapidly released from the discs upon exposure to an aqueous environment at 37°C [2]. Pig hearts were obtained from an abattoir and in vitro coronary artery endothelial function (relaxation to bradykinin; BK, 0.1 nM – 10 μM) was measured in arteries by myography. Segments lacking reactivity to BK following removal of the endothelium were then exposed for 10 minutes to NO-loaded MOFs Ni_2(dhtp) or Mg_2(dhtp). In separate experiments, human umbilical vein endothelial cells (HUVEC), passage 1 to 3, were exposed for 1, 6, 24 or 72h to medium conditioned for 1h in the presence of unloaded Ni_2(dhtp) and Mg_2(dhtp) MOFs to assess toxicity

by MTT assay. Data are presented as mean ± SEM; statistical analysis was by *t*-test or 2-way ANOVA with *post hoc* analysis, as appropriate.

Endothelium-denuded pig coronary arteries constricted with 0.1 μM U46619, a thromboxane mimetic, showed significantly greater relaxation in the presence of NO-loaded Ni_2(dhtp) compared to Mg_2(dhtp) MOFs (59.1±9.4%, *n*=5 vs 9.5±3.5%, *n*=3; *p* 0.004). Unloaded MOFs induced no vascular reactivity (data not shown). Colourimetric analysis of mitochondrial activity (MTT assay) in HUVECs showed significantly greater toxicity of Ni_2(dhtp) than Mg_2(dhtp) MOF-conditioned medium at all time-points except 1h (fig 1).

The data indicate that capacity for storage and release of NO is much greater in MOFs which use Ni^{2+} as the core metal ion rather than Mg^{2+}, but the greater performance in releasing biologically relevant amounts of NO is, in this case, offset by an increased risk of toxicity to endothelial cells. Use of the Ni_2(dhtp) MOF design for delivery of gasotransmitters in pathophysiological settings should be restricted to procedures which do not involve chronic exposure of endothelium. Other more sensitive bioassays are required to fully assess the potential of Mg_2(dhtp) MOFs.

VEGF signalling is required for arteriolarisation resulting from a combination of shear stress and Ang1

O.A. Stone and D.O. Bates

Microvascular Research Laboratories, Univ Bristol, Bristol, UK

The generation of arterioles (arteriolargenesis) from capillaries in response to shear stress requires members of the vascular endothelial growth factor (VEGF) and Angiopoietin (Ang) families of growth factors. While Ang1 is known to be involved in pericyte recruitment and VEGF in endothelial growth, how these two signaling pathways interact during cell recruitment to the vessel wall during flow is not clear. To test the hypothesis that both Ang1 and VEGF are required for functional remodelling (generation of arterioles from capillaries as well as new pericyte covered capillaries), we used adenovirus-mediated over-expression of eNOS, Ang1, and the VEGF inhibitor sFlt1, in the fluothane anaesthetised (3-5% in 75%O2) adult rat mesentery after laparotomy as a model of blood flow dependent vascular remodeling. Blood flow and angiogenesis /arteriolargenesis were assessed by intravital and confocal microscopy respectively. The effects of VEGF inhibition and Ang1 inhibition were investigated using Ad-Flt1 and Ad-sTie2 respectively. Ang1+eNOS increased angiogenesis (vascular area 43±3% of mesenetery, p<0.01) compared with eNOS alone (30±1%), and this was inhibited by sFlt1 (33±2%). However, the Ang1 induced increase in pericyte coverage (50±1% vessel coverage compared with 27±2% without Ang1) was enhanced, not inhibited by sFlt1 (65±2%). This was accompanied by an inhibition of the Ang1 induced smooth msucle cell coverage (from 8.6±1.3% to 0%, p<0.01). Thus, in this setting, inhibition of endogenous VEGF signaling impaired VSMC recruitment, but enhanced pericyte coverage. Thus, while VEGF signaling inhibits pericyte recruitment, it is required for VSMC recruitment.

These results indicate that the de novo formation of a functional, mature vasculature, with VSMC-containing arterioles requires tight control of endogenous VEGF and exogenous Angiopoietin signaling. Therapeutic vascular remodeling paradigms may therefore require treatments that activate endogenous VEGF, in combination with exogenous Ang1, to effectively remodel the vasculature.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

The tyrosine phosphatase SHP-2 enhances angiogenic processes during hypoxia by HIF-1α stabilisation

H. Mannell[1], Y. Stampnik[1], J. Pircher[1], K. Zimmermann[2], U. Pohl[1] and F. Krötz[3]

[1]Walter-Brendel Centre of Experimental Medicine, Ludwig-Maximilians-University, Munich, Germany, [2]Institute of Pharmacology and Toxicology, Bonn University, Bonn, Germany and [3]Interventional Cardiology, Starnberg Community Hospital, Munich, Germany

Question: The tyrosine phosphatase SHP-2 plays an important role in growth factor signalling. We previously demonstrated its importance for growth factor dependent angiogenesis. Here we studied whether SHP-2 influences endothelial cell proliferation, vessel sprouting and HIF-1α signalling upon hypoxia.

Methods: Overexpression of wild type (SHP-2 WT), catalytically inactive (SHP-2 CS) or constitutively active (SHP-2 E76A) SHP-2 in human microvascular endothelial cells (HMEC) was achieved by lentiviral transduction. Vessel sprouting was assessed by the aortic ring assay. Cells and isolated aortae were exposed to hypoxia (95 % N_2, 5% CO_2) for 4h or 24h. Proliferation was assessed by MTT reduction. HIF-1α protein levels and ERK activity (Thr/Tyr-phosphorylation) were detected by western blot. HIF-1α mRNA levels were quantified using real-time PCR.

Results: Compared to SHP-2 WT, expression of constitutively active SHP-2 enhanced proliferation during normoxia by 48±8% and hypoxia by 57±10% (both p<0.05, ANOVA, n=8). After hypoxia exposure, vessel sprouting *ex vivo* (p<0.05, ANOVA, n=5) as well as hypoxia inducible factor 1α (HIF-1α) protein levels (p<0.05, ANOVA, n=4), but not mRNA levels (n=3), were enhanced by 5-fold and 1.3-fold respectively in cells expressing constitutively active SHP-2. This was associated with an enhanced activity of the potential HIF-1α regulator MAPK ERK1/2 (n=3).The increased hypoxic proliferation was com-

pletely blocked upon HIF-1α inhibition (Echinomycin 10ng/ml, p<0.05, t-test, n=6) and also upon treatment with a MAPK-pathway inhibitor (GW5074, p<0.05, t-test, n=6).
In contrast, expression of catalytically inactive SHP-2 impaired proliferation during normoxia (p<0.05, ANOVA, n=7) and hypoxia (p<0.05, ANOVA, n=8) as well as *ex vivo* vessel sprouting after hypoxia exposure (p<0.05, n=4) compared to SHP-2 WT. In addition, hypoxic HIF-1α protein accumulation (p<0.05, ANOVA, n=4) and ERK1/2 activity (n=3) were reduced. However, the reduction in HIF-1α protein was rescued by treatment with proteasomal inhibitors (MG132 or Epoximicin, n=3).
Conclusion: In addition to being important for angiogenic processes during normoxia, SHP-2 also affects endothelial cell proliferation and vessel sprouting during hypoxic conditions. During hypoxia endothelial cell proliferation and HIF-1α protein stabilisation is further enhanced when increasing SHP-2 catalytic activity, possibly through ERK activation. Thus, controlled induction of SHP-2 catalytic activity may be therapeutically promising for angiogenesis induction in ischemic conditions.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Pulse arrival time to the capillary bed of the finger tip compared to the carotid-radial pulse transit time during and after aerobic exercise

N. Potocnik[1], A. Danieli[2,3], H. Lenasi[1] and V. Starc[1]

[1]Institute of Physiology, University of Ljubljana, Ljubljana, Slovenia, [2]Department of Neurology, University medical centre Ljubljana, Ljubljana, Slovenia and [3]Barsos Medical Centre, Ljubljana, Slovenia

Physical activity is known to have beneficial effects on prevention of cardiovascular disease and on microcirculation. The aim of our study was to compare the carotid-radial pulse transit time as a measure of small artery compliance being under strong sympathetic control and the pulse arrival time to the capillary bed of the finger tip as a measure of the state of the microvasculature in middle aged healthy subjects before, during and 20 minutes after aerobic exercise.
Experiments were performed on 11 males, 47±6 years old. The study was accordant to the Declaration of Helsinki and approved by the national Ethics Committee. We measured ECG, arterial blood pressure using Finapres Ohmeda with a finger cuff on the middle finger of the right hand, laser Doppler skin blood flow on the finger pulp of the pointer finger of the same hand and carotid or radial pulse with a tonometer (Millar SPT 30). After 5 minutes supine rest subjects mounted the cycloergometer and their right arm was fixed on an armrest. They rested in sitting position for additional 5 minutes, than they started a graded exercise at the workload of 40 W. The workload increased in steps of 50W lasting 3 minutes each until 85% of the estimated maximal heart rate was reached. After ceasing exercising, the parameters were measured for subsequent 25 minutes. Carotid-radial pulse transit time (c-rtT) and pulse arrival time to the capillary bed (PATc) using pulse arrival time to the radial artery on the same hand as a reference were calculated. RR interval duration was determined using ECG.
Our results revealed that c-rtT exhibited no statistically significant differences before and 20 minutes after exercise (100,8 ±3,1ms and 99,3 ±2,0ms), but was significantly decreased at highest workload (84,1±0,2ms). On the other hand PATc was increased 20 minutes after exercise compared to resting values (126,0 ±9,2ms and 116,7 ±5,2ms) and significantly decreased at highest workload (107,8±1,6ms). The heart rate at peak exercise was 150,2±0,9bpm, 20 minutes after exercise it remained significantly higher then at rest (82,4 ±1,5 bpm and 62,8 ±1,3bpm respectively), while arterial blood pressure returned to control values short after the cessation of exercise. A linear correlation between c-rtT and corresponding RR interval duration during exercise was found (p<0.001) but no correlation between PATc and RR.
We conclude that during exercise increased sympathetic tone is the main reason for increasing c-rtT, but other mechanisms should contribute to the regulation of the finger tip skin microcirculation, where termoregulation plays a major role. Further experiments are needed to elucidate exact mechanisms involved in the small artery and microvasculature response to exercise.

Dysregulation of hydrogen sulfide producing enzyme cystathionine γ-lyase contributes to maternal hypertension and placental abnormalities in preeclampsia

K. Wang[1], W. Abu-Alkhier[1,5], S. Ahmad[1], M. Cai[1], J. Rennie[2], T. Fujisawa[2], F. Crispi[3], J. Baily[2], R. Wang[4], E. Gratacós[3], I. Buhimschi[5], C. Buhimschi[5] and A. Ahmed[1]

[1]Vascular Biology Unit, Aston University, Birmingham, UK, [2]Gustav Born Centre for Vascular Biology, University of Edinburgh, Edinburgh, UK, [3]Department of Maternal-Fetal Medicine, University of Barcelona, Barcelona, Spain, [4]Lakehead University, Thunder Bay, ON, Canada and [5]Yale School of Medicine, Yale University, New Haven, CT, USA

The exact aetiology of preeclampsia is unknown, but there is a good association with an imbalance in angiogenic growth factors and abnormal placentation (Ahmad & Ahmed, 2004). Hydrogen sulphide (H2S), a gaseous messenger produced mainly by cystathionine γ-lyase (CSE), is pro-angiogenic vasodilator (Yang et al, 2008; Papapetropoulos et al, 2009). We hypothesized that a reduction in CSE activity may alter the angiogenic balance in pregnancy and induce abnormal placentation and maternal hypertension. Plasma levels of H2S were significantly decreased in preeclamptic women (p<0.01), which was associated with reduced CSE message and protein expression in human placenta as determined by real-time PCR and immunohistochemistry. Inhibition of CSE activity by DL-propargylglycine (PAG) in first trimester (8-12 weeks gestation) human placental explants had reduced placenta growth factor (PlGF) production as assessed by ELISA and inhibited trophoblast invasion in vitro. Endothelial CSE knockdown by siRNA transfection increased the endogenous release of soluble fms-Like tyrosine kinase-1 (sFlt-1) and soluble endoglin, (sEng) from human umbilical vein endothelial cells while adenoviral-mediated CSE overexpression inhibited their release. Administration of PAG to pregnant mice induced hypertension, liver damage, and promoted abnormal labyrinth vascularisation in the placenta and decreased fetal growth. Finally, a slow releas-

ing, H2S-generating compound, GYY4137, inhibited circulating sFlt-1 and sEng levels and restored fetal growth that was compromised by PAG-treatment demonstrating that the effect of CSE inhibitor was due to inhibition of H2S production. These results imply that endogenous H2S is required for healthy placental vasculature and a decrease in of CSE/ H2S activity may contribute to the pathogenesis of preeclampsia.

Blast injury and its effects on the endothelium

A. Spear[1], E. Davies[2,1], E. Kirkman[1], C. Taylor[1], M. Midwinter[2] and S. Watts[1]

[1]Dstl, Salisbury, UK and [2]RCDM, Birmingham, UK

Introduction: It is known that the tolerance for return to normal neuromuscular function in tissue exposed to ischemia with concomitant hemorrhagic shock is significantly reduced compared to ischemia alone (Hancock et al., 2011). With an increased incidence of explosive related injuries in military casualties, the ischemic tolerance following blast injury with or without hemorrhagic shock may also be altered. A possible mechanism of altered tolerance is via damage to the endothelium. Endothelial integrity may influence clinical outcomes locally and systemically.
Aim: This study determined whether blast injury alone caused activation of, or damage to, the endothelium and whether this was correlated with the level of blast load.
Methods: Experiments were performed under the auspices of Animals (Scientific Procedures) Act 1986 and thus had undergone local Ethical Review. Groups of terminally anaesthetised female New Zealand White rabbits were exposed to 4 different levels of blast over the gastrocnemius muscle via a compressed air device. Arterial blood samples were taken pre-injury and 1, 6 and 11hr post-injury to determine levels of circulating endothelial cells (CECs) using CD146-based immunomagnetic separation. 12 hours post injury animals were culled with an overdose of anaesthetic and tissue removed for histological and gene expression analysis. The incidence of haemorrhage, oedema and inflammatory cell infiltration were subjectively scored. mRNA levels of markers associated with the activation of the endothelium were measured using qRT-PCR with multiple reference gene normalisation. Differences in CECs between groups were assessed with 2-way ANOVA ($p<0.05$ and power = 0.8). Histology scores were assessed using a Cuzicks trend test ($p<0.05$). qRT-PCR results were expressed as calibrated normalised relative quantities (CNRQ), transformed and assessed using one-way ANOVA ($p<0.05$).
Results: At 6 hr post-injury, the number of CECs in blood was significantly higher in the high blast group versus no blast group ($p<0.05$). There was a significant trend ($p<0.0001$) in increasing scores for oedema, haemorrhage and cell infiltrate with increased blast load. Expression of a variety of endothelial activation markers were significantly increased in the high blast versus no blast group including E-selectin, TNFα, HIF-1α and Thrombomodulin.
Conclusions: This study demonstrates that blast injury causes activation and damage to the endothelium and surrounding muscle tissue and that this is dependent on blast load. This has the potential to impact on limb salvage strategies and requires further investigation to determine the implications for casualties injured in an explosion. Understanding the mechanism of damage may also identify possible mitigation strategies.

Vitamin D preserves endothelial function and blood pressure in inflammatory prone mitogen and stress kinase 1/ 2 knock-out mice *In vivo*

N. Akbar[1], S.J. Arthur[2], J.J. Belch[1] and F. Khan[1]

[1]Vascular and Inflammatory Diseases Research Unit, University of Dundee, Dundee, Angus, UK and [2]The MRC Protein Phosphorylation Unit, University of Dundee, Dundee, Angus, UK

Background: Cardiovascular diseases are united in pathology by atherosclerosis; signal transduction is essential in this process for the expression of cell adhesion molecules early in the disease, capturing, tethering and transmigrating monocytes into the sub-endothelial space. Mitogen and stress activated kinases (MSK) 1/ 2 are critical for the homeostatic control of cytokine expression through interleukin-10 and dual specificity protein-1 (DUSP-1). Macrophages from MSK 1/ 2 knock-out (KO) animals display reduced IL-10, DUSP-1 expression and bare a hyperinflammatory phenotype. Calcitrol, the active form of vitamin D, exerts its anti-inflammatory effects through up regulation of IL-10 and DUSP-1 *in vitro*, with an ability to curb cytokine expression (tumour necrosis factor-α and IL-6); however the effector pathway remains poorly understood with limited *in vivo* studies.
Aim: To elucidate the relationship between Calcitrol and MSK 1/ 2 in endothelial dysfunction.
Method: Skin microcirculation was assessed on the flanks of anesthetised (1.5-2% isoflurane with oxygen) 16 week old C57/Black MSK 1/ 2 KO (n=24) mice. Following baseline measurements animals were fed a proatherogenic diet (2% cholesterol) and subdivided (n=12) to receive vehicle (carboxymethyl cellulose sodium 0.5%) or 200ng Calcitrol twice a week for the study duration (16 weeks). Laser Doppler Imaging (LDI) in combination with iontophoresis of phenylepherine (PE), acetylcholine (ACh), sodium nitroprusside (SNP) and localised skin heating (44^0C) were used to measure vascular function. Results are expressed as group mean, skin perfusion in arbitrary units (AU)±standard error of mean (SEM). Blood pressure was assessed non-invasively using a tail cuff system (mmHg±SEM);

cardiac hypertrophy was calculated by: cardiac mass (mg)/body weight (g).T-test analysis was used for statistical significance (p <0.05).

Results: There were no significant differences at baseline for vascular responses. Vehicle (259±6AU) treated animals displayed reduced ACh responses at 16 weeks when compared to Calcitrol (292±5AU) treated mice (p = 0.0006). There were no significant differences for endothelium-independent responses (SNP) or cardiac mass between the two groups. Calcitrol supplemented animals displayed lower systolic (119±3 mmHg VS. vehicle 129±3 mmHg, p = 0.04) and diastolic (84±3 mmHg VS. vehicle 99±2 mmHg, p = 0.01) blood pressures.

Conclusion:ACh induced vasodilation was significantly reduced in MSK 1/ 2 KO vehicle mice, but was preserved in Calcitrol treated animals. Maximal dilatory capacity was not significantly different between groups, suggesting modulation at the level of the endothelium. For the first time we provide *in vivo* longitudinal data showing the protective effects of vitamin D on endothelial dysfunction, possibly through modulation of inflammation.

Molecular and functional characterisation of TRPV3 and TRPV4 channels in the retinal microvascular endothelium

J. McNaughten, M.K. McGahon, G. McGeown and T. Curtis

Centre for Vision and Vascular Science, Queens Universtiy Belfast, Belfast, UK

Transient receptor potential vanilloid (TRPV) channels are members of a superfamily of non-selective cation channels possessing a vast range of physiological functions. Our aim was to fully characterise the molecular and functional expression of TRPV3 and TRPV4 channels in the retinal microvascular endothelium.

Retinal microvascular endothelial cells (RMECs) were cultured from bovine retina. mRNA transcripts were detected for TRPV3 and V4 using RT-PCR. Protein expression was confirmed by Western blot analysis. Fura-2-based Ca2+ microfluorimetry was used to test for the functional expression of TRPV3 and V4 in RMECs using a selection of appropriate agonists and antagonists. The TRPV3/TRPA1 activator, carvacrol (100uM), evoked consistent [Ca2+]i responses in RMECs (0.2±0.03 R340/380, mean±SEM, n=5), which were reduced, but not abolished in the presence of the TRPA1 inhibitor, HC-030031 (10μM) (0.14±0.01 R340/380, n=6; p<0.05 v carvacrol alone). The functional expression of TRPV4 channels was tested using the selective activator GSKA (100nM). This drug elicited a transient rise in [Ca2+]i (1.88±0.62 R340/380, n=13) that was blocked by pre-incubation with the specific TRPV4 antagonist, HC067047(1uM) (0.06±0.04 R340/380, n=6; p<0.01 v. GSKA alone). The cellular localisation of TRPV3 and TRPV4 channels was subsequently examined in bovine retinal wholemounts and isolated RMECs using immunohistochemistry. TRPV3 was located predominantly in the nuclei of endothelial cells in retinal wholemounts with some punctate staining in the cytoplasm. No differences in localisation were observed in endothelial cells of arteries, capillaries and veins. RMECs also showed predominantly nuclear staining for TRPV3. TRPV4 was found to be located in both the nuclei and cytoplasm of endothelial cells lining the vasculature in retinal wholemounts. Interestingly sparse, punctate TRPV4 staining was noted in endothelial cells on the arterial side of the circulation, while those on the venous side presented with noticeably increased TRPV4 staining in both the nuclei and cytoplasm. In isolated RMECs, TRPV4 was localised to both the nucleus as well as tubular-like structures in the cytoplasm. Localisation patterns for each channel were confirmed using multiple antibodies to different epitopes and the specificity of staining was confirmed using blocking antigens.

This study provides molecular and functional evidence for the expression of TRPV3 and V4 in bovine retinal endothelial cells. Further research is now required to elucidate their physiological significance.

Altered vascular response to acetylcholine and reduced pO2 in isolated carotid arteries in rats fed by chow containing varied zinc and selenium content

I. Ivic[1], S. Novak[2], A. Cosic[2], A. Cavka[2], I. Grizelj[2], Z. Loncaric[3], A. Koller[1] and I. Drenjancevic[2]

[1]Department of Pathophysiology and Gerontology, Medical School University of Pecs, Pesc, Hungary, [2]Department of Physiology and Immunology, Faculty of Medicine Osijek, University of J.J. Strossmayer Osijek, Osijek, Croatia and [3]Desk of Plant Nutrition and Fertilization, Faculty of Agriculture Osijek, University of J.J. Strossmayer Osijek, Osijek, Croatia

Objective: Since zinc (Zn) and selenium (Se) are important components for cell protection against certain oxygen species it has been suggested that Zn and/or Se deficiency impairs the potent antioxidant defense capacity and may be involved in the initiation of endothelial dysfunction (1-5). However, there is a lack of functional studies to address this issue. The aim of this study was to determine if changes in dietary content of Zn and Se affect vascular responses in rat isolated carotid arteries.

Methods: Fifteen male Sprague Dawley rats were fed with 3 types of custom made rat chow (Faculty of Agriculture University of Osijek, Croatia) from weaning for 10 weeks: a) high Zn(70.81mg/kg)-low Se(0.043mg/kg) group (N=5); b) high Se (0.363mg/kg)-low Zn(30.16mg/kg) group (N=5) and c) low Zn(28.56mg/kg)-low Se(0.03mg/kg) group (N=5). Prior to decapitation, rats were anesthetized with 75 mg/kg ketamine+2.5 mg/kg midazolam. Carotid arteries were isolated and their isometric tensions were measured by DMT multi-wire Myograph system. We tested dose responses to ACh (10-9-10-5 M) and response to reduced pO2 (in the bath bubbled with gas mixture containing N2 95%, CO2 5%) after precontraction with noradrenaline (NA) for 5 minutes, in the absence/presence of the NOS inhibitor L-NAME or COX-1,2 inhibitor indomethacin (INDO) in the tissue bath. Viability of rings at the end of the hypoxic relaxation protocol was tested with their ability to contract in bath solution bubbled with 95% O2-5% CO2 gas mixture. To compare differences between groups and treatments One-way ANOVA or t-test was used when appropriate. Statistical significance was set at P<0.05 (SigmaPlot v11.2).

Results: ACh induced relaxation (AchIR) was significantly reduced in low Zn-low Se group and high Se-low Zn group compared to high Zn-low Se (P<0.001 for 10-7-10-4 M Ach con-

centration). L-NAME (P<0.001 for 10-7-10-4 M Ach concentration) and INDO (P<0.001 for 10-6-10-4 M Ach concentration) blocked AChIR in all three groups of rats. Hypoxia induced relaxation (HIR) was significant in all study groups. However, there was no difference in HIR among groups. L-NAME and INDO significantly blocked HIR in high Zn-low Se and high Se-low Zn groups. In low Zn-low Se group HIR was blocked only after INDO administration.

Conclusions: These data suggest: 1) Zn and Se deficiency affected vascular response to ACh and reduced pO2 in rat isolated carotid arteries and 2) it seems that for ACh dependent relaxation Zn level is more important than Se level.

Alpha calcitonin gene-related peptide (αCGRP) plays a long-lasting protective role in both the onset and sustained models of angiotensin-II induced hypertension and vascular inflammation/remodelling

S. Smillie[1], R. King[1], G. Pozsgai[1], L. Liang[1], E. Fernandes[1], P. De Winter[2], R. Siow[1] and S. Brain[1]

[1]Cardiovascular Division, Kings College London, LONDON, UK and [2]Division of Surgery and Interventional Science, University College London, LONDON, UK

Calcitonin gene-related peptide (CGRP) is a sensory nerve-derived neuropeptide and the most potent microvascular vasodilator known to date. Suggested previously to be protective in a range of models of hypertension1, the aim of this study was to learn the influence of CGRP on vascular mechanisms in an angiotensin-II (Ang II) model of hypertension. Matched C57BL/6 wildtype (WT) and selective αCGRP knockout (KO) mice were anaesthetised and osmotic minipumps with Ang II (1.1 mg/kg/day for 14 days or 0.9mg/kg/day for 21 days) or vehicle (saline) were implanted as described previously2. Blood pressure was recorded by tail-cuff plethysmography until days 14/28 when the experiment was terminated. Vascular hypertrophy was assessed by histology and mRNA expression by RT-qPCR. Data were analysed using ANOVA plus Bonferroni's post test. CGRP deletion did not affect baseline blood pressure regulation under normotensive conditions. Systolic pressure significantly increased after 14 days Ang II in WT (129±3.84) and αCGRP KOs (140±7.23, p<0.001), this being significantly enhanced in the αCGRP KOs (p<0.001). This exacerbated hypertensive response was still apparent at day 28 (204±9.8, p<0.01). αCGRP mRNA expression was upregulated in the aorta and mesentery of hypertensive WTs at both 14 (p<0.01) and 28 (p<0.001) days, indicating the potential for αCGRP to influence in a chronic, in addition to acute manner. Vascular inflammation/remodelling was apparent in hypertensive subjects, characterised by increased collagen expression. This remodelling was exacerbated in Ang II-treated αCGRP KOs at both time-points (p<0.001). This study provides evidence that i) CGRP is upregulated at the vascular level in hypertension and ii) deletion of CGRP is associated with enhanced Ang II-induced hypertension and vascular injury. This suggests a sustained protective role for CGRP in this model.

Suppressed Nrf2 mediated redox signalling and decreased DJ1 expression in human foetal endothelial cells from gestational diabetes: prenatal priming of endothelial dysfunction in offspring

X. Cheng[1,2], S. Chapple[1], B. Patel[1], W. Puszyk[1], R.C. Siow[1] and G.E. Mann[1]

[1]Cardiovascular Division, British Heart Foundation Centre of Research Excellence, School of Medicine, King's College London, London, UK and [2]Cardiac Surgery Department, Peking University Third Hospital, Beijing, China

Increased generation of reactive oxygen species is associated with endothelial dysfunction and targeting endogenous antioxidant defences has only recently been considered in the treatment of vascular diseases (Cheng et al., 2011). Offspring from gestational diabetic (GDM) pregnancies are predisposed to endothelial dysfunction in later life (Buchanan & Xiang, 2005), and endothelial cells from GDM umbilical cords exhibit abnormal nitric oxide production and reduced growth rates, indicating phenotypic changes caused by GDM (Sobrevia et al., 1995; Mann et al., 2003). To investigate the underlying mechanisms, we examined redox regulation in human umbilical vein endothelial cells (HUVEC) from GDM (n=40) and normal (n=47) pregnancies cultured in M199 (with 20% or 1% FCS). Mitochondrial superoxide production measured by luminescence in GDM HUVEC was significantly higher than normal controls (210 ± 22 vs 81 ± 6 mean light units, mean ± SEM, n=6, P<0.001) whereas basal DNA fragmentation was comparable between groups. However, GDM HUVEC were more susceptible to the lipid peroxidation (4-hydroxynonenal, 20μmol/L) induced DNA fragmentation (n=5, P<0.05). Basal and HNE stimulated levels of glutathione (GSH), a key intracellular antioxidant, were also lower in GDM HUVEC. Moreover, HNE induced activation of the redox sensitive transcription factor NF-E2 related factor 2 (Nrf2), which mediates adaptive increases in GSH synthesis (Mann et al., 2003), was suppressed in GDM

(n=5, p<0.05). Deficits in Nrf2 mediated redox signalling were further confirmed by abrogated HNE induced mRNA expression of the cystine/glutamate transporter (xCT) and phase II defence enzyme NAD(P)H quinone oxidoreductase 1 (NQO1) (n=6, P<0.05 and P<0.01 respectively). Nrf2 silencing in normal HUVEC partly reproduced the phenotypic changes of GDM HUVEC. To examine whether Nrf2 in GDM cells is epigenetically silenced, methylation of CpG islands in the promoter region of Nrf2 was measured by bisulphate restriction analysis. Although we could not detect differences in methylation between normal and GDM cells, protein expression of DJ-1, a known cytosolic Nrf2 stabilizer, was markedly reduced in GDM HUVEC (n=7, P<0.01). In summary, an altered vascular phenotype in utero may contribute to the increased risk of type 2 diabetes and cardiovascular disease in the offspring of gestational diabetic mothers in later life.

PCC401

A new role for the regulator of G-protein signalling-1 in inflammatory cell function in angiotensin ii-induced aortic aneurysm formation

J. Patel, E. McNeill, G. Douglas, J.P. de Bono, D.R. Greaves and K.M. Channon

Oxford University, Oxford, UK

Chemokine-induced macrophage recruitment into the vascular wall is critical in the progression of atherosclerosis and aortic aneurysm formation. Macrophage activation and chemotaxis can be mediated by chemokine ligation of multiple G-protein coupled receptors. The Regulator of G-Protein Signalling-1 (RGS1) acts to down-regulate the response to sustained chemokine stimulation. Studies in our laboratory have shown it to be up-regulated in ApoE-/- mice in association with atherosclerotic plaque progression and with monocyte-macrophage activation; however an in vivo role for RGS1 in macrophage function has not been investigated.

RGS1 has a non-redundant role in macrophage chemotaxis in vitro. Rgs1-/-ApoE-/-macrophages have significantly enhanced migratory responses to the chemokines CCL2, CCL3 and CCL5 (p<0.05) and have impaired desensitisation to repeated or sustained chemokine signalling, such that they show increased migration to CCL5 re-stimulation (p<0.001). RGS1 has a role in the accumulation of macrophages in lesions in the initial stages of atherosclerosis. In the absence of RGS1, atherosclerosis is attenuated in early lesions in the aortic root and aortas of female ApoE-/- mice (p<0.001). This was accompanied by reduced levels of macrophages in the aortic root.

To investigate aortic leukocyte trafficking, an Angiotensin II model of acute vascular inflammation was used. At 9 weeks of age, Rgs1-/-ApoE-/- mice had significantly less CD45+ leukocytes and CD11b+ myeloid cells in aortas than ApoE-/- mice (p<0.05) after 5 days of Angiotensin II infusion. Notably, during a 2 week infusion, ApoE-/- mice were more susceptible to aortic aneurysm rupture in comparison to Rgs1-/-ApoE-/- mice with 56% survival vs. 94% (p=0.0147). Furthermore, between days 2 and 10, Angiotensin II treatment increased systolic blood pressure more in Rgs1-/-ApoE-/- mice than ApoE-/- mice (ApoE-/-117.4±4.0 mmHg vs. Rgs1-/-ApoE-/- 137.7±3.1 mmHg) suggesting aneurysm formation in these mice is independent of Angiotensin-II induced hypertension. To examine the effects of Rgs1 disruption on vasomotility, myography studies were undertaken using the Gαq-coupled agonists; phenylephrine, angiotensin II and PGF2-α. Preliminary experiments showed only the contraction to phenylephrine was significantly enhanced in ApoE-/- rings compared to Rgs1-/-ApoE-/- (p<0.01) which may indicate a compensatory down regulation of α1-adrenergic receptors in Rgs1-/-ApoE-/- aortas.

These findings identify a new role for RGS1 in inflammatory cell function and support a role for RGS1 in Angiotensin II induced-aneurysm formation. Furthermore, these data suggest a potential interaction between RGS1 and Gαq-coupled receptors that could account for the alterations in vascular contractile function and blood pressure observed in Rgs1-/-ApoE-/- mice.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC402

An *in vitro* model system of hyperoxia-induced retinal endothelial cell death and senescence

O.M. Galvin, K.S. Edgar, T.A. Gardiner and D.M. McDonald

CVVS, Queen's University Belfast, Belfast, UK

Purpose:Hyperoxia is a dominant pathogenic factor in retinopathy of prematurity (ROP) resulting in an arrest of normal retinal vascular development accompanied by vaso-obliteration of pre-established vessels. The increased generation of endothelial cell-derived reactive oxygen species (ROS) and reactive nitrogen species (RNS) are associated with vessel loss during hyperoxia; in particular, dysregulated endothelial nitric oxide synthase (eNOS) is implicated in aberrant generation of such effectors in animal models of ROP. Defining the key pathways involved in vaso-obliteration will aid the discovery of therapeutic targets that protect the retina from hyperoxia-induced vascular damage. Therefore we established a model system to investigate the effect of hyperoxia and eNOS over-expression on retinal microvascular endothelial cells *in vitro*, examining nitrosative stress, cell death via apoptosis and cellular senescence.

Methods:Primary retinal microvascular endothelial cells (RMECs) were exposed to physiologically relevant 6% oxygen, standard cell culture incubator conditions (21% oxygen) and 70% oxygen. Apoptosis was quantified by nuclear morphology, active caspase-3 and TUNEL staining. Mechanisms of cell injury were investigated using inhibitors and scavengers of superoxide and of peroxynitrite and nitrotyrosine quantified by western blotting. Senescence was determined by β-galactosidase staining the co-localisation of γH2AX and 53BP-1 nuclear foci, and the formation of multiple nuclei. eNOS overexpression was achieved by viral infection with an adenovirus encoding eNOS-GFP and compared to control, GFP expressing virus.

Results:24 hour hyperoxia treatment of RMECs increased nitrotyrosine formation and apoptosis. Inhibition of either peroxynitrite or inhibition of superoxide reduced hyperoxia-mediated apoptosis. In addition, hyperoxia induced a significant

increase in the senescence markers β-galactosidase and 53BP-1. eNOS over-expression further increased apoptosis under hyperoxic conditions.
Conclusions:Collectively, our results demonstrate that hyperoxia increases cellular senescence and cell death via apoptosis in RMECs. This apoptosis can be reduced through inhibition of ROS and RNS. eNOS over-expression increased RNS production, leading to a further increase in hyperoxia induced apoptosis.

Antioxidant and vascular protective effect of curcumin on phenylhydrazine-induced hemolytic anemia in rats

K. Sompamit[1], V. Kukongviriyapan[3], W. Donpunha[2], U. Kukongviriyapan[2] and P. Surawattanawan[4]

[1]Preclinic, Mahasarakham University, Muang, Mahasarakham, Thailand, [2]Physiology, Khon Kaen University, Muang, Khon Kaen, Thailand, [3]Pharmacology, Khon Kaen University, Muang, Khon Kaen, Thailand and [4]Government Pharmaceutical Organization, Rajatevee, Bangkok, Thailand

Curcumin, a major active component from turmeric (Curcuma longa), widely grown in tropical regions of Asia. Normally, it was used as a spice to give specific flavor and color of food. Moreover, curcumin is a medicinal plant which possesses neuroprotective, cardioprotective, anti-carciogenic, anti-inflammation, and antioxidant properties. Phenylhydrazine (PHZ) is a strong oxidant agent and has been used in an animal model of hemolytic anemia (1). PHZ oxidation causes free iron release resulting in massive free radicals generation, oxidative stress and vascular dysfunction (2). The aim of this study was to investigate the effect of curcumin on PHZ-induced hemolytic anemia in rats. Male Sprague-Dawley rats were obtained from National Animal Laboratory Center, Thailand, and were housed and treated at North-Eastern Laboratory Animal Center, Khon Kaen University, Thailand. All animal procedures were reviewed and approved by the Institutional Animal Ethics Committee of Khon Kaen University (AE 41/2555). Rats (n= 8/group) were exposed to PHZ (15 mg/kg/day; i.p.) and orally administered with curcumin (30 and 100 mg/kg/day) for 8 days. After 8 days of PHZ administration, rats were anaesthetized with pentobarbital sodium (60 mg/kg; i.p) then arterial blood pressures and hind limb blood flow (HBF) were measured. At the end of experiment, blood samples were collected from abdominal aorta for assays of hematocrit values, non-transferrin bound iron (NTBI), oxidative stress markers including, plasma malondialdehyde (MDA) and protein carbonyl levels. Tissue samples, heart, kidneys, and liver, were also removed to measure MDA and protein carbonyl levels. Subsequently, the thoracic aorta was excised rapidly from the animals and used for measurement of superoxide production. The systolic, diastolic and mean arterial blood pressure of PHZ treated rats were markedly decreased whereas HBF and serum NTBI level were dramatically increased when compared with normal controls. Interestingly, the restoration of hemodynamic disturbance and anemia during PHZ exposure were related to the alleviation of free iron release, superoxide production and oxidative stress status. Results in this study reveal the effects of curcumin that may offer potential advantage of practical use in prevention of vascular dysfunction and oxidative stress in PHZ treated rats.

The endothelial glycocalyx surface layer depth, measured directly using confocal microscopy, is altered in the mesenteric microvessels of proteinuric rats

K.B. Betteridge[1], K.P. Arkill[2], C.R. Neal[1] and A.H. Salmon[1]

[1]School of Physiology and Pharmacology, University of Bristol, Bristol, UK and [2]School of Physics and Astronomy, University of Birmingham, Birmingham, UK

The luminal surface of blood vessels is coated with a size limiting, specialised, composite endothelial glycocalyx-surface layer (EG-SL) which has a fundamental role in microvessel permeability. EG-SL disruption occurs in major global diseases (inc. diabetes, atherosclerosis, sepsis, advanced kidney disease). Advancing knowledge about the EG-SL is seriously limited by difficulties in detecting, imaging and accurately quantifying the EG-SL, particularly in functioning vessels in vivo. We have developed a new technique for studying the EG-SL in vivo, and used this system to demonstrate changes in the EG-SL in an animal model of early kidney disease.
Male Sprague Dawley rats were injected with either Puromycin Aminonucleoside to cause Nephrosis (PAN) or PBS (sham controls). Mesenteric microvessels of pentobarbitone-anaesthetised (60 μg per g in weight) rats were exposed, cannulated, and perfused with octadecyl-rhodamine-B chloride (R18: membrane label) and Fluorescein-Isothiocyanate-conjugated Wheat Germ Agglutinin (FITC-WGA lectin: EG-SL label), and imaged using Confocal Microscopy (Nikon D-eclipse C1, CM) with a 60x objective (1.4 NA, Nikon). Vessels of sham injected rats were then perfused with neuraminidase for 20min, an enzyme that cleaves sialic acid residues within the glycocalyx, and re-imaged. EG-SL depth was estimated based on the anatomical distance between peak fluorescence of FITC-WGA and R18 signals (FIJI/IMAGEJ, NIH) at the maximum vessel width.
EG-SL depth in sham rats was 288±24nm (n=5). This value was significantly reduced to 185±32nm following perfusion of the same vessel with neuraminidase ($p<0.01$, paired t-test). EG-SL depth in PAN was 147±23nm (n=5), demonstrating significantly reduced EG-SL depth in these proteinuric rats compared with sham-treated rats ($p<0.01$, unpaired t-test).
We have demonstrated a sensitive technique for measuring changes to EG-SL depth in vivo using CM. EG-SL depth is significantly reduced in proteinuric PAN-treated rats, perhaps a contributing factor to the increased systemic permeability observed in proteinuric patients.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

The cellular density of Myeloid Angiogenic Cells alters their secretome profile and determines the angiogenic potential of retinal microvascular endothelium

C.L. O'Neill, R.J. Medina, M.T. O'Doherty, S.E. Chambers, J. Guduric-Fuchs and A.W. Stitt

Centre for Vision and Vascular Sciences, Queens University Belfast, Belfast, UK

Endothelial progenitor cells (EPCs) promote angiogenesis and facilitate vascular repair. Recent clinical trials have demonstrated the feasibility, effectiveness and safety of EPCs for treatment of various ischaemic diseases. However, results from such trials have been inconsistent. This is due to the heterogeneous mix of cells used, as the term EPC has been applied to a broad range of blood derived cells that display endothelial markers and enhance angiogenesis. We have previously characterised two EPC subsets in vitro, Myeloid angiogenic cells (MACs) and Outgrowth endothelial cells (OECs). Although OECs are the EPC subset with progenitor and endothelial characteristics, MACs may still play an important role in angiogenesis indirectly. We have recently shown that cell therapy using MACs significantly enhanced vascular repair in a murine model of retinal ischaemia. This MAC response is mediated by the paracrine release of IL8 since it can be blocked using CXCR receptor inhibitors or a neutralising IL8 antibody. This pro-angiogenic potential of MACs could be harnessed as a novel cellular therapy for the treatment of ischaemic retinopathy but further optimisation of MACs as a cell therapy, including optimisation of the density of cells is required.

A co-culture system of MACs with retinal microvascular endothelial cells (RMECs) was used as an *in vitro* angiogenesis model to determine MACs effects at various densities. An angiogenesis protein array was then used to identify conditioned media components.

An *in vitro* angiogenesis assay demonstrated that MACs significantly increased RMEC tube formation ($p<0.01$) when used at a ratio of 4/1(RMECs/MACs). However, RMECs co-cultured with a higher density of MACs significantly decreased RMEC tube formation ($p<0.01$). Analysis of conditioned media by an angiogenesis protein array highlighted upregulation of specific anti-angiogenic factors (PTX3, PAI1, CXCL16) in the high density group, whilst showing a significant decrease in IL8 levels and an imbalance in the MMP9/TIMP1 ratio. Exposure of RMECs to recombinant PTX3 confirmed the anti-angiogenic role of this protein by showing a significant decrease in tube formation ($p<0.05$) and migration ($P<0.01$). Furthermore, the anti-angiogenic effect of high density MACs was partly rescued by using an antibody targeted against PTX3 ($p<0.01$).

We have shown that MACs are capable of inducing angiogenesis and act as M2 macrophages. However, at high density, MACs significantly inhibit angiogenesis. This effect is due to secretome changes, and release of negative regulators of angiogenesis, such as PTX3. Therefore, MACs density is an important consideration when using them as a cellular therapy for ischaemic retinopathy.

Aging modulates the anti-contractile effects of perivascular adipose tissue; the role of nitric oxide

H.M. Melrose, A. Heagerty, G. Edwards and C. Austin

FMHS, University of Manchester, Manchester, UK

Introduction: Aging is widely considered the biggest independent risk factor for cardiovascular disease, the leading cause of death worldwide. Advanced age is associated with endothelial dysfunction, hypertension and increased risk of stroke and myocardial infarction; the mechanisms behind these increased risks are little understood. It has long been known that there is an age-related endothelial dysfunction, due to decreased bioavailability of the endogenous vasodilator nitric oxide (NO), synthesised in the vascular endothelium (Barton et al., 1997). Vascular reactivity is further regulated via the perivascular adipose tissue (PVAT), which has a net anti-contractile effect (Greenstein et al., 2009). PVAT is also known to be a source of NO (Gil-Ortega et al., 2010), in addition to secreting locally acting factors that augment endothelial NO production (Gao et al., 2007).

Hypothesis: PVAT dysfunction may occur with aging, and is due at least in part to reduced bioavailability of NO.

Methods and Results: Third order mesenteric arteries were taken from male Wistar rats aged 3 months old (m.o.), 12 m.o., 18 m.o. and 24 m.o. and contractility to increasing concentrations of the thromboxane A2 receptor agonist U46619 (10nM-3μM) assessed via wire-myography in the presence and absence of PVAT and the NO-synthase inhibitor Nω-nitro-L-arginine (L-NNA) (50μM). Results were analysed via two-way ANOVA (Bonferroni post-hoc). PVAT was anti-contractile in 3 m.o. rat arteries (-PVAT max change in tension to U46619 (mN/mm) +1.2±0.52 (n=6), +PVAT +0.55±0.07 (n=3)) and 12 m.o. rat arteries (-PVAT +0.61±0.06 (n=5), +PVAT +0.44±0.13 (n=5), p=0.0280) but that this effect had been lost by 18 months (-PVAT +0.99.±0.11 (n=7), +PVAT 0.96±0.18 (n=5)), and remained absent at 24 m.o. (-PVAT 0.85.±0.11 (n=8), +PVAT 0.88±0.15 (n=8)). Incubation with L-NNA prevented the anti-contractile effect of PVAT at 3 months (+PVAT/+L-NNA +1.09±0.36 (n=4)). At 24 months, incubation with L-NNA had no effect on contractility (+PVAT/+L-NNA +0.64±0.28 (n=7)) in either the presence of absence of PVAT.

Summary: The anti-contractile effect of PVAT is lost with age in rats, due at least in part to a reduced bioavailability of NO. Further studies are currently being undertaken to further investigate the mechanisms involved.

Correlative 3D estimation of the vascularization in the murine hind limb

L. Schaad, C. Sollberger, R. Hlushchuk, S. Barré and V. Djonov

Institute of Anatomy, Bern 9, Switzerland

Background: According to PubMed, at least 3000 articles are published in the field of "blood vessels in muscle" every year. The skeletal muscles of the rodent hind limb are the most frequently used experimental model. However, most of the studies are based on a single muscle and and usually on solitary cross-sections. Taking into account that capillarization differs dramatically between different muscles and even within the same muscle, we decided to introduce a complex 3D assay of structure of the vasculature in the murine hind limb.
Methods & Results: Although imaging and quantification of bones by μCT is well developed and established, visualization of striated muscle capillaries is a challenging issue, mainly due to lack of satisfactory contrast agents. Therefore, to visualize the 3D structure of the vascular network with a resolution up to the level of capillaries, vascular casting with PU4ii® polymer (vasQtec, Zurich) has been performed. To enhance the contrast, after maceration the casts have been immersed in osmium tetraoxide and freeze-dried thereafter and investigated with a μCT (Skyscan 1172, voxel size below 1μm). Additionally, special a histological approach has been employed. Since cutting of mineralized bone with an ordinary microtome is not feasible, the entire hind limb was decalcified in EDTA for 4 days. Subsequently, the limb was embedded in paraffin and series of 5μm-thick sections of the entire hind limb obtained. After deparaffinization and trypsinization of the tissue sections, the capillaries were stained with BS-1 lectin. This method allows comparative evaluation of the capillary-to-fibre ratio, capillary density, fibre type i) of all 11 muscles on a single cross-section; ii) at different levels in the same muscle, i.e. proximal to distal. Based on this method, we were able to show alterations among the above-mentioned parameters depending on the level examined.
Implications: We present a comparative method to evaluate the vasculature of all skeletal muscles on a cross-section of the whole hind limb simultaneously and at different levels. This method allows a time-efficient, 3D and comparative evaluation of the hind limb vascularization.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC409

Effects of hypoxia & inflammation on vascular reactivity in rats: a model of co-morbidities in chronic obstructive pulmonary disease?

A. Gassama[1], A. Turner[1], S. Egginton[1,2] and P. Kumar[1]

[1]Clinical & Experimental Medicine, University of Birmingham, Birmingham, UK and [2]Biomedical Sciences, University of Leeds, Leeds, UK

Chronic obstructive pulmonary disease (COPD) is characterised by a poorly reversible airflow limitation. It is a complex disease associated with both pulmonary and systemic vascular inflammation, linked to subsequent development of cardiovascular complications including pulmonary hypertension. Inflammatory mediators and hypoxia promote endothelial damage causing an imbalance between vasodilator and vasoconstrictor intermediaries, thus altering vascular tone. These lead to increased smooth muscle cell proliferation and vasoconstriction as well as vascular remodelling and subsequently resulting in an increased pulmonary arterial pressure.[1,2] The pathogenesis of systemic effects of COPD has not yet been fully elucidated.
Pulmonary artery (PA) was dissected from normoxic control (C) and chronically hypoxic (CH – 10% O_2; 1 week) Wistar rats and 2 mm segments of the vessels were mounted on a wire myograph in physiological saline (95% O_2, 5% CO_2, 37°C). U46691 was used to generate a pre-tone and a cumulative dose-response curve for a vasodilator (carbachol -CC or sodium nitroprusside –SNP) was constructed. A pro-inflammatory cytokine (TNF-α, IL-8 or IL-β) was then added for 1 hour before vasodilator responses were re-assessed. Right ventricular (RV) to left ventricular and septum (LV+S) ratio was used to assess RV hypertrophy in control and chronic hypoxic rats. All procedures were in accordance with current UK legislation. Significance was taken as $P<0.05$.
One week hypoxia induced a significant increase in RV hypertrophy in rats (C= 0.27±0.026, CH= 0.40±0.028 n=3 t-test). Our preliminary data on control and CH rats did not show any significant difference in the maximum percentage of the endothelial dependent vasodilation by CC (C= 62±8.1% n=8, control+IL-8= 57±6.5% n=8, CH= 83±16.1% n=3 CH+IL-8= 68±7.6% n=3 ANOVA). CH increased the maximum vasodilatation by endothelial independent vasodilator, SNP by ~25% when compared to the control (CH=36±3.9% n=3, C=45±6.3% n=4) and the addition of IL-8 augmented SNP induced vasodilation in both groups (control+IL-8= 41±5.7% n=6, CH+IL-8= 30±3.1% n=3). However, these differences did not reach significance in both groups.
Our findings suggest that (1) acute cytokine exposure has little effect on vasoreactivity; (2) one-week CH can cause structural changes in RV, even though a functional difference was not observed in PA vasodilatation in the same time. This might represent a difference in the time course for structural changes to be observed in the cardiovascular and pulmonary systems consequent to CH, or that hypoxia and pro-inflammatory cytokine effects are synergistic, and future longitudinal studies are planned.

Impact of circulating endothelial progenitor cells and platelet microparticles on platelet activation in hypertension associated with hypercholesterolemia

N. Alexandru, D. Popov, E. Andrei, E. Dragan and A. Georgescu

Pathophysiology and Pharmacology, Institute of Cellular Biology and Pathology 'Nicolae Simionescu', Bucharest, Romania

Aim: The purpose of this project was to evaluate the influence of circulating endothelial progenitor cells (EPCs) and platelet microparticles (PMPs) on blood platelet function in experimental hypertension associated with hypercholesterolemia. Methods: Golden Syrian hamsters were divided in six groups: (i) control, C; (ii) hypertensive-hypercholesterolemic, HH; (iii) 'prevention', HHin-EPCs, HH animals fed a HH diet and treated with EPCs; (iv) 'regression', HHfin-EPCs, HH treated with EPCs after HH feeding; (v) HH treated with PMPs, HH-PMPs, and (vi) HH treated with EPCs and PMPs, HH-EPCs-PMPs. Results: Compared to HH group, the platelets from HHin-EPCs and HHfin-EPCs groups showed a reduction of: (i) activation, reflected by decreased integrin β3, FAK, PI3K, src protein expression; (ii) secreted molecules as: SDF-1, MCP-1, RANTES, VEGF, PF4, PDGF and (iii) expression of pro-inflammatory molecules as: SDF-1, MCP-1, RANTES, IL-6, IL-1β; TFPI secretion was increased. Compared to HH group, platelets of HH-PMPs group showed increased activation, molecules release and proteins expression. Compared to HH-PMPs group the combination EPCs with PMPs treatment induced a decrease of all investigated platelet molecules, however not comparable with that recorded when EPC individual treatment was applied. Conclusion: EPCs have the ability to reduce platelet activation and to modulate their pro-inflammatory and antithrombogenic properties in hypertension associated with hypercholesterolemia. Although, PMPs have several beneficial effects in combination with EPCs, these did not improve the EPC effects. These findings reveal a new biological role of circulating EPCs in platelet function regulation, and may contribute to understand their cross talk, and the mechanisms of atherosclerosis.

Back to physiology: adaptation of human endothelial cells to normoxia alters Nrf2 antioxidant defences and redox homeostasis

S. Chapple[1], D. Mastronicola[2], T. Keeley[1], R. Siow[1] and G. Mann[1]

[1]Cardiovascular Division, King's College London, London, UK and [2]Department of Biochemical Sciences, Sapienza University of Rome, Rome, Italy

Conventional in vitro models classically use cells cultured in ambient air/5% CO2 which are hyperoxic compared to the environmental milieu in vivo. Given the intrinsic role of molecular O2 in determining reactive oxygen species (ROS) production and redox homeostasis, the current study sought to determine whether redox homeostasis is altered in cells adapted to physiological O2 tensions. Experiments were conducted using primary human umbilical vein endothelial cells (HUVEC) cultured under conventional 21% O2 or adapted to physiological 5% O2 for 1-day or 5-days. Using specialised oxygen workstations, we assessed (i) transcriptional DNA binding activity of the key redox-sensitive transcription factor Nrf2 by ELISA, (ii) induction of Nrf2-mediated antioxidant and phase II enzymes, GSH related genes or Nrf2 negative regulatory proteins Keap1 and Bach1 mRNA and protein by qPCR or immunoblotting, (iii) GSH synthesis by OPA fluorescence and (iv) cellular and mitochondrial ROS generation using DHE fluorescence. Whilst Nrf2 nuclear translocation or DNA binding of Nrf2 was not altered under 5% O2 conditions, progressive adaptation of cells to normoxic 5% O2 resulted in a depression of Nrf2-mediated antioxidant heme oxygenase-1 (HO-1) and NAD(P)H:quinone oxidoreductase (NQO1) induction in response to the known electrophilic Nrf2 inducer diethylmaleate. In contrast, GSH synthesis or induction of critical GSH related genes glutamate cysteine ligase catalytic subunit (GCLC) or the cystine glutamate transporter (xCT) were unaltered, whereas induction of the negative Nrf2 regulator Bach1, but not Keap1, was elevated under normoxic conditions. Measurement of cellular ROS generation using DHE or mitochondrial targeted DHE (Mitosox Red), revealed that adaptation of cells to normoxic 5% O2 results in alterations in ROS output with enhanced sensitivity to the mitochondrial complex I inhibitor antimycin A. Collectively these findings suggest that under normoxic 5% O2 conditions human endothelial cells exhibit a dramatically altered redox profile to cells cultured under standard air/5% CO2 conditions. Differential Nrf2 regulation of HO-1, GCLC and Bach1 suggests that undetermined factors modulated by O2 tension influence Nrf2 gene transcription, with significant implications for cellular ROS generation and ultimately cell redox homeostasis.

Circulating microparticles and endothelial progenitor cells in atherosclerosis; pharmacological effects of irbesartan

A. Georgescu[1], N. Alexandru[1], E. Andrei[1], I. Titorencu[1], E. Dragan[1], C. Tarziu[2], S. Gheorghe[2], E. Badila[2], D. Bartos[2] and D. Popov[1]

[1]Pathophysiology and Pharmacology, Institute of Cellular Biology and Pathology 'Nicolae Simionescu' of Romanian Academy, Bucharest, Romania, Bucharest, Romania and [2]Emergency Hospital, Bucharest, Romania, Bucharest, Romania

Aims: This study aimed to (a) employ our newly designed model, the hypertensive–hypercholesterolemic hamster (HH) in order to find whether a correlation exist between circulating microparticles (MPs), endothelial progenitor cells (EPCs) and their contribution to vascular dysfunction and (b) to assess the effect of irbesartan treatment on HH animals (HHI). Methods and Results: The results showed that compared to control (C) group, HH displayed: (i) a significantly increase in plasma cholesterol and triglyceride concentration, and an augmentation of systolic and diastolic arterial blood pressure, and of heart rate; (ii) a marked elevation of MPs and a significant decrease in EPCs; (iii) structural modifications of arterial wall correlated with altered protein expression of MMP2, MMP9, MMP12, TIMP1, TIMP2 and collagen type I and III; (iv) a considerably altered reactivity of arterial wall closely correlated with MPs and EPC adherence; (v) an inflammatory process characterised by augmented expression of P-Selectin, E-Selectin, vWF, TF, IL-6, MCP-1, RANTES. Additionally, the experiments showed the potential of irbesartan to correct all altered parameters in HH and to mobilize EPCs by NO, chemokines and adhesion molecules dependent mechanism. Conclusions: Hypertension associated with hypercholesterolemia is accompanied by structural modifications and expression of pro-inflammatory molecules by vessel wall, the alteration of vascular tone, enhanced release of MPs and reduced EPCs; the ratio between the latter two may be considered as a marker of vascular dysfunction. Irbesartan that exhibit a pharmacological control on the levels of MPs and EPCs has the potential to restore homeostasis of the arterial wall.

PCC413

Involvement of TRPA1 and reactive oxygen species in cinnamaldehyde-induced vasodilatation in the peripheral vasculature

A.A. Aubdool[1], X. Kodji[1], E.S. Fernandes[1], S. Bevan[2] and S.D. Brain[1]

[1]Cardiovascular Division BHF-Centre of Cardiovascular Excellence and Centre for Integrative Biomedicine, King's College London, London, UK and [2]Wolfson CARD Centre, King's College London, London, UK

The non-selective transient receptor potential ankryrin-1 (TRPA1) channels have been previously reported to be a major chemosensory receptor for reactive oxidants in sensory neurons in both in vivo and in vitro studies, but its importance to the vascular field has yet to be investigated. We have previously shown that cinnamaldehyde can activate TRPA1 and release potent microvascular vasodilators neuropeptide CGRP and nitric oxide (Aubdool et al., 2012) and, causes vasodilatation. We hypothesised that reactive oxygen species (ROS) are involved in the downstream signalling mechanism and this was investigated using the mouse ear model. Using laser Doppler flowmetry, cutaneous blood flow was measured in male CD1 mice (20-25g) under anaesthesia (ketamine-75mg/kg; medetomidine-25mg/kg, i.p.) and following topical application of cinnamaldehyde (10%) and vehicle (10% DMSO in ethanol). Ear samples were collected and hydrogen peroxide (H2O2) levels were assessed using the amplex red assay. All animals were randomly assigned to drug-treated or respective control groups. Results were expressed as mean + S.E.M. in arbitrary flux units and analysed by 2-way ANOVA + Bonferroni's test. A sustained (30 min) increase in vasodilatation was observed after topical application of cinnamaldehyde and this was significantly attenuated by a treatment of ROS scavenger N-acetylcysteine (NAC, 300mg/kg), (379.0 + 40.1 x 1000 flux units for control-treated vs 168.4 + 24.2 x 1000 flux units for NAC-treated, n=5-6, $p<0.001$). No change in H2O2 levels was observed in cinnamaldehyde-treated ears compared to vehicle. There was no significant change in cinnamaldehyde-induced vasodilatation in vehicle or NADPH oxidase inhibitor apocynin (20mg/kg, i.v.) pre-treated wild-type (WT) mice (n=6, $p>0.05$). However, TRPA1-mediated vasodilatation was significantly reduced by a co-treatment of superoxide dismutase (SOD) and catalase (25000U/kg, $p<0.01$, n=6), but not deactivated enzymes, supporting a novel role for ROS generation. This response was also attenuated in WT mice pre-treated with the iron chelator deferoxamine (25mg/kg, $p<0.001$, n=6) or the permeable SOD mimic TEMPOL (30mg/kg, $p<0.001$, n=6), suggesting a potential involvement of hydroxyl radicals and oxidative stress. These studies provide novel evidence that ROS are involved in TRPA1-dependent neurogenic vasodilatation in vivo.

Hydrogen peroxide via thromboxane A_2 receptors mediates myogenic response of small skeletal muscle veins in rats

B. Debreczeni[2,1], E. Gara[2], Z. Veresh[2,3], A. Marki[2], A. Racz[2], R. Matics[4], J. Hamar[4], R. Tamas[1] and A. Koller[2,4]

[1]Department of Plastic Surgery, Military Hospital, Budapest, Hungary, [2]Department of Pathophysiology, Semmelweis University, Budapest, Hungary, [3]First Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary and [4]Department of Physiology and Gerontology and Szentagothai Res Centre, University of Pécs, Pécs, Hungary

We aimed to test two hypotheses: 1) Isolated small veins develop substantial myogenic tone in response to elevation of intraluminal pressure. 2) H_2O_2 contributes to the mediation of myogenic response via activation of arachidonic acid (AA) cascade and release constrictor prostaglandins.
Methods:Small veins were isolated from gracilis muscle of male rats, then cannulated. Changes of diameter to increases in intraluminal pressure, H_2O_2 and arachidonic acid in the presence and absence of various inhibitors were measured by videomicroscope and microangiometer. At the end of experiments the passive diameter were obtained in Ca^{2+} - free PSS solution.
Results: Isolated rat gracilis muscle small veins developed a substantial myogenic tone in response to increases in intraluminal pressure (1 - 12 mmHg). Calculated maximum myogenic tone was 70 ± 5 % at 10 mmHg. Presence of catalase or indomethacin or SQ 29,548 reduced significantly the pressure-induced myogenic response. Also, H_2O_2 (10^{-9} - 10^{-5} M) and arachidonic acid (10^{-7} - 10^{-4} M) elicited concentration dependent constrictions, which were inhibited by the presence of indomethacin or SQ 29,548.
Conclusion:We propose that both myogenic response and pressure-induced release of H_2O_2 play important roles in regulating the vasomotor function of venules both in physiological and pathological conditions.
Key words: small veins, myogenic response, prostaglandins, hydrogen peroxide, indomethacin, SQ 29,548, catalase, arachidonic acid

Angiopoietin-1 increases turnover of endothelial glycocalyx in glomerular endothelial cells

S. Desideri[1,2], B. Foster[2], S. Satchell[2] and A. Salmon[1,2]

[1]School of Physiology & Pharmacology, University of Bristol, Bristol, UK and [2]Academic Renal Unit, University of Bristol, Bristol, UK

Endothelial glycocalyx is a gel-like structure present on the luminal surface of blood vessels [Weinbaum et al, Annu Rev Biomed Eng. 2007, 9:121:67]. Endothelial glycocalyx comprises proteoglycan core proteins, glycosaminoglycans (GAG) chains, sialoglycoproteins and contributes to the selective sieving action of the glomerular capillary wall. The endothelial glycocalyx is a critical determinant of permeability in kidney glomeruli. Disruption of the endothelial glycocalyx is linked with microalbuminuria in diabetes.Angiopoietin-1 is a paracrine growth factor synthesised by glomerular podocytes, that exerts paracrine actions on glomerular endothelail cells. Angiopoietin-1 decreases the ultrafiltration coefficient of single isolated glomeruli. In other capillary beds, parallel actions of angiopoietin-1 on hydraulic conductivity are mediated by increased depth of the endothelial glycocalyx. We have examined release of GAGs from the surface of human conditionally immortalized glomerular endothelial cells (ciGEnC) in vitro, and studied the effect of angiopoietin-1 on this process. Primary GEnCs, previously immortalised in our laboratory [Satchell et al, Kidney Int. 2006, 69 (9): 1633 - 1640] proliferate at 33°C, and differentiate to a non-proliferative quiescent state at 37°C. These ciGEnCs were differentiated and grown to 60–70% confluency, serum-starved for 3 hours, in the presence or absence of angiopoietin-1 (200ng/ml). After harvesting this supernatant, cell monolayers were exposed to either pronase (0.01%) or vehicle for 1 minute and the supernatant again aspirated. Harvested supernatant was added to an Alcian Blue solution, and the linear relation between GAG mass and decreased absorption of 488 nm light by Alcian Blue solution was used to quantify supernatant glycosaminoglycan content, referenced to known concentrations of GAG (chondroitin sulphate) standards. Supernatant GAG concentration was 72.57±39.65 (n=4) μg/ml from vehicle-treated endothelial cells, and significantly higher (150.3±61.81 (n=4) μg/ml) from pronase-treated endothelial cells ($p<0.01$, paired t-test). Supernatant harvested from endothelial cell monolayers exposed to angiopoietin-1 (90.94±21.89 μg/ml, n=3) demonstrated significantly higher GAG concentrations than supernatant from monolyers treated with serum-free media alone (50.35±13.73 μg/ml, n=3) ($p<0.05$, paired t-test). Increased GAG turnover by glomerular endothelial cells in response to angiopoietin-1 matches physiological data and studies in other capillary beds. The glycocalyx of glomerular endothelial cells thus appears modifiable by endogenous, paracrine agents.

Nebivolol induces dilation in isolated rat cerebral artery, independent of NO-cGMP pathway

P. CSEPLO[1,2], Z. Vamos[2,3], O. Torok[1], I.Z. Batai[1], J. Hamar[1] and A. Koller[1,4]

[1]Department of Pathophysiology and Gerontology, Univ Pecs, Medical School, Pecs, Hungary, [2]Hungarian National Ambulance Service, South-Danubian Region, Hungary, [3]Department of Anesthesiology and Intensive Therapy, Univ Pecs, Medical School, Pecs, Hungary and [4]Department of Physiology, New York Medical College, Valhalla, NY, USA

Keywords: nebivolol, cerebral artery, vasomotor, basilar artery, isolated artery, NO, cGMP
INTRODUCTION: Experimental and clinical studies have demonstrated that nebivolol has antiarrhythmic, antihypertensive effects and in peripheral arteries elicits dilation, in which mediation for nitric oxide (NO) has been suggested. However, its effect on the diameter of cerebral vessels has not been investigated. We hypothesized that nebivolol increases the diameter of isolated cerebral arteries.
METHODS: Basilar arteries (BA) were isolated from male Wistar rats and were mounted into a pressure-flow myograph chamber and cannulated at both ends. Vessels were incubated until a spontaneous active diameter developed. Diameters (D)

of vessels were measured with video-microscopy. Vasomotor function of vessels was studied in response to nebivolol and the nitric oxide (NO) donor sodium nitroprusside (SNP). NO synthase was inhibited by Nω-nitro-L-arginine methyl ester (L-NAME). Soluble guanylate cyclase was blocked by 1H-[1,2,4]oxadiazolo[4,3-a]quinoxalin-1-one (ODQ). At the end of the experiments the passive diameter of vessels (PD) was determined in Ca2+-free Krebs solution.
RESULTS: The active diameter of BA was ~220 μm (n=9). Nebivolol caused significant vasodilation (10-5M: ΔD = 67±18 μm; p<0,05). Incubation of BA with L-NAME significantly reduced the active diameter (by ΔD = 25±10 μm). In the presence of L-NAME nebivolol caused significant vasodilation, similar to control conditions (10-5 M: ΔD = 47±10 μm). Also, in the presence of ODQ, nebivolol elicited significant vasodilation (10-5 M: ΔD = 87±16 μm), whereas the SNP-induced dilation was significantly decreased (SNP 10-4 M: from ΔD[1] = 126±14 μm to ΔD[2] = 1±17 μm).
CONCLUSION: These findings demonstrate that in isolated cerebral arteries 1) nebivolol elicits significant dilation, 2) NO contribute to the development of basal tone, 3) but NO-cGMP pathway does not contribute significantly to the nebivolol-induced dilation. Elucidating the underlying mechanisms could contribute to a better understanding of the effects of nebivolol on cerebral circulation.

Novel role of the Plasma Membrane Calcium ATPase protein as an endogenous inhibitor of VEGF-induced angiogenesis

R.R. Baggott[1], A. Alfranca[2], T.A. Mohamed[3], B.C. Ornés[2], M.D. López-Maderuelo[2], A. Escolano[2], J. Oller[2], F.B. Rowther[1], D. Oceandy[3], J. Brown[4], E.J. Cartwright[3], W. Wang[1], L. Neyses[3], J.M. Redondo[2] and A.L. Armesilla[1]

[1]Research Institute in Healthcare Science, University of Wolverhampton, Wolverhampton, UK, [2]Dept of Vascular Biology and Inflammation, Centro Nacional de Investigaciones Cardiovasculares CNIC, Madrid, Spain, [3]Cardiovascular Research Group, University of Manchester, Manchester, UK and [4]Aston Research Centre for Healthy Ageing, Aston University, Birmingham, UK

A large body of data has demonstrated that aberrant expression of VEGF (Vascular Endothelial Growth Factor) plays a critical role in the abnormal vascularisation associated with several human diseases. Angiogenic responses stimulated by VEGF involve the activation of the calcineurin/NFAT (Nuclear Factor of Activated T-cells) signal transduction pathway. We have previously identified an inhibitory interaction between the Plasma Membrane Calcium ATPase (PMCA) family of proteins and calcineurin in HEK-293 and breast cancer cells. PMCAs are enzymatic low capacity, high-affinity systems involved in the extrusion of Ca^{2+} from the cell. It is thought that PMCA regulates the activity of the calcineurin/NFAT pathway by tethering calcineurin to low Ca^{2+} microdomains created by the Ca^{2+} extrusion activity of the pump. Given the relevance of the calcineurin/NFAT pathway in the progression of angiogenesis, we have investigated whether PMCA plays a significant role as an endogenous inhibitor of VEGF-mediated angiogenesis.
"Gain of function" studies conducted in HUVEC cells overexpressing PMCA4 by infection with Ad-PMCA4 (an adenovirus encoding human PMCA4), resulted in a significant decrease in the VEGF-induced activation of the calcineurin/NFAT pathway (31.92±8.74% reduction compared to the value observed in cells infected with control adenovirus Ad-LacZ, n=5). Similarly, VEGF-induced up-regulation of the NFAT-dependent, angiogenic genes Cox-2 and RCAN-1 was significantly attenuated (55.04±4.12%, n=5, and 48.42±4.72%, n=5, decrease respectively) by infection with Ad-PMCA4. PMCA4 overexpression also reduced the migration (39.8±4.08 reduction, n=6) and in vitro tube formation (42.24±10.92 reduction, n=5) of VEGF-stimulated HUVEC cells infected with Ad-PMCA4b. Moreover, *in vivo* angiogenesis assays performed by subcutaneous inoculation of a mixture of low growth factor-matrigel, VEGF and adenoviral vectors, in mice anesthetized with an intra-peritoneal injection of ketamine (75mg/kg)-xylazine (10mg/kg) showed a reduction of blood vessel formation (41.8±8.55 decrease, n=8) in plugs containing Ad-PMCA4.
Conversely, "loss of function" experiments performed in mouse lung endothelial cells (MLEC) isolated from PMCA4-/- knockout animals showed a significant increase in the activation of the calcineurin/NFAT pathway (4.25±1.08 fold-increment), the expression of the RCAN-1 protein as observed by western blot (n=3) and the migration of cells in wound-healing assays (1.66±0.56 fold-increment) when compared to the corresponding values in wild-type MLEC cells
These results strongly demonstrate that PMCA4 plays a critical role as a negative regulator of VEGF-mediated angiogenesis *via* inhibition of the calcineurin/NFAT pathway. Thus, modulation of endothelial PMCA4 activity might be exploited in clinic to design new anti-angiogenic approaches.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCC418

Ferrous ion potentiates ascorbate-dependent iron release from ferritin in vitro

C. Badu-Boateng, R.C. Siow, G.E. Mann and R.J. Naftalin

Cardiovascular Division, BHF Centre of Research Excellence, School of Medicine, King's College London, London, UK

Ferritin is a multimeric protein that stores 30% of human body iron as oxidised crystalline ferric phosphate, mainly in liver and heart muscle and in haemopoetic tissue and endothelium. Ascorbate causes iron release from ferritin by reducing stored iron (Km≈ 2 mM). Raised concentrations of non-protein bound iron catalyse formation extracellular and intracellular reactive oxygen species (1). Since intracellular and extracellular concentrations of ascorbate are generally within the range 40-250μM, this process is considered unlikely to contribute to pathological oxidation reactions. Only when ascorbate is raised > 2mM by i.v. injection is it deemed to be pro-oxidant (2). However, we have observed that ascorbate-dependent ferrous iron loss from horse spleen ferritin 50 nM (Sigma-Aldrich, UK), monitored for 2-3 h using a plate reader at 24°C to detect changes in absorption of ferrozine at 562μm (pH 7.0 buffered with sodium citrate 10 mM; MOPS 50 mM and 75μM ferrozine) is synergized by ferrous iron > 2 μM). Raising Fe(II) from 0 to 10μM decreases the Km of ascorbate-dependent Fe(II) release to 185±10μM (P < 0.001) and increases the Vmax of release 5-fold from 11.4±0.2 to 60±2.0 nmol Fe(II) mg-1ferritin min-1(P < 0.001). In the absence of external iron, hydrogen peroxide

acts as a potent non-competitive inhibitor of Vmax of ascorbate-dependent iron release by promoting two electron Fe(II) oxidation within ferritin(I.C50 111±34 μM). The IC50 of H2O2 on the apparent Km of ascorbate-dependent Fe(II) release is 352±92μM; addition of 10 μM Fe(II) with superoxide dismutase (50 units ml-1) reduces the IC50 to H2O2 30±42μM ($P < 0.01$) without altering the Vmax of Fe(II) release. Thus, H2O2 changes from a non-competitive inhibitor of ascorbate dependent of Fe(II) release in the absence of external Fe(II) to a competitive inhibitor when Fe(II) is present. These results suggest that single electron reactions generated by iron-ascorbate interaction, possibly resulting from ascorbyl and ferryl radical are a potent means of iron reduction and release from ferritin (3,4) and that this release mode differs from that caused by ascorbate alone, which may reduce bound di-Fe(III) at the ferroxidase centre by a bidentate two-electron reduction. Our novel finding that ascorbate and iron synergistically exacerbate iron release from ferritin has many implications relating to inflammatory mechanisms, the most immediate provides a rationale for iron-chelation therapy of arthritis and atherosclerosis, where iron and ascorbate and H2O2 released from necrotic macrophages and endothelium provide essential substrates for Fenton-Haber-Weiss reactions continuously generating superoxide and •OH radicals (5).

Signalling pathways involved in 5-HT-induced contraction dependent on connexin 43 and superoxide anion production in rat intrapulmonary arteries

N. Khoyrattee[1], M. Billaud[2], A. Bourdieu[1], G. Cardouat[1], R. Marthan[1], J. Savineau[1] and C. Guibert[1]

[1]Centre de Recherche Cardio-Thoracique de Bordeaux, Bordeaux, France and [2]Robert M. Berne Cardiovascular Researh Center - University of Virginia, Charlottesville, VA, USA

We previously showed that serotonin (5-HT) produces superoxide anion ($O_2^{\bullet-}$) in the intrapulmonary artery (IPA) smooth muscle. Then, $O_2^{\bullet-}$ passes through the myoendothelial junction (connexin (Cx) 43) to decrease the bioavailability of endothelial NO and strengthen IPA vasoreactivity (Billaud et *al.,* 2009). Here, we further addressed the signalling pathways involved in such process.

Male Wistar rats were humanely killed according to national guidelines. IPA were used for immunofluorescence labellings and recording of $O_2^{\bullet-}$ levels by electron paramagnetic resonance (EPR). Mitochondrial Ca^{2+} (Ca^{2+}_m) was assessed in smooth muscle cells with Rhod-2. Isometric contraction was recorded on IPA rings with an organ bath system. Results were expressed as mean ± S.E.M. Significance was considered when $P<0.05$ and tested with Mann-Whitney (unpaired samples) and Student *t*-Test (paired samples). n represents the number of rats for EPR and immunofluorescence, the number of arterial rings for the contractile studies and the number of cells for Ca^{2+}_m recordings.

5-HT (100 μM) significantly increased $O_2^{\bullet-}$ levels in rat IPA (8672.8 ± 752.9 arbitrary units per $mg.ml^{-1}$ of proteins in response to 5-HT vs 5205 ± 589.7 in basal conditions, n=12-13). Endothelin-1 (ET-1) (0.1 μM) and phenylephrine (Phe) (10 μM) had no effect. Ketanserin (1 μM), a blocker of $5\text{-}HT_{2A}$ receptors significantly decreased 5-HT-induced $O_2^{\bullet-}$ production whereas blocking the $5\text{-}HT_{1B}$ receptors and the 5-HT transporter (5-HTT) by GR 127935 (1 μM) or citalopram (1 μM) respectively had no effect (n=11-12). EPR recordings showed that removal of extracellular Ca^{2+} (Ca^{2+}_e) decreased 5-HT-induced $O_2^{\bullet-}$ increase (6310 ± 585.8, p=0.016) whereas depleting intracellular Ca^{2+} stores with thapsigargin (1 μM) had no effect (n=12-13). Blockers of $O_2^{\bullet-}$ sources namely apocynin (30 μM) and rotenone (5 μM) for NADPH oxidase (Nox) and the complex I of the mitochondrial respiratory chain (MRC I) respectively, reduced 5-HT-induced $O_2^{\bullet-}$ increase (n = 10-19). 5-HT enhanced the Ca^{2+}_m level with or without Ca^{2+}_e (n=30-40). Inhibition of PKC_ε significantly reduced $O_2^{\bullet-}$ production to its basal level (n=8-9). Unlike $5\text{-}HT_{1B}$ and ET_B receptors, both $5\text{-}HT_{2A}$ and α_{1D} receptors (Phe receptors) colocalised with Cx 43. $5\text{-}HT_{2A}$ receptors and Cx 43 also colocalised with caveolin-1. Unlike the contraction to ET-1, the contraction to 5-HT and Phe was significantly modified after caveolae removal with methyl-β-cyclodextrin (7 mM) (n=12-26).

Altogether, 5-HT acts on $5\text{-}HT_{2A}$ receptors and induces a calcium influx responsible for Ca^{2+}_m increase and $O_2^{\bullet-}$ production (via MRC I). This process activates PKC_ε which in turn may activate $O_2^{\bullet-}$ production by Nox. Interestingly, $O_2^{\bullet-}$ production in rat IPA seems to be 5-HT specific and would happen in caveolae localised near to Cx43.

Tissue plasminogen activator and plasminogen activator inhibitor-1 promote biointegration of porous polyethylene implants

M.E. Hessenauer[1,2], C.A. Reichel[1,2], A. Berghaus[2] and S. Strieth[3]

[1]Walter Brendel Centre of Experimental Medicine, Munich, Germany, [2]Department of Otorhinolaryngology, Head and Neck Surgery, Ludwig-Maximilians-Universität München, Munich, Germany and [3]Department of Otorhinolaryngology, Head and Neck Surgery, Goethe-University, Frankfurt/M., Germany

Background

Rapid fibrovascularization and a moderate inflammatory response are considered as prerequisites for a successful engraftment of porous polyethylene (PPE) implants. Plasmin is the principal effector protease in the fibrinolytic system and has recently been implicated in tissue integration of biomaterials. Tissue plasminogen activator (tPA) is the main plasminogen activating protease, whose activity is tightly controlled by plasminogen-activator inhibitor-1 (PAI-1). So far, the functional relevance of tPA and PAI-1 for the engraftment of biomaterials remains largely unclear.

Materials and Methods
Using *in vivo* fluorescence microscopy, vessel density and leukocyte-endothelial cell interactions were evaluated on days 7, 10, and 14 after implantation of PPE implants in dorsal skinfold chambers in wild-type, tPA-/-, or PAI-1-/- mice. Tissue integration was analyzed on day 14 by measuring the force needed for mechanical removal of the implant out of the host tissue. Collagen deposition within the implant was assessed by second-harmonic imaging microscopy. PPE implants coated with recombinant or modified proteins were analyzed in a separate set of experiments. All surgical procedures were performed under anesthesia with ketamine (75 mg/kg b.w. i.p.) and xylazine (25 mg/kg b.w. i.p.). For statistical analysis, the ANOVA on ranks test followed by the Student-Newman-Keuls test was used.
Results
Vessel density and leukocyte-endothelial cell interactions in the host tissue did not significantly differ among experimental groups. In contrast, vessel density and leukocyte-endothelial cell interactions in the implant on days 7 and 10 after implantation as well as collagen deposition within the implant were significantly diminished in tPA- or PAI-1-deficient animals. Moreover, mechanical integration of the implant material was significantly attenuated in tPA or PAI-1 deficient animals. Conversely, surface coating with recombinant tPA or PAI-1 significantly accelerated implant vascularisation in wild-type mice, while leukocyte-endothelial cell interactions in the implant or the host tissue as well as mechanical integration of the implant were not significantly altered. Surface coating with a tPA mutant lacking its enzymatic activity did not significantly improve implant vascularisation.
Conclusions
Endogenous tPA and PAI-1 promote functional tissue integration of PPE biomaterial through effects on implant fibrovascularisation. In this context, tPA is thought to mediate these effects largely via its proteolytic properties. As a clinical perspective, surface coating with recombinant tPA or PAI-1 might provide a novel strategy for accelerating the vascularisation of PPE implants under unfavorable conditions for implantation.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Semi-automatic analyses of skin capillary density: validation and reproducibility studies

D. Muris[1,2], E. Gronenschild[3], M. Schram[1,2], . Karaca[1,2], C. Stehouwer[1,2] and A. Houben[1,2]

[1]Department of Internal Medicine, Maastricht University, Maastricht, Netherlands, [2]Cardiovascular Research Institute Maastricht (CARIM), Maastricht University, Maastricht, Netherlands and [3]Department of Psychiatry and Neurophychology, Maastricht University, Maastricht, Netherlands

Background: Skin capillaroscopy has been proven to be a valid tool to study microvascular function non-invasively in humans. Unfortunately, the analysis of capillary density from video-clips is very time-consuming, since this is done manually. This impedes the use of this technique in large-scale studies. We aimed to develop a (semi-)automated assessment of skin capillary density.
Methods: CapiAna (Capillary Analysis) is a newly developed semi-automatic image analysis application. The technique involves four steps: 1) movement correction, 2) positioning of the region of interest (ROI) and selection of the frame range, 3) automatic detection of capillaries, and 4) manual correction of detected capillaries. We assessed accuracy, reproducibility, and time-savings of the semi-automatic method as compared to the manual counting procedure. For this, finger skin capillary density was measured in 10 healthy participants (6 women; mean age 55.7 (49 – 68) years). First, to investigate agreement between the semi-automatic method and the manual procedure, we used linear regression and Bland-Altman analysis. Second, intra- and interobserver reproducibility of the semi-automatic method was assessed by calculating coefficients of variation (CV). For this, an experienced investigator semi-automatically counted the number of capillaries twice with a two week interval. In addition, a second experienced investigator semi-automatically counted the number of capillaries in exactly the same ROI. Finally, the difference in analysis-time between the semi-automatic and the manual method was assessed.
Results: Linear regression of the data resulted in a correlation (r) of 0.88 between the semi-automatic method and the manual procedure. The comparison between the semi-automatic method and the manual method by the Bland-Altman analysis, showed a bias of -3.9 capillaries/mm2 (<5%) and limits of agreement (± 2 SD) of +13.6 to -21.4 capillaries/mm2 (approximately 17%). The intra- and interobserver CV of the semi-automatic method were 2.0% and 5.4% respectively. Finally, the mean analysis time for the semi-automatic method was on average 30 minutes versus 90 minutes for the fully manual procedure.
Conclusion: In conclusion, we have developed a semi-automatic image analysis application for the assessment of skin capillary density. The results indicate that the semi-automatic method is in good agreement with the manual procedure, with a good correlation and with a small bias and reasonable limits of agreement. In addition, the semi-automatic method is more reproducible as compared to previous data for the manual procedure. Finally, analysis time with the semi-automatic method was significantly reduced. This new analysis technique offers opportunities for skin capillaroscopy as a tool to estimate microvascular function in large-scale studies.

Targeted lentiviral gene delivery to the vasculature using the magnetic microbubble technology

Y. Stampnik[1], F. Krötz[5], J. Pircher[1], K. Zimmermann[2], D. Eberbeck[6], M. Wörnle[4], M. Anton[3], U. Pohl[1] and H. Mannell[1]

[1]Walter-Brendel Centre of Experimental Medicine, Ludwig-Maximilians-University, Munich, Germany, [2]Institute of Pharmakology and Toxicology, Bonn University, Bonn, Germany, [3]Institute of Experimental Oncology and Therapy Research, Klinikum rechts der Isar, Technical University, Munich, Germany, [4]Nephrology, Medical Policlinic, Ludwig-Maximilians-University, Munich, Germany, [5]Interventional Cardiology, Starnberg Community Hospital, Munich, Germany and [6]Physikalisch-Technische Bundesanstalt, Berlin, Germany

Question: Achievement of site-specificity and potent gene transfer is a great therapeutic challenge. Here we investigated whether intravascular application of lentiviruses (LVs) coupled to magnetic microbubbles (MMBs) could efficiently establish a localised gene transfer *in vivo*. As a technique for tissue spe-

cific targeting the efficiency of a combination of trapping the MMBs by localized magnetic field (MF) application and their subsequent destruction by ultrasound (US) exposure in the mouse dorsal skin fold chamber model was tested.
Methods: Coupling of LVs containing a membrane GFP-fusion protein to MMBs was verified by flow cytometry. Mice (C57BL/6) were anesthetized with intraperitoneal injection of 3mg/kg body weight Midazolam, 0.03mg/kg body weight Fentanyl and 0.3mg/kg body weight Medetomidinhydrochloride in 0.9 % NaCl. *In vivo*, LV-coupled MMBs (1.6x106-1.5x107 infectious particles) were targeted to vessels of the mouse dorsal skin after intra-arterial injection by combined MF (1T) and US exposure (1MHz, 2W/cm2, DC50%, 30sec). Reporter gene expression (GFP) in the dorsal skin and in organs not exposed to MF and US was assessed by real-time PCR in tissue homogenates obtained 48-96h after treatment. Biodistribution of MNPs, to assess time of tissue clearance, was measured in homogenized organs by magnetic particle spectrometry 1h and 96h after injection of MMBs. Residual viral particle amount in blood, urine, stool and saliva 48-96h after treatment was analyzed with p24 ELISA and cell culture.
Results: LVs readily associated with MMB *in vitro* (20-fold increase in fluorescent units, $p<0.05$, ANOVA, n=3). *In vivo*, MMB specifically delivered the coupled genetic material to the dorsal skin after MF and US application. The achieved gene transfer efficiency of LV-associated MMB in the dorsal skin was enhanced 120-fold compared to pDNA-associated MMB, as assessed by reporter gene expression ($p<0.05$, t-test, LV n=4; pDNA n=10). MNP accumulation was detected mainly in the lung and liver (19±4% and 41±9% of administered dose respectively, n=5) 1h after treatment, which was strongly reduced 96h after treatment (0.2±0.07% and 0.3±0.09% of administered dose respectively, n=4). No residual LVs were detected in the collected biological samples 48-72h after LV-MMB application (n=3).
Conclusion: Magnetically-guided microbubbles were successfully applied as carriers for lentiviral gene vectors. Using the combination of magnetic targeting and US induced MB destruction, they allow for highly efficient and site-specific vascular gene transfer. Moreover, our data provides evidence that the coupled magnetic nanoparticles are effectively cleared from the organism indicating the aptitude of our method as a biocompatible therapy approach. In conclusion, the LV-associated MMB technology may represent a valuable tool for vascular gene therapy.

Waist circumference and blood pressure are associated with microvascular vasomotion in a healthy population: the Maastricht Study

D. Muris[1,2], M. Schram[1,2], A. Houben[1,2] and C. Stehouwer[1,2]

[1]Department of Internal Medicine, Maastricht University, Maastricht, Netherlands and [2]Cardiovascular Research Institute Maastricht (CARIM), Maastricht University, Maastricht, Netherlands

Background: Microvascular vasomotion, i.e. rhythmic changes in vascular diameter, is thought to play an important role in ensuring optimal delivery of nutrients and oxygen to tissue. Impaired microvascular vasomotion has been demonstrated in states of obesity and type 2 diabetes mellitus (T2DM) (i.e. decreased vasomotion), and hypertension (i.e. enhanced vasomotion). It is unclear however, which factors influence microvascular vasomotion. Therefore, we investigated associations between traditional risk factors and microvascular vasomotion in a healthy population.
Methods: We measured skin microvascular vasomotion in 241 healthy individuals (mean age 56 ± 8 years, 42% men, mean body mass index (BMI) 25.4 ± 3.6 kg/m2) enrolled in the Maastricht Study. We selected a healthy population without T2DM, hypertension, prior cardiovascular disease, or use of cardiovascular medication. Skin blood flow was measured with a laser Doppler probe at the dorsal side of the left wrist. Fast-Fourier transform analysis was performed to determine the five frequency components to the variability of the laser Doppler signal (i.e., endothelial, 0.01–0.02 Hz; neurogenic, 0.02–0.06 Hz; myogenic, 0.06–0.15 Hz; respiratory, 0.15–0.40 Hz; and heart beat, 0.40–1.60 Hz). The associations of age, sex, waist circumference, total-to-HDL cholesterol, 24-h mean arterial pressure (MAP), fasting plasma glucose, and cigarette smoking with microvascular vasomotion was analyzed by use of multiple linear regression analysis.
Results: Higher waist circumference and 24-h MAP were associated with a lower and higher total microvascular vasomotion, respectively. Per one standard deviation (SD) higher waist circumference total microvascular vasomotion was -0.17 SD (95%CI: -0.32; -0.03) lower. One SD higher 24-h MAP was independently associated with a 0.18 SD (0.04; 0.32) higher total microvascular vasomotion. We found no associations of microvascular vasomotion with age, sex, total-to-HDL cholesterol, fasting plasma glucose, or smoking. Analysis of the five frequency bands revealed that these results were largely attributable to the contributions of the endothelial, neurogenic, and myogenic components. Sub-analysis with exclusion of the obese subjects (BMI>30 kg/m2; n = 23) gave similar results.
Conclusion: In conclusion, in a healthy population waist circumference is inversely associated with microvascular vasomotion. In addition, blood pressure is directly associated with microvascular vasomotion. These data suggest that both elevations in waist circumference and blood pressure may affect microvascular vasomotion, and subsequently optimal nutrients delivery and tissue perfusion.

PCD001

Cyclic AMP binds to the HCN2 C-terminus with higher affinity than cyclic GMP

S.S. Chow, F. Van Petegem and E. Accili

University of British Columbia, Vancouver, BC, Canada

Pacemaker HCN channels are found in a variety of excitable cells in heart and brain to control membrane potential. Both cAMP and cGMP facilitate HCN2 opening to the same extent, but the former is more potent (1,2). We asked if the greater cAMP potency, based on electrophysiological assay of its effects on channel opening, was due to better binding or to a more sensitive post binding event. Here, we purified the HCN2 C-terminus and measured binding affinity of cAMP and cGMP to the tetrameric form using isothermal titration calorimetry. We show that cGMP binds to the HCN2 C-terminus with negative cooperativity, as does cAMP, but with a lower affinity for single the high affinity site and the three low affinity binding sites. The overall lower affinity of cGMP binding to the

HCN2 channel explains its lower potency as compared to that of cAMP. Nevertheless, high affinity binding of cGMP, K_d < 1M, occurs in a range of concentrations that could be relevant *in vivo*.

Importance of Caveolin-1 in ouabain-induced Na^+K^+-ATPase signaling and cardiac hypertrophy but not in inotropic effect in mouse hearts

Y. Bai, J. Wu, D. Li and L. Liu

Biochemistry, University of Toledo, Toledo, OH, USA

Cardiac glycoside ouabain, when bound to cardiac Na^+K^+-ATPase (sodium pump), inhibits the pump leading to positive inotropy. It also stimulates sodium pump interacting with other proteins and activates several signaling pathways including phosphatidylinositol 3-kinases (PI3K) /Akt and ERK pathways (1,2). These events originate in the plasma membrane caveolae (3,4). In cardiomyocytes, caveolins 1, 2 and 3 are present. This study aims to examine the role of caveolin-1 in Na^+K^+-ATPase mediated cardiac signaling and cardiac function using wild type (WT) and caveolin-1 knockout (cav-1KO) mice. Ouabain-induced PI3K/Akt and ERK activation and - caused cardiac hypertrophy were reduced markedly in cav-1 KO cardiomyocytes. Additionally, association of the Na^+K^+-ATPase α1 subunit and caveolin-3 was decreased in cav-1 KO cardiomyocytes. Moreover, ouabain-induced interaction of the α1 subunit of Na^+K^+-ATPase and PI3K was also reduced in cav-1 KO cardiomyocytes. Deletion of cav-1 reduced protein content of PI3K/Akt and the β1 subunit of Na^+K^+-ATPase in caveolar fractions in cardiomyocytes. Transient ouabain infusion increased cardiac contractility in WT and KO mice monitored through cardiac catheterization. Surprisingly, the effect of ouabain on cardiac contractilities was not reduced when cav-1 was absent. This was further confirmed with isolated working hearts from WT and cav-1 KO mice. Our data indicate that ouabain-induced cardiac signaling and hypertrophy is mediated by a mechanism through interaction of cav-1 and Na^+K^+-ATPase. However, ouabain exerted caveolin-1-independent cardiac contractility.

Identification a pool of cardiac phospholemman that does not interact with the sodium pump

K. Wypijewski[1], J. Howie[1], L. Reilly[1], K. Aughton[2], M.J. Shattock[2], S. Calaghan[3] and W. Fuller[1]

[1]Division of Cardiovascular & Diabetes Medicine, College of Medicine Dentistry & Nursing, University of Dundee, Dundee, UK, [2]Cardiovascular Division, King's College London, London, UK and [3]School of Biomedical Sciences, Faculty of Biological Sciences, University of Leeds, Leeds, UK

Phospholemman (PLM), the principal quantitative sarcolemmal substrate for protein kinases A and C in the heart, regulates the cardiac sodium pump. Much like phospholamban, which regulates the sodium pump-related calcium ATPase SERCA, PLM is reported to oligomerise. We investigated subpopulations of PLM in adult rat ventricular myocytes based on phosphorylation status.

Calcium-tolerant ventricular myocytes (ARVM) were isolated from adult male Wistar rats (200-250g) by retrograde perfusion of collagenase in the Langendorff mode. Myocytes were left to recover for 2 hours at 35ºC before experiments.

Coimmunoprecipitation identified two pools of PLM: one not associated with the sodium pump phosphorylated at serine 63 (S63), and one, associated with the pump, both phosphorylated at serine 68 and unphosphorylated. Phosphorylation of PLM at S63 following activation of PKC did not abrogate association of PLM with the pump, so its failure to associate with the pump was not due to phosphorylation at this site. All pools of PLM co-localised to cell surface caveolin-enriched microdomains with sodium pump α subunits, despite the lack of caveolin-binding motif in PLM. Mass spectrometry analysis of phosphospecific immunoprecipitation reactions revealed no unique protein interactions for S63- phosphorylated PLM, and crosslinking reagents also failed to identify any partner proteins for this pool. The sodium pump α subunit co-immunoprecipitated with PP2A from ARVM lysates. Since PLM-S63 is the only phosphorylation site in PLM dephosphorylated by PP2A, this likely explains the lack of S63-phosphorylated PLM associated with the pump.

In lysates from hearts of heterozygous transgenic animals expressing wild type and unphosphorylatable PLM, S63- phosphorylated PLM co-immunoprecipitated unphosphorylatable PLM, therefore confirming the existence of PLM multimers.

Hence we report the existence of a subpopulation of PLM that interacts only with other PLM molecules and not with the Na pump, with a unique phosphorylation status driven by differential proximity of protein phosphatases. Like phospholamban regulation of SERCA, PLM exists as a sodium pump inhibiting monomer and an un-associated oligomer. The distribution of different PLM phosphorylation states to different pools may be explained by their differential proximity to protein phosphatases, rather than a direct effect of phosphorylation on PLM association with the pump.

PCD004

Proteome-wide characterisation of lipid raft proteins in adult rat ventricular myocytes

K. Wypijewski[1], M. Tinti[2], S.C. Calaghan[3] and W. Fuller[1]

[1]Division of Cardiovascular & Diabetes Medicine, College of Medicine Dentistry & Nursing, University of Dundee, Dundee, UK, [2]College of Life Sciences, University of Dundee, Dundee, UK and [3]School of Biomedical Sciences, Faculty of Biological Sciences, University of Leeds, Leeds, UK

The lipid raft concept proposes that membrane environments enriched in cholesterol and sphingolipids cluster certain proteins and form platforms to integrate cell signalling. In cardiac muscle, caveolin-enriched rafts concentrate signalling molecules and ion transporters, and therefore play a vital role in adrenergic regulation of cardiac excitation-contraction coupling. The aim of this project was to define the proteome of cardiac lipid rafts, and to investigate dynamic changes in the protein constituents of rafts following activation of α1, β1 and β2 adrenoceptors (AR).

Calcium-tolerant ventricular myocytes (VM) were isolated from the hearts of adult male Wistar rats by retrograde perfusion of collagenase. Myocytes were left to recover for 2 hours at 35ºC before experiments. VM were treated with methyl-β-cyclodextrin (MβCD) to deplete cholesterol and disrupt lipid rafts. Rafts were prepared from MβCD-treated and control cell lysates using a standard discontinuous sucrose gradient. Buoyant rafts were harvested, pelleted, resolubilised, alkylated, digested and labeled with iTRAQ reagents, and proteins identified by LC-MS/MS on a LTQ Orbitrap Velos Pro. Proteins were defined as lipid raft resident if they were consistently depleted from the raft fraction following MβCD treatment, and as contaminants (principally mitochondrial) if they were not.

We typically identified 600-850 raft proteins per experiment, of which 254 were defined as high-confidence lipid raft residents. Functional annotation clustering indicates that cardiac lipid rafts are enriched in integrin signalling, guanine nucleotide binding, ion transport, and insulin signalling clusters. The presence of selected proteins of each group in the lipid rafts was validated by immunoblotting.

In order to define changes in cardiac lipid rafts during adrenergic signalling, field-stimulated VM were treated with α- (10μM phenylephrine, 10μM atenolol), β1- (100nM isoprenaline, 100nM ICI118,551) and β2- (10μM zinterol, 300nM CGP20712A) AR agonists for 10 min prior to lysis and preparation of lipid rafts. Following iTraq analysis, raft resident proteins showing a change in abundance in a minimum 3 out of 4 experiments were selected. β1 AR activation is associated with a decrease in abundance of PKA RIIα and an increase in abundance of cavin isoforms in cardiac lipid rafts. β2 AR stimulation increases the abundance of G protein and L-type Ca channel subunits in cardiac rafts.

In conclusion, we have identified 254 lipid raft proteins in adult rat cardiac myocytes and shown for the first time that these domains are re-organised on an acute timescale in response to β-AR stimulation. Dynamic changes in certain raft components may be necessary to ensure a rapid and high fidelity response to adrenergic stimulation in cardiac muscle.

PCD005

Metabolic stress alters the balance between palmitoylation and glutathionylation of the Na pump regulatory protein phospholemman

J. Howie[1], J. Swarbrick[1], M.J. Shattock[2] and W. Fuller[1]

[1]Cardiovascular and Diabetes medicine, University of Dundee, Dundee, UK and [2]Cardiovascular Division, King's College, London, UK

Acute regulation of the cardiac Na pump by extracellular stimuli is crucial in allowing the heart to match its output to systemic requirements. Phospholemman (PLM) regulates the cardiac Na pump. Unphosphorylated PLM inhibits the pump, and PLM phosphorylation causes pump activation. Phospholemman is also palmitoylated at cysteines 40 and 42, which inhibits the pump, and glutathionylated at cysteine 42, which relieves oxidative inhibition of the pump.

Since PLM may be palmitoylated and glutathionylated at the same cysteine, we investigated competition between these post-translational modifications during oxidative and metabolic stress in freshly dispersed adult rat ventricular myocytes (ARVM, isolated from adult male Wistar rats) and FT293 cells stably expressing wild type (WT), C40A and C42A PLM. Palmitoylation was measured by resin-assisted capture of acylated proteins followed by quantitative immunoblotting, and glutathionylation by streptavidin affinity purification after loading cells with biotinylated glutathione ethyl ester. Data are presented as mean±SEM, with differences analysed by t-test.

Acute exposure of ARVM and FT293 cells expressing wild type PLM to hydrogen peroxide (1μM–10mM, 30min at 37˚C) was without effect on PLM palmitoylation. Metabolic stress was induced in FT293 cells expressing WT PLM by 18 hours culture in media supplemented with glucose (HG, 25mM) and / or palmitic acid (HP, 0.4mM). Although HG or HP alone were without effect on PLM palmitoylation, combined HG/HP caused a substantial reduction in PLM palmitoylation (5.7±2.4 fold reduction compared to untreated cells, n=4, $p<0.05$). Glutathionylated PLM was undetectable in untreated FT293 cells expressing WT PLM, but readily detectable following 18 hours HG/HP culture.

In order to identify which palmitoylation site in PLM is susceptible to metabolic stress, FT293 cells expressing palmitoylation site mutants were cultured in HG or HG/HP conditions. HG/HP culture induced a substantial reduction in palmitoylation of C40A PLM (3.0±0.8 fold reduction compared to untreated cells, n=3, $p<0.05$), but was without effect on the palmitoylation of C42A PLM.

In conclusion, metabolic but not acute oxidative stress promotes glutathionylation of PLM cysteine 42 with a concomitant reduction in palmitoylation at this site. Metabolic stress may therefore influence Na pump activity by promoting glutathionylation over palmitoylation of PLM. The cellular outcome of HG/HP stress is mitochondrial free radical production, yet exogenous hydrogen peroxide is without effect on PLM palmitoylation, so the subcellular location at which oxidising species are generated or the duration of an oxidant stress are important determinants of the balance between PLM palmitoylation and glutathionylation.

PCD006

Kolaviron, a biflavonoid of Garcinia kola seed offered cardioprotection against ischaemic/reperfusion injury by up-regulation of pro-survival and down-regulation of apoptotic signaling pathways

A.A. Oyagbemi[1,2], E.O. Farombi[2,1], J.D. Bester[2,3] and A.J. Esterhuyse[2,3]

[1]Veterinary Physiology, Biochemsitry and Pharmacology, University of Ibadan, Ibadan, Oyo, Nigeria, [2]Drug Metabolism and Toxicology Unit, Department of Biochemistry, College of Medicine, University of Ibadan, Ibadan, Oyo, Nigeria and [3]Oxidative Stress Research Centre, Department of Biomedical Sciences, Cape Peninsula University of Technology, Bellville, 7535, South Africa, Cape Town, Western Cape, South Africa

Possible cardioprotective effect of Kolaviron (KV) administration and the molecular mechanism (s) involved in ischaemic/reperfusion injury of isolated rat hearts were assessed. Twenty rats were used for this study. They were grouped into ten rats of group of two. Rats in group I received 2ml/kg of corn oil (vehicle) while animals in groups II received 200 mg/kg body weight of Kolaviron (KV) for four weeks respectively. Isolated rat hearts were stabilized for 5 minutes on Langendorff, perfused on working heart model for 10 minutes and subjected to global ischaemia for 15 minutes followed by 25 minutes reperfusion. Antioxidant enzymes, markers of oxidative stress and western blot analyses were carried out on snap-frozen heart tissues. There was significant ($p<0.05$) increase in superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx), oxygen radical absorbance capacity (ORAC) and concomitant significant ($p<0.05$) decrease in malondialdehyde (MDA) and intracellular reactive oxygen species (ROS) in isolated rat hearts of animals that received KV compared to the control. Western blot analysis revealed significant up-regulation of Akt/PKB, p- Akt/PKB, HSP27, p-HSP27 and down-regulation of p38 MAPK, Caspase 3, cleaved Caspase 3and cleaved PARP. Taken together, KV offered cardioprotection by enhancing the expression of pro-survival signaling pathway and abrogation of apoptotic pathway in isolated rat hearts subjected to ischaemic/reperfusion injury

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Targeting ventricular arrhythmias: MKK7 a remarkable player?

S.K. Chowdhury[1], M. Zi[2], W. Liu[1,2], H. Tsui[2], Y. Wang[2], H. Shiels[1], E.J. Cartwright[2], M. Lei[2] and X. Wang[1]

[1]Faculty of Life Sciences, University of Manchester, Manchester, UK and [2]Cardiovascular Research Group, School of Biomedicine, Faculty of Medical & Human Sciences, University of Manchester, Manchester, UK

Heart failure and cardiac arrhythmias are known consequences of ventricular remodelling. Key signalling pathways responsible for such hypertrophic remodelling include the mitogen-activated protein (MAP) kinase cascade. MAP kinase kinase 7 (MKK7), positioned at a bottleneck of this stress-responsive pathway, is known to be vital for survival under hypertrophic stimulation (1,2).

To assess the role of MKK7 in arrhythmogenesis, ventricular cardiomyocyte specific MKK7 knockout (MKK7CKO) and littermate wild-type mice (male, 8-12 wks old) were subjected to different stress stimuli. Chronic Angiotensin-II (Ang-II, 0.7μgm/kg/min) stimulation for 14-days using subcutaneous mini-osmotic pumps and transverse aortic constriction (TAC) for 3-days (3% Isoflurane or Ketamine-Xylazine anaesthesia, Buprenorphine 0.1mg/kg analgesia) were provided to mimic chronic hypertension and acute pressure overload, respectively. Mean (± S.E.M.) values were appropriately compared by ANOVA or paired T-tests. In both cases, MKK7CKO mice had augmented cardiac hypertrophy under stress, evidenced by increases in heart weight / tibia length ratios (n=9-16/group) and cardiomyocyte cross-sectional areas (n=3-4/group). Transthoracic echocardiography confirmed an associated comparative decrease in left ventricular contractile function (n=8-15/group). Masson's trichrome staining revealed 3-4 folds increases in ventricular fibrosis in the MKK7CKO mice compared to wild-types receiving similar stimuli (n=3-4/group).

A striking finding was the electrical remodelling featuring about 25-30% longer rate-corrected mean QT (Bazett's) intervals in the stressed MKK7CKOs (n=8-12/group) *in-vivo* ECG recorded under terminal anaesthesia (Tribromoethanol, 200mg/kg). Programmed electrical stimulation induced more arrhythmias in MKK7CKOs than controls following stress. Between S1S2 delays of 100-40ms, 78% Ang-II treated MKK7CKOs generated ventricular arrhythmias or premature contractions, compared to 10% similarly treated wild-types and none of the untreated mice (n=8-10/group). Ventricular effective refractory periods increased after TAC, more so in MKK7CKOs, but without any statistical significance (n=8-12/group). Molecular analysis of whole ventricle extracts revealed, MKK7CKOs undergoing TAC had reduced versatile membrane-adapter Ankyrin-B and inward-rectifier potassium channel subunit Kir6.2 transcript (n=6-9/group) and protein levels (n=3-5/group) than similarly-treated wild-type mice.

This study reveals the significant role of MKK7 in preserving the functional integrity and rhythmicity of the heart, as well as indicating novel and therapeutically promising signalling regulation of hearts electrical activities under hypertrophic stress.

Cardioprotective adaptation of rats to chronic hypoxia is accompanied by changes in myocardial adenylyl cyclase signaling

K. Hahnova[1], B. Volfova[1], L. Hejnova[1], J. Neckar[2], F. Kolar[2] and J. Novotny[1]

[1]Department of Physiology, Charles University, Faculty of Science, Prague, Czech Republic and [2]Department of Developmental Cardiology, Academy of Sciences, Institute of Physiology, Prague, Czech Republic

It is known that cardiovascular diseases are the leading cause of morbidity and mortality in the western world. Recently it was observed that adaptation of myocardium to chronic hypoxia can contribute to the improvement of ischemic tolerance of myocardium. Chronic hypoxia can induce a wide range of adaptive changes in myocardium, which could be considered as cardioprotective, but exact molecular mechanism of these adaptive changes is still unclear. Adaptation to chronic hypoxia leads to increased activity of the sympathetic nervous system, thus increasing catecholamine levels in the body. The increased level of catecholamines and their effect on β-adrenergic signaling could contribute to the development of cardioprotection. Beta-adrenergic receptors (β-ARs) form an interface between the sympathetic nervous system and cardiovascular system and therefore they act as effective regulators of cardiac activity, which can be modulated by sympathetic transmitters.

The aim of this study was to pursue changes in the β-adrenergic signaling in rat myocardium after adaptation to two different regimens of hypoxic conditions: 1/ intermittent normobaric hypoxia - INH/R (23 h hypoxia, 1 h reoxygenation) and 2/ continuous normobaric hypoxia - CNH (24 h hypoxia). We assessed the effect of adaptation to hypoxia on the total amount of β-ARs, the ratio of β-ARs subtypes (β1-ARs to β2-ARs) and activity of adenylyl cyclase (AC) in the left (LV) and right ventricles (RV). The results determined in the hearts from rats (male, 250-350 g, n=10 in each group) adapted to hypoxia were compared with those obtained in the corresponding normoxic animals.

It was found that adaptation to INH/R and CNH was accompanied by a significant decrease (about 25%) in the total number of β-ARs in the RV. Although the statistical analysis (one-way ANOVA) revealed significant changes (decrease) in the ratio of β1-ARs to β2-ARs only for CNH model in the RV, there was a clear downward trend in the transcription and expression of β1-ARs in the RV from rats adapted to CNH or INH/R. Activity of AC was also affected by the adaptation of rats to INH/R and CNH. Whereas AC activity stimulated by different activators (GTPγS, NaF or forskolin) was increased in the LV, it was decreased in the RV. These results indicate that AC signaling may play an important role in the adaptive process to chronic hypoxia.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Chronic morphine treatment alters the adenylyl cyclase signaling system of the rat heart

J. Skrabalova[1], B. Volfova[1], J. Novotny[1], L. Hejnova[1], J. Neckar[2] and F. Kolar[2]

[1]Department of Physiology, Charles University in Prague, Faculty of Science, Prague, Czech Republic and [2]Department of Developmental Cardiology, Academy of Sciences, Institute of Physiology, Prague, Czech Republic

Morphine is a very potent analgesic which is widely used for treatment of both acute and chronic pain. This drug is highly addictive and its repeated use may cause dependence. Cellular effects of morphine are mediated by opioid receptors (ORs) and their cognate Gi proteins. Since all the basic components of opioid signaling system are present in heart tissue, it is conceivable that morphine may influence function of this organ. Interestingly, it has been observed that morphine can significantly limit tissue damage that occurs during myocardial ischemia (Schultz et al., 1996), but the molecular mechanisms by which morphine acts on the heart are still very poorly understood.

The aim of this study was to investigate the effects of chronic (10- and 27-day) administration of low (1 mg/kg/day, i.m.) and high (10 mg/kg/day, i.m.) doses of morphine to rats (male, 290-370 g, n=10 in each group) on the expression of selected G-protein coupled receptors (GPCRs), G-protein subunits and the expression and activity of adenylyl cyclase (AC) in the heart. Whereas 27-day morphine treatment decreased the expression of κ-ORs by about 18 % (Student t-test), 10-day treatment had no effect. Determination of the expression of β-adrenergic receptors by saturation binding studies showed an appreciable increase by 57 % in the total number of these receptors after 27-day treatment with high doses of the drug. Morphine did not affect the expression of any of the selected G-protein subunits (Gsα, Gi/oα, Gzα, Gq/11α and Gβ), but high doses of the drug significantly (by 50-80 %) elevated the amount of AC isoforms type V/VI. Subsequently, the expression level of AC was reduced in proportion to the time after discontinuation of morphine administration. Low doses of morphine increased by 23 % the expression of AC type V/VI only after 27-day administration. These changes were accompanied by increase in AC activity stimulated by Mn2+ (66 %), NaF (91 %), forskolin (73 %) and isoprenaline (105 %). On the other hand, the ability of OR agonists DADLE and U-50488 to inhibit forskolin-stimulated AC activity was rather decreased.

Our results indicate that chronic morphine treatment does not primarily induce changes in the amount of myocardial κ-ORs and G-proteins, but significantly enhances the expression of AC V/VI. Increased amount of AC may at least partially explain the observed supersensitization of the enzyme. It can be concluded that prolonged morphine exposure may strongly affect myocardial β-adrenergic receptor-mediated AC signaling.

Effects of exercise training on cardiac myocytes and fibroblasts intercellular coupling

M.M. Alves, P. Kaur, J.B. Moreira, K. Solvang-Garten, H. Morten, R. Rosbjorgen, G. Silva and U. Wisloff

ISB, NTNU, Trondheim, Norway

Cardiac fibroblasts (CF) are emerging as key components of normal cardiac function, as well as the response to stressors and injury, by interacting with cardiomyocytes (CM) via paracrine mechanisms and direct cell–cell interactions (Chilton et al, 2007; Kakkar and Lee, 2010). We have previously shown that in a direct contact cell-to-cell or by the use of cell inserts, CF leads to reduced calcium contractility and prolonged time of calcium decay in sedentary rats. We aimed to test on CF and CM interaction, a program of exercise training (TR), which mimics some therapeutics agents, and has been shown to improve cardiomyocytes (CM) contractility (Wisloff et al, 2001). Adult Female Spague-Dawley rats, n=35, weighting 220-350g, were given inhalational anesthesia with isoflurane (5% for 2-3 min). CM and CF were isolated as previously described with minor modifications for CF centrifugation time (Guatimosim et al, 2002). We used a noncontact protocol by keeping freshly isolated cardiomyocytes in conditioned media from CF of trained (TR) and sedentary (SED) rats, CF were used when they achieved 60-70% of confluence. Epifluorescence measurements (using Fura 2) have shown reduced Ca2+ transient amplitude in cardiomyocytes (n>7 CM for each treatment) (Control: 0,198±0.02, vs SED FB: 0,118±0,007, vs TR FB: 0,095±0,008, fura ratio, $p<0.05$,) and reduced shortening (Control: 6,2±1.1, vs SED FB: 2,23±0.29, vs TR FB: 2.52±0,56, % of shortening, $p<0.05$), but not diastolic calcium removal as measured as time interval to 50% decay of Ca2+ concentration (Control: 0.176±0.01, vs SED FB: 0.222±0.01, vs TR FB: 0.223±0,03, seconds, $p<0.05$) when CM were alone (Control) or together with SED FB or TR FB, for 18h. Values are means ± S.E., compared by ANOVA. Conditioned media did not have altered pH compared to control media (approximately 7.67 and 7.68, pH, respectively). We initially conclude that CF from SED and TR rats have paracrine secretion which leads to reduced CM maximum rate of shortening and reduced Ca2+ transient amplitude and this does not seem to be related to altered media pH.

Na+/K+-ATPase activities in normotensive human subjects with and without family history of hypentension in south - Western Nigeria

O.S. Oyekunle[1] and A.O. Soladoye[2]

[1]Physiology, Ladoke Akintola University of Technology,, Ogbomoso, Oyo, Nigeria and [2]Pyhsiology Department, University of Ilorin, Ilorin, Kwara, Nigeria

Hypertension is a global cardiovascular diseases where treatment remains a major financial burden (Lloyd-Jones et al., 2009). Some studies have identified important aetologic factors while others on mechanisms focused on genetic factors and ATPase activities (Manesh et al., 1987) but the findings are inconclusive. Therefore, erythrocyte Na+/ K+ -ATPase activities were measured in 99 normotensive human subjects aged 16-30 years with and without family history of essential hypertension (FH/WF H). Na+/ K+ -ATPase activities were measured using inorganic phosphate (Pi) released from ATP hydrolysis. The level of Pi was determined by the method of Fiske and Subbarow (1925). Only subjects who consented and were medically fit were allowed in the study. Erythrocyte membrane preparation and protein estimation were determined using standard procedure (Hamlyn and Duffy, 1978; Stewart, 1974). Mean values + S.E.M were recorded in this study and statistical analysis was by student's t-test. The results showed that in males with FH, Na+/ K+-ATPase activities were lower (13.46 + 1.242, n=35) than corresponding values WFH males (16.72+ 1.831, n= 64; $p<0.0001$). The Na+/K+-ATPase values in FH females and WFH females were not different. Furthermore, the systolic and diastolic blood pressure (SBP & DBP) values were not significantly different. It is therefore concluded that Na+/K+-AT Pase activities in hypertensive subjects with FH and WFH groups are familial and may underlie membrane cation transport in these subjects.

The soluble guanylate cyclase activator BAY 58-2667 protects against morbidity and mortality in endotoxic shock by recoupling organ systems

B. Vandendriessche[1], E. Rogge[1], V. Goossens[1], P. Vandenabeele[1], J. Stasch[2], P. Brouckaert[1] and A. Cauwels[1]

[1]Department for Molecular Biomedical Research, VIB - Ghent University, Ghent, Belgium and [2]Institute for Cardiovascular Research, Bayer HealthCare, Wuppertal, Germany

Sepsis and septic shock are associated with mortality rates of up to 50-70% and the majority of patients die due to complications of multiple organ failure. The cyclic GMP (cGMP) producing enzyme soluble guanylate cyclase (sGC) is crucially involved in the maintenance of (micro)vascular homeostasis, cardiac function and, consequently, organ function. Reactive oxygen species (ROS) can inactivate sGC by oxidizing the iron in the haem group, the resulting haem-free sGC can be reactivated by BAY 58-2667 (Cinaciguat) (Evgenov et al., 2006). We tested BAY 58-2667 in a murine model of endotoxic shock because of its assumed specificity for tissues that are suffering from (metabolic) hypoxia and oxidative stress. To induce shock, mice were injected i.v. with 190-220 μg E. coli lipopolysaccharide (LPS). We report that post-treatment with BAY 58-2667 can protect against endotoxic shock-induced progressive hypothermia (compared to vehicle controls, repeated measure ANOVA, n = 15) and mortality (66% vs. 0% survival rate for vehicle controls, log-rank test, n = 15), which was associated with reduced cardiomyocyte apoptosis (assessed by TUNEL assay, 77.9 ± 11.73 (mean ± SEM) vs. 47.9 ± 8.9 TUNEL positive cells, normalized over surface area, one-way ANOVA). The sGC stimulator BAY 41-2272 and phosphodiesterase 5 (PDE5) inhibitor Sildenafil did not have a beneficial effect on either LPS-induced morbidity or mortality. Furthermore, we assessed mean arterial pressure (MAP), heart rate (HR) and BP variability (BPV) indices continuously in conscious, freely moving mice. Mice were anaesthetized with isoflurane and PA-C10 radio-transmitters (Data Sciences International) were implanted. MAP and HR were both significantly decreased for 180 min post-treatment compared to vehicle controls (linear mixed model). Linear (normalized low frequency, LF (nu)) and nonlinear (detrended fluctuation analysis, DFA) indices of BPV were calculated in Labchart (ADInstruments) and software from the PhysioNet toolkit (Goldberger et al., 2000). The difference in BPV index trends was examined 40 min pre-treatment vs. 40 min post-treatment. Treatment with BAY 58-2667 increased LF (nu) and DFA scaling factors, compared to vehicle controls (n = 4), indicative for improved communication between the autonomic nervous system and the heart. Our results emphasize the pivotal role of sGC signaling in endotoxic shock. Stabilization of sGC function with BAY 58-2667 can prevent mortality induced by endotoxic shock when given in the correct treatment window, which probably depends on the dynamics of the haem-free sGC pool, in turn influenced by ROS production. We speculate that the effect of BAY 58-2667 on microcirculatory perfusion and (metabolic) hypoxia supports organ function by recoupling inter-organ communication pathways.

Glucagon-like peptide-1 eluting mesenchymal stem cells reduce apoptosis and improve viability of ischemic human cardiomyocytes in vitro

E.J. Wright[1], C. Wallrapp[2], A.L. Lewis[3], M. Kassem[4], N. Malik[1] and C.M. Holt[1]

[1]Institute of Cardiovascular Science, University of Manchester, Manchester, UK, [2]CellMed AG, Alzenau, Germany, [3]Biocompatibles UK Ltd, Farnham, UK and [4]KMEB, University of Southern Denmark, Odense, Denmark

Aims: Cell therapy is a promising treatment for myocardial infarction. Increasingly, cells are being modified to enhance secretion of cardioprotective factors to improve efficacy in vivo. This study utilized human mesenchymal stem cells (MSCs) that were immortalized and engineered to secrete a fusion protein of Glucagon-like Peptide-1 (GLP-1). We have previously shown a cardioprotective effect of this therapy in vivo (1). To investigate direct paracrine effects on apoptosis, these cells were tested against ischemic adult human cardiomyocytes (hCMs) in vitro.

Methods and Results: hCMs underwent ischemia for 1 hour before incubation with either: MSC conditioned media, MSC+GLP-1 conditioned media, 100nM GLP-1, 100nM Exendin-4 or normal media. Cells were pre-incubated with the inhibitors Exendin-9, Wortmannin or U0126 to investigate pathways involved. After 24 hours, apoptosis was measured using TUNEL staining (n=8). After 48 hours, cell viability was measured using trypan blue to identify live/dead cells (n=4). MSC+GLP-1 conditioned media significantly reduced TUNEL+ cells compared to media alone (media: 6.14±0.48%, GLP-1: 3.96±0.56%; Ex-4: 5.1±1.22%; MSC media: 3.71±0.56%; MSC+GLP-1 media: 2.97±0.4%, P<0.05). All agonists reduced the number of dead cells (trypan blue stained) compared to normal media (media: 19.05±6.80%; GLP-1: 5.05±0.54%; Ex-4: 7.88±0.39%; MSC media: 5.41±0.39%; MSC+GLP-1 media; 2.58±1.65%, P<0.05). All agonists increased cell viability, normalised to media alone (GLP-1: 8.40±5.77%; Ex-4: 25.48±6.85%; MSC: 26.29±14.21%; MSC+GLP-1: 26.95±7.14%, P=NS). All antagonists/inhibitors appeared to partially block the effects on apoptosis and cell viability.

Conclusions: MSC+GLP-1 conditioned media had a significant beneficial effect on both apoptosis and viability of ischemic hCMs in vitro, greater than MSC conditioned media. This effect appeared to be mediated through the GLP-1R and the PI3K and ERK1/2 pathways.

Investigating the role of epicardial fat as an imaging biomarker in type-2 diabetes

D.B. Cassidy[1], S.J. Gandy[3,4], S. Duce[1], F. Khan[2], P. Martin[3], R.S. Nicholas[3,4] and J.G. Houston[1,3]

[1]The Institute of Cardiovascular Research, University of Dundee, Dundee, UK, [2]Vascular & Inflammatory Diseases Research Unit, University of Dundee, Dundee, UK, [3]Clinical Radiology, NHS Tayside, Ninewells Hospital, Dundee, UK and [4]Medical Physics, NHS Tayside, Ninewells Hospital, Dundee, UK

Introduction: Visceral obesity is associated with an adverse metabolic and cardiovascular risk profile.[1] Myocardial fat deposited around the heart can be subdivided into epicardial adipose tissue (EAT), enclosed by the visceral pericardial sac, and pericardial layer, anterior to EAT. It has been postulated that the outer pericardial layer remains relatively inert however EAT hosts a metabolic active role [2] MRI has become gold standard for assessing the structure and function of the heart, but quantitative assessment of myocardial fat using MRI may provide additional prognostic information. The purpose of this study was to measure the extent of EAT in a diabetic population (DM) with cardiovascular disease (CV) using MRI, and to correlate these measures with MRI-derived pulse wave velocity (PWV) as an index of arterial stiffness.
Methods: Fifty fully consenting patients were recruited into the following cohorts: (G1) Type 2 DM with CVD, (G2) Type 2 DM without CVD, (G3) no DM with CVD, and (G4) no DM and no CVD. Each patient underwent a cardiovascular MR imaging assessment on a 3T Magnetom Trio MRI scanner (Erlangen, Germany). For derivation of the EAT region, a cardiac-gated 2D CINE segmented TrueFISP sequence was acquired in the four-chamber orientation. Segmentation of the region was manually contoured at end-diastole (ED) and subsequently reviewed by an experienced radiologist. The PWV was acquired from axial oblique cardiac-gated 2D segmented free-breathing CINE phase-contrast MRA (PC-MRA) sequences at slice locations across the aortic arch and the descending aorta above the renal bifurcation. Image processing was performed using Segment v1.9 R1917 (Heiberg, Germany). The PWV was calculated using the transit time method, and the distance between each measurement plane. Results are expressed as mean+/- SD. Comparison of variables was performed by means of a two-tailed t-test.
Results: For EAT, G1 (5.32+/-1.9cm^2), G2 (4.52+/-2.07cm^2) and G3 (4.98+/-1.80cm^2) were found to be highly significant in comparison to G4 (P<0.001) however no significance was between patient groups. PWV values in G1 (DM and CVD) 8.42+/-2.55 m/s and G3 (CVD) 8.98 +/-3.14 m/s compared to control cohort G4: 6.50+/-1.74 m/s was found to be significant (p=0.03, p=0.02). No significance was found with G2 (DM only) and G4 or between the patient groups (G1,2,3).
Conclusion: Recent studies are beginning to highlight EAT playing an active role as a cardiometabolic risk factor.[3] In this study, EAT was found to be associated with CVD and DM. However arterial stiffness, a known marker of CVD and DM,[4] showed an association with CVD and DM but not solely DM.

[1]Physiology, Sri Ramachandra University, Chennai, Tamilnadu, India, [2]Environmental Health Engineering, Sri Ramachandra University, Chennai, Tamilnadu, India, [3]Physiology, Tagore Medical College, Chennai, Tamilnadu, India, [4]Physiology, Donor Action Program, National Network of Organ Sharing, Chennai, Tamilnadu, India, [5]Physiology, Sree Balaji Medical College, Chennai, Tamilnadu, India and [6]Endocrinology, Sri Ramachandra University, Chennai, Tamilnadu, India

Background: Globally, the most important risk factor for chronic lung diseases is smoking of tobacco. Cigarette smoke, passive smoking, biomass smoke and infectious organisms may activate alveolar macrophages, bronchial epithelial cells and other cellular elements in the airways of genetically susceptible individuals leading to the development of chronic lung diseases. But, unfortunately, a first diagnosis of such disease is established in smokers and/or exposed to other smoke exposures only at a later stage after being exposed for several decades. However, before reaching this clinical stage, lot of structural and functional changes in the respiratory tract do occur deteriorating respiratory defence mechanisms leading to appearance of symptoms, worsening of quality of life and ultimately death. Early diagnosis of such impairment may have important stimuli to either quit smoking or to participate in smoke intervention programmes. With this background, this study was conducted to evaluate the nasal mucociliary clearance (mirror image of bronchial clearance/biomarker of nasal mucosal function) of subjects exposed to tobacco smoke, cook smoke and to compare with that of the healthy volunteers unexposed to such smoke.
Materials & Methods: NMC was measured in 25 smokers, 25 non smokers,50 biomass fuel users and in 50 clean fuel users of age group ranging from 18 – 45 years who had no medications and no systemic illness. The time elapsing until the first experience of sweet taste at posterior nasopharynx, following the placement of saccharin particle approximately 1cm behind the anterior end of inferior turbinate was recorded as NMC clearance time.
Results: Mean NMC of the smokers (481.2 ± 29.8 secs) was significantly higher than that of non smokers (300.32 ± 17.4 secs), (p<0.01). NMC was found to be increasing as the duration of smoking increased. (NMC in smoking <1 year =492.25 ± 79.93 secs, NMC in smoking for 1 – 5 years = 516.7 ± 34.01 secs, > 5 years = 637.5 ± 28.49 secs). NMC was also significantly (p =0.02) prolonged in biomass fuel users (604.97 ± 220.42 secs) in comparison to clean fuel users (455.12 ± 161.76 secs). Prolonged clearance observed in smokers and biomass fuel users may be due to the toxic effects of the components of smoke.
Conclusion: NMC measurement is a simple, inexpensive, non-invasive, screening test which can be used as an early diagnostic tool for respiratory diseases caused by exposure to air pollutants such as cook smoke and tobacco smoke. Our study impresses upon the important role of NMC in the health of sinonasal cavities and the need for initiating smoking cessa-

tion programs and efforts to promote cleaner fuels, improved stoves, better home ventilation which in turn may promote the lung health of the general population.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD017

Correlates of cigarette use in High Schools in Chatsworth, Durban, South Africa

P. Gathiram[1], T.M. Esterhuizen[2] and S.S. Naidoo[3]

[1]College of Health Sciences, Unievrsity of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa, [2]College of Health Scineces, University of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa and [3]School of Health Sciences, Durban University of Technology, Durban, KwaZulu-Natal, South Africa

Introduction: Approximately 1 billion men and 250 million women in the world smoke, accounting for about 35% of men in high-resource countries to about 50% in developing countries [1]. The increasing trend of earlier age of smoking initiation in children and early adolescents leads to greater use in adulthood, especially in the developing world [2]. The aim of this study was to assess the prevalence of regular and frequent smoking in high school learners as well as the factors associated with cigarette use. Early identification of correlates and risk factors for cigarette use will be useful in designing intervention and prevention programmes.

Methods: This cross-sectional study used a validated questionnaire to assess the extent of and factors associated with cigarette use among learners from Chatsworth high schools. Following institutional ethics approval, the study was conducted among a cluster sample of 1612 learners in grades 10 to 12 from 10 of the 18 Chatsworth public high schools. An IBM SPSS (version 20) package was used for data analysis. Crude and adjusted factors associated with regular smoking were assessed using logistic regression analysis. The cluster effect of school was dealt with by controlling for school in the analysis. A p value <0.05 was considered as statistically significant. Results are presented as odds ratios and 95% confidence intervals by gender.

Results: In grades 10, 11 and 12 prevalence of regular smokers in males were 23.8%, 34.8% and 38.6%, respectively, with an overall of 30.7%, and in females 17.7%, 12.1% and 14.2%, respectively, with an overall of 15.2%. The total prevalence was 22.5%. The prevalence of frequent smokers among males by grade was 11.2%, 19.5% and 28% respectively, with an overall of 17.8% and females, 3.6%, 4.9% and 7.8%, respectively and an overall of 5%, whilst the total prevalence was 11.1%. The prevalence was significantly higher in males than females in all grades. After adjusting for school clusters and other confounders, in males there was a significant increase in risk of smoking from grade 10 through grade 12. In both genders, Zulu speaking learners were at lower risk of smoking than English speaking learners, and having a brother, sister and best friend who smokes significantly increased the risk. In females, a significant association existed between regular smoking females and having peers who smoke, as well as with having repeated a grade.

Conclusion: This study showed an increase in the prevalence of cigarette smoking especially among female smokers compared with a similar study in 1993 [3]. The percentage of frequent smokers in the current study was slightly lower than in the USA (13.8%) [4]. These data warrants an urgent intervention programme to be initiated at all levels beginning at home and then at school.

Cardiac systolic and diastolic functions in spinal cord injured patients during lower body heating

M. Shibasaki[1], Y. Umemoto[2], T. Kinoshita[2], K. Kouda[2], T. Ito[2], T. Nakamura[2], C.G. Crandall[3,4] and F. Tajima[2]

[1]Nara Women's University, Nara, Japan, [2]Wakayama Medical University, School of Medicine, Wakayama, Japan, [3]Institute for Exercise and Environmental Medicine, Texas Health Presbyterian Hospital, Dallas, TX, USA and [4]University of Texas Southwestern Medical Center, Dallas, TX, USA

Elevations in skin blood flow and sweating during heat stress are driven through an integration of elevated internal and skin temperatures, with internal temperature being the primary controller. Passive heat stress increases cardiac output through elevated heart rate coupled with maintained stroke volume, the latter of which is achieved by improved systolic function and maintained diastolic function in healthy individuals. The contribution of thermal inputs from the skin in mediating these cardiac responses is unknown. This study tested the hypothesis that cardiac responses during heat stress are primarily mediated by internal temperature. To test this hypothesis, eight healthy (AB) and seven spinal cord injured (SCI) volunteers underwent a lower body heat stress; heating applied only to insensate skin in the SCI subjects. Echocardiographic indices of diastolic and systolic function were performed at normothermia and after an increase in internal temperature of approximately ~1.0 °C. Cardiac output (CO_2 rebreathing) increased during heat stress in both groups, but the increase was smaller in SCI (1.7±0.4(SD) l/min) relative to AB (2.3±1.0 l/min; P=0.06). The table shows the effects of heat stress on indices of diastolic and systolic function.

These data suggest that improved ventricular systolic function during heat stress primarily occurs by increases in internal temperature, with little to no influence from skin thermoceptors. Notably, smaller increases in atrial and ventricular systolic function in SCI subjects may contribute to their impaired increase in cardiac output during heat stress.

	Healthy (AB)		Spinal cord injured (SCI)	
	Normothermic	Hyperthermic	Normothermic	Hyperthermic

Localizing the intracellular ADP diffusion restrictions in trout cardiomyocytes

N. Sokolova, M. Sepp, M. Vendelin and R. Birkedal

Laboratory of Systems Biology, Institute of Cybernetics, Tallinn University of Technology, Tallinn, Estonia

Permeabilized cardiomyocytes have intracellular structures that restrict the diffusion of ADP from the surrounding medium to the mitochondria. Intracellular diffusion restrictions are also present in rainbow trout (Oncorhynchus mykiss) cardiomyocytes. This was surprising, because trout cardiomyocytes are no more than a few μm thick, lack t-tubules, have a lower sarcoplasmic reticulum density and only a single layer of myofilaments surrounding a central core of mitochondria. However, the extent of diffusion restrictions is smaller than in mammalian cardiomyocytes. The aim of the present study was to locate the diffusion restrictions in permeabilized trout cardiomyocytes. We measured mitochondrial respiration stimulated by ADP and ATP, and evaluated the rate of inhibition of ATP stimulated respiration by an ADP trapping system, consisting of phosphoenolpyruvate (PEP) activating endogenous and exogenous pyruvate kinase (PK), which competes with mitochondria for ADP. We found a high activity of hexokinase, which stimulates mitochondrial respiration when activated by glucose. To study its role in more detail, all experiments were performed in the absence and presence of 2 mM glucose. Additionally, we performed ADP titrations on cells alone, in the presence of glucose, and in the presence of creatine kinase and creatine. Our results showed that in contrast to rat cardiomyocytes, there is no functional coupling between creatine kinase and respiration. Trout cardiomyocytes have a high activity of hexokinase, which is functionally coupled to respiration. This suggests that trout cardiomyocytes have a different ADP-feedback system than mammalian cardiomyocytes. The experimental results were fitted with a mathematical model showing that diffusion is restricted in cytosol as well as by the outer mitochondrial membrane.

The influenses of hand work and stand up on the function of autonomic nervous system during menstrual cycle in healthy female college students

Y. Itoi[1], M. Onozaki[1], T. Shimizu[2] and T. Okada[3]

[1]International University of Health and Welfare, Otawara, Japan, [2]Toin University of Yokohama, Yokohama, Japan and [3]Juntendo University Graduate School of Medicine, Bunkyouku, Japan

Purpose: The purpose of this study was to examine the correlation between functional modulation of the autonomic nervous system and the menstrual cycle.Methods: Subjects were comprised of 11 healthy female college students (19.5±0.5 years old) with regular menstrual cycles. The changes in emotional sweating induced by hand work (beans work and puzzle) and the modulation in autonomic nervous system(electrocardiograph and heartbeat) with active orthostatic load were compared among the follicular, luteal and menstrual phases. The Japanese version of the Profile of Mood State (POMS), healthy life habit (DIHAL.,2,junior high school student~adult) were also examined. Analysis: Effect size of the difference between group or correlation were evaluated. Results:Emotionalsweating(task is beans work) during the menstrual phase was significantly higher than those during follicular and luteal phases and it associated with the high score of “depression dejection” of POMS factors. Group with the highest T score (standardized score) of “depression dejection” emotional sweating was significantly higher during luteal phase. In addition, the group which complained subjective low healthy state, showed higher emotional sweating (beans work) during luteal phase.Fluctuations of heart rate at rest(the size of the activity),during menstrual phase was significantly higher than those during follicular phase, although it was a normal range.The balance of the autonomic nervous activity at rest (balance) was significantly higher during luteal phase compared to menstrual phase, indicating predominance of sympathetic nervous system. Active orthostatic load-induced fluctuations of heart beat(powers of the response)was significantly higher during follicular phase compared to those during menstrual and luteal phase, although it was a normal range. Fluctuations of balance of the active orthostatic load (powers of the change) was significantly higher during menstrual phase than that during follicular phase; the range which need special medical attention. In addition, there found an association between balance and “confusion”. Group with the highest T score of “confusion” factors, showed predominant sympathetic nervous system during menstrual phase.Conclusion:These findings suggest that Stresses of beans work may influence the function of the autonomic nervous system to during menstrual phase . In addition, these findings suggest that powers of the change was higher during menstrual phase, the range which need special medical attention. Students with the high T score of “confusion” factors, showed the balance is sympathetic nerve predominance during menstrual phase.

PCD021

The beginning of the calcium transient and contraction in rat embryonic heart

T. Kobayashi, S. Maeda, N. Ichise, T. Sato, T. Miyakawa, Y. Yamada and N. Tohse

Cellular Physiology and Signal Transduction, Sapporo Medical University School of Medicine, Sapporo, Japan

Although many researchers have examined the embryonic heart, the precise relationship between the morphological changes of the heart and heart function, i.e., excitation- contraction coupling, around the period of the beginning of the heartbeat remains obscure. Here, we recorded and evaluated the beginning of the calcium transient and contraction of the Wistar rat heart. The heart primordium, the so-called cardiac crescent, of Wistar rats begins to contract at embryonic day 9.99-10.13. The contracting area is initially small and becomes enlarged with time. Repetitive calcium transients are observed regularly in the whole heart primordium, before the initiation of contraction. Nifedipine, but not ryanodine, abolished the calcium transients. Thapsigargin did not affect the calcium transients. These results indicate that the calcium transients involve exclusively calcium entry through L-type calcium channels, in contrast to the situation in mature hearts. This study reveals the precise relationship between morphological changes in the heart primordium and the beginning of the calcium transient and contraction.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD023

Postnatal change of heart rate and sinoatrial node pacemaker activity in mice

T. Adachi, S. Shibata, Y. Okamoto, S. Sato, S. Fujisawa, T. Ohba and K. Ono

Cell Physiolosy, Akita University Graduate School of Medicine, Akita, Japan

It is well established that heart rate (HR) changes during the course of postnatal development in mammalian species. In general, the HR of large animals, including humans, rabbits, and dogs, decreases with development. The HR of small animals such as mice and rats has been reported to increase after birth. These contrasting HR changes may be related to the size of the body and heart, and may be purposely designed to most effectively propel the blood around the body in various mammalian species. Nevertheless, the physiological significance and mechanisms underlying these postnatal changes in HR remain poorly understood. In the present study, we examined the mechanisms of postnatal change in murine HR using *in vivo* non-invasive measurement of HR and electrophysiological analysis of ion channels in isolated sinoatrial node (SAN) cells. Non-invasive measurement of murine HR was accomplished using a piezoelectric transducer (PZT) sensor. Mice were simply placed on the PZT sensor, and the heart sound signal was extracted and used for calculating HR. In this method, HR was 323 ± 17 bpm at P0, and increased daily during 2 weeks after birth. The HR at P14 was 685 ± 18 bpm. Under pharmacological blockade of the autonomic nervous system, the HR of approximately 300 bpm was largely constant at P0–5, and then increased daily to 500 bpm at P14. In intracellular potential recordings, the spontaneous beating rate of the SAN tissue preparation was traced to similar curve of *in vivo* HR under pharmacological blockade. These findings indicate that the postnatal increase in HR is derived from increased sympathetic influence that becomes apparent immediately after birth, and increased intrinsic activity of SAN cells that emerges 5–6 days after birth. In spontaneous action potential recordings in isolated SAN cells by the whole cell patch clamp method, the beating rate and diastolic depolarization rate of SAN cells was significantly less in neonatal mice than in adult mice. Isolated pacemaker cells possessed similar morphological and electrophysiological characteristics for sinoatrial pacemaker cells. The I_{CaL} was activated at more positive potentials and the current amplitude was smaller in newborn SAN cells than in adult cells, however no significant difference was detected in the I_f and I_{CaT} density and kinetics. Quantitative PCR using the SAN tissue preparations revealed no statistical differences in the expression levels of $Ca_V1.2$, $Ca_V1.3$, $Ca_V3.1$, $Ca_V3.2$, and HCN4 between neonate and adult SAN tissues. We conclude that the postnatal increase in HR is caused by increased sympathetic influence and the intrinsic activity of SAN cells, and that the different conductance and kinetics of I_{CaL} may be involved in the postnatal increase in pacemaker activity.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD024

The role of extracellular Ca2+o and voltage-gated calcium channels in vasculogenesis in the fetal lung

S.C. Brennan[1], B.A. Finney[2,1], D. Al Alam[3], R.L. Townsend[1], M. Lazarou[1], D. Adriaensen[4], E. Jesudason[3,5], D. Warburton[3], P.J. Kemp[1] and D. Riccardi[1]

[1]Cardiff School of Biosciences, Cardiff University, Cardiff, UK, [2]Center for Cardiovascular Sciences, Institute for Biomedical Research, University of Birmingham, Edgbaston, UK, [3]Developmental Biology and Regenerative Medicine Program, Saban Research Institute, Children's Hospital Los Angeles, Los Angeles, CA, USA, [4]Department of Veterinary Sciences, Laboratory of Cell Biology and Histology, University of Antwerp, Antwerp, Belgium and [5]Division of Child Health, University of Liverpool, Liverpool, UK

Postnatal lung function depends on a tightly controlled and complex developmental programme which regulates lung branching morphogenesis, vasculogenesis and fluid secretion. A number of these processes begin during the pseudoglandular stage (weeks 9 – 17 in human, and embryonic day (E)11.5 – 16.5 in the mouse) and occur in a relatively hypercalcemic environment (~1.7 mM v ~1.2 mM for a normocalcemic adult [1]). Previously, our group has demonstrated that this increase in extracellular calcium ([Ca2+o]) is an important extrinsic factor for lung development, suppressing branching and cellular proliferation and enhancing Cl—dependent fluid secretion through activation of the calcium-sensing receptor (CaSR) [2]. To further understand the role of Ca2+o in lung development, we have now examined the effect of fetal hypercalcemic conditions on vasculogenesis using the Flk-1+/LacZ reporter mouse model. Fetal liver kinase (Flk)-1, a receptor for vascular endothelial growth factor-A, is predominately expressed in the early stages of mouse lung development (E9.5 – E13.5), during which vascular endothelial cells have been shown to actively proliferate [3]. E12.5 mouse lung explants cultured for 48 h

in medium containing adult Ca2+ concentrations (1.05 mM) showed Flk-1 expression confined to the mesenchymal spaces between developing branches. However, culturing lung explants in the presence of fetal (1.70 mM) [Ca2+o] induced a marked increase in Flk-1 expression, accompanied by a change in localization with the vasculature criss-crossing over and around the developing branches. The addition of the CaSR activator NPS-568 (30 nM) at 1.05 mM Ca2+o did not affect Flk-1 expression, suggesting that the CaSR is not directly involved in regulation of vasculogenesis. Immunohistochemistry of E12.5 whole mouse embryos and human fetal lungs showed expression of a number of voltage-gated calcium channels – including the L- and R-type calcium channels Cav1.2, Cav1.3 and Cav2.3 – within the epithelium of the developing lung, suggesting an alternate mechanism for [Ca2+o] sensitivity. Functional experiments with the L-type calcium channel blocker nifedipine and the R-type calcium channel blocker SNX-482 at 1.70 mM Ca2+o led to significant increases in lung branching (39.8 ± 4.1% n=11 vs. 70.6 ± 4.5% n=9 p<0.01 and 81.1 ± 11.7 n=6 p<0.001 respectively. Values are mean ± SEM, compared by ANOVA) and further increases in Flk-1 expression over 48h. In summary, functional L-/R-type calcium channels may provide an alternative and complementary mechanism for the [Ca2+o] sensitivity of fetal lung development, including branching morphogenesis and vasculogenesis.

Effect of postnatal Leptin on cardiac structure and function

A. Samuelsson[1], J. Clark[2], M.J. Shattock[2], O. Rudyk[2], J. Pombo[1], S. Eun Bae[1], T. South[1], C.W. Coen[1], L. Poston[1] and P.D. Taylor[1]

[1]Division of Women's Health, Women's Health Academic Center, King's College London and King's Health Partners, UK, King's College London, London, UK, London, UK and [2]Cardiovascular Division, King's College London, UK., London, UK

Obesity in pregnancy is associated with cardiovascular dysfunction in adult offspring. We have previously reported an exaggerated leptin surge, in neonatal offspring of obese rats (1) associated with the development of sympathetic mediated hypertension and cardiac hypertrophy (2-3). We have now addressed the hypothesis that the high levels of leptin in early postnatal life may underlie early origin of hypertension and cardiac hypertrophy.

To investigate the role of increased neonatal leptin exposure on the development of sympathetic mediated hypertension and the cardiac hypertrophy in offspring of obese dams.

Pups from lean Sprague-Dawley rats were randomly assigned for intraperitoneal administration of recombinant rat leptin (L-Tx, 3mg/kg) or saline (S-Tx) at postnatal day 9-15. At day 23, juvenile rats were subjected to radiotelemetry surgery under general anaesthesia (2% isofluorane in O_2 at 2 l/ min) using a carotid artery placement of the small animal transmitters (DSI-PhysioTel® PA-C10). Pre and post-operative analgesia (Buprenorphine 0.1 mg/kg, intramuscular) was maintained for 24h. Heart rate and blood pressure were recorded after one-week recovery by schedule sampling for 10 s every 5 min using A.R.T.10 software (Dataquest IV, DSI). Heart structure and function were analysed using *in vivo* micro-echocardiography (2% isofluorane, Vevo 770-ECHO system) and *ex vivo* langerdorf perfusion. The cardiomyocyte number and surface area were determined using hemomtoxylin-eosin and anti-laminin immunoflourescence.

Neonatal leptin treated male and female rats (L-Tx) showed increased night-time (active period) systolic blood pressure (SBP [mmHg] mean±SEM: male L-Tx, 132±1 versus S-Tx, 119±1, n=6, p< 0.05; female L-Tx, 132±2 versus S-Tx, 119±1, n=6, p< 0.01, *RM-ANOVA*), in comparison to S-Tx.

Female L-Tx demonstrated increased heart weight (P<0.05, n=6,*t-test*) with evidence of increased cardiomyocyte number at day 30. The *in vivo* imaging revealed altered left ventricle dimensions and diminished left ventricular systolic function and isolated heart showed evidence of impaired contractile function in the L-Tx versus S-Tx.

This study implicates a central role for neonatal leptin in the origins of sympathetic mediated hypertension and cardiac morphology and function, in offspring of obese rodents. Evidence of cardiac dilatation together with impaired contractility may reflect early stages of heart failure.

PCD026

Maternal high fat diet during pregnancy and lactation alters mitochondrial electron transport chain activity and gene expression in adult mouse offspring heart

M. Bordbar Amirian, K.L. Hyde, K.D. Bruce, H. Thomas, C.D. Byrne, M.A. Hanson and F.R. Cagampang

Institute of Developmental Sciences, Human Development and Health, University of Southampton Faculty of Medicine, Southampton, UK

Increasing diabetes prevalence and life expectancy are two key factors raising the health care burden from the consequences of cardiovascular disease (CVD). Whereas an obesogenic diet in adulthood is a known risk factor for type 2 diabetes and CVD, there is growing evidence that obesogenic diets during pregnancy increase CVD and diabetes susceptibility in the offspring later in life. While most studies focused on changes in vascular physiology that result from maternal high fat (HF) feeding, the metabolic and molecular changes that occur in the offspring's heart itself remains to be elucidated. The mitochondria play a key role in the normal functioning of the heart, and in the pathogenesis and development of various types of heart disease. We therefore examined whether mitochondrial electron transport chain (ETC) activity and expression of genes with key roles in mitochondrial metabolism were altered in heart tissues of offspring from obese mothers fed a HF diet. Female C57/BL6J mice were maintained

under controlled conditions and fed either a HF diet (HF; 45% kcal fat) or standard chow diet (C; 21% kcal fat) 4-6 weeks prior to and during gestation and lactation. Weaned offspring were fed the HF or C diet, generating the dam-offspring groups: C/C, C/HF, HF/C, HF/HF. Hearts were taken from 15-week old male offspring (n=4-5 per offspring group). The left ventricle (LV) was dissected and processed for the analysis of mitochondrial Complex I and II enzyme activity using spectrophotometric assay, and for qPCR of the mitochondrial sirtuin Sirt3, uncoupling proteins UCP2 and UCP3, the adenine nucleotide translocases ANT1 and ANT2, the transcriptional coactivator PGC1α, and the nuclear respiratory factor NRF1. Complex I and II activity was reduced by 1.5 fold ($p<0.001$, ANOVA) in the HF/HF offspring heart vs C/C. Complex II activity also reduced by 3-fold ($p<0.0001$) in the HF/C group vs C/C. Sirt3 mRNA level was 2.6-fold lower ($p<0.01$) in offspring hearts from HF-fed dams (HF/C and HF/HF groups) vs C/C group. UCP2 and UCP3 mRNA levels were 2.3 and 4-fold higher (both at $p<0.0001$), in HF/HF vs C/C hearts, with UCP2 also increased 5-fold ($p<0.0001$) in the HF/C hearts vs C/C. Furthermore, ANT1 and ANT2 transcript levels were reduced by more than 1.3-fold ($p<0.01$) in HF/HF hearts vs C/C. PGC1α mRNA levels were 1.4-fold lower ($p<0.01$) while NRF1 mRNA levels were 3-fold higher ($p<0.0001$) in HF/HF hearts vs C/C. NRF1 transcript levels were also 2.5-fold ($p<0.0001$) higher in the HF/C tissues vs C/C. The results suggest maternal high fat diet during pregnancy and lactation alters mitochondrial ETC activities and expression of genes involved in mitochondrial function and biogenesis. This priming effect in early life increases offspring risk to cardiac pathologies in later life.

PCD028

Distribution of the pacemaker cardiomyocytes in the vertebrate heart

V.I. Prosheva

Institute of Physiology, Syktyvkar, Russian Federation

It is known that there are large differences in the morphology of the vertebrate heart: from the Cyclostome and fish hearts with its single atrium and single ventricle to the bird and mammalian hearts with two fully separated atria and ventricles. At present it is necessary to revise the data on the topography of the atrial pacemakers in the vertebrate heart. Pacemaker cells have some specific electrophysiological properties that make them different from atrial working myocardium and conducting cells. In this study, we aimed to establish a functional topography of the pacemaker cardiomyocytes in the isolated sinoatrial and atrioventricular areas of the heart in different representatives of vertebrates: lamprey (Lethenteron japonocum), carp (Carassius carassius L.), frog (Rana temporaria L.), lizard (Lacerta vivipara L.), chicken (Gallus gallus domesticus), pigeon (Columba livia L.), mouse (Mus musculus) and cat (Felis catus L.), using microelectrode mapping of action potentials (APs). All experimental procedures conformed to the Guide for the care and use of laboratory animals published by the US National Institutes of Health (NIH publication No. 85-23, revised 1985). It was found that in the lamprey, carp, frog and lizard hearts APs of pacemaker cells were recorded from the base of leaflets of sinoatrial and atrioventricular valves. In the chicken and pigeon hearts sinoatrial pacemaker is localized in the base of the right sinoatrial valve. In the atrioventricular area pacemaker cells are embedded in fibrous tissue and located near the base of the right muscle atrioventricular valve and in the region of the coronary sinus. In the mouse and cat hearts, cells with pacemaker activity are distributed in the region of the mouth of the superior vena cava, in the area adjacent to the coronary sinus and also in the base and in the leaflets of the atrioventricular valves. In the studied animals the maximal depolarization rate of pacemaker APs in the sinoatrial area increases in the anterograde direction, while their APs duration decreases. In the atrioventricular area the reverse regularity of the APs parameters distribution is observed. Thus the areas of the valves are supposed to be specific places of pacemaker cells localization in the Cyclostome, fish, amphibian, reptilian, avian and mammalian hearts. The data obtained indicate the conservatism of the evolution of cardiac pacemakers.

The features of regulation of the heart rate and external respiration observed in Aborigines and Europeans of the Russia's northeast

A. Maximov

Laboratory for Physiology of Extreme States, Scientific-Research Centre "Arktika" FEB RAS, Magadan, Russian Federation

Recently a population of the residents born in the north within their 1st – 3rd generations being Europeans, is forming in Russia's northeast. Besides, an Aboriginal population also resides in the region. It is presented by ethnic Chukchee and Evens. The Aborigines of the north are characterized by having some morphofunctional parameters that are fixed at genetic levels, in contrast to the north-born Europeans whose adaptation changes are mainly determined by a phenotype. To study physiological profiles of the adaptive changes in the north-born Europeans in comparison with the Aborigines, we examined young male people aged 17–21 (n = 350) being residents of Magadan region that is situated within the range of 60–64° NL and 145–162° EL. The average year temperature in the region is 7° C below zero. The examined people underwent general measurements of registering their heart rate R-R intervals at rest and at orthostatic exercise as recommended by the European and North America's Association of Cardiologists. Based on the values of the heart rate variability, its statistical and spectral-wave characteristics were calculated. The results found no reliable difference between the heart rate variability indices of the north-born Europeans and the Aborigines at rest. However, during the orthostatic test that can reveal cardiovascular system's reserves, a reliable difference between the examined populations was observed in the following indices: mode (Mo), variation range (MxDMn), standard deviation (SDNN), stress index (SI), total power of the spectrum of the heart rate frequencies (PT) as well as its low (HF) and very low (VLF) components. Of note that, the heart rate structure difference suggested more pronounced tension of regulatory mechanisms in the Aborigines compared to the Europeans, at the background of activation in the sympathetic vegeta-

tive nervous system and lower functional reserves of cardiohemodynamics. Found that, only two of the 11 values of the external respiration function registered at rest, showed a reliable difference. The Aborigines demonstrated the lung vital capacity and the volume of the expired air per second, respectively, 570 ml and 410 ml less than those of the Europeans. Thus, we can suggest that the north-born Europeans and the Aborigines of Russia's north have no difference in the series of cardiorespiration parameters. This fact enables to say of the forming of a convergent type of adaptation in the modern population of Russia's north. In the meantime, the Aborigines proved to have reliably lower functional reserves in some physiological systems as compared to those of the European north-born residents.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD030

A new noninvasive method to estimate mixed venous oxygen content with a pulse oximeter

K. Uchida

Physical Therapy, Yamagata Prefectural University of Health Sciences, Yamagata, Japan

To assess the gas exchange in a lung mixed venous oxygen content (CvO2) is one of the most important factors connecting cardiac output and oxygen uptake. Unlike the other fundamental factor arterial oxygen content (CaO2), CvO2 cannot be easily measured. Therefore, estimation of CvO2 is in high relevance to clinical medicine as well as to basic research. Oxygen saturation (SpO2) and heart rate (HR) were measured for 13 healthy students (4 males and 9 females ages 20 to 24) of Yamagata Prefectural University of Health Sciences, who joined a study tour in Colorado from Sep. 19 to 27, 2012. The means and standard deviations for their height and body weight were 162.0 ± 9.5 cm and 58.0 ± 7.8 kg. They had no cardio-respiratory diseases. SpO2 and HR were measured using a pulse oximeter (PULSOX-2, KONICA MINOLTA) with their informed consents. They put their fingers into the oximeter in a sitting position to measure SpO2 and HR. Averaged values of SpO2 for 13 students were 98 ± 0.95, 97 ± 1.4, 94 ± 1.9, 93 ± 1.7 and 87 ± 2.8 % at the Narita Airport (altitude 130 m), Denver City (1,609 m), Estes Park (2,499 m), Hidden Valley (2,816 m) and the Alpine Visitor Center (3,595 m), respectively. Averaged HR values simultaneously measured with SpO2 were 75 ±11, 78 ±5.8, 74 ± 7.4, 92 ±11 and 85 ±7.6 beats/min. These values except for those at the Narita Airport were measured within 6 hours on the fourth day for staying in Denver. Despite more than 10 % decrease in SpO2 within 6 hours, no student felt unwell at the height of 3,595 m. Based on the Fick principle, a correlation of SpO2 in % with 1/HR in min/beats was described with a regression line that SpO2 = 2650(1/HR) + 60.6 with a coefficient of determination 0.600. With the standard oxygen content combined to hemoglobin in arterial blood 20.1 vol% by assuming the normal hemoglobin concentrations for each student, CvO2 was estimated from the intercept of the regression line as 12.2 vol%1). The difference between the CaO2 values obtained from SpO2 and the estimated CvO2 (CaO2 – CvO2) at the Narita Airport was obtained as 7.8 vol%, which was consistent with that estimated by a rebreathing method at similar altitude as Narita2). The CaO2 – CvO2 value at 3,595 m was 5.2 vol%, which was higher than that reported by Wolfel et al.3) 4.0 vol% at Pikes Peak 4,300 m. This difference is probably due to the lower CaO2 at the higher altitude. These results suggest that CvO2 can be estimated from the regression line between SpO2 and 1/HR measured at different altitudes. At low altitudes SpO2 in healthy subjects is hardly less than 90 % even with severe exercise, and in this sense the application of our noninvasive method to estimate CvO2 is limited. However, our method can be used by measuring SpO2 and HR with inspired gases at various low O2 concentrations which simulate high altitudes.

Background: Chronic heart failure (CHF) is a clinical syndrome with high morbidity and mortality and the full understanding and adequate treatment of this pathology remain a challenge. Nitric oxide (NO), a short half-life gas, plays an important role in the regulation of vascular homeostasis, influencing both endothelium and platelets. NO bioavailability depends not only on its synthesis but also its degradation, mediated by reactive oxygen species (ROS), mainly superoxide anion (O2.-). We have previously demonstrated that CHF patients with sinus rhythm have platelet hyperggregability associated with alterations in NO bioavailability and oxidative stress1. Objective: The aim of this study is to investigate the effect of physical training (PT) on the intraplatelet L-arginine-nitric oxide pathway, oxidative stress and inflammatory markers in CHF without arrhytmias. Methods: Thirty CHF patients with left ventricular ejection fraction (LVEF) of 31±1% were randomized to 24 weeks of supervised exercise training (consisting of 30 minutes of moderate intensity treadmill exercise followed by resistance and stretching exercises, performed three times a week) or to a control group that remained sedentary. Blood was drawn before and after the intervention for platelet and plasma obtainment. The Ethical Committee of the State University of Rio de Janeiro approved this work (CEP-1435), and informed consent was obtained from each of the patients. The student t test was used for statistical analysis and statistic difference was considered when $p<0.05$. Results: Exercise tolerance was significantly increased in CHF patients who were submitted to exercise training. Platelet aggregation induced by ADP and collagen was significantly reduced in CHF patients after 24 weeks

of exercise training. Paradoxically, nitric oxide synthase activity in platelets, assessed by the conversion of L-[3H]-arginine into L-[3H]-citrulline, decreased after exercise training, and no significant difference was observed in intraplatelet cGMP levels among the groups. In relation to oxidative stress markers, systemic and intraplatelet TBARS production and carbonylation were diminished after 24 weeks of training in CHF patients. Moreover, systemic levels of CRP, fibrinogen and TNF-α were also reduced in CHF after training. Conclusion: Our results suggest that chronic exercise has anti-oxidant, anti-inflammatory and anti-aggregant effects, regardless of NO production, showing it be an important non-pharmacological tool in the treatment of CHF.

Angiotensin II serum levels after different exercise intensities in human

S. van Ginkel[1,2], M. Flueck[1], A. de Haan[2] and J. de Koning[2]

[1]IRM Manchester, Manchester, UK and [2]Vrije Universiteit, Amsterdam, Netherlands

High blood pressure (hypertension) indicates the deterioration of the set points of metabolic fitness and is one of the most frequent metabolic risk factors in Western countries. Pharmacological inhibition of angiotensin 2 (ANGII) by ACE inhibition action may have undesirable side effects, particularly, in the situation when one wants to exploit the sympatholytic and angiogenic benefits of physical therapy. Limited studies investigated ANGII levels related to exercise intensity and duration, but it seems to be that there is only an increase above with exercise intensity above the anaerobic threshold. The aim of this research is to detect changes in human ANGII levels after exercises of different intensities at or above the anaerobic threshold. On three separate occasions fit healthy male subjects (n=10, age: 29.6±2.1 year, length: 180.9±7.6 cm, mass: 76.1±5.6 kg) performed a maximal incremental exercise tests, a 12-minutes test at an intensity were they reached their aerobic threshold intensity and a 3-minutes test their ventilator compensation point intensity. Expired air was measured breath-by-breath, blood samples were taken before and 0, 3, 6 and 12 minutes after exercise and subject were screened for the ACE I-allele polymorphism. Blood was measured on lactate concentration and serum on ANGII levels. Values are means ± S.E.M. Direct after the 3-minutes cycling test there was a 1.8-fold increase in ANGII serum levels compared to resting levels (paired T-Test, 3.20±0.83 vs. 5.75±0.81 pg/mL, p=0.001) and after the 12-minutes test there was a 1.2-fold increase (paired T-Test, 4.4±1.47 vs. 5.5±1.30 pg/mL, p=0.24). ANGII levels were not affected after the maximal exercise test. 12 minutes after maximal exercise subjects with the ID/DD genotype had a significant lower ANGII serum level compared to subjects with the II genotype (ANOVA, 1.7±1.0, 9.6±5.5, p<0.05). ANGII levels were not correlated with blood lactate levels. ANGII could be detected after a non-maximal high intensity exercise. The data indicate that variability in the response of the major vasoconstrictor, ANGII, in serum after exercise is related to the ACE genotype dependent but not blood lactate.

Block-face imaging of wax-embedded tissue as a modality to aid three-dimensional histological reconstruction of the heart

U. Siedlecka[1], R. Casero Canas[2], R. Burton[3], C. Afonso[4], C. Bollensdorff[6,1], V. Grau[4,2] and P. Kohl[1,5]

[1]Cardiac Biophysics and Systems Biology, Imperial College London, Harefield, UK, [2]Oxford e-Research Centre, University of Oxford, Oxford, UK, [3]Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, UK, [4]Department of Engineering Science, University of Oxford, Oxford, UK, [5]Department of Computer Science, University of Oxford, Oxford, UK and [6]Qatar Cardiovascular Research Center, Doha, Qatar

Introduction: The histo-anatomical structure of the heart is a key determinant of cardiac function. Histological staining of sectioned tissue provides high-resolution identification of cells and sub-cellular structures in two dimensions (2D). However, the sections cannot easily be projected to 3D images, as they do not represent an inherently co-registered stack. In order to develop detailed 3D representations of heart structure, spatial reintegration of serial 2D sections has been guided by additional data, such as magnetic resonance imaging (MRI) [1,2]. However, histology processing involves dehydration and re-embedding, causing significant changes in volume and shape of wax-embedded sample in comparison to the MRI images. This makes the combination of data obtained with both methods challenging. To overcome this, we introduce block-face imaging of black wax-embedded tissue as an intermediate imaging step in the processing pipeline for tissue reconstruction.

Method: Briefly, rat hearts were excised after Schedule 1 killing according to the UK Home Office guidance on the Operation of Animals (Scientific Procedures) Act of 1986, and swiftly perfused via the aorta with normal Tyrode solution (mM: NaCl 140; KCl 5.4; MgCl2 1; HEPES 5; Glucose 10; CaCl2 1.8; pH 7.4). After washing, hearts were arrested using modified Tyrode containing elevated potassium (20mM), and fixed with a fast-acting Karnovsky's fixative. For histological follow-up, hearts were embedded in black wax to improve the contrast between wax and tissue surface. Wax blocks were mounted on Leica SM2400 heavy-duty sledge-type microtome. Sections were cut at 10μm thickness, and an image of wax block surface was taken prior to each section. Images were taken with a remote-controlled Canon EOS 450D camera mounted above the sledge, equipped with a polarisation filter. The LED light was coupled to a beam-splitter in front of the camera. Suitable rotational alignment of the collection filter allowed selection of reflected (polarized) light from the topmost layer of the wax/exposed tissue. This was used to identify the outline of tissue contained in the next section.

Discussion: Detailed reconstruction of extended tissue volumes, such as whole hearts, requires a combination of imaging methodologies, ideally ranging from *in vivo* cine MRI, to *ex vivo* fixed tissue anatomical and diffusion-tensor MRI, through to histology allowing identification of cells. 3D reconstruction of histology stacks, and registration to other modalities,

is aided significantly by an approach providing a set of inherently aligned images of the tissue acquired as it is serially sectioned. Block-face imaging of the wax-embedded tissue provides its consistent 3D volume, which can be used to guide spatial reconstruction of serial histology sections.

3D reconstruction of the human cardiac conduction system based on micro-CT and histology

A. Atkinson, T. Nikolaidou, M.R. Boyett and H. Dobrzynski

Institute of Cardiovascular Sciences, University of Manchester, Manchester, UK

Introduction
3D computer models of the heart are important tools for teaching, research and drug discovery. In current human heart models, the heart's wiring system (the cardiac conduction system, CCS) is oversimplified or omitted and the aim of this study is to create a 3D model including the CCS: the sinus node (SN), the paranodal area (transitional pacemaker tissue bordering the sinus node; PN (1)), atrioventricular node (AVN) and His-Purkinje system.
Methods
A whole human heart as well as an isolated human SN preparation (intercaval region of right atrium) were scanned using micro-CT at resolutions of 86 and 31 μm, respectively. The whole heart was then serially sectioned in the coronal plane at 50 μm thickness onto adhesive collection tape using a cryomacrotome and the SN was sectioned parallel to the crista terminalis at 30 μm thickness onto Superfrost Plus slides. Masson's trichrome histology was performed on whole heart sections at 1 mm intervals and SN sections at 500 μm intervals. Immunolabelling of the pacemaker channel HCN4 was carried out on sister sections to help identify the tissues of the CCS.
Results
Many of the major components of the CCS, including SN and AVN, were identified in whole human heart sections. The PN, as well as the SN, were identified in the sections of the isolated human SN preparation. The PN appears as a region of loosely-packed myocytes in close proximity to the SN. However, the PN, whilst being in close proximity to the SN, is at no point in direct contact with it. The SN extends from the superior vena cava along the crista terminalis about a third of the distance to the inferior vena cava. In contrast, the PN is a far more extensive structure than the SN and was traced along much of the length of the crista terminalis extending from the superior to the inferior vena cava. This could be reason why the leading pacemaker site in the human can be at any point from the superior to the inferior vena cava. Avizo software is being used to align histology sections with the micro-CT data and image analysis is being used to segment the SN, PN, AVN and His-Purkinje system. Following segmentation, we will create a 3D reconstruction of the whole human heart incorporating the CCS.
Conclusion
We are using a novel combination of techniques to create a detailed 3D reconstruction of the whole human heart including the CCS. The 3D reconstruction will enable more accurate simulations of cardiac electrophysiology.

PCD035

The inter-relationship between the junctional SR and the sarcolemma; a big hug that makes your heart beat

C. Pinali, H. Bennett, B. Davenport, A.W. Trafford and A. Kitmitto

University of Manchester, Manchester, UK

The ultrastructural morphology of the sarcoplasmic reticulum (SR) is not well understood being represented as a sequence of compartmentalised domains limited by the sarcomere [1] or as a continuous network spread across the cell [2]. Since structure is dictated by function it is of primary importance to investigate it. We used serial block face imaging SEM to produce the first 3D reconstruction of the SR within a cardiomyocyte and identified junctional domains at the sarcolemma. We used sheep heart since its size and rate are similar to those of man. Sheep (n=4) were killed with an overdose of pentobarbitone (200mg/kg iv). All procedures were carried out in accordance to the United Kingdom Animals Act of 1986 and the University of Manchester's ethical review process. Small portions of left ventricle were put in 4% PFA and 2.5% GA in 0.1M sodium cacodylate buffer with 50mM CaCl2 to enhance the staining of the SR [3]. After washings, samples were put in 1% OsO4 and 1.5% K4Fe(CN)6, dehydrated and embedded in Taab LV. Resin blocks were trimmed to ~ 0.5 mm3, gold coated and positioned in a FEI Quanta 250 FEG SEM equipped with a Gatan 3View system which takes an image of the block face after a slice has been cut at a specific thickness, with images taken after each slice to generate 3-D data with a resolution of ~15nm in the X and Y directions (block surface) and ~ 50 nm in the Z direction (entering into the block). Images were aligned, analysed, reconstructed and segmented in Fiji [4] or IMOD [5]. The size of the tissue examined means that the SEM images at least 5-8 cells with the removal of each slice, generating volumetric data for each myocyte. Using the staining described the SR is highly contrasted and appears black. 3D reconstruction showed that the SR runs along the mitochondria throughout the cell and is also in close contact to the myofilaments parallel to the mitochondria. It also forms connections perpendicular to the myofilaments mostly located at the Z-line and is a continuous network connecting one end of the cell to the other. We found that junctional portions of the SR (jSR) not only form patches in apposition to the t-tubules but also adopt a similar organisation with the sarcolemma. This novel technique has generated detailed images of entire SR network within a cell at a resolution close to 15 nm. The identification of the jSR patches in close apposition to the sarcolemma is consistent with a functional role for spark generation in myocytes at the surface of the cell. A similar organisation would be relevant to myocytes which do not have a developed t-system like atrial myocytes of small mammals. The SR is also in close contact with the mitochondria which

may underlie a critical role in local Ca2+ transfer between the two organelles.

The comparison of the kinetics of of rapid and slow delayed rectifier currents in undiseased human, dog, rabbit and guinea pig ventricular myocytes

C. Corici[1], Z. Kohajda[1], A. Horvath[1], M. Bitay[3], G. Bogats[3], J.G. Papp[1,2], L. Virag[2,1], A. Varro[2,1] and D. Jost[1,2]

[1]Division of Cardiovascular Pharmacology, Hungarian Academy of Sciences, Szeged, Hungary, [2]Department of Pharmacology & Pharmacotherapy, University of Szeged, Szeged, Hungary and [3]2nd Department of Medicine, Division of Cadiac Surgyery, University of Szeged, Szeged, Hungary

To understand the large inter-species variation in the drug effect on repolarization, and to identify the most human like species, the properties of the rapid (IKr) and the slow (IKs) components of the delayed rectifier potassium currents were compared in myocytes isolated from undiseased human donor (HM), and from three commonly used animal model, the dog (DM), rabbit (RM) and guinea pig (GM) ventricles by applying the patch-clamp and conventional microelectrode techniques at 37 °C. The amplitude of the IKr tail current measured at -40 mV after, a 1 s long test pulse to 20 mV, was very similar in HM and DM (0.35±0.07 and 0.38±0.02 pA/pF, respectively, n=12-15) but larger in RM and GM (0.66±0.05 pA/pF and 1.0±0.08 pA/pF, respectively, n=10). The IKs tail current was considerably larger in GM (amplitude at -40 mV, after a 5 s long test pulse to 50 mV was 3.3±0.6 pA/pF, n=10) than in RM (1.22±0.7 pA/pF, n=7) and DM (0.9±0.05 pA/pF, n=24). In HM IKs tail was even smaller than in DM (0.2±0.05 pA/pF, n=14). IKr activated rapidly and monoexponentially in each studied species. The corresponding activation time constants measured at 30 mV were: 36±3 ms in HM, 53±6 ms in DM, 35±3 ms in RM and 30±2 ms in GM, respectively (n=6-26). The deactivation of IKr in HM, DM and RM measured at -40 mV, after a pulse to 30 mV was slow and biexponential (t1=0.6±0.05 s and t2=6.7±0.9 s in HM; t1=0.4±0.02 s and t2=3.3±0.3 s in DM ; t1=0.6±0.03 s and t2=6.5±0.3 in RM, respectively, n=8-26), while in GM the IKr tail current was best fitted triexponentially (t1=0.14±0.01 s, t2=0.8±0.01 s and t3=6.6±.06 s, n=10). IKs measured at 30 mV, activated slowly and had apparently a monoxponential time course in HM, DM and RM (t=0.9±0.2 s in HM, t=1±0.1 s in DM, and t=0.8±0.05 in RM, respectively, n=6-21). In contrast, in GM the activation was clearly biexponential (t1=0.5±0.02 s and t2=3.2±0.01 s, n=10). In HM, DM and RM IKs deactivation measured at -40 mV, was fast and monoexponential (t=0.15±0.02, t=0.14±0.01 s and t=0.16±0.05, respectively, n=6-22), while in GM, in addition to the fast component (t1=0.16±0.01 s, A1=860±98 pA) an another slower component was also revealed (t2=0.6± 0.1 s, A2=670±79 pA, n=10). Selective IKr blockade resulted in substantial and comparable APD lenghthening in all species, while IKs blockade lengthened significantly APD only in GM, but not in HM, DM and RM (Fig 1). These results suggest that IK in HM resembles that measured in DM and RM, and considerably differs from that observed in GM. These findings suggest that the dog and rabbit IKr and IKs currents resemble more human than guinea pig and these species are more appropriate for preclinical evaluation of new potential drugs expected to affect cardiac repolarization.

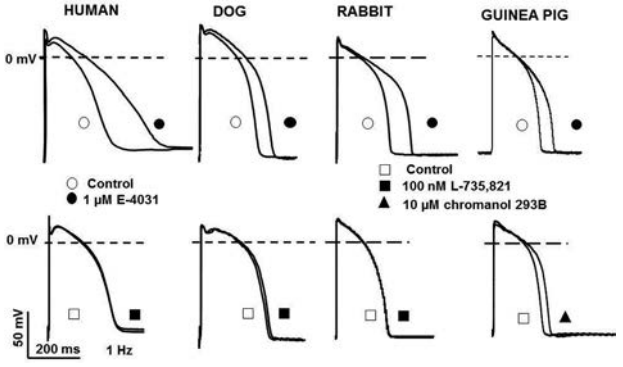

Fig. 1. Effect of selective IKr and IKs blockade on the APD in right venricular HM, DM, RM and GM at the 1 Hz simulation frequency.

PCD037

An integrated method to quantify calcium fluxes in cardiac excitation-contraction coupling

M. Laasmaa, M. Vendelin and R. Birkedal

Institute of Cybernetics, Tallinn University of Technology, Tallinn, Estonia

In cardiac excitation-contraction (EC) coupling, calcium enters the cytosol via L-type Ca^{2+}-channels (I_{Ca}), reverse Na^{+}/Ca^{2+}-exchange (NCX_{rev}), or is released from the sarcoplasmic reticulum (SR) by Ca^{2+}-induced Ca^{2+}-release (CICR). The magnitude of calcium influx via the different pathways varies with the state of the cell. For example, in case of heart failure, CICR decreases and influx via NCX_{rev} increases. We have developed a new method to quantify the calcium influxes in EC coupling. We used a combination of perforated patch clamp with fluorescence microscopy and mathematical modeling to study rainbow trout (*Oncorhynchus mykiss*) cardiomyocytes. First, the action potential (AP) of each cell was recorded at a fre-

quency of 1.1 Hz. Second, we used the recorded AP to stimulate the cell in voltage clamp. I_{Ca} or NCX were inhibited to determine their respective currents with or without inhibition of SR. Fluorescence changes induced by Ca^{2+}-transients were recorded by loading the cells with Fluo-4 AM. To estimate the contribution of I_{Ca}, NCX, and CICR, we composed a mathematical model of Ca^{2+}-dynamics, which also takes into account intracellular buffering. For the given buffering constants, using spline approximated fluxes through I_{Ca}, NCX and CICR, and fluorescence gain as parameters, the model estimates the intracellular Ca^{2+} and fluorescence transients. Spline approximation of I_{Ca} and NCX fluxes can be found directly from the current measurements. CICR fluxes and other model parameters were found by least square fitting of the calculated and recorded fluorescence. Recordings of 27 different cells were used for analysis. In the control case, 9 cells were used to measure I_{Ca} and 6 cells to measure NCX current. When SR was inhibited, 6 cells were used to measure both I_{Ca} and NCX currents. Experiments were performed at 23 ºC. Our data and analysis suggest that during in trout cardiomyocytes at the given temperature and frequency, the Ca^{2+}-influxes are: 15-20% via L-type Ca^{2+}-channels, 15-20% via NCX_{rev} and 60-70% via CICR. When the SR was inhibited, we saw ~10% increased influx via L-type Ca^{2+}-channels and ~40% increase via NCX_{rev} compared to respective influxes in control case. The method is applicable to different species – including genetically modifiable mice and zebrafish – to study the cardiac functional phenotype under a range of physiological conditions.

PCD038

A novel steady-state K^+ current inhibited by noradrenaline via a pertussis toxin-sensitive β_2 adrenoceptor-mediated pathway in rat atrial myocytes

R. Bond, S.C. Choisy, S.M. Bryant, J.C. Hancox and A.F. James

Physiology and Pharmacology, University of Bristol, Bristol, UK

Steady state outward K^+ currents (I_{Kss}) activate rapidly on depolarisation, show little inactivation and are thought to be important in action potential repolarisation. In ventricular myocytes, I_{Kss} has been suggested to be under adrenergic control (Choisy *et al*. 2004, Ravens *et al*. 1989, Scamps 1996). At present, however, there are no published data describing a noradrenaline (NA) –sensitive I_{Kss} in atrial myocytes. This study was designed to characterise I_{Kss} and investigate its modulation by NA in atrial myocytes. Procedures were approved by the Ethics Committee of the University of Bristol and were conducted in accordance with UK legislation. Male Wistar rats were anaesthetised by sodium pentobarbital (60-100 mg/kg i.p.) and left atrial myocytes isolated from the excised heart as previously described (Choisy *et al*. 2004). Ionic currents were recorded in whole cell voltage clamp mode using an external Tyrode's solution and K^+-based pipette solution. Superfusion of cells with 1 μM NA potentiated the L-type Ca^{2+} current (I_{CaL}) at 0 mV by 205±39.7 % and inhibited I_{Kss} at +50 mV by 44±4.6 % ($p \leq 0.001$, Student's paired t-test, n=6). While the effect of NA on I_{CaL} was abolished by the β_1-antagonist atenolol (10 μM), the inhibition of I_{Kss} was unaffected. The inhibitory action of NA on I_{Kss} was also unaffected by the α_1-antagonist, prazosin (5 μM), or atenolol plus prazosin. However, in the presence of the β_1/β_2-antagonist, propranolol (1 μM), the NA-induced inhibition of I_{Kss} was abolished. Furthermore, the action of NA on I_{Kss} was mimicked by the β_2-agonist, zinterol (1 μM) in the presence of atenolol (10 μM).

The steady state outward current was markedly reduced and the inhibitory effect of NA lost when recordings were made under K^+-free conditions, indicating the involvement of a K^+-selective current. NA reduced the power of the noise of I_{Kss}. Power spectral analysis of the NA-sensitive current indicated a single channel conductance of 27.6±5.1 pS (n=14). The NA-sensitive current was partially inhibited by 4-aminopyridine (3 mM). The action of NA on I_{Kss} in rat atrial myocytes was abolished in pertussis toxin-treated cells. The effect on action potential duration (APD) of I_{Kss} inhibition by NA was examined in the presence of 10 μM atenolol to prevent changes in I_{CaL}. In cells stimulated at 1 Hz, 1 μM NA prolonged APD_{30} by 17±5.4 % ($P \leq 0.05$, Student's paired t-test, n=8) but had no effect on APD_{60} or APD_{90}. In summary, these data demonstrate the existence of a steady state K^+ current that plays a role in modulation of APD by NA via a pertussis toxin-sensitive β_2-adrenoceptor mediated pathway in rat atrial cells.

PCD039

Use of chimeras to investigate the molecular basis of differences in agonist and antagonist action between human P2X1 and P2X2 receptors for ATP

R. Allsopp, L.K. Farmer, A.G. Fryatt and R.J. Evans

Department of Cell Physiology and Pharmacology, University of Leicester, Leicester, UK

P2X receptor subtypes can be distinguished by their sensitivity to ATP analogues and selective antagonists. We have used chimeras between human P2X1 and P2X2 receptors to address the contribution of the extracellular loop, transmembrane segments and intracellular termini to the action of partial agonists (higher potency and efficacy of BzATP and AP5A at P2X1 compared to P2X2 receptors) and antagonists (NF449 ~ 1,500 fold more potent at P2X1 compared to P2X2). P2X receptors and chimeras were expressed in Xenopus oocytes and currents recorded with TEVC.

Replacing the extracellular loop of the P2X1 receptor with that from P2X2 (P2X1-2EXT) produced a receptor that had low sensitivity to NF449 equivalent to that at the WT P2X2 receptor. Sensitivity similar to WT P2X1 receptors was recorded in the reciprocal P2X2-1EXT chimera for NF449. These data show that antagonist sensitivity was conferred by the extracellular loop, and indicates that these chimeras do not result in major conformational changes. In contrast the effectiveness of partial

agonists was increased above P2X1 levels for both the loop transfers suggesting interactions with the rest of the receptors played an important role in regulating agonist sensitivity and efficacy.
Swapping TM1 increased the efficacy of AP5A and BzATP at P2X1-2TM1 and P2X2-1TM1 chimeras. Replacement of the TM2 region had reciprocal effects on partial agonist efficacy; P2X1-2TM2 showed partial agonist sensitivity similar to that at P2X2 and P2X2-1TM2 showed partial agonist sensitivity intermediate between P2X1 and P2X2. These results suggest a complex interaction between the TMs and the rest of the receptor in regulating partial agonist efficacy.
Exchanging the intracellular N- terminus had no effect on agonist potency, but increased partial agonist efficacy at P2X2-1N and decreased it at P2X1-2N chimeras. This demonstrates that potency and efficacy can be independently regulated. Further subdivision of the N- terminus showed amino acid residues 1-16 predominate in the control of efficacy. The C-terminal chimera P2X2-1C had no effect of partial agonist sensitivity, whereas the reciprocal chimera (P2X1-2C) had partial agonist efficacy intermediate between P2X1 and P2X2. Chimeras and point mutations also identified residues in the C-terminus that regulated recovery from channel desensitization.
In summary this study shows that interactions between the extracellular, transmembrane and intracellular portions of the P2X receptor regulate channel properties and suggest that transitions to channel opening, the behaviour of the open channel and recovery from the desensitized state can be controlled independently.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Regulation of cardiac ion channels is essential for functional expression of ion channels and excitability of cardiac cells. Previous results with dystrophin-deficient (*mdx*) mice showed that disruption of the dystrophin-syntrophin macromolecular complex impairs excitability and impulse propagation by interfering with the interaction between the PDZ domain-binding motif of the cardiac sodium ion channel Nav1.5 and syntrophin at the lateral membrane of cardiomyocytes. In addition, interfering with the association between Nav1.5 and another PDZ domain-containing protein, SAP97 that is located at the intercalated discs, led to reduction of sodium current (I_{Na}).
To study the *in vivo* significance of this PDZ domain-binding motif on Nav1.5 function, we created and characterized a homozygous knock-in mouse strain which removed this motif by truncating the last three amino acids, Ser-Ile-Val (ΔSIV), of the Nav1.5 C-terminus. Western blots detected a 25% decrease in Nav1.5 protein level in ΔSIV hearts, while levels of associating proteins were unaffected. Immunostainings revealed loss of Nav1.5 expression at the lateral cardiomyocyte membrane but not at the intercalated discs. This reduction corresponded to a 36% decrease of whole-cell I_{Na} in ΔSIV cardiomyocytes and a 62% reduction of I_{Na}, specifically at the lateral membrane, in macropatch recordings. A significant slowing of 35% of maximal upstroke velocity of the cardiac action potential was detected. On surface ECGs, ΔSIV mice displayed a pronounced QRS-interval prolongation, indicating impeded ventricular conduction. This was confirmed with optical mapping of ΔSIV hearts showing prolongation of activation time and increased anisotropy due to a preferential decrease in transversal conduction velocity.
We also investigated the effects of a specific mutation within the PDZ domain-binding motif of Nav1.5 (p.V2016M) that was found in a patient with Brugada syndrome. This mutation changes the last amino acid of the PDZ domain-binding motif from valine to methionine (SIV to SIM) at the Nav1.5 C-terminus. HEK293 cell transfections of mutant V2016M channels revealed a 24% decrease in cell surface expression compared to WT in biotinylation experiments. Patch-clamp recordings of V2016M mutant channels revealed a 49% decrease in peak I_{Na}. Pull-down experiments with Nav1.5 WT or mutated C-terminus GST fusion proteins showed a significant decrease in the interaction of Nav1.5 and SAP97. Taken together, these results emphasize the importance of the Nav1.5 PDZ domain-binding motif in correct ion channel expression, protein interaction, and cardiac function.

Altered Ca^{2+}-handling features in TRIC-A channel-deficient and overexpressing vascular smooth muscle cells

D. Yamazaki[1], N. Miyuki[1], J. Ma[2] and H. Takeshima[1]

[1]Graduate School of Pharmaceutical Sciences, Kyoto University, Kyoto, Japan and [2]Davis Heart and Lung Research Institute, Ohio State University, Columbus, OH, USA

Intracellular Ca^{2+} stores are functionally maintained by Ca^{2+} uptake and release processes, both of which are electrogenic events. It has been predicted that counter-ion movements may balance the membrane potential to establish efficient Ca^{2+} release and uptake mechanisms in intracellular stores. However, molecular components mediating counter-ionic currents are unknown. We recently identified TRIC channel subtypes derived from distinct genes, namely TRIC-A and TRIC-B. TRIC channels are distributed to the endo/sarcoplasmic reticulum (ER/SR) and nuclear membranes in various cell types; TRIC-A is preferentially expressed in excitable tissues, while ubiquitous expression is observed for TRIC-B. TRIC channels are composed of ~300 amino acid residues, and contain three putative membrane-spanning segments to form a bullet-shaped homo-trimeric assembly. Both purified native and recombinant TRIC subtypes form functional monovalent cation-selective channels in a lipid bilayer reconstitution system. Based on the electrophysiological data indicating that TRIC channels behave as K^+ channels under intracellular conditions, we have been examining the physiological roles of the TRIC subtypes

using the gene-knockout and transgenic mice. Animal experiments were conducted with approval of the Animal Research Committee according to Kyoto University regulations. All surgical procedures were performed under pentobarbital anesthesia (50 mg/kg, intraperitoneal). Double-knockout mice lacking both TRIC subtypes show embryonic heart failure, and Ca^{2+} release during excitation-contraction coupling is compromised in the mutant cardiomyocytes. *Tric-a*-knockout mice develop hypertension resulting from vascular hypertonicity, and the knockout vascular smooth muscle exhibits depolarized resting potential due to insufficient spontaneous Ca^{2+} sparks for inducing hyperpolarization. In contrast, mutant mice carrying the smooth muscle-specific *Tric-a* transgene develop hypotension. Moreover, *Tric-b*-knockout mice show respiratory failure at birth and Ca^{2+} release essential for surfactant handling is impaired in the mutant alveolar epithelial cells. Therefore, TRIC channels seem to mediate ER/SR counter-K^+ movements in part to facilitate physiological Ca^{2+} release mediated by ryanodine and inositol-trisphosphate receptor channels in various cell types. This poster highlights the *Tric-a*-knockout hypertension and *Tric-a*-transgenic hypotension, and sets out the proposed physiological functions of TRIC channel subtypes in vascular smooth muscle cells.

Class 3 inhibition of hERG K^+ channel by caffeic acid phenethyl ester (CAPE) and curcumin

S. Choi[1], D. Shin[1], K. Kim[1], H. Yoo[1], H. Choe[2], W. Kim[3], Y. Zhang[1] and S. Kim[1]

[1]Physiology, Seoul National University Seoul National University College of Medicine, Seoul, Republic of Korea, [2]Physiology, University of Ulsan, College of Medicine, Seoul, Republic of Korea and [3]Internal Medicine, Dongguk University, Seoul, Republic of Korea

Human *ether-á-go-go* related gene (hERG) K^+ channel current (I_{hERG}) is inhibited by various compounds and genetic mutations, potentially resulting in cardiac arrhythmia. Here we investigated effects of caffeic acid phenethyl ester (CAPE) and curcumin, two natural anti-inflammatory polyphenols, on I_{hERG} in HEK-293 cells overexpressed with hERG. CAPE dose-dependently deceased repolarization tail current of hERG ($I_{hERG,tail}$; IC50, 10.6 ± 0.5 μM). CAPE also shifted half-activation voltage (V1/2) to the left (from –17.5 to –26.5 mV), and accelerated activation and inactivation kinetics. The CAPE inhibition of $I_{hERG,tail}$ was not attenuated in the pore-blocker site mutants of hERG (Y652A and F656A). A point mutation of Cys723 (C723S) mimicked the effects of CAPE; left shift of V1/2 and acceleration of $I_{hERG,tail}$ deactivation. However, $I_{hERG,tail}$ inhibition by CAPE was still observed in C723S. Taken together, CAPE inhibits hERG channel by class 3 mechanism, i.e. modification of gating, not by blocking the pore. Curcumin induced changes of I_{hERG} similar to those of CAPE while additional interaction with pore blocking sites was suggested from attenuated $I_{hERG,tail}$ inhibition in Y652A and F656A. Interestingly, I_{hERG} induced by human action potential voltage clamp was increased by CAPE while decreased by curcumin. Above results revealed intriguing roles of Cys723 in hERG kinetics, and suggested that conventional drug screening by using step pulse protocol for $I_{hERG,tail}$ would overlook the hERG kinetics modulations that could compensate the apparent decrease of $I_{hERG,tail}$.

PCD045

Functional targeting of the $K_{ir}2.1$ 3′ UTR by multiple microRNAs

J.M. Yarham, L. Ferguson, M. McGahon, D. Simpson and A. Collins

CVVS, Queen's University, Belfast, Antrim, UK

MicroRNAs are increasingly recognised as important downregulators of gene expression. Luciferase-based assays have traditionally been used for identifying microRNA targets but these are limited. Previously we have reported miR-212 targeting of the $K_{ir}2.1$ 3' UTR using a novel functional microRNA targeting assay and here we report targeting by miRs-15b, -132 and -424. These microRNAs have been shown to be upregulated in heart failure, which features downregulation of $K_{ir}2.1$ activity in its pathophysiology. In the assay the 3′ UTR of the inward rectifier K^+ channel $K_{ir}2.1$ was inserted downstream of the mCherry red fluorescent protein sequence in an expression plasmid. MicroRNA, siRNA control or non-targeting control (SCR) sequences were inserted into the pSM30 expression vector, which provides enhanced green fluorescent protein as an indicator of microRNA expression. HEK293 cells were transiently co-transfected with the pSM30- and mCherry-based plasmids and the mean red and green intensity of each cell was measured using Volocity software. The principle of the assay is that functional targeting of the 3′ UTR by the microRNA decreases the cell red/green fluorescence intensity ratio. It was validated with a siRNA targeting the 3′ UTR of $K_{ir}2.1$ and used to investigate targeting of the $K_{ir}2.1$ 3′ UTR by miR-15b, miR-132 and miR-424 as predicted by bioinformatics. Red/green intensity ratio was significantly lower in siRNA-expressing and microRNA-expressing cells vs. SCR-expressing controls ($p<0.001$ for all microRNAs and siRNA by ANOVA; n range 322 to 2935). Similar results were obtained in 3 independent experiments for each microRNA. These results indicate functional targeting of the 3′ UTR of $K_{ir}2.1$ by miR-15b, miR-132 and miR-424, and suggest their involvement in $K_{ir}2.1$ downregulation in heart failure.

PCD046

The basis of antagonist binding at cardiovascular P2X receptors for ATP

L. Farmer and R.J. Evans

University of Leicester, Leicester, UK

P2X1 and P2X4 receptors have important roles in the cardiovascular system, including contributions to blood clotting and

blood pressure control. Therefore subtype selective P2X antagonists have therapeutic potential for treatment of cardiovascular disease. The mechanism of antagonist binding at P2X receptors is currently unclear. NF449 is a potent antagonist at the human P2X1 receptor (hP2X1) and has an IC50 of ~1nM. The rat P2X4 (rP2X4) receptor is insensitive to NF449 up to concentrations of 100μM. The difference in antagonist sensitivity between hP2X1 and rP2X4 subtypes can be used to investigate the molecular basis of antagonism.

In this study chimeras have been generated between the two cardiovascular P2X receptors to replace regions of one receptor with corresponding residues from the other. The effects of these mutations on NF449 potency have then been observed. Initially four chimeras were generated, A,B,C and D which split the ligand binding extracellular loop into four sections of approximately equal size. Each of these sections incorporated a section of the residues surrounding the ATP binding pocket, a site at which antagonist binding has been implicated. The chimeras were expressed in Xenopus oocytes and two electrode voltage clamp recordings performed.

Replacing residues 56-133 (chimera A) and 261-324 (chimera D) of the NF449 sensitive hP2X1 receptor with residues of insensitive rP2X4 had no significant effect on NF449 potency. Therefore the variant residues within these sections of the extracellular loop do not account for the difference in NF449 action. When residues 136-181 of hP2X1 were replaced with those of rP2X4 (chimera B), antagonist sensitivity was reduced ~130 fold compared to WT hP2X1. Region 136-181 therefore plays a role in the antagonist sensitivity of the hP2X1 receptor. Within this region four positive charges at positions 136-140 have previously been shown to be involved in NF449 action. Reintroducing these charges to chimera B gave nanomolar NF449 potency, highlighting their importance. Neither making the reciprocal chimera (hP2X1 into rP2X4), nor introducing the four charges alone, gave antagonist sensitivity to the insensitive rP2X4 receptor. Other residues within the receptor must therefore be needed for NF449 to inhibit the current.

Replacing residues 184-261 of hP2X1 with those of the rP2X4 receptor (chimera C) also caused a significant ~130 fold decrease in NF449 potency. Residues within this region are therefore likely to be involved in the inhibition of the hP2X1 receptor by NF449. This fits with a model of NF449 binding to the four positive residues and an area within chimera C. In ongoing work, sub-chimeras are being made within this region to find specific residues/regions that the NF449 molecule may be interacting with.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD047

Regulation of hERG channel function and pharmacology by a KCNE1 variant

C. Du[1], A. El Harchi[1], N. Kerr[2] and J.C. Hancox[1]

[1]School of Pgysiology and Pharmacology, University of bristol, Bristol, UK and [2]School of Clinical Sciences, University of Bristol, Bristol, UK

The rapid delayed rectifier K^+ current (I_{Kr}) plays an important role in ventricular repolarisation in the mammalian heart. The pore-forming subunit of I_{Kr} is considered to be encoded by human *ether-à-go-go-related gene* (hERG)(Sanguinetti and Tristani-Firouzi, 2006). In *vivo*, functional I_{Kr} channels may involve other ancillary subunits (Abbott et al., 2007). KCNE1, a protein which is best known as the β-subunit of the slow delayed rectifier K^+ current (I_{Ks}), has been suggested to modify hERG channel function (McDonald et al., 1997). Diverse clinically-used drugs produce hERG channel blockade and lead to acquired long QT syndrome. There is some evidence that KCNE1 variants may influence hERG current (I_{hERG}; eg.Ohno et al., 2007); however it is not known whether or not such variants may influence susceptibility to drug induced arrhythmias by influencing I_{hERG} pharmacology. We have addressed this issue through experiments on recombinant hERG channels co-expressed with either wild-type (WT) KCNE1 or a variant (A8V) that has previously been reported to influence I_{hERG} magnitude and be associated with a long QT phenotype (Ohno et al., 2007). Whole-cell patch-clamp measurements of I_{hERG} were made at 37°C. Consistent with prior observations (McDonald et al., 1997), we found that expression of WT KCNE1 in hERG expressing cells produced a hyperpolarising shift in the voltage dependence of I_{hERG} activation ($V_{0.5}$ of -16.06 ± 0.97 mV for I_{hERG}, n= 14 cells; and $V_{0.5}$ of -26.94 ± 1.09 mV for $I_{hERG\text{-}KCNE1}$, n= 9 cells). A similar shift was also seen for A8V KCNE1 variant ($V_{0.5}$ of -26.40 ± 1.8 mV for A8V KCNE1, n= 9 cells, p>0.05 versus WT KCNE1). The amplitude of I_{hERG} was smaller for A8V KCNE1 + hERG than for WT KCNE1 + hERG, under both conventional voltage clamp and "action potential" clamp (AP clamp; performed using a physiological ventricular AP waveform). Using paired AP commands, with the second AP waveform applied at varying time-intervals to mimic premature ventricular excitation, the response of I_{hERG} carried by A8V KCNE1 + hERG was reduced in comparison to that of WT KCNE1 + hERG. The I_{hERG} blocking potency of the Class I antiarrhythmic drug quinidine was similar between WT KCNE1 (IC_{50} of 0.54 ± 0.13 μM) and A8V KCNE1 (IC_{50} of 0.47 ± 0.11 μM). On the other hand, the I_{hERG} inhibitory potency of the antibiotic clarithyromycin was reduced for the A8V KCNE1 variant (IC_{50} of 80.26 ± 9.2 μM) compared with WT KCNE1 (IC_{50} of 40.85 ± 4.39 μM). These results demonstrate that, in principle, the A8V KCNE1 variant may alter the protective response of hERG channels to premature excitatory stimuli and the sensitivity of hERG channels to inhibition by drugs linked to acquired long QT syndrome.

PCD048

Voltage-dependent stochastic gating of TRIC-B channels derived from TRIC-A knockout mouse skeletal muscle

A. Matyjaszkiewicz[1,2], E. Venturi[1], D. Yamazaki[3], M. Nishi[3], K. Tsaneva-Atanasova[4], H. Takeshima[3] and R. Sitsapesan[1]

[1]School of Physiology & Pharmacology, NSQI and Bristol Heart Institute., University of Bristol, Bristol, UK, [2]Bristol Centre for Complexity Sciences, University of Bristol, Bristol, UK, [3]Graduate School of Pharmaceutical Sciences, Kyoto University, Kyoto, Japan and [4]Department of Engineering Mathemathics, University of Bristol, Bristol, UK

The trimeric intracellular cation channels, of which there are two subtypes (TRIC-A and TRIC-B), are located on endo/sarcoplasmic reticulum (ER/SR) and nuclear membranes where they are thought to provide counter-current for ER/SR Ca^{2+}-release [1, 2]. TRIC-B knockout mice die immediately after birth demonstrating the essential role of this isoform [3]. We aimed to define the key aspects of TRIC-B channel gating and investigate how gating is regulated by voltage. Both TRIC-A and TRIC-B are present in most tissues and therefore to be certain that we record only TRIC-B single-channel events, we incorporated skeletal muscle light SR from TRIC-A knockout mice into artificial membranes under voltage-clamp conditions [2]. Recordings were obtained in symmetrical 210 mM K-PIPES, pH 7.2. Single-channel recordings were idealized using the segmental k-means (SKM) algorithm implemented in QuB software [4]. We developed Markov models of TRIC-B gating, with up to 4 distinct sub-conductance states (S1-S4), using both QuB and our own software. Mean-variance histograms [5] were computed using our own code. There was a high degree of variability in TRIC-B gating behaviour but almost 90% of channels (7 of 8 channels) exhibited voltage-dependent gating where channel activity was higher at positive than at negative holding potentials. At positive potentials, gating was characterised by long closures interspersed with bursts of openings in which the majority of time was spent in the full open state. At negative potentials, channel openings were rare and usually consisted of brief openings to the lower-conductance open states (S3 and S4). Even at positive holding potentials, Po plateaued to relatively low levels (< 0.2) over the voltage range +20 to +60 mV. Transitions to the full open state were typically preceded by brief transitions through a range of sub-conductance states. During an opening burst, TRIC-B often gated rapidly between the full open state and the higher-conductance open states, S1 and S2. Closure of the channel at the end of a burst also usually consisted of a tail of transitions through multiple sub-conductance states. The variable gating of TRIC-B and the frequent, rapid transitions between sub-conductance states prevents the development of reliable gating models using conventional single-channel analysis alone. We have therefore used mean-variance plots to provide additional quantitative and visual information that allows us to describe the key features of TRIC-B gating. Our model of TRIC-B gating provides the basic framework for developing an understanding of how TRIC-B may be regulated in situ and will help us to determine the individual and combined roles of TRIC-A and TRIC-B in supporting intracellular Ca^{2+}-release.

PCD049

pH regulates the single-channel gating behaviour of TRIC-B channels derived from TRIC-A knockout tissue

F. O'Brien[1], E. Galfré[1], E. Venturi[1], A. Matyjaszkiewicz[1,2], D. Yamazaki[3], M. Nishi[3], H. Takeshima[3] and R. Sitsapesan[1]

[1]School of Physiology & Pharmacology, NSQI and Bristol Heart Institute., University of Bristol, Bristol, UK, [2]Bristol Centre for Complexity Sciences, University of Bristol, Bristol, UK and [3]Graduate School of Pharmaceutical Sciences, Kyoto University, Kyoto, Japan

TRIC-B is one of two subtypes of trimeric intracellular cation channels found in the endo/sarcoplasmic reticulum (ER/SR) [1, 2]. The TRIC-B knockout mouse dies in respiratory failure following birth and there is evidence that release of intracellular Ca^{2+} in the alveolar type II epithelial cells is severely disrupted [3]. The unique physiological role of TRIC-B and the mechanisms that regulate channel opening are not fully understood. Since monovalent cation flux across ER/SR membranes is known to be influenced by pH changes, we have investigated whether TRIC-B function is sensitive to pH. We incorporated the light SR membrane fraction isolated from skeletal muscle of TRIC-A knockout mice into artificial membranes under voltage-clamp conditions [2]. Recordings were obtained in symmetrical 210 mM K-PIPES at pH 6.2, 7.2 and 9.2. Where multiple channels incorporated, noise analysis was performed because the complex sub-conductance state gating prevented accurate assessment of the probability of dwelling in the various open states. Student's t-test was used to to access significance.We found that the single-channel conductance of the TRIC-B full open state was not affected by changing the pH on the cytosolic side of the channel. The full open state single-channel conductance was 205.8±2.18 pS at pH 6.2, 205.3±1.57 pS at pH 7.2 and 204.9±0.06 pS (SEM; n=3-7) at pH 9.2. As previously observed [2], TRIC-B channels were more open at positive holding potentials and exhibited variable gating behaviour with a wide range of open probabilities. For example, at pH 7.2 and at the holding potential of +30 mV, the single-channel mean current obtained from noise analysis was 1.55±0.58 pA/s (SEM; n=7) but this ranged from 0.03 to 3.36 pA/s for individual experiments. We observed that TRIC-B channels became more open as the cytosolic pH was increased. At +30 mV, as pH was raised from 7.2 to 9.2, we observed a 32.16 fold increase in the single-channel mean current (SD; n=3; p<0.

01) whereas when pH was lowered from pH 7.2 to 6.2, mean current decreased 2.08 fold (n=4).
In summary, we find that in addition to being a voltage-regulated channel, TRIC-B activity is also modulated by cytosolic pH. Such regulation may be particularly relevant for excitation-contraction coupling in skeletal muscle during fatigue or in cardiac muscle under conditions of myocardial ischaemia. Further work is necessary to understand the mechanisms governing TRIC-B activity in a cellular situation and how TRIC-B channel opening is important in supporting ER/SR Ca^{2+}-movements.

PCD050

Effects of muscarinic agonists and RGS4 on voltage-dependent responses of cardiac g protein-gated potassium currents

I. Chen, K. Furutani, A. Inanobe and Y. Kurachi

Osaka University, Osaka, Japan

ACh released from vagal nerve terminals opens G protein-gated potassium (KG) channels at nodal cells, thereby leading to bradycardia. One of the characteristics of ACh-induced KG currents in native cardiac myocytes is a time-dependent slow increase in current amplitude during hyperpolarizing voltage steps (1). This feature is referred to as "relaxation". We previously reported that RGS (regulators of G-protein signaling) proteins are responsible for the relaxation behavior (2, 3). RGS proteins are known to accelerate the GTP hydrolysis of G protein α subunits, and sequestrate free G protein $\beta\gamma$ subunits. Thus, the proteins hasten the speed of activation and deactivation of ACh-induced KG current, and cause the slowly developed current response. The voltage-dependent regulation of G protein-signaling underlies the latter response. In the present study, we examined the KG currents elicited by several muscarinic agonists (such as ACh and pilocarpine) in atrial myocytes. For electrophysiological experiments, the myocytes were enzymatically isolated from hearts removed from adult male Wistar rats, which were deeply anesthetized by intraperitoneal injection of a combination anesthetic (0.3 mg/kg of medetomidine, 4.0 mg/kg of midazolam, and 5.0 mg/kg of butorphanol). Unlike the relaxation of ACh-induced KG currents, the pilocarpine-induced KG currents were time-dependent slow decrease in current amplitude during hyperpolarizing voltage steps. In order to clarify the molecular mechanism underlying this voltage-dependent response, we reconstituted the KG channels in Xenopus oocytes by expressing Kir3.1 and Kir3.4. In oocytes that express Kir3.1/Kir3.4 with m2 muscarinic receptor, we recorded the pilocarpine-induced KG current which did not show the deactivation and failed to reproduce the current response of myocytes. However, when co-expressed with RGS4, we succeeded to record the voltage-dependent response resembling to cardiac KG current. By expressing truncation mutants of RGS4, we could reproduce the result of our previous study that only RGS domain itself was needed to reproduce the relaxation of ACh-induced KG current (3). However, we found that both N-terminus and RGS domain of RGS4 were essential to reproduce the voltage-dependent response of pilocarpine-induced KG currents. These data suggest that RGS4 proteins are critical for the voltage-dependent response, and the RGS4-induced modulation of G protein-signaling are varied with muscarinic agonists.

PCD051

Remodeling of the diaphragm in mice during the development of heart failure

T. Gillis[1], M. Plat[2], A. Arkell[2], A. Foster[2] and J. Simpson[2]

[1]Integrative Biology, University of Guelph, Guelph, ON, Canada and [2]Human Health and Nutritional Sciences, University of Guelph, Guelph, ON, Canada

In this study we examined the contractile function, and protein composition of diaphragm muscle following 18 weeks of transverse aortic constriction (TAC) induced heart failure in mice Diaphragm function was characterized following 2 and 18 weeks of TAC. Hearts after 18 weeks of TAC had multiple indicators of systolic and diastolic dysfunction, demonstrated a reactivation of the fetal gene program and interstitial fibrosis. Contractile function of skinned diaphragm muscle preparations (~2.9 mm x 250 μM) was measured over a range of Ca concentrations at a sarcomere length of 2.3 μM. At each Ca concentration the maximum activated force was measured, as was the rate of force redevelopment following rapid release and re-stretch. The Ca sensitivity of force generation was significantly reduced in the 18 week TAC group compared to the sham mice and the two week TAC group. The Kf½ (Ca concentration at half maximum force generation) for the 18 week TAC group was 2.2 ± 0.17 μM while that for the sham group and 2 week TAC group were 1.86 ± 0.14 and 1.90 ± 0.15 μM respectively. In addition, the maximum Ca activated force was significantly lower for the 18 week TAC mice (22.1 ± 2.4 mN mm-2) compared to those from the sham group and 2 week TAC group, 30.5 ± 2.6 and 25.1 ± 2.2 mN mm-2, respectively. Western blotting indicates a significant increase in the presence of a high molecular weight protein complex containing TnT in diaphragm from the 18 week TAC group. There was also a reduction in the rate of cross-bridge cycling, in the diaphragm from the 2 and 18 week TAC as compared to sham. In the sham

group, as Ca activated force increased there was a parallel increase in the rate of cross-bridge cycling. Comparatively, in the 2 and 18 week TAC groups, as force increased there was an initial increase in cross-bridge cycling but this reached an asymptote and then decreased before maximum force was reached. As a result, the rate of cross-bridge cycling in the diaphragms from the two treatment groups was significantly lower compared to those from the sham group for the latter half of the Ca activation curve. This reduction in cross-bridge cycling rates may be a compensatory mechanism to reduce the metabolic cost of contraction. However, this would reduce the rate of force development and therefore power generation by the muscle. The results of this study indicate that chronic hypertension initiates a series of changes in diaphragm contractility that have the potential to cause dysfunction in heart failure and may play a role in exercise intolerance and dyspnea, the chief complain from patients with heart failure.

Increased glomerular water permeability in streptozotocin-induced diabetes: roles of hyaluronan and chondroitin sulphate

A. Russell and A.H. Salmon

Microvascular Research Laboratories, University of Bristol, Bristol, UK

Changes in glomerular permeability, manifesting as albuminuria, occur early in diabetic nephropathy. The endothelial glycocalyx is an important regulator of glomerular permeability, and is disrupted in diabetic patients with albuminuria (Nieuwdorp et al (2006). Which component of the endothelial glycocalyx contributes to altered glomerular permeability in diabetes is not known. We have examined the roles of hyaluronan and chondroitin sulphate in regulating glomerular water permeability in healthy and diabetic animals.
Male Sprague Dawley rats received sodium citrate (sham) or streptozotocin (45 mg/kg) i.v. to induce diabetes. On day 7, rats were anaesthetised (sodium pentobarbital) and kidneys were perfused via the abdominal aorta with Ringer-Albumin solution. Right renal perfusate also contained Octadecyl-Rhodamine-B Chloride (R18: cell membrane label) and either Chondroitinase ABC (7.25U/kg) or Hyaluronidase (15000U/kg). Successful selective glomerular perfusion was confirmed with confocal microscopy. Following exsanguination and nephrectomy, glomeruli were sieved from the cortex of each kidney, aspirated onto a micropipette and equilibrated in 1% BSA perifusate. Perifusate switch to 8% BSA caused glomeruli to shrink. The initial rate of change in glomerular volume was recorded, calculated off-line, and used to determine volume-corrected glomerular water permeability (LpA/Vi: min-1 mmHg-1), assuming σ=1. One-way ANOVA (Bonferroni correction) was used to compare mean±sem(n) LpA/Vi between groups.
Glomerular LpA/Vi was increased in diabetic rats (sham: 0.85±0.08(58); streptozotocin: 1.23±0.13(39); p<0.0001). Neither chondroitinase nor hyaluronidase significantly altered LpA/Vi in sham- treated animals (chondroitinase: 0.844±0.08(28); hyaluronidase: 0.678±0.06(30); both p>0.05 vs vehicle-sham). In diabetic animals, only hyaluronidase modified LpA/Vi (chondroitinase: 1.22±0.27(19); hyaluronidase: 0.674±0.10(19)*; *p>0.05 vs vehicle-streptozotocin).
Glomerular water permeability (LpA/Vi) is increased in diabetic animals. Hyaluronan appears to be an important contributor to this diabetes-related change in glomerular water permeability.

Respiratory health status of rural Indian women. Does Domestic Cooking fuel really matter?

M. Phatak and N. Sukhsohole

Physiology, Indira Gandhi Govt. Medical college, Nagpur, Maharashtra, India

Whether continued use of biomass fuels along with other fuels in presence of poor domestic cooking conditions is as detrimental to respiratory health as the exclusive use of biomass fuels is unknown. The present study is an attempt to assess the risks associated with indoor air pollution in the context of adverse domestic cooking environmental conditions in rural women of central India. Hence we conducted a community based, cross-sectional study in 760 non-smoking, rural women of central India – 265 used non-biomass fuels (Group A), 243 biomass and other fuels (Group B) while 252 exclusively biomass fuels (Group C). Exposure to domestic smoke was estimated according to the average time per day spent near the fireplace (exposure index). Abnormal pulmonary function of the study subjects was assessed by the measurement of peak expiratory flow rate (PEFR) according to standards recommended by American thoracic society. PEFR less than 80% of the predicted was considered as abnormal pulmonary function. It was observed that robust multivariate analyses which adjusted for height, illiteracy, physical activity, environmental exposure to tobacco smoke (ETS), mud house, overcrowding, inadequate ventilation and respiratory morbidity revealed that illiteracy [Odds ratio (OR) 2.48, 95 % Confidence interval (CI) 1.04-5.87]; physical activity (OR 3.93, 95 % CI 1.52-10.14); inadequate cross ventilation (OR 2.43, 95 % CI 1.23-4.77) and respiratory morbidity (OR 2.65, 95 % CI 1.38-5.08) were significant predictors of low PEFR for group C (P<0.05). Whereas none of the predictors were found to be significantly associated with group B. Since women using partial biomass fuels showed no association of low PEFR with domestic cooking environment and respiratory morbidity even after robustly adjusting for confounding variables, we can conclude that even partial abolition of biomass use may be beneficial in improving the lung function of rural, non-smoking women in spite of having inadequate domestic cooking environment.

PCD055

Characterization of a new mouse model of COPD via conditional over-expression of RAGE by alveolar epithelium

P.R. Reynolds

Physiology and Developmental Biology, Brigham Young University, Provo, UT, USA

Receptors for advanced glycation end-products (RAGE) are multiligand cell-surface receptors detected abundantly in pulmonary tissue. Our previous work revealed increased RAGE expression in cells and lungs exposed to tobacco smoke (1) and that the initiation of RAGE signaling following smoke exposure leads to cytokine expression via pro-inflammatory mechanisms mediated by Ras and NF-kB (2,3). Furthermore, we have discovered important pro-apoptotic embryonic effects when RAGE is genetically upregulated in mice (4,5). RAGE expression is elevated in various pathological states, including chronic obstructive pulmonary disease; however, precise contributions of RAGE to the progression of emphysema and pulmonary inflammation are yet unknown. In the current study we generated a RAGE transgenic mouse (RAGE TG) that conditionally over-expressed RAGE by ATII cells in the respiratory compartment. RAGE was induced from weaning (20 days of age) until sacrifice date at 50, 80, and 110 days (representing 30, 60, and 90 days of RAGE over-expression). H&E staining and mean chord length measurement revealed incremental dilation of alveolar spaces as RAGE over-expression persisted. TUNEL staining and electron microscopy confirmed increased apoptosis and blebbing of alveolar epithelium in lungs from RAGE TG mice when compared to controls. Immunohistochemistry using specific antibodies for matrix metalloproteinase 9 (MMP-9) revealed an overall increase in MMP-9 expression, which correlated with decreased elastin expression in RAGE TG mice. Furthermore, RAGE TG mice manifested significant inflammation measured by elevated bronchoalveolar lavage protein, leukocyte infiltration, and secreted cytokines. These data support the concept that innovative transgenic mice that over-express RAGE may model pulmonary inflammation and alveolar destabilization independent of tobacco smoke. Furthermore, it validates RAGE signaling as a target pathway in the prevention or attenuation of smoke-related inflammatory lung diseases.

Characterization of respiration in mice with Rett syndrome mutations T158A and R168X

J.M. Bissonnette[1], S.J. Knopp[1], L.R. Shaevitz[2] and Z. Zhou[3]

[1]Oregon Health & Science University, Portland, OR, USA, [2]Tufts University, Medford, MA, USA and [3]University of Pennsylvania, Philadelphia, PA, USA

The X-linked disorder, Rett syndrome (RTT), is caused by mutations in the gene encoding methyl-CpG-binding protein 2 (MeCP2). A featuring phenotype of RTT is abnormal respiration characterized by frequent apnea and an irregular inter-breath pattern. Mice with a large deletion of Mecp2 show similar breathing abnormalities to RTT. Here we characterize respiration in two mouse models that genetically mimic common RTT mutations, heterozygous females with a missense mutation, T158A (Mecp2T158A/+) or a nonsense mutation R168X (Mecp2R168X/+). Previous studies demonstrated that MeCP2 T158A protein shows impaired binding to methylated DNA and MeCP2 R168X retains the methyl-DNA binding domain but lacks the large C-terminus of the protein including the transcription repression domain. Oregon Health & Science University IACUC approved the protocol that was in agreement with the National Institutes of Health "Guide for the Care and Use of Laboratory Animals". Mice were 7.7 to 12.5 months old when studied, un-anaesthetized, in a body plethysmograph. We found that both mutant strains show abnormal breathing consisting of a slower frequency, frequent apnea and an irregular inter-breath interval, compared to their respective wild type littermates (Mecp2+/+) (Table 1).

The breathing phenotype in Mecp2R168X/+ mice, however, varies significantly among individuals as might be expected in an X-linked disorder. For comparison, we classified Mecp2R168X/+ mice into a mild group and a severe group based on phenotypic severity. Mecp2T158A/+ mice fall between these two groups. Our findings demonstrate that there is considerable inter animal symptom variability in mouse models of RTT, reflecting the fact that RTT is a spectrum disorder. This is likely due to a combination of random X-chromosome inactivation and the different types of mutations on MeCP2. These heterozygous females are well suited for preclinical treatment trials that utilize respiration as an outcome measure, but classification of individual animal respiratory severity is necessary prior to treatment trials. In addition the varied respiratory phenotype in these mutant mice affords an opportunity to further define mechanisms that underlie abnormal breathing in Rett syndrome.

Table 1

Strain	Number	Frequency (bpm)	Apnea (# / hour)	Irregularity score (variance)
Mecp2+/+	8	223±4.7	7.1±2.2	4.9±1.3
Mecp2T158A/+	8	198±7.6*	41.1±5.4**	11.3±1.3*
Mecp2+/+	7	190±6	3.8±1.5	1.99±0.33
Mecp2R168X/+ (mild)	4	169±4.8*	14.4±4.2*	3.5±0.62*
Mecp2R168X/+ (severe)	4	119±9.1***	111±46.7***	13.9±2.6***

Apoptotic cell instillation promotes antifibrotic feedback loop between COX-2/PGE2 signaling and HGF in the bleomycin-stimulated lung

Y. Yoon[1,2], Y. Choi[1,2] and J.L. Kang[1,2]

[1]Physiology, Ewha Womans University, Seoul, Republic of Korea and [2]Tissue Injury Defense Research Center, Ewha Womans University, Seoul, Republic of Korea

Previous our study reported that instillation of apoptotic cells after bleomycin induces persistent HGF production and protects from fibrosis, but the mechanism underlying this antifibrotic effect remains unclear. In the present study, we investigated immediate and prolonged effects of apoptotic cell instillation on the potent antifibrotic molecules, such as COX-2/PGE2. Furthermore, we characterized the functional interaction between these molecules and HGF upon in vivo exposure to apoptotic cells in the injured lung processing extensive fibrosis, using selective inhibitors of these molecules. Apoptotic cell instillation after bleomycin results in further enhancement of immediate and prolonged expression of COX-2 in lung and alveolar macrophages compared with those of bleomycin only treated mice. Coadministration at the same time with apoptotic cells and sequential administration of the COX-2 selective inhibitor, NS-398, the selective PGE2 receptor EP2 inhibitor, AH6809, reversed the increases in immediate and prolonged mRNA and protein expression of HGF in lung and alveolar macrophages. On the other hand, inhibition of HGF signaling using the c-Met antagonist PHA-665752 reversed the immediate and prolonged increases in COX-2 mRNA and protein expression as well as PGE2 production in lung and alveolar macrophages following apoptotic cell instillation. In functional relevance, these inhibitors, including NS-398, AH6809, and PHA-665752, reversed the reduction of hydroxyproline content, as well as proapoptotic activity of caspase-3 and -9 and MPO activity following apoptotic cell instillation. These findings indicate that interaction with apoptotic cells in vivo induces persistent upregulation of COX-2/PGE2 and HGF in a positive feedback loop. The greater and prolonged production of these molecules may be an important mechanism whereby apoptotic cell instillation exerts the net results of anti-inflammatory, anti-apoptotic and anti-fibrotic action.

PCD059

Effects of asthma, TGF-β treatment and allergen sensitization on expression of p115-RhoGEF and other RhoA-associated proteins in human airway smooth muscle cells and mouse lung

Y. Shaifta, K. O'Brien, D. Wright, N. Irechukwu, J. Ward and G. Knock

Asthma, Allergy& Lung Biology, King's College London, London, UK

The cytokines transforming growth factor-β (TGF-β) and interleukin-13 (IL-13) have been implicated in the patho-physiology of asthma (Vignola et al., 1997; Batra et a., 2004) and may be contributing to the associated altered airway smooth muscle function. We hypothesized that these cytokines may be mediating this altered smooth muscle function through changes in RhoA/Rho-kinase signalling, which has also been implicated in allergen-induced airway hyper-responsiveness (Chiba et al., 2004). Human airway smooth muscle cells (hASMC) were obtained by bronchoscopy from moderate asthmatic or healthy subjects. We examined the protein expression of RhoA, Rho-kinase (ROCK), myosin phosphatase targeting subunit-1 (MYPT-1), myosin light-chain-20 (MLC20), and the Rho-specific guanine nucleotide exchange factor p115-RhoGEF in serum-starved healthy hASMC with or without prior 24 hr incubation with TGF-β (10ng/ml) or IL-13 (10ng/ml) or the two cytokines in combination. We also investigated differences in the protein expression of p115-RhoGEF in serum-starved hASMCs derived from moderate asthmatics compared to gender-matched healthy subjects (all male), and in lung tissue of ovalbumin (OVA) sensitized 1295SVJ/Black Swiss mice, compared to non-sensitized controls. Expression of MLC20, MYPT-1 and p115-RhoGEF in healthy hASMCs were all significantly enhanced by TGF-β and by TGF-β in combination with IL-13, but not by IL-13 alone, whereas expression of RhoA and ROCK were not altered by any of the treatments (Fig. 1; expressed as percentage of control vehicle treated cells; * $P<0.05$, $^{**}P<0.01$, $^{***}P<0.001$; derived from one-way repeated measures ANOVA with Holm-Sidak post-tests for individual comparisons). Expression of p115-RhoGEF was approximately 3-fold greater both in asthmatic hASMC compared to controls and in OVA-sensitized mouse lung compared to controls (Fig. 2, $^{*}P<0.05$ by unpaired t-test, n=3 in all cases, data expressed as a ratio of p115-RhoGEF/GAPDH expression). Our data suggest that TGF-β-induced changes in expression of RhoA-associated proteins may contribute to altered airway smooth muscle function in asthma. In particular, the guanine nucleotide exchange factor p115-RhoGEF, which activates RhoA in response to G-protein coupled receptor activation and integrin engagement (Wells et al., 2001; Dubash et al.,2007), may be important in mediating enhanced RhoA/Rho-kinase activity in asthmatic and allergen-sensitized airways.

Protein	Effects of treatment on protein expression (mean ± SEM)		
	TGF-β	IL-13	TGF-β + IL-13
MLC_{20} (n=6)	253 ± 31***	126 ± 12	268 ± 31***
MYPT-1 (n=6)	199 ± 28**	123 ± 14	199 ± 27**
p115-RhoGEF (n=6)	223 ± 41*	92 ± 6	252 ± 46**
RhoA (n=5)	109 ± 3	113 ± 8	109 ± 6
ROCK (n=5)	111 ± 9	125 ± 15	120 ± 9

Nitro-oxidative stress markers with diagnostic and prognostic value in occupational exposure to isocyanates

P. Alina Elena[1], C. Florinela[2], P. Ovidiu[3], T. Marian Aurel[4] and O. Remus[2]

[1]Pathophysiology, Iuliu Hastieganu University of Medicine and Pharmacy, Cluj Napoca, Romania, [2]Physiology, Iuliu Hastieganu University of Medicine and Pharmacy, Cluj Napoca, Romania, [3]Occupational Medicine, Regional Public Health Center, Cluj Napoca, Romania and [4]Pathology, University of Agricultural and Veterinary Sciences, Cluj Napoca, Romania

Experimental and human studies have demonstrated that dermal exposure to isocyanates is a significant risk factor for sensitisation to isocyanates. Recent occupational medicine studies demonstrated the link between exposure to isocyanates, skin sensitization and astma. The aim of the study was to evaluate the nitro-oxidative stress markers in human subjects with occupational exposure to isocyanates and without clinical and functional manifestations of occupational asthma. Workers occupationally exposed daily for two weeks to isocyanates and without asthma (n = 70, M/F =23/47) were compared to a control group of healthy individuals (n=50, M/F=25/25) not exposed to isocyanates or other toxic agents. Nitro-oxidative stress was evaluated by measuring serum nitrotyrosine (3NT), total nitrites and nitrates (NOx), total oxidative status (TOS), total antioxidant reactivity (TAR) and oxidative stress index (OSI). Tissue injury was appreciated by measuring serum MMP-9. Values are means ± S.E.M., compared by ANOVA. In subjects occupationally exposed to isocyanates the systemic levels of NOx (85,11±5,46 vs. control 42,46±6,12μmol/L, p<0.05), 3NT(358,96±52,04 vs. control 161,72±14,48 μmol/l, p<0.05) TOS (13,95± 1,22 vs. control 11,95±0,29 μmol echivalent H2O2/L, p<0.05), OSI (3,71±0,32 vs. control 1,23±0,0005, p<0.05) and MMP-9 (13,55±1,99 vs. control 10,34±1,24 ng/ml, p<0.05) were significantly increased, and TAC (0,37±0,08 vs. control 1,23±0,05 mmol echivalent trolox/L, p<0.05) was lower than in healthy subjects. The nitro-oxidative stress parameters did correlate with serum MMP-9 level. These data suggest that occupational exposure to isocyanates is associated with systemic nitro-oxidative stress before onset of clinical signs of occupational asthma. 2. Serum nitro-oxidative stress tests correlate with MMP-9. 3. These tests may be recommended for early diagnosis in hypersensitivity to isocyanates.

Fasudil, but not N–Acetylcystein or Hyperoxia accelerates recovery from pulmonary hypertension induced by exposure to chronic hypoxia

O. Vajnerova[1], K. Plocova[1], H. Maxova[2], M. Vizek[2] and J. Herget[1]

[1]Physiology, 2nd Med Sch, Charles University, Prague, Czech Republic and [2]Pathophysiology, 2nd Med Sch, Charles University, Prague, Czech Republic

Pulmonary hypertension (PH) is frequent complication in patients of advanced heart failure and it is a sign of poor clinical outcome (Ghio et al, 2001). We studied rats recovering in air for two weeks after hypoxic PH induced in isobaric hypoxic chamber (FiO2 = 0.1, 3 wks).
To accelerate the recovery we used antioxidant N-acetylcysteine (NAC) (group H+NAC, n = 9, 20 g / l drinking water, 2 wks), Rho-kinase inhibitor fasudil (group H+F, n = 10, 30mg/kg/day, i. p., 2 wks). Control group recovered in ambient air was treated with saline (n = 9). The third experimental group recovered in hyperoxic environment (FiO2 = 0.3, 2 wks) (group H+HO, n = 7), controls (n=8) recovered in air.
After two weeks of recovery all rats were anesthetized with Thiopental (40 mg/kg, i.p.) and pulmonary arterial mean blood pressure, cardiac output and ratio of the weights of the right and left heart ventricles were determined. Groups H+NAC, H+HO and relevant controls did not differ in any of measured parameters. In rats treated with fasudil the mean pulmonary arterial blood pressure was after two weeks recovery significantly lower (20 ± 4 mmHg, mean ± SEM) than in controls (27 ± 4 mmHg). The ratio of the weights of the right and left heart ventricles, however, did not differ from controls. Cardiac output did not differ between the groups.
Inhibition of Rho kinase pathway but not change in metabolism of oxygen radicals are related to the pattern of recovery of lung circulation after chronic hypoxia.

PCD062

Onset to hypoxia produces increased matrix metalloproteinase activity in peripheral pulmonary arteries and generation of collagen fragments

J. Novotna[1] and J. Herget[2]

[1]Medical Biochemistry, 2nd Med Sch, Charles University, Prague, Czech Republic and [2]Physiology, 2nd Med Sch, Charles University, Prague, Czech Republic

Chronic ventilatory hypoxia results in remodelling of pulmonary vasculature and hypoxic pulmonary hypertension. Hypoxia increases the turnover of extracellular matrix proteins in peripheral pulmonary blood vessels.
We studied hypoxia – induced changes in collagen isolated from pulmonary peripheral arteries and from systemic mesenteric peripheral arteries. Our hypothesis is that presence of collagen cleavage products in the walls of hypoxic peripheral pulmonary arteries starts the vascular remodelling.
Two groups of rats were exposed to hypoxia (FiO2 = 0,1) for four days (pulmonary arteries - H4, N=7 - and mesenteric arteries - systH4, N=6) and three weeks (pulmonary arteries - H21, N=7 and mesenteric arteries - systH21, N=6). Two relevant control groups were kept in air. Collagen proteins ex¬tracted from arteries by limited pepsin digestion were studied using SDS polyacryl amide electrophoresis and Western blot. Presence of collagenolytic enzyme, matrix metalloproteinase-13 (MMP-13) and inducible NO synthase (iNOS) were also studied using Western blot. In the peripheral pulmonary arteries of rats exposed to hypoxia three weeks we found already described ~75 kDa cleavage fragment (three-fourth fragment of collagen type I molecule) but not its one-fourth (~25 kDa) counterpart. In peripheral pulmonary arteries of rats exposed to 4 days hypoxia, however, both three-fourth and one-fourth fragments of collagen type I and type III were identified. In the control normoxic group no collagen cleavages were detected in lung vessels. Three-fourth and one fourth fragments of collagen type I were found also in mesenteric peripheral arteries of rats exposed four days to hypoxia but theirs relative density was significantly lower than in lung vessels. MMP-13 and iNOS were detected in early phase of pulmonary hypoxic hypertension in peripheral pulmonary arteries but not in arteries of rats exposed to hypoxia three weeks or any systemic vessels. We interpret breakdown of collagen to one-fourth and three-four fragments in an early phase of hypoxia exposure as a result of relative low resistance of poorly cross-linked molecule to proteolysis by specific MMPs. Resulting accumulation of collagen cleavages ("matrikines") stimulates the fibrotization of prealveolar pulmonary vessels.

Switching of lower jaw movements between the inspiratory and expiratory phases generated by chemoreceptor inputs

K. Nakayama[1], M. Yokomatsu[2], A. Mochizuki[1], T. Inoue[1] and I. Yazawa[3]

[1]Department of Oral Physiology, Showa University Shcool of Dentistry, Tokyo, Japan, [2]Department of Pediatric Dentistry, Showa University Shcool of Dentistry, Tokyo, Japan and [3]Department of Anatomy, Showa University Shcool of Medicine, Tokyo, Japan

Using electrophysiological techniques in a decerebrate and arterially perfused *in situ* rat preparation (P9–24 days; n = 28), extracellular recording were recorded to investigate the interplay of neuronal discharge patterns involved in relationships between a respiratory state and lower jaw movements. The perfusate was an oxygenated (95% O_2-5% CO_2) Ringer's solution containing an oncotic agent (Ficoll 70). Body temperature was set at room temperature. Respiratory discharge was recorded from the phrenic and/or the hypoglossal nerve, and neuronal discharge regarding lower jaw movements was obtained from the trigeminal nerve controlling the digastric muscle. The frequencies of neuronal burst discharges from all nerves increased with increases in the perfusion flow rates. When the flow rate was set at about 6× the total blood volume per minute, the phrenic discharge showed "eupneic pat-

tern" and "regular rhythm". As the flow rate further increased, the preparation was exposed to a hyperoxic/normocapnic state and all nerve discharges became clearly organized into episodes of greater frequency and duration, punctuated by periods of quiescence. All neouronal discharges involved in lower jaw movements were synchronous to the phrenic discharge at all flow rates tested. Although the frequencies of all burst discharges became faster when body temperature was set at above 25°C, the same results as mentioned above were obtained in all cases (n = 3). It was indicated that opening movements of mouth were generated in the inspiratory phase.
When the preparation was perfused by Ringer's solution infused with a 92% O_2-8% CO_2 gas mixture at room temperature, the same results mentioned above were obtained in all cases (n = 6) though the amplitude of all neuronal discharges increased. After the preparation was temporarily exposed to anoxia by applying 500 μM sodium cyanide (NaCN), the trigeminal discharge was produced in both the inspiratory and expiratory phases. After the preparation was exposed to an anoxic state by applying 500 μM NaCN for 1 to 2 minutes, the trigeminal discharge was completely produced in the expiratory phase (n = 5). Based on these results, it was indicated that the amount of inputs from the peripheral and central chemoreceptors changed the timing of opening and closing mouth.
From the above, it was suggested that switching of lower jaw movements between the inspiratory and expiratory phases was generated by increasing and decreasing inputs from chemoreceptors.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD066

The importance of the diaphragmatic ligament in maintaining contractile function in the preterm sheep diaphragm

G.J. Pinniger[1], K. Karisnan[1,2], C. Berry[2], P. Noble[1,2], J.J. Pillow[1,2] and A.J. Bakker[1]

[1]School of Anatomy, Physiology and Human Biology, The University of Western Australia, Crawley, WA, Australia and [2]Centre for Neonatal Research and Education, School of Paediatrics and Child Health, The University of Western Australia, Crawley, WA, Australia

The diaphragm is an atypical skeletal muscle in that its length is not determined by changes in joint angle, but rather is influenced by negative intrapleural pressure and movement of the rib cage. In this arrangement, the diaphragm may be susceptible to large changes in sarcomere length thus compromising contractile function and predisposing it to damage. The diaphragmatic ligament may be important in setting muscle length and protecting against muscle damage, particularly during development (1). Therefore, we examined the influence of the diaphragm ligament on contractile function and susceptibility to stretch induced damage in the diaphragm of preterm sheep.
This study was approved by the animal ethics committee of the University of Western Australia. Preterm lambs were delivered via hysterotomy at 121 d gestational age (term = 150 d) and killed immediately with pentobarbitone (150 mg/kg IV). The costal diaphragm was dissected and longitudinal strips of muscle fibres were isolated and mounted in an in vitro test system. An adjacent strip of fibres, from which the diaphragm ligament had been carefully removed, was mounted in a second system for concurrent analysis. Muscles were maintained in mammalian Ringer solution (pH 7.3, 25°C) bubbled with carbogen. Each muscle strip was manually adjusted to optimal muscle length (Lo) at which maximum tetanic force (Po), maximum twitch force (Pt), time to peak twitch force (TTP), half relaxation time (½ RT) and maximum rate of force development (df/dt) were determined. Maximum unloaded shortening velocity was determined using the slack test method and susceptibility to muscle damage evaluated from a series of 5 eccentric contractions in which the fibres were stretched to 110% Lo while stimulated. Muscle mass and Lo were recorded for calculation of CSA and specific force (N.cm2). Differences between ligament (LIG: n = 11) and no ligament (NL: n=11) groups were analysed by student t-tests.

Removal of the diaphragm ligament had no significant effect on Po or Pt. However, the twitch time course was slower in the NL group as reflected by significant increases (~50%) in TTP and ½ RT and significantly lower df/dt (NL 389 ± 41 g/s, LIG 525 ± 44 g/s; $P<0.05$). The maximum unloaded shortening velocity was 14% lower in the NL group compared LIG and the decrease in peak force after 5 eccentric contractions was significantly greater without the ligament (NL 4.2 ± 2.2%; LIG 1.2 ± 0.1%; $P<0.05$). Lo was not significantly different between the groups.
These data indicate the importance of the diaphragmatic ligament in maintaining contractile function in the preterm diaphragm and support previous studies suggesting the diaphragmatic ligament provides a structural framework for diaphragm muscle fibre development (2).

PCD067

Effect of active sensitisation to acarian allergen on rat airway function and morphology

B. Mounkaila[3] and E. Roux[1,2]

[1]U1034 Adaptation cardiovasculaire à l'ischémie, Bordeaux Segalen University, Pessac, France, [2]U1034 Adaptation cardiovasculaire à l'ischémie, INSERM, Pessac, France and [3]Faculty of Health Sciences, Abdou-Moumouni University, Niamey, Niger

This study has analysed the occurrence of hyperreactivity and airway remodelling in a model of asthmatic disease in brown Norway rats sensitized to Dermatophagoides pteronyssinus allergen (D pter).
Male brown Norway rats (250-300 g) (n=7) were sensitized by 2 subcutaneous injections of D pter (50 IR/ml) (Stallergenes AS, France) and Al_2O_3 at days 0 (D0) and 3 (D3), followed at D17 by intratracheal instillation of D pter. Control (C) rats (n=5) underwent the same protocol but with saline solution instead of D pter. Witness (W) rats (n=5) were not submitted to any treatment. At D24, enhanced expiratory pause (Penh), used as an index of airway resistance, was measured using a barometric plethysmograph for conscious animals. At D25, rats were killed, a bronchoalveolar lavage (BAL) was performed, and isometric contraction was measured on rings isolated from

trachea (T), extrapulmonary (EPB) and intrapulmonary bronchi (IPB) using an organ bath system. Maximal contraction (Fmax) and LogEC50 were derived from cumulative concentration response curves to -8 to-3 LogM carbachol (CCh). Wall thickness and smooth muscle area of proximal and distal bronchi were measured on Masson's trichrome stained serial paraffin slides of lung. Results are expressed as mean ± SEM. Statistical comparisons were done by non parametric tests using SPSS software. Differences were considered significant when $P < 0.05$.

Allergen challenge increased Penh in S, but not in C and W rats. In vitro stimulation by D pter induced contraction of T, EPB and IPB rings isolated from S, but not C and W rats. In response to metacholine (MCh) challenge, MCh concentration (in LogM) inducing 300 % increase in Penh was significantly lower in S (-4.36 ± 0.44) and C (-3.92 ± 0.54) versus W (-2.86 ± 0.55) rats. Fmax to CCh was significantly higher in IPB from S (1966 ± 232 mg/mg wet weight) versus C (1613 ±189 mg/mg ww) and W rats (1191 ± 113 mg/mg ww), and LogEC50 (in LogM) significantly lower (S: -6.22 ± 0.03; C: -5.64 ± 0.02; W: -5.23 ± 0.02). In BAL fluid, cellular density was significantly higher in S (334 ± 52 cells/μl) versus C (217 ± 18 cells/μl) and versus W (165 ± 52 cells/μl) rats, as was the percentage of eosinophils (S: 8.75 %; C: 1.74 %; W: 0.7 %) and mast cells (S: 0.5 %; C: 0.2 %; W: 0 %). No significant difference was found for bronchial wall thickness and smooth muscle area between S and W rats.

Sensitized rats showed (i) in vivo and ex vivo specific bronchoconstriction to allergen stimulation, (ii) in vivo hyperresponsiveness and ex vivo hyperreactivity and hypersensitivity to cholinergic stimulation, and (iii) increased proportion of eosinophils and mast cells in BAL fluid, indicating that such sensitized rats are a relevant model of asthma. Absence of significant morphometric change indicates that airway hyperresponsiveness associated change occurs prior to airway remodelling.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD069

Simulating bronchoconstriction in a patient specific model of the major airways

R.M. Bordas[1], B. Brook[2], D. Kay[1] and K. Burrowes[1]

[1]Computer Science, University of Oxford, Oxford, UK and [2]Mathematical Sciences, University of Nottingham, Nottingham, UK

The use of computational fluid dynamics (CFD) to simulate ventilation in the major airways of the lung has been shown to demonstrate greater specificity in assessing lung function over spirometry measures and visual analysis of computed tomography (CT) images. Currently, CFD is limited to simulating ventilation in a static airway geometry derived directly from CT. It cannot be used to assess the change in ventilation as a result of acute bronchoconstriction or long term remodelling of the airway wall. We have developed a multiscale biomechanical model of bronchoconstriction in the major airways. The model integrates an active tension produced by airway smooth muscle (ASM) and the passive mechanical properties of airway walls and lung parenchyma to simulate constriction and allow assessment of changes in ventilation.

Initially, a finite element model (FEM) of the mechanics of a single airway embedded in a layer of parenchyma was developed. The model was used to parameterise material laws governing the airway wall mechanics in generations 1-10 and to validate the mechanical behaviour of the model in comparison to experimental data. ASM is embedded circumferentially in the model acting at a given angle to the airway cross section. The model is used to assess the reduction in airflow in response to ASM contraction in both normal and remodelled airway wall cases and the distribution of mechanical stress in the airway wall.

To extend the methodology to a patient specific setting, a CT scan of a healthy adult was segmented to obtain a surface mesh of the airway wall. A volumetric mesh encompassing the airway walls was subsequently generated for use with the FEM model. Wall thickness in the mesh is varied to represent airway wall remodelling.

The single airway model was used to investigate changes in airway resistance in response to remodelling. For example, a 19.5x increase in resistance between a normal and a remodelled generation 3 airway in response to a ASM activation (15 degree fibre angle at 8 cmH2O pleural pressure) was shown. The patient specific model was used to demonstrate the change in airflow and material stress around a number of bifurcations for several prescribed ASM tensions, again demonstrating the change in flow in response to ASM constriction and airway wall thickening.

We have developed a methodology for simulating bronchoconstriction on patient specific geometries. The single airway model is well validated and validation of the patient specific model against clinical data is ongoing. The method reveals the importance of the structure of airway bifurcations in governing total airflow in the major airways. The results suggest that simulating bronchoconstriction on patient specific geometries can provide insight into the reduction in ventilation due to acute ASM contraction and chronic airway wall remodelling.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD070

Simulation of pulmonary function test using a one dimensional airway ventilation model

M. Kim, D. Kay and K.S. Burrowes

Department of Computer Science, University of Oxford, Oxford, UK

Pulmonary function test is the most common diagnostic method to evaluate the integrated mechanical capacity of lung ventilation. This test can help to assess the conditions of airway diseases such as asthma and chronic obstructive pulmonary disease (COPD). The constricted airways in these diseases disturb the normal stream of respiratory flow and cause heterogeneous ventilation leading to ventilation-perfusion mismatch affecting gas exchange.1,2 However, none of the lung ventilation models to-date presented the lung function test in the full conducting airway geometry. The goal of the current study is to simulate the lung function test using one dimensional (1D) ventilation model and to demonstrate the difference between a normal and a constricted lung models.

One dimensional (1D) centerlines of central airways were obtained from patient-specific geometry segmented from CT images. Then, the skeletons of conducting airways down to terminal bronchioles were generated using a volume-filling branching algorithm within the lung surface boundary.3 In addition to the normal case, the bronchoconstricted lung was

modelled by reducing radii of selected airways. To compute the dynamic pressure distribution, a fully coupled mathematical model including acinar tissue deformation and airway network flow was introduced.4 We assumed quiet breathing and minimal airway wall compliance to simplify the model. For the input boundary condition, a wave representing the changes in pleural pressure during the lung function test was imposed on each acinar unit. Flow volume and flow rate during inhalation and exhalation were computed to test the function of the model.

The respiratory flow in the normal lung model showed a physiologically reasonable level of lung capacity. Both peak flow rate and tidal volume decreased in the bronchoconstricted lung model. According to the reduction of the lung capacity, heterogeneity in ventilation was increased in the constricted airway model. Computed parameters of the lung function test such as FEV1, FVC and FEV1/FVC in the normal lung were in the clinically acceptable range for the healthy subjects. But, those values were notably decreased by bronchoconstriction. The inspiratory flow-volume curves showed typical shape of normal and constricted lung curves as reported in clinical measurements.

We simulated pulmonary function tests in normal and bronchoconstricted lungs. The pulmonary function of the lung model weakened as the constriction and ventilation heterogeneity increased. The ventilation model presented in this study could be an effective tool to assess respiratory flow characteristics and increase our understanding of the lung function.

PCD071

Respiratory pattern of newborn male rats (P6) exposed to fluoxetine during prenatal period

V. Biancardi, L.A. Patrone, K.C. Bícego and L.H. Gargaglioni

Animal Physiology and Morphology, FCAV - UNESP, Jaboticabal, Sao Paulo, Brazil

Selective serotonin reuptake inhibitors (SSRIs) as fluoxetine are generally prescribed as antidepressant for depression treatment. Fluoxetine administration during pregnancy might be a risk factor for cardiorespiratory diseases in human fetus, as persistent pulmonary hypertension (Chambers et al., 2006). Serotonin (5-HT) is a neurotransmitter involved in nervous maturational processes even at the fetal stage, being an important modulator of respiratory rhythm. The serotoninergic receptors 5-HT1A and 5-HT2A are found within respiratory neurons and they play a key role in this process, beyond they are related to hypercapnia and hypoxia responses. Therefore, the goal of the present study was to evaluate the possible effects of an exposure to SSRIs during a critical period of the development, prenatal period, on respiratory control system of newborn male rats (P6). To this end, pregnant female rats received via oral gavage vehicle (apyrogenic sterile saline + 0.2% Tween-80) or fluoxetine (10mg/kg) from 15th to the 21st day of gestation and the ventilation of pups was studied. The pups were divided in control group (mother received saline during pregnancy) or SSRI group (mother received fluoxetine during pregnancy). We calculated minute ventilation (VE) of newborn male rats (P6) by using the pressure-plethysmography from the body chamber method which shows the pressure signal that we measured during breathing is directly proportional to tidal volume (VT). These measurements were made during 30 min exposure to room air followed by 30 min exposure to 7% CO2 (hypercapnia) or 30 min exposure to 10% O2 (hypoxia), then the newborns were recovered in normocapnic/normoxic conditions for 45 min and exposed to 10% O2 or 7% CO2 for 30 min. Hypercapnia exposure induced an increase in VE in the control group but did not change ventilation in the SSRI group. There were differences between groups [20 min of hypercapnia: control group: 112.95±1.31 (% of baseline); SSRI group: 104.76±3.61 (% of baseline), $p<0.05$, two-way ANOVA]. Hypoxia induced an increase in VE in both groups, however the ventilatory response to hypoxia was higher in SSRI group [30 min of hypoxia: control group: 128.14±13.76 (% of baseline); SSRI group: 163.91±11.72 (% of baseline), $p<0.05$, two-way ANOVA]. The depressor response to hypoxia in the control group is not observed in SSRI group. These preliminary results suggest that in SSRI group the CO2 chemosensitivity might be reduced whereas the O2 chemosensitivity might be increased.

The orexin receptor 1 (OX1R) in the Locus Coeruleus contributes to the hypercapnic chemoreflex in unanesthetized rats

M.B. Dias[1], M.C. Vicente[2] and L.H. Gargaglioni[2]

[1]Physiology, UNESP, Botucatu, SP, Brazil and [2]Animal Morphology and Physiology, UNESP, Jaboticabal, SP, Brazil

It has been suggested that orexin is involved in the ventilatory response to CO2. As the Locus coeruleus (LC) is a chemoreceptor site and expresses an extensive population of orexin receptor 1 (OX1R), we tested the hypothesis that OX1R located in the LC is involved in chemoreception. For the surgical procedures, male Wistar rats were subjected to general anesthesia by i.p. ketamine (100 mg/kg) and xylazine (10 mg/kg). One week later, in unanesthetized rats, we injected SB-334867 (OX1R antagonist, 5 mM) unilaterally into the LC. Pulmonary ventilation (VE) was recorded in a whole body plethysmograph, together with body temperature (Tb, dataloggers), mean arterial pressure (MAP) and heart rate (fH) in air followed by hypercapnia (7% CO2). Hypercapnia caused an increase in VE, which resulted from increases in respiratory frequency (fR) and tidal volume (Vt), but did not affect MAP, fH or Tb in all groups. SB-334867 caused a significant attenuation (70% reduction), of the hyperventilation induced by hypercapnia (n=9) compared with its vehicle (n=6; $P< 0.05$). This effect was due to

both decreased Vt and f. Basal ventilation, MAP, fH or Tb, were not affected by OX1R antagonism. These results suggest that projections of orexin-containing neurons to the LC contribute via orexin R1 to the hypercapnic chemoreflex control in unanesthetized rats.

PCD073

Theoretical estimates of pulmonary diffusing capacity

T.K. Roy[1] and T.W. Secomb[2]

[1]Dept of Anesthesiology, Mayo Clinic, Rochester, MN, USA and [2]Dept of Physiology, University of Arizona, Tucson, AZ, USA

The process of pulmonary oxygen uptake is analyzed to obtain quantitative estimates of pulmonary diffusing capacity $D_{LO}2$. An axisymmetric model is used to represent radial diffusion of oxygen from alveoli through the alveolar-capillary membrane, through the plasma, and into the erythrocytes. Analysis of unsteady diffusion due to the passage of the discrete erythrocytes shows that the transport of oxygen through the alveolar-capillary membrane occurs mainly in the regions adjacent to erythrocytes, and that oxygen transport through regions adjacent to plasma gaps can be neglected. Calculations are performed for a range of discharge hematocrit and capillary diameter values. The model developed above is used to calculate values of $D_{LO}2$ as a function of capillary diameter and hematocrit. The values obtained range from 50 to 90 ml O_2 min^{-1} $mmHg^{-1}$, with values at the higher end of the range corresponding to higher hematocrit and lower capillary diameter and therefore a high lineal density of erythrocytes. These values are much lower than the estimates obtained by others using the morphometric method, which considers the total membrane area and the specific uptake rate of erythrocytes. Representing relative resistances in terms of an inverse Sherwood number demonstrates that under normal circumstances, resistances due to intraerythrocyte diffusion, plasma diffusion, and alveolar-capillary membrane are of similar magnitude, and that the transport resistance due to oxygen unloading is negligible. Additional calculations performed for increasing alveolar-capillary membrane thickness demonstrate the expected effect of decreasing lung diffusing capacity. Finally, simulations of pulmonary oxygen uptake based on the new estimates of lung diffusing capacity are consistent with experimental data on oxygen uptake in exercise and hypoxia.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Coal dust in the working environment- Effects on Forced Expiratory Flow 25 – 75 % amongst Sri Lankans

S. Wimalasekera[1], L. Wanigabadu[2], A. Senevirathne[3], S. Paranevitane[4] and V. Palipane[5]

[1]of Physiology, Faculty of Medical Sciences, University of Sri Jayewardenepura, Nugegoda, Sri Lanka, [2]of Community Medicine, Faculty of Medical Sciences, University of Sri Jayewardenepura, Nugegoda, Sri Lanka, [3]Family Medicine, Faculty of Medical Sciences, University of Sri Jayewardenepura, Nugegoda, Sri Lanka, [4]Family Medicine, Ceymed Health care services, Nugegoda, Sri Lanka and [5]Labour, Ministry of Labour, Sri Lanka, Nugegoda, Sri Lanka

Exposure to dust in the work environment is often responsible for respiratory disability. To what extent does this exposure contribute to respiratory dysfunction? This question has led to controversies and research in occupational settings for a long time. Subsequent studies have given controversial results on the level of exposure to dust and its effects on respiratory symptoms and respiratory function. Coal mining is one of the earliest industries known to affect respiratory function in the world. Many studies have assessed the effect of coal dust on the function of the respiratory system on coal miners but the effects of coal dust on workers handling coal are scarce. Many workers are currently involved in the coal power generation industry in Sri Lanka. It is the first coal power operated plant in the country and therefore the workers are not aware of the respiratory and other hazards they may encounter in this industry.

The objectives were to study the respiratory function amongst the workers engaged in the coal power generation industry in Sri Lanka and to determine the association between coal exposure and respiratory function amongst coal handlers and non coal handlers.

A descriptive cross sectional study was done on workers exposed to coal dust in the Norochcholai coal power plant. The workers (n=80) consisted of Coal handlers (CH) (n=51)and non-coal handlers (NCH) (n=29). The respiratory symptoms were determined using an interviewer administered questionnaire and all subjects were clinically examined. Respiratoy function was assessed using a Vitallograph spirometer (Vitallograph Inc. UK). Spirometry data were analysed at uni-variate level using t test and at multi-variate level using Pearson's correlation coefficient.

Measured FEF25 – 75 % was significantly lower amongst Non coal handlers ($p = 0.031$) and ($p = 0.047$) respectively. Measured FEF25 – 75 % was a significant correlate with duration of work (Pearson correlation coefficient 0.242, and $p = 0.031$). Percentage FEF25 – 75 % was a significant correlate with duration of work (Pearson correlation coefficient 0.239, $p = 0.033$).This study highlights the use of FEF25 – 75 % as an important index in detecting early impairment of lung function. Previously undetected early impairment of lung functions was noted among non-coal handlers. Protective appropriate face masks should be worn by all workers to prevent respiratory disability. The study highlights the need for further longitudinal studies to assess the impact of coal exposure on lung function of the workers and the people living in the vicinity of the coal power plant.

PCD077

Heparanase upregulation in the inflammatory airway facilitates syndecan shedding and sustained inflammation

L. Wu[1], S. Chan[1], M. Ip[2] and D. Shum[1]

[1]Biochemistry, The University of Hong Kong, Pokfulam, Hong Kong and [2]Medicine, The University of Hong Kong, Pokfulam, Hong Kong

Unopposed protease activity resulting from anti-elastase resistant supramolecular complexes of neutrophil elastase and shed syndecan-1 in the airway fluids is thought to be the cause of persistent inflammation resulting in airway damage and deteriorating lung function in COPD and bronchiectasis (1, 2). We aim to develop strategies to decrease syndecan-1 shedding for the treatment of COPD and bronchiectasis.

The levels of heparanase, syndecan-1 and MMP-7 activity were measured in sputum samples of local patients. Values are means ± S.E.M., compared by Student's T-test. The sputum from such patients contained elevated levels of heparanase (n=3, normalized pixel densities from Western blot, $p<0.05$) and shed syndecan-1 (200 ± 11 ng/ml in bronchiectasis patients n=13 and 128 ± 7 ng/ml in COPD patients n=20 vs 21 ± 4 ng/ml in induced sputum from healthy individuals n=5, $p<0.05$ respectively) but not elevated levels of matrix metalloproteinase (MMP) activity (3.22 ± 0.14 in COPD n=5 and 17.90 ± 5.06 in bronchiectasis n=5 vs 2.99 ± 1.36 μM/μg/min in induced sputum from healthy individuals n=3, p=0.8 and 0.04 respectively), we propose that the action of the GAG digesting enzyme heparanase on syndecan-1 modifies it such that it becomes more susceptible to shedding by MMP cleavage.

We show in vitro that heparanase induced syndecan-1 shedding in air-liquid interface cultured human epithelial cells (shed syndecan concentration in medium 11.2 ± 0.7ng/ml vs 131.5 ± 1.8 ng/ml after heparanase treatment, $p<0.05$), and that heparanase-treated recombinant syndecan-1 was more readily cleaved by MMP-7 than control treatment of the recombinant syndecan-1(0.21 vs 1.22 ng/ml/h, determined by ELISA). Surface plasmon resonance analysis demonstrated an increase in affinity of syndecan-1 for MMP-7 upon heparanase treatment (affinity constant increase from 6.83 × 105 to 2.31 × 1010 M^{-1}, n=5). Co-immunoprecipitation study targeting syndecan-1 found associated MMP-7 higher in the sputum samples of bronchiectasis and COPD patients than in induced sputum of healthy individuals; normalized pixel density ratios of MMP-7: syndecan-1 of bronchiectasis and COPD patients (7.0 and 5.7 vs 1.8 in induced sputum) reinforced the suggestion of increased affinity of MMP-7 for syndecan-1 that had been exposed to heparanase activity. The results support that heparanase activity in the inflammatory airway environment enhances shedding of syndecan-1 and thus a target for the treatment of bronchiectasis and COPD.

PCD078

A fast fibre optic sensor with potential to detect rapid arterial PO2 oscillations in Acute Respiratory Distress Syndrome (ARDS)

F. Formenti, R. Chen, H. McPeak, A.D. Farmery and C.W. Hahn

Nuffield Division of Anaesthetics, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK

In healthy humans arterial PO2 is almost constant, showing virtually no oscillations within the respiratory cycle [1]. In Acute Respiratory Distress Syndrome (ARDS) [2], arterial PO2 is thought to oscillate widely due to breath-by-breath variations in pulmonary shunt as a consequence of atelectasis, when alveoli open and collapse during each respiratory cycle. Commercially-available fibre optic oxygen sensors [3] are not suitable for clinical intravascular use, and may not be sufficiently fast to detect these arterial PO2 oscillations at elevated respiratory rate (RR).

We have developed an in house, fast (response time ~ 50 ms) fibre optic intravascular sensor [4] (which can be placed into standard arterial cannulae) to detect oxygen oscillations at different simulated RR, and compared the performance of our sensor with a commercially-available sensor (response time ~ 470 ms; Foxy-AL300, Ocean Optics, USA).

The sensors were tested in an extracorporeal circuit comprising two standard paediatric oxygenators (Medos-HILITE1000) through which minimally heparinised lambs' blood was circulated at 39° C via two coupled peristaltic pumps [5]. This provided two independent parallel circuits, in which PO2 was 5 or 50 kPa, and PCO2 was 5 kPa; these values were constantly controlled by a precision gas mixing pump, and monitored through samples for gas analysis before each experiment. A computer-controlled electronic switch opened and closed solenoid valves that diverted the circuits exposing the sensor to PO2 values oscillating between 5 and 50 kPa, simulating arterial PO2 oscillations in ARDS, where severe cyclical shunt exists. The simulated RRs studied were 10, 30 and 50 breaths per minute (bpm).

Figure 1 shows results from the PO2 oscillations' tests in blood. The in house and the AL300 sensors performed comparatively well at a simulated RR of 10 bpm, where they recorded the whole PO2 oscillation amplitude from 5 to 50 kPa. In contrast, only the in house sensor was able to detect the full dynamic range of the oxygen oscillation at simulated RRs of 30 and 50 bpm, where the AL300 sensor detected only about 70% of the actual PO2 oscillation amplitude.

Improvements in fibre optic sensing technology and materials may afford the development of an intravascular sensor for real-time detection of rapid oxygen oscillations, and hence cyclical atelectasis, in ARDS. Further studies are needed to validate the use of this fast intravascular technology in vivo and in clinical trials of whether this information can better inform individualised ventilation management in adult and paediatric intensive care units.

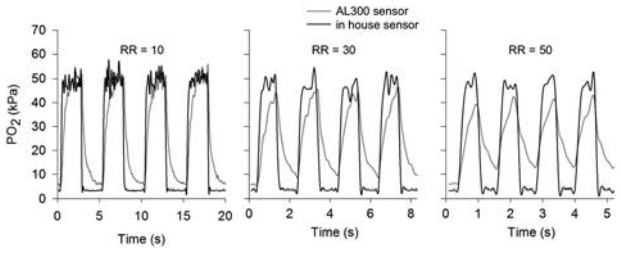

Figure 1. PO2 values recorded by the two sensors are shown as a function of time for simulated respiratory rates of 10 (left), 30 (middle), and 50 (right) breaths per minute. Black and grey lines indicate results from the in house and the AL300 sensor respectively

Gender variation in lung function; could it be explained by difference in respiratory muscle power?

A.A. Magzoub[1], O.A. Musa[1], A.A. Bashir[2] and S.E. Ibrahim[3]

[1]Physiology, Faculty of Medicine,National Ribat University, Khartoum, Sudan, [2]Physiology, Faculty of Medicine, El Imam Elmahdi University, Kosti, Sudan and [3]Physiology, Faculty of Medicine, University of Gezira, Madani, Sudan

Gender variation in lung function is more evident in lung volumes and capacities involving forced muscle contraction. Few studies have been done to demonstrate the reason behind gender difference in lung function and none was conclusive. This study aimed to investigate gender difference in respiratory muscle power and its correlation with the lung function test parameters.

The study was performed in two groups of University students 25 males and 25 females matched for age, height and weight at National Ribat University in Khartoum, Sudan during January 2011. The two groups were of the same ethnic class, socioeconomic status and perfect health. Lung Function Tests including Forced Vital Capacity (FVC), Forced Expiratory Volume in the first second (FEV1), and Peak Expiratory Flow (PEF) were performed using a digital spirometer and maximum inspiratory and expiratory pressers (MIP &MEP) as indicators for respiratory muscle power were measured using a Respiratory Pressure Meter (MicroRPM).For MIP test: after fitting the mouth piece the subject was asked to exhale to residual volume then perform a forced inhalation against the MicroRPM with as much effort as possible for as long as possible. For MEP test: the subject was asked to inhale to total lung capacity then perform a forced exhalation against the MicroRPM as maximum and long as possible. To ascertain a best value, each test was repeated 3 times. Data were analyzed using SPSS software and independent t- test was used to compare the mean difference in results.

The mean age (year), height (cm) and weight (Kg) of males group under the study were 20.32 ± 0.80, 167.88 ± 2.99 and 61.36 ± 5.87 respectively while in females group were 20.00 ± 0.64, 165.96 ±4.36, 61.88 ± 7.15 respectively. Mean FVC(L), FEV1(L) and PEF(L/min.) in males group were 4.09 ± 0.51, 3.68 ± 0.45 and 561.60 ± 70.10 respectively, while in females group FVC, FEV1 and PEFR were 2.93 ± 0.45, 2.80 ± 0.36, 389.60 ± 46.68 respectively. Statistically significant sex difference was found in the three lung function test parameters ($p<0.001$).

Mean MEP and MIP (cm/H2O) were 143.48 ± 23.83 and 111.92 ± 15.05 respectively in the males group compared to 87.72 ± 20.02 and 73.08 ± 12.35 respectively in the females group with statistically significant sex difference ($p < 0.001$). A significant positive correlation between respiratory muscle power indicators (MEP or MIP) and lung function parameters (FEV1, FVC and PEF in both sexes ($p < 0.001$).

In conclusion: gender variation in lung function is likely explained by gender difference in the power of the respiratory muscles. MEP and MIP measuring could be applied to study sport variation in lung function and low lung function in conditions affecting muscle power.

PCD080

Effects of gremlin haploinsufficiency on the pulmonary vascular endothelium in the hypoxic murine lung

S.C. Rowan, E. Cahill and P. McLoughlin

School of Medicine and Medical Sciences, University College Dublin, Dublin 4, Ireland

Chronic exposure to hypoxia such as at high altitude causes pulmonary hypertension (PH). PH is characterised by vasoconstriction, remodelling of the pulmonary vessels and sustained increases in pulmonary vascular resistance. The bone morphogenetic proteins (BMPs) play a vital role in maintaining normal pulmonary vascular homeostasis. Attenuated BMP signaling has been found in many common forms of PH including hypoxic PH. Recent work in our laboratory indicated that lung specific, hypoxia induced, upregulation of expression of the BMP antagonist gremlin1 (Grem1) plays a central role in the pathogenesis of hypoxic PH (1). Grem1 may act as a VEGFR2 agonist leading to VEFR2 dependent angiogenic responses (2). VEGFR2 activation increases eNOS production of NO, which has essential anti-remodelling and pro-angiogenic roles in the lung. However, through its BMP blocking action a hypoxia induced increase in grem1 could lead to a reduction in eNOS expression and activity (3). Given these potentially antagonist roles we examined the effect of heterozygous loss of grem1 on angiogenesis and eNOS expression and activity in the hypoxic mouse. Wild-type (WT) and gremlin heterozygous knockout mice (Grem+/-) were exposed to either normoxia (FIO2=0.21) or hypoxia (FIO2=0.10) for 2 days or 3 weeks. Following exposure they were anaesthetized (sodium pentobarbital 60mg.kg-1, i.p.) and exsanguinated. The lungs were removed and the resistance assessed using an isolated ventilated perfused lung preparation (n=17-20 per group). Separate groups of lungs (n=10-12 per group) were fixed for stereological assessment of the pulmonary vascula-

ture as previously described (4). eNOS expression and NO activity were measured by western blot (n= 8 per group). In agreement with our previous work Grem+/- mice showed an attenuated increase in PVR (2.92±0.08 mmHg.ml.min-1) that was significantly lower (P<0.01, t-test) than that observed in the wild type mice (3.31±0.06 mmHg.ml.min-1). eNOS expression and NO activity were significantly elevated (P<0.01, Mann Whitney U) in 2 day hypoxic Grem+/- mice in comparison to WT controls. Quantitative stereology demonstrated similar significant (P<0.05, t-test) hypoxia induced increases in epithelial and endothelial surface area, consistent with hypoxia-induced angiogenesis, in both hypoxic WT and Grem+/- mouse lungs. These data suggest that the loss of grem1 protects against hypoxic PH, at least in part, by increasing NO expression and activity. The heterozygous loss of grem1 did not lead to a reduction in hypoxia-induced angiogenesis. These finding suggest that gremlin does not have a significant VEGFR agonist activity in the hypoxic lung but primarily acts to antagonise BMP signaling.

The transcription factor CREB1 is required to maintain normal pulmonary vascular resistance

L. Li[1], K. Howell[1], M. Sands[1], M. Banahan[1], S. Frohlich[1,2], S.C. Rowan[1], D. Ryan[2] and P. McLoughlin[1]

[1]School of Medicine and Medical Science, Conway Institute, Dublin, Ireland and [2]Department of Anaesthesia and Critical Care, St Vincent's University Hospital, Dublin, Ireland

Chronic hypoxia causes pulmonary hypertension associated with structural alterations in pulmonary vessels and sustained vasoconstriction. The transcriptional mechanisms responsible for these distinctive changes are unclear. We have previously reported that CREB1 is activated in the lung in response to alveolar hypoxia but not in other organs (1). To directly investigate the role of CREB1 in the regulation of pulmonary vascular resistance we examined the responses of mice in which the α and Δ isoforms of CREB had been inactivated by gene mutation, leaving only the β isoform intact (CREB$^{\alpha\Delta}$ mice) (2). Wild type and CREB$^{\alpha\Delta}$ mice were exposed to hypoxia (10% O2) or normoxia (21% O2) for three weeks following which they were anaesthetized (sodium pentobarbital 60mg.kg-1, i.p) and exsanguinated. The lungs were removed and pulmonary vascular resistance (PVR) assessed using an isolated ventilated perfused preparation (n=5-13). After the baseline of measurements, a potent rho-kinase inhibitor Y-27362 (10-5 M) was added and the inhibitory effect of Y-27362 on PVR was assessed. Separate groups of lungs (n=8-9) were isolated and fixed for stereological assessment of the pulmonary vasculature as previously described (3). Gene expression (n=10-28) was investigated by real-time PCR. Protein expression (n=8) was measured by western blot.

Expressions of CREB regulated genes, brain derived neurotrophic factor (BDNF), follistatin (FST), and tissue plasminogen activator (PLAT), was increased in the CREB$^{\alpha\Delta}$ mice ($p<0.05$, Mann-Whitney U). CREB$^{\alpha\Delta}$ mice had greater pulmonary vascular resistance than wild types, both basally in normoxia and following exposure to hypoxic conditions for 3 weeks ($p<0.01$, 2-way ANOVA). There was no difference in vasoconstrictor activity between CREB$^{\alpha\Delta}$ and wild type mice. Stereological analysis of pulmonary vascular structure showed characteristic wall thickening and lumen reduction in wild-type mice, with similar changes observed in CREB$^{\alpha\Delta}$. CREB$^{\alpha\Delta}$ mice had larger lungs with reduced epithelial surface density ($p<0.01$, 2-way ANOVA) demonstrating increased pulmonary compliance, which caused increased vascular resistance.

These findings show that CREB1 regulates homeostatic gene expression in the lung. Furthermore normal CREB1 activity is essential to maintain low pulmonary vascular resistance in both normoxic and hypoxic conditions and is required to maintain the normal alveolar wall structure and compliance. Interventions that enhance the transcriptional activity of CREB1 warrant further investigation as a potential therapeutic strategy in hypoxic lung diseases.

PCD083

Lung microvascular endothelial cells exposed to hypoxia reveals novel microRNAs that may contribute to the pathophysiology of chronic lung disease

N. Ali[1], N. Mah[2], P. McLoughlin[1] and C. Costello[1]

[1]UCD Conway Institute, University College Dublin, Dublin, Ireland and [2]Max Delbrück Center for Molecular Medicine, Berlin, Germany

Pulmonary hypoxia is a common complication of chronic lung diseases leading to the development of pulmonary hypertension. The underlying sustained increase in vascular resistance is a response unique to the lung, suggesting that there are genes whose expression is selectively modulated in the lung in hypoxia. Recent studies suggest an important role for microRNAs (miRNAs) in hypoxia-mediated responses. miRNAs are short RNA sequences that modulate gene expression. The aim of the present study was to elucidate the miRNA profile underlying lung-selective gene expression in hypoxia.

Primary human microvascular endothelial cells from lung (HMVEC-L) and cardiac (HMVEC-C) cells were cultured in normoxia or hypoxia (1% O2) for 3hr, 24hr or 48hrs (n=6 experiments for each time-point). To identify lung-selective miRNAs, total RNA was extracted and hypoxic conditions confirmed by real time PCR using the hypoxic responsive gene VEGF-A. RNA was probed to miRNA microarrays (MRA-1001; 1,719 human miRNAs), and results confirmed by real time PCR analysis. In silico analysis using TargetScan and microRNA.org iden-

tified genes targeted by identified miRNAs. The predicted gene targets were confirmed by real time PCR.
Using a subtractive miRNA strategy, 238 lung-selective hypoxic responsive miRNAs were identified (ANOVA p<0.05) which were differentially regulated in response to hypoxia in the pulmonary (p<0.05), but not the cardiac cells. Confirmatory real time PCR experiments showed that miR-125a-5p and miR-424 were significantly up-regulated in response to hypoxia in vitro. In silico analysis predicted that miR-424 targets aquaporin 11 (AQP11). Aquaporins are water channels that have been documented to transport gases such as the vasodilator Nitric Oxide. Furthermore, miR-424 targets cullin 2 (CUL2), which has previously been shown to stabilize hypoxia-inducible factor-α and promote angiogenesis. In line with miRNA inhibiting expression of their target genes, real time PCR confirmed that both AQP11 and CUL2 were down-regulated in response to hypoxia in HMVEC-L.
We conclude that hypoxia, causes alterations in miRNA expression in the pulmonary endothelium in a manner that is specific to that cell type and is different from the pattern of gene response observed in cardiac endothelial cells. We have identified a number of miRNAs which are potentially important mediators of vascular changes in hypoxic lungs disease. Little has been reported of many of the hypoxic responsive lung-selective miRNAs identified in our microarray, however, based on current knowledge of gene function, miR-424 may play important roles in pulmonary vascular remodelling and angiogenesis.

In utero inflammation impaired preterm lamb diaphragm function

K. Karisnan[1], G. Pinniger[1], A. Bakker[1], S. Yong[1,2], C. Berry[2], P. Noble[1,2] and J.J. Pillow[1,2]

[1]School of Anatomy, Physiology and Human Biology, The University of Western Australia, Crawley, 6009, WA, Australia and [2]Centre for Neonatal Research and Education, School of Paediatrics and Child Health, The University of Western Australia, Crawley, 6009, WA, Australia

The integrity of the immature diaphragm may critically influence the susceptibility to respiratory failure after preterm birth. We aimed to investigate the effect of LPS administered at single or multiple doses at different time points during gestation on the function of preterm diaphragm. This study was approved by the Animal Ethics Committee of The University of Western Australia. Pregnant Merino ewes received ultrasound guided intra amniotic injections of LPS (10 mg) or saline. LPS exposures consisted of single injections at either 2, 7 or 21 day (d) or multiple injections (7+14+21 ds) before operative delivery (pentobarbitone;150 mg/kg I.V) at 121 d gestational age. Preterm lambs were killed with pentobarbitone (150 mg/kg I.V) and the right hemi-diaphragm was dissected. One diaphragm strip was frozen in liquid nitrogen for skinned fibre force analysis. Another strip was mounted in an *in vitro* muscle test system and contractile parameters and fatigue resistance were assessed (1). For skinned fibre analysis, muscle strips (control and 21 d LPS) were processed as described by Ottenheijm., 2010 (2). Small bundles of fibre were attached to the force transducer and activated in solutions of different pCa and pSr (4.1-8.0). Single 21d and multiple LPS exposures during gestation significantly reduced P_0 by ~40 %, relative to saline control (Table 1). The P_t decreased by ~30 %, and was accompanied by a significant increase in ½ RT and TTP. 21d LPS exposure did not alter either the pCa_{50} or F_{max} compared to controls. The severity of contractile dysfunction was greater when the initial exposure occurred 21 d prior to delivery and multiple LPS exposures did not cause additional impairment in contractile function. The skinned fibre results suggest that the muscle weakness (at 21 day exposure) is mediated by altered calcium handling rather than myofilament dysfunction.

Table 1

		LPS Groups			
	Saline controls n=8	2 d n=6	7d n=6	21 d n=7	7+14+21ds n=5
P_t (N.cm^2)	8.0 ± 0.9	5.7 ± 0.8*	5.5 ± 0.4*	5.3 ± 0.2*	5.3 ± 0.4*
P_0 (N.cm^2)	15.6 ± 1.5	11.2 ± 1.3*	10.5 ± 0.3*	9.3 ± 0.5*	9.6 ± 0.6*

Respiratory parameters and molecular profile of anti-inflammatory therapy in experimental meconium aspiration syndrome

P. Mikolka[1], D. Mokra[1], J. Kopincova[1], L. Tomcikova[1], J. Hatok[2] and A. Calkovska[1]

[1]Department of Physiology, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia and [2]Department of Medical Biochemistry, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia

Aims: Pathophysiology of neonatal meconium aspiration syndrome (MAS) is complex and includes airway obstruction, dysfunction of pulmonary surfactant, and induction of local inflammation followed by formation of lung edema. Standard therapy of MAS is based on ventilatory support and administration of exogenous surfactant, but in serious cases it can be ineffective. The reduced effect of therapy is caused by generation of inflammation, signalling through TLR4/MD-2 CD14 complex, and increasing production of inflammatory markers, reactive oxygen species and proteolytic enzymes which can inactivate and degrade surfactant (Salvesen et al, 2010). Therefore, an agent affecting pro-inflammatory transcription factors, budes-

onide, was used to inhibit expression of inflammatory markers, as we expected that budesonide may improve effectiveness of surfactant therapy in MAS (Mokra et al, 2007).
Methods: In anesthetized and oxygen-ventilated New Zealand rabbits, respiratory failure was induced by intratracheal administration of meconium. Animals were divided into four groups: without therapy (Mec), with surfactant therapy (Surf), with budesonide therapy (Bud), and with combined surfactant and budesonide therapy (Surf+Bud). Saline was given instead of meconium in the control group (Sal). Blood gases, ventilatory pressures, and other respiratory parameters were registered before and after meconium instillation, and 0.5, 1, 2, 3, 4, 5 hours after the therapy. After sacrificing the animals, inflammation markers were determined in lung tissue and plasma. Lung edema expressed as wet/dry weight (W/D) ratio, oxidative damage of lipids (thiobarbituric acid-reactive substances, TBARS) and proteins (3-nitrotyrosine), levels of interleukins (IL)-1b and -8 and TNFα in plasma, and mRNA expression of IL-2, -10, -13, and TNFα were analysed.
Results: Combined Surf+Bud therapy rapidly improved oxygenation and lung function parameters compared with other groups ($p<0.05$) since 30 min of the therapy and this improvement persisted till the end of experiment. Combined therapy reduced both W/D ratio and TBARS ($p<0.05$ vs. Mec group). All kinds of therapy decreased levels of IL-1b and IL-8 ($p<0.5$ vs. Mec) in plasma, but effect of Surf+Bud was superior (IL-1b $p<0.009$, IL-8 $p<0,003$). Similarly, the most potent effect of therapy on mRNA expression of IL-13 and TNFα was observed in the Surf+Bud group.
Conclusions: Combined surfactant and budesonide therapy had positive and long-term effects on lung functions and reduced lung edema, oxidative damage of lipids and proteins, and inflammation expressed by decrease in interleukins on protein and mRNA levels. The results indicate that addition of anti-inflammatory agent to surfactant therapy may reduce surfactant inactivation and enhance effectiveness of the therapy of MAS.

PCD089

A statistical model to predict expected pulmonary function Indices in type 2 diabetes individuals

M.A. Kanpurwala[1,2], Z. Ayoob[2], M.A. Qureshi[2] and Z. Shaikh[3]

[1]Physiology, University of Karachi, Karachi, Sindh, Pakistan, [2]Physiology, Dow University of Health Sciences, Karachi, Pakistan and [3]Diabetes & Endocrinology, Dow University of Health Sciences, Karachi, Pakistan

Type 2 Diabetes Mellitus (T2DM) is a chronic disease with increasing prevalence throughout the world. Almost every system of the body is affected by the disease [1-3]. Pulmonary function impairment has also appeared to be a complication of diabetes [4,5]. The aim of this study is to develop a statistical model as a primary prevention tool which can predict pulmonary function indices in diabetic individuals at an early stage in situations where spirometry is not possible because of any means.

73 Diabetics and 77 age matched Non Diabetics' individuals, who were non smokers and had no apparent pulmonary diseases were recruited. All subjects underwent screening with detailed history, anthropometry, HbA1c and spirometric measurements. There was a significant reduction in the Force vital capacity (FVC) [mean difference (95% CI) 0.495L (0.27, 0.72) $P < 0.001$], Force expiratory volume in first second (FEV1) [mean difference (95% CI) 0.34L (0.15, 0.53) $P < 0.001$] and FEV1/FVC ratio [mean difference (95% CI) -0.018 (-0.036, -0.0003) $P \leq 0.05$] in the diabetic subjects as compared to the healthy individuals. A model was built using multivariable regression analysis to predict FVC with adjusted R2 value of 0.778. The model equation is as follows. FVC = $\beta0 + \beta1(X1) + \beta2(X2) + \beta3(X3) + \beta4(X4) + \beta5(D1) + \beta5(D2)$. Whereas, $\beta0 = -2.78$ (constant), X1=gender, X2=height, X3=age, X4=HbA1c, D¬ = duration of disease >10years.
Female gender taken as reference, Duration of disease: ≤5 years (reference), 6 – 10 years (non significant) & > 10 years
T2DM individuals had subclinical lower FVC and FEV1 as compared to the non diabetics. The effect on the FVC was even more pronounced in diabetics who had inadequate glycemic control and prolonged duration of disease. Therefore, regular assessment of the diabetic patients for the subclinical pulmonary function impairment should be done either through spirometry or from the statistical model derived above so as to prevent the respiratory complications that may follow later.

Pulmonary Function tests in diabetic and non diabetic groups

	Non Diabetic (77) Mean ± SD	Diabetic (73) Mean ± SD	Mean difference (95% CI)	P value
FVC (L)	3.33 ± 0.79	2.84 ± 0.61	0.495 (0.27 - 0.72)	< 0.001
FEV1 (L)	2.69 ± 0.63	2.36 ± 0.53	0.34 (0.15 - 0.53)	< 0.001
FEV1/ FVC ratio	0.81 ± 0.06	0.83 ± 0.05	-0.018 (-0.036 - 0.0003)	≤ 0.05

Neonatal conditioning of rat upper airway dilator muscle by chronic intermittent hypoxia

F.B. McDonald[1] and K.D. O'Halloran[2]

[1]School of Medicine and Medical Science, University College Dublin, Dublin, Ireland and [2]Department of Physiology, University College Cork, Cork, Ireland

Introduction: Chronic intermittent hypoxia (CIH) is a feature of respiratory diseases such as obstructive sleep apnoea and apnoea of prematurity. There is a relative paucity of information on the effects of CIH on respiratory muscle physiology despite the clinical relevance. We have shown that CIH causes an age- and sex-dependent impairment of upper airway dilator muscle. The intensity, duration and pattern of CIH exposure are all key determinants of the respiratory muscle phenotype. Recently we reported that CIH exposure during early life causes upper airway dilator muscle weakness, an effect that persists for several weeks upon return to normoxia. Aim: We wished to determine 1) if neonatal exposure to CIH (nCIH) persists into adulthood and 2) if nCIH increases sensitivity to CIH exposure during adulthood. Methods: Six Wistar litters (with respective dams) were exposed to alternating bouts of hypoxia (5% O2 at the nadir) and normoxia (21% O2) for 12 cycles per hour, 8h/day for 3 weeks from the first day of life (a paradigm that causes sternohyoid dysfunction in neonatal but not adult animals). Sham experiments (continuous normoxia) were run in parallel. The litters were then returned to normoxia for 10 weeks. At this point, rats were treated with CIH for 3 weeks or normoxia. All groups were studied at 16 weeks. Sternohyoid tissue was harvested for functional assessment. Contractile and endurance properties of the muscle were determined in an in vitro isometric bath preparation in Krebs solution gassed with 95%O2/5%CO2 at 35°C. Results: At 16 weeks, sternohyoid force-frequency relationship in nCIH rats was not significantly different from the sham group (P>0.05; 2-way ANOVA) i.e. muscle weakness had fully recovered. Adult exposure to CIH had no effect on sternohyoid function. However, in nCIH rats re-treated with CIH the sternohyoid muscle was weaker (P=0.016). CIH had no effect on sternohyoid muscle endurance. Conclusion: CIH exposure in early life causes airway dilator muscle weakness that persists for several weeks in normoxia but recovers in adulthood. However, repeat exposure to the same CIH paradigm - that in-of-itself has no effect on adult muscle - is sufficient to cause muscle weakness in nCIH rats highlighting a persistent susceptibility ('deficit memory') to CIH in nCIH muscle. The upper airway dilator muscles play a crucial role in the breath-by-breath control of airway patency. A similar phenotype in human infants exposed to CIH, such as that occurring in apnoea of prematurity, could lead to long-term susceptibility of the upper airway muscles to hypoxia in later life. We speculate that nCIH could increase the propensity for airway collapse in mature adults. Our data may have relevance to the association of apnoea of prematurity in infants with obstructive apnoea in later life.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD091

Effect of petrol vapours on the petrol pump workers lung function indices

M.A. Kanpurwala

Physiology, University of Karachi, Karachi, Sindh, Pakistan

Various studies have indicated that petrol and its vapours affect proper functioning of many organs, and some of the constituents of petrol are considered to be carcinogen. Incidence of lungs, kidneys, liver, pharyngeal, and laryngeal cancers were in higher petrol pump workers as compare to the normal population[1,2]. Studies have shown that petrol pump workers have lower value of Force vital capacity (FVC) and force expiratory volume in first second (FEV1) as compare to the control group [3,4]. Hence, the present study aims to confirm the decline in the respiratory functions in petrol pump workers (filling attendants) who are continuously exposed to petrol/diesel vapours during duty hours. Petrol pump workers in Karachi, Pakistan are working on a 24 hours shift, which is a considerable amount of time of exposure to petrol and its vapours. A comparative cross sectional study was conducted on 60 males working at petrol pump served as study group, while 40 age match healthy individuals were chosen to be control group. Petrol Stations were visited by the research team and after meeting with the manager; consent was taken from him and the subjects (petrol pump workers) who were involved in this study. Subjects were asked about demographic data, and after that were asked to perform the spirometry on vitalograph three times after the explanation about the procedure. The best value out of those was recorded for the analysis. Height and Weight were also measured along with the pulmonary functions. The two groups were compared by using 'independent - t' test and p value of less than 0.01 was considered significant. The mean FVC and FEV1 values of the study group was 3.15 ± 0.45 and 2.85 ± 0.56 compared to control group's which was 3.92 ± 0.62 and 3.27 ± 0.63 respectively. While the FEV1/FVC ration were within the normal range in both of these groups. These results showed that both FVC and FEV1 values were significantly lower i.e. $P < 0.001$ and $P \leq 0.001$ respectively in petrol pump workers as compare to the control group. Due to the nature of the job, petrol pump workers are constantly exposed to petrol vapours and these findings shows that these petrol and diesel vapours are causing considerable damage to the pulmonary functions mainly on lower airways showing restrictive pattern of disease. Therefore efforts are required in this area both at the government as well as at the private level so that we can come up with a solution to negate these effects to ensure healthier environment. Hence cohort studies are needed to analyse these effects in further details.

Comparision of Pulmonary Function Indices of Petrol Pump workers to Control group

Pulmonary Function Indices	Petrol Pump Workers (60)	Healthy Individuals (40)	P value
FVC	3.15 ± 0.45	3.92 ± 0.62	< 0.001
FEV1	2.85 ± 0.56	3.27 ± 0.63	≤ 0.001
FEV1/FVC	90.28 ± 12.6	83.82 ± 10.6	< 0.01

Amygdala and prefrontal cortex mediate respiratory activation in response to brief and prolonged stressors

E. Bondarenko[1,2], D.M. Hodgson[2] and E. Nalivaiko[1]

[1]School of Biomedical Sciences, University of Newcastle, Callaghan, NSW, Australia and [2]School of Psychology, University of Newcastle, Callaghan, NSW, Australia

Respiratory arousal is one of the most sensitive indices of autonomic activation, but despite close links between emotions and respiration in humans, few studies have assessed these links in animals. We have earlier reported that: a) respiratory activation is much more sensitive to brief alerting stimuli than traditionally used cardiovascular indices (1); b) these respiratory responses are sensitive to anxiolytics (2); and c) they are abolished after pharmacological inhibition of dorsomedial hypothalamus (3), a major neuronal centre of autonomic integration. Our current aim was to investigate potential roles of central amygdala (CAm) and medial prefrontal cortex (mPFC) in mediation of respiratory responses to alerting stimuli and stress.

Outbred Wistar rats were implanted with guide cannulas targeting CAm (n=8) or mPFC (n=6) under isoflurane (2% in O_2) anaesthesia. Respiratory recordings (whole-body plethysmography) were performed after microinjections of either $GABA_A$ agonist muscimol (200 nmol/ 200 nl) or saline to the targeted areas. Subsequently, rats were presented with six acoustic stimuli (40-90 dB, white noise, 0.5 sec) and subjected to restraint stress (15 min).

Values presented are means ± S.E.M. compared by 1-tail paired samples t-tests between saline and muscimol pre-treatment trials. Acoustic stimuli produced brief increases in respiratory rate proportional to stimulus intensity, ranging from 12±9 cpm increase over baseline after 40 dB stimulus to 276±67 cpm increase after 90 dB stimulus. Inhibition of CAm by muscimol significantly decreased amplitudes of responses to 70, 80 and 90 dB stimuli (from 180±49 to 15±8 msec, p=.009; from 219±49 to 59±27 msec, p=.021; and from 276±67 to 103±49 msec, p=.043, respectively), but did not affect latencies of responses. Inhibition of mPFC, on the other hand, did not affect amplitudes, but increased latencies of respiratory responses to 80 and 90 dB stimuli (from 101±31 to 149±20 msec, p=.014, and from 33±4 to 81±16 msec, p=.024, respectively). Restraint stress elevated resting respiratory rate from 98±12 to 155±7 cpm (p<.001). Inhibition of CAm significantly reduced this stress-provoked increase in respiratory rate during the first 5 minutes of restraint from 57±12 to 12±15 cpm (p=.024), while inhibition of mPFC significantly decreased it during the last 5 minutes from 40±10 to 11±4 cpm (p=.02).

Our study is the first where latency of autonomic responses to sensory stimuli was assessed at the timeframe compared to that of initial sensory processing in the brain. Our major novel finding is that PFC provides tonic influences favoring faster processing. Our data also indicate that integrity of amygdala neurons is essential for the expression of respiratory responses to brief arousing stimuli and for generating of initial, but not late-stage, tachypnoeic response to prolonged stressor.

Lidocaine prevents lung proinflammatory response secondary to ischemia reperfusion

L. Rancan[1], C. Muñoz[1], C. Garcìa[1], E. Vidaurre[2], I. Garutti[3], C. Simon[2] and E. Vara[1]

[1]Biochemistry and Molecular Biology III, School of Medicine, Complutense University, Madrid, Spain, [2]Thoracic surgery, Universitary Hospital Gregorio Maranon, Madrid, Spain and [3]Anesthesiology, Universitary Hospital Gregorio Maranon, Madrid, Spain

Ischemia reperfusion injury (IRI) is an increasingly important problem in clinical transplantation. Its pathogenesis involves a variety of mechanisms including the increase of proinflammatory mediators. Different prophylactic and therapeutic measures have been investigated to prevent lung injury secondary to IRI. Lidocaine (Lido) is a commonly used local anesthetic agent which has also been found to possess anti-inflammatory activity in several disorders but data available are not enough to demonstrate this fact on lung tissue. This study was designed to investigate a possible protective effect of lidocaine on lung injury secondary to IRI. Two groups (LIDO and control) of six large-white pigs each were submitted to a left lung autotransplant. Both groups received the same anesthetic induction (fentanyl 3 ug/Kg, propofol 3 mg/Kg, atracurium 0,5 mg/Kg). In addition animals of LIDO group received a continuous IV of lidocaine 1,5 mg/kg during surgery. Lung tissue samples were taken in four different moments: 1) pre-pneumonectomy (5 min before pulmonary artery clamp), 2) pre-reperfusion (5 min before reperfusion), 3) 30 min post-reperfusion (PR30) and 4) 60 min post-reperfusion (PR60). mRNA and protein expression of different proinflammatory mediators (interleukin 1 (IL-1), tumor necrosis factor alpha (TNFa), monocyte chemoattractant protein 1 (MCP-1), interleukin 10 (IL10), and endothelial nitric oxide synthase (eNOS)) were measured. Each lung sample was immediately frozen in liquid nitrogen. mRNA expression was measured by means of RT-PCR using the SYBR Green PCR Master Mix and 300 nM concentrations of specific primers. Relative changes in gene expression were calculated using the 2-ddCt method. Western blots were used to measure the protein expression (4 replicates). In addition, plasma NO and CO levels were determined by spectrophotomety. Non-parametric tests were used to find statistical meaning. The Mann-Whitney U-test was applied to establish differences between the analysed groups. In addition, the Wilcoxon test for paired data was used to study the evolution of the intra-group values. Lung ischemia reperfusion (I/R) significantly increased both mRNA and protein expression of TNFa ($p<0.01$), IL-1 ($p<0.05$) and MCP1 ($p<0.05$). This expression was even higher after 60 minutes of reperfusion ($p<0.05$). On the contrary, I/R decreased IL10 expression ($p<0.05$). Lung

I/R decreased eNOS expression ($p<0.05$) and this effect was accompanied by a decrease in plasma NO levels ($p<0,01$). These effects were blocked by lidocaine. No changes were observed in CO levels. These results suggest that lidocaine prevents I/R-induced lung injury through the reduction of proinflammatory cytokines. The administration of lidocaine might be a prospective management for preventing lung injury secondary to I/R.

PCD097

The role of TRPM8 channels in normal rat trachea function

B. Hicks[1], A. Zholos[2] and C. Johnson[1]

[1]Biomedical Science Education, Queen's University, Belfast, UK and [2]Centre for Vision and Vascular Science, Quen's University, Belfast, UK

Several TRP channel subtypes have been found previously in airway smooth muscle. Several recent studies have found that airways respond to cold and to menthol, both of which may act through the TRPM8 channel, possibly present in epithelial cells and afferent nerve fibres (see Fischer, 2011). Our recent studies have identified that TRPM8 channels contribute to control of vascular smooth muscle tone (Johnson et al, 2009). There have been no studies as to whether this channel is present in airway tissue. Here we examined whether this channel is present in rat trachea by a combination of PCR and functional isometric tension studies.

Tracheas were taken from sacrificed male Sprague-Dawley rats (250-350g). Semi-quantitative PCR was performed for TRPM8 mRNA with 3 different primers. All 3 primers were positive at the appropriate bands, both with the epithelium in tact and removed (N=1, n=3 for each primer). Isometric contraction studies were conducted in tracheal rings pre-tensed to 0.5 g with endothelium in tact. TRPM8 agonists, menthol, (300 or 600μM in ethanol; N=7, n=24), icilin (10 μM; N=3, n =10) failed to cause any contraction (where N=animals, n= preparations). Contraction (0.92 ± 0.03 g (ave.±s.e.), N=7, n=24) induced by KCl (60mM) was markedly relaxed on addition of menthol (66±1%, N=7, n=24; $P<0.001$, Student's paired t-test). Ethanol alone failed to cause any relaxation to the KCL contraction (N=5, n=14). As recent studies have shown that menthol may have non-specific actions on L-type calcium channels (Baylie et al., 2010), protocols were repeated in the presence of the L-type calcium channel blocker, nifedipine (10 μM). Contraction was still present (0.64±0.02g). Menthol-induced relaxation was reduced compared with no nifedipine ($P<0.001$) but still present (88±2 %, N=4, n=7, $P<0.01$). In the presence of the TRPM8 antagonist, AMTB (20 μM), the relaxatory affect of menthol was unaffected. We conclude that menthol has a relaxatory effect in normal rat trachea that is mediated mainly by L-type calcium channels, although some of this relaxation may involve activation of TRPM8 channels.

Rotating phase advanced shifts of lighting regimen disturb circadian rhythms of heart rate, blood pressure clock genes expression and plasma hormones in rats

M. Zeman, L. Molcan, M. Okuliarova, A. Vesela and I. Herichova

Physiology and Ethology, Comenius University, Bratislava, Slovakia

Disturbances of endogenous circadian rhythms may result in adverse effects on metabolic and cardiovascular processes and participate in a higher incidence of diseases in shift workers. Physiological mechanisms underlying negative effects of chronodisruption are not completely understood and animal studies are needed for identifying key negative factors. In our study, in two independent experiments, we exposed mature male Wistar rats to repeated 8h phase advance shifts (PAS) of light/dark (LD) regimen (3 shifts per week) for12 weeks. In the first experiment blood pressure (BP), heart rate (HR) and locomotor activity (LA) were measured by radiotelemetry (Data Sciences Inc. USA) in 12 rats. Pressure sensor (TA11PA-C40) was implanted into the abdominal aorta under ketamine (75mg kg-1)/xylazine (10mg kg-1, i.p.) anaesthesia. Two weeks after surgery HR, BP and LA were monitored one week under control LD12:12 and then on week 1, 5, 10 and 11 of PAS exposure. Data were recorded continuously in 30s intervals over 24 hours (Dataquest ART 4.1, DSI). In the second experiment, male rats were exposed either to PAS (n=36) or control LD12:12 (n=36) and after 12 weeks they were killed by decapitation under CO2 anaesthesia in regular 4h intervals over 24 hours. Melatonin and corticosterone were measured by radioimmunoassay in plasma and melatonin was measured also in the pineal gland, heart and kidney. Clock gene (Bmal1 and per2) expression was measured by real time PCR in the heart. Data were evaluated with Cosinor analysis and ANOVA. As expected, higher values of BP, HR and LA were observed during the dark than the light phase of the day under control LD conditions. Circadian rhythms of BP, HR and LA were desynchronized in rats after exposure to repeated PAS but we did not find an increase of BP values. A transitory increase of absolute values in BP and HR was recorded only during the first week of phase shifts. Both mesor (1273 vs. 772 pg/gland) and amplitude (1554 vs. 611 pg/gland) of melatonin rhythm were damped in the pineal gland of PAS animals as compared to controls and no rhythmic changes were found in the plasma of PAS rats. The melatonin rhythm in the heart of PAS rats was damped and its acrophase was phase advanced by 4h in comparison with controls. Circadian rhythms of both clock gene expression in the heart were suppressed but in the phase with controls. Plasma corticosterone rhythm was found in controls but was absent in PAS rats in which high levels persisted during the passive phase of the day. We conclude that under repeated and frequent phase advanced shifts the circadian system is damped, animals may lose their ability to predict regular environmental loads with negative consequences on health in stressful environment.

Chronodisruption alters cardiovascular and behavioural responses to emotional stressors in rats

M. Okuliarova, L. Molcan, A. Vesela and M. Zeman

Animal Physiology and Ethology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia

Chronodisruption can be involved in development of several diseases and it is necessary to elucidate possible causal physiological, behavioural and psychosocial mechanisms underlying these adverse effects. In our model of chronic phase shifts in a lightning regimen disturbed rhythms of cardiovascular parameters and activity were found in rats. In the present study, we manipulated either the lightning schedule or both lightning and feeding regimens to analyse an ability of desynchronized rats to cope with emotional stressors. Adult male Wistar rats (n=12) were implanted into the abdominal aorta with radio-telemetric transmitter TA11PA-C40 (DSI, Minnesota, USA) to continuously monitor heart rate (HR) and blood pressure (BP). A mixture of ketamine (75mg kg-1) and xylazine (10mg kg-1, i.p.) was used as anaesthesia. Following synchronisation to the LD regimen of 12:12h, one half of the rats were exposed to phase delay shifted (PDS) schedule (by 8 hours longer dark phase every second day over 5 weeks). In both groups, diet (Fresubin-isocaloric liquid drink, Fresenius Kabi, Germany) was provided only during the passive phase of the day. Cardiovascular response to a novelty (open-field test) was measured before (0w) and 5 weeks (5w) after the treatment. In addition, two groups of non-implanted rats were simultaneously housed under either control LD (n=8) or PDS (n=8) regimens with standard diet ad libitum. After 5 weeks, their behaviour was quantified in the open-field test, the black-white box and the elevated plus maze using video-tracking software Any-maze (Stoelting Co.). Cardiovascular response was analysed as an increase of HR and systolic BP over the basal levels during the 20-minute test. An area under the curve was calculated (means ± S.E. are given) and compared between 0w and 5w within each treatment by paired t-tests. Rats on the control LD regimen with diet in antiphase decreased their cardiovascular response between 0w and 5w (HR: 118694±15596 vs. 48427±18632; BP: 23045±474 vs. 17857±705) while no changes were found in rats on PDS regime with diet in antiphase (HR: 103633±8198 vs. 71717±23414; BP: 22438±2996 vs. 19506±4198). Behaviour of non-implanted rats on control LD and PDS regimens was analysed by independent t-tests. As compared to controls, PDS rats displayed increased locomotion and rearing in both the open-field and black-white box tests. They spent more time in the white compartment of the black-white box and showed increased risk assessment behaviour and decreased grooming in the elevated plus maze. In conclusion, disturbances of two strong Zeitgebers influenced the pattern of stress induced changes in HR and BP as well as spontaneous motor activity and exploration in rats. Results indicate that weakened circadian organization may alter an ability to cope with stressful events.

PCD100

Simulation of developmental changes in energy metabolism between fetal and adult ventricular cells

T. Toki[1,2], H.I. Sano[1,3], C. Okubo[1,3], Y. Naito[1,3] and M. Tomita[1,3]

[1]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan, [2]Department of Policy Management, Keio University, Fujisawa, Japan and [3]Department of Environment and Information Studies, Keio University, Fujisawa, Japan

Ventricular cells in fetal guinea pigs have higher anaerobic glycolytic capacity and lower activities of mitochondrial enzymes. In general, embryonic ventricular cells contain approximately 10 times more glyocogen than adult ventricular cells. Although embryonic ventricular cells consume more energy for growth and differentiation, they also utilize contractile proteins that consume less energy than adult ventricular cells. Also, it has been reported that several glycolytic enzyme activities are different between embryonic and adult ventricular cells. As such, the neonatal ventricular cells can maintain the ATP concentration longer than the adult ventricular cells in hypoxic condition; ATP concentration was decreased by 44% in adult rabbit ventricular tissues and 18% in neonatal rabbit ventricular tissues after perfusion of the heart to hypoxic condition (Jarmakani *et al*., 1978). Although high glycogen content is considered as a cause for the fetal ventricular cells to retain ATP concentration under hypoxic condition, role of the developmental changes in activities of several glycolytic enzymes in ATP production of fetal ventricular cells remain uncertain.

We have previously modeled developmental changes in action potentials of rodent ventricular cells (Itoh *et al*., 2007) on the basis a guinea pig ventricular cell model (Kuzumoto *et al*., 2008). The quantitative changes in individual ionic components on both cellular membrane and sarcoplasmic reticulum were represented as relative current densities, which were computed from current-voltage curves of the specific ionic components in rodent ventricular cells. Here, we further modified the model to represent the developmental changes in energy metabolism of ventricular cells by implementing glycolytic pathway from glycogen to lactate (Lambeth *et al*., 2002), and hexokinase kinetics (Lueck *et al*., 1974), both of which were reported in rodent skeletal muscles. The developmental changes in enzymatic activities were presented as the activities relative to those in the adult ventricular cells, and implemented accordingly to the model to represent specific stages in development. We then simulated effects of hypoxic condition to dynamic changes in contractile force and ATP concentration using the modified model.

As a result, the developmental changes in concentrations of intermediate metabolites in glycolytic pathway were well represented in the simulation. Also, we showed that the fetal ventricular cells maintained ATP for longer periods of time than the adult cells, which is consistent with the reported dynamics of the changes under hypoxic condition. On the basis of the simulation, we showed that developmental changes in enzymatic activities of several glycolytic enzymes play important role in maintenance of intracellular ATP concentration under hypoxic condition.

PCD101

Simulation of developmental change in structure of transverse tubules and intracellular Ca^{2+} dynamics using cardiac ventricular cell models

R. Aoki[1,2], H.I. Sano[1,2], C. Okubo[1,2], Y. Naito[1,2] and M. Tomita[1,2]

[1]Institute for Advanced Biosciences, Keio University, Yamagata, Japan and [2]Department of Environment and Information Studies, Keio University, Fujisawa, Japan

Transverse tubules (t-tubules) are largely absent in neonatal cells and develop rapidly after birth. In adult ventricular cells, a mobile Ca^{2+} buffer calmodulin exists predominantly near t-tubules in the cell. Ca^{2+} influx via the L-type Ca^{2+} channel (I_{CaL}) triggers Ca^{2+} release from the sarcoplasmic reticulum (SR) via the ryanodine receptor (RyR), and Ca^{2+} flow in a restricted subspace located between the junctional SR and t-tubules. On the other hand, t-tubule network is largely absent, SR is relatively sparse, and I_{CaL} expression is diminished in neonatal ventricular cells; as such, Ca^{2+} transient in neonates occurs predominantly at the periphery of the cell. In addition, the maximal binding capacity of Ca^{2+} buffer is much lower than that of Ca^{2+} buffer in adult ventricular myocytes. Here, we utilized human ventricular cell model (tenTusscher *et al*., 2006) and guinea pig ventricular cell model (Kuzumoto *et al*., 2008) to assess the differences between neonatal and adult ventricular cells in terms of intracellular Ca^{2+} dynamics and structure of t-tubules.

In our previous study (Itoh *et al*., 2007), we showed that a developmental change in action potentials (APs) can be well reproduced with common sets of mathematical equations and by changing relative densities of ion currents on the Kyoto model, a guinea pig ventricular cell model. In this study, we first modified the human ventricular cell model by implementing the relative densities to represent developing ventricular cells at early and late embryonic stages. We then removed t-tubules and accompanying subspaces from the model to represent ventricular cells without t-tubules. As a result, removal of the subspace structure increased the amplitude of Ca^{2+} transient by four-fold and prolonged the basic cycle length by 800ms in early embryonic ventricular cell model. On the other hand, the amplitude of Ca^{2+} transient was decreased by 30 % in late embryonic ventricular cell model without subspace, which indicates that existence of the subspace structures affect the amplitude of Ca^{2+} transient in both early and late embryonic ventricular cell models.

The Kyoto model was then expanded to represent developmental changes in the t-tubule structures by implementing the subspace structure to the model. We also considered predominant localization of the I_{CaL} and I_{NaCa} (sodium-calcium exchange current) on t-tubules and assessed the effect of Ca^{2+} release via the I_{NaCa} to intracellular Ca^{2+} dynamics. We simulated APs and dynamic behaviors of currents with the Kyoto model considering the developmental changes of t-tubules structures in four different stages. As a result, the effects of the developmental changes in t-tubule structures and intracellular subspace at four different stages were simulated in terms of the excitation-contraction coupling.

PCD102

Perlecan heparan sulfate in hypoxia-induced pulmonary vascular remodeling

Y. Chang[1], P. Tannenberg[1], C. Tseng[1], P. Tran[2], U. Hedin[1] and K. Tran-Lundmark[1]

[1]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden and [2]Department of Cardiothoracic Surgery, Uppsala University Hospital, Uppsala, Sweden

Motivation:
Chronic hypoxia can induce pulmonary vascular smooth muscle cell (SMC) proliferation, which contributes to blood vessel constriction and lumen narrowing, leading to pulmonary hypertension. Perlecan is the major heparan sulfate proteoglycan in the basement membrane. The heparan sulfate chains of perlecan have been shown to inhibit SMC proliferation in the carotid artery. In this study, we examine if perlecan heparan sulfate can inhibit pulmonary SMC proliferation induced by hypoxia.
Methods:
Mice with heparan sulfate deficient perlecan (*Hspg2*$^{\Delta 3/\Delta 3}$) were compared to wild-type (Wt) controls. 8-11 week-old female mice were subjected to hypoxia (10% O_2) for 7 weeks. Controls were kept in normoxia. This generated 4 groups, *Hspg2*$^{\Delta 3/\Delta 3}$ versus Wt, with or without hypoxic treatment. Hemoglobin levels and the right ventricle/left ventricle+septum weight ratio (RV/(LV+S)) were measured. Serial sections from lung tissue were obtained for immunohistochemical and morphological analysis. Degree of muscularization of intra-acinar vessels was determined by double staining for von Willebrand factor and smooth muscle α-actin, followed by manual counting. Proteins and total RNA were isolated from whole lung homogenate. Genotype and treatment were blinded for all data acquisition.
Results:
To our surprise, at baseline (normoxia) *Hspg2*$^{\Delta 3/\Delta 3}$ mice have a significantly lower proportion of muscularized intra-acinar vessels compared to Wt. After 7 weeks of hypoxia, a significant increase in muscularized vessels was found in both *Hspg2*$^{\Delta 3/\Delta 3}$ (2.8 fold) and Wt mice (1.5 fold). The RV/(LV+S) ratio, as a measurement of right ventricular hypertrophy, is the same in *Hspg2*$^{\Delta 3/\Delta 3}$ and Wt at normoxia, and it increases significantly following hypoxia, with no difference between the genotypes. For Wt mice, RNA expression of FGF-2 and PDGF-B are both upregulated in hypoxia. In *Hspg2*$^{\Delta 3/\Delta 3}$ mice, FGF-2 is upregulated already in normoxia, possibly as a compensation for increased elimination. For PDGF-B the increase

following hypoxia is higher in *Hspg2*$^{\Delta 3/\Delta 3}$ mice compared to Wt.

Conclusions:

The lower proportion of muscularized vessels at baseline in *Hspg2*$^{\Delta 3/\Delta 3}$ mice is interesting and needs to be further investigated. With hypoxia treatment, the relative difference in the increase of muscularization, 2.8-fold in *Hspg2*$^{\Delta 3/\Delta 3}$ versus 1.5-fold in Wt, indicates that *Hspg2*$^{\Delta 3/\Delta 3}$ mice are more reactive in their vessels and therefore may be more vulnerable to hypoxia. The differences in muscularization may be caused by defective sequestration of heparin binding growth factors in the extracellular matrix and thereby also different regulation of those growth factors in response to hypoxia. The results suggest that perlecan heparan sulfate chains are important for the regulation of muscularization of pulmonary vessels during vessel development and during hypoxia.

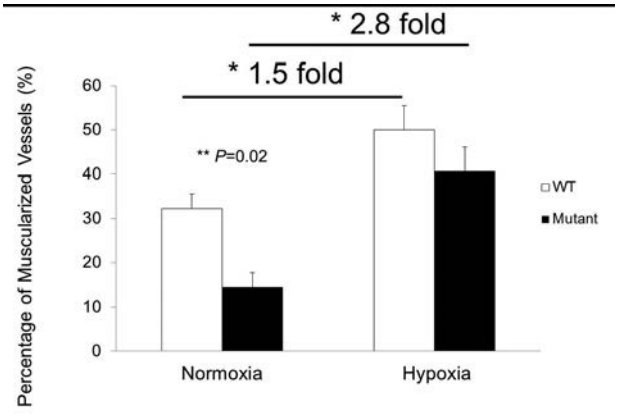

Figure 1. Degree of muscularization of intra-acinar vessels following hypoxia treatment (n = 10 for *Hspg2* $^{\Delta 3/\Delta 3}$, and n = 9 for Wt) as compared to normoxia (n = 6 for *Hspg2* $^{\Delta 3/\Delta 3}$, and n = 6 for Wt). The data shown are averages of four sets of double staining for von Willebrand factor and smooth muscle α-actin. Values are expressed as mean±SEM. (* $p< 0.05$, ** $p=0.02$)

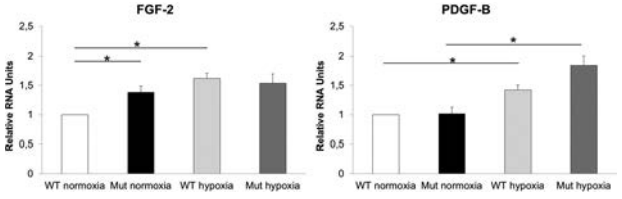

Figure 2. Quantitative PCR on mRNA from whole lung homogenates show different regulation of heparin binding growth factors in *Hspg2* $^{\Delta 3/\Delta 3}$ mice, compared to Wt controls. (n = 4 for *Hspg2* $^{\Delta 3/\Delta 3}$, and n = 3 for Wt, * $p<0.05$)

Comparison of the agonist activities of treprostinil and naxaprostene in systemic blood vessels

N.H. Syed[1,2] and R.L. Jones[1]

[1]SIPBS, University of Strathclyde, Glasgow, Scotland, UK and [2]University College of Pharmacy, University of the punjab, Lahore, Punjab, Pakistan

Treprostinil, a prostacyclin analogue, is used to treat pulmonary hypertension. However, the mechanism of action whereby this drug modifies the pathophysiological status may involve more than prostacyclin (IP) receptors, as Whittle et al (2012) have shown that it activates human recombinant prostanoid DP1, EP2 and IP receptors.

In view of the recent emergence of highly selective EP2 receptor antagonists (e.g. PF-04418948; Forselles et al., 2011), it was decided to determine whether our current armoury of prostanoid antagonists was adequate to elucidate the complex pharmacology of treprostinil. Treprostinil lacks the ether oxygen moiety at C6-9 present in prostacyclin (PGI2) and has a benzene ring inserted in its α-chain. Naxaprostene also has both functionalities and we decided to compare its inhibitory profile with that of treprostinil.

In the current study, we have used isolated preparations of rabbit saphenous vein (rSV) and inferior vena cava (rVC). 5 mm rings were dissected from male rabbits (1.5-2.5 kg) and were mounted under isometric conditions (resting tension of 0.75 – 1.0 g) in 10 ml baths at 37°C. Contractions were elicited by adding histamine and phenylephrine (300-600 nM) respectively. We have used BW-245C, ONO-AE1-259, TCS-2510 and AFP-07 as selective DP1, EP2, EP4 and IP agonists respectively. The corresponding antagonists were BW-A868C and MK-0524, ACA-23 (same series as PF-04418948), GW-627368 and RO-1138452 (Jones et al., 2009).

A simple antagonist reversal protocol showed that both preparations contain inhibitory DP1, EP2, EP4 and IP receptors. In further experiments, preparations were pretreated with 3 of the antagonists (e.g. BW-A868C / ACA-23 / GW-627368), followed by cumulative doses of treprostinil or naxaprostene and finallyfollowed by the fourth antagonist (CAY-10441) in an attempt to reverse the relaxation. In this way we could apportion DP1, EP2 and IP agonism to treprostinil, but only IP agonism to naxaprostene. In some preparations naxaprostene behaved as a partial agonist. The relevance of these findings to the therapeutic use of prostacyclin analogues will be discussed.

Particles, pore size, pulse and pressure - the physico chemistry of osmosis

F. Prior[1,2] and G. Clegg[2,1]

[1]The Laboratory, The Osmosis Unit, Longnidddry, UK and [2]Emergency Medicine, Edinburgh Royal Infirmary Medical School, Edinburgh, UK

The Kedem Katchalski equation has been the standard formula describing fluid balance and exchange in the capillary. The osmotic component in this formula is suggested to be the difference in osmolalities between the plasma and interstitium corrected by a factor c described as the osmotic reflection coefficient.

Our in vitro studies show that the membrane osmotic pressure (MOP) of plasma components are curvelinear with concentration (MOP= ac2 + bc +i where c = concentration) and inversely proportional to membrane pore size. Small increases in membrane pore size can greatly reduce plasma MOP even where there is no change in concentration of plasma.

As the pore size in the capillary is highly dynamic, and as pore size is the major factor controlling plasma osmotic pressure, we suggest a better model of fluid balance and exchange is required to describe fluid balance and exchange.

Hypertension, oedema and shock - diseases of capillary fluid imbalance?

F. Prior[1,2], G. Clegg[2] and S. Richardson[2]

[1]The Osmosis Unit, Longnidddry, UK and [2]Emergency Medicine Dept, Edinburgh Royal Infirmary, Edinburgh, UK

In order to achieve fluid balance, the mean capillary pressure must be equal and opposite to the membrane osmotic pressure (MOP) across the capillary membrane. Capillary pressure is difficult to measure but mean arterial pressure (MAP) can be used as a surrogate 1,4 . If fluid balance is achieved when MAP = MOP then four imbalance situations can be envisaged; high MAP + low MOP, high MAP +high MOP, low MAP + low MOP and low MAP + high MAP. These correspond to oedema, hypertension and high and low osmotic pressure shock (Fig1).

The MAP's and MOP10K's of 30 healthy volunteers 1,4 fell within the "normal area". The outliers to the right had consumed party volumes of alcohol the night before the study! Thirty five patients with clinical oedema 1,2 had high MAP's and low MOP10K's. The MAP and MOP10K's of 22 hypertension patients fell into the raised MAP and MOP sector 1,2. Our most recent study of 57 patients admitted with shock, 23 had low (<24mmHg), 17 had normal (24-27mmHg) and 13 had high MOP's. These results are shown graphically in Fig 2.

These studies give growing support to the concept that oedema, hypertension and shock are osmotic diseases resulting from imbalances between MAP and MOP10K

PCD106

Factors released from the placenta cause changes to glutamate and GABA receptors in cortical neurones

T. Phillips, P. Case, V. Leinster and E. Molnar

University of Bristol, Bristol, UK

Schizophrenia is a severally debilitating conditions affecting approximately 1% of the world's population. While there is no defining sign or symptom of schizophrenia the range of symptoms can be classified as positive (e.g. hallucinations), cognitive (e.g. impaired memory) and negative (e.g. social incompetence). Despite having 0.8 heritability Schizophrenia has no classical Mendelian inheritance patterns or fully penetrant genes. The highly homogenous nature of Schizophrenia has lead to a variety of theories as to its etiology with the current prevailing evidence suggesting a developmental insult leading to hyper levels of glutamate and hypo-function of the NMDA receptors of the glutamatergic system(1).

It has recently been found by our group that the placental tissue when exposed to hypoxic conditions releases an increased concentration of glutamate(2) into the surrounding media. It was hypothesised that this glutamate release might alter the presentation and function of receptors in the developing brain. To investigate this, human first trimester placental explants were exposed to oxygen concentrations of 2-8% and 21% in neurobasal media which was then collected. Cortical neurones from e18 rats were cultured on Poly-L-Lysine coated coverslips for 12 days then exposed to the conditional media for 7 days before fixation. Other neuronal cultures were similarly grown then exposed to varying concentrations of glutamate. Fluorescent immunostaining was performed on permalised and non-permalised cultures using antibodies for NMDA R1, NR3A, GABA A α1 and GABA B1. These targets were chosen to provide information on the functional capacity of the excitatory and inhibitory systems in the cultures.

It was found that increasing the concentration of glutamate leads to a reduction in the detection of NMDA R1 and an increase in the detection of NR3A. This would indicate that the increase in glutamate is causing the neurones to reduce the number and function of NMDA receptors(3). This effect was mirrored when using hypoxia conditioned media where 2-8% conditioned media resulted in increased detection of NR3A and reduced levels of NMDA R1. These finding correspond to those found in post mortem studies of patients with schizophrenia(4). The increased levels of hypoxia and glutamate were shown to cause a reduction in the presentation of GABA A α1 and an increase in the presentation of GABA B1 suggesting a deregulation of the gabaergenic system(5).

This findings suggest that factors, notably glutamate, secreted by the placenta during an hypoxic event cause alterations to the excitatory and inhibitory signalling systems on neurones in a similar manner to that recorded in Schizophrenic patients.

PCD107

Glutamate release from placenta can be blocked to protect foetal neurones from injury

A. Sood and P. Case

Musculoskeletal Research Unit, University of Bristol, Bristol, UK

Disturbances in the prenatal environment have been postulated to play a role in the pathogenesis of conditions such as schizophrenia and autism later in life. For example in preeclampsia and intra-uterine growth restriction, where there is a change in oxygen flow to the foetus, resulting in short term hypoxia, have been linked with a higher incidence in schizophrenia and foetal growth restrictions. The excitatory amino acid glutamate is involved in many cellular and physiological processes. In many neurological disorders, glutamate is implicated as being over expressed, and may be the key molecule that could cause dendrite shortening and simplification of the neurones. For this reason during pregnancy, it is important to regulate the levels of glutamate the foetus is exposed to.

We used first trimester placental tissue and a primary trophoblast cell barrier model to condition media after the effects of 2%, 21% and 2-8% and 2-21% oxygen changes. This media was then applied to E18.5 rat cortical cultures after 12 days in vitro and found to cause reductions in dendrite lengths, as measured via MAP2 staining and GFP transfections, after 6 days of exposures. In addition, the neurones were also simplified in structure and found to contain fewer spines, therefore impacting on their action potentials and their ability communicate with one another.

On analysis of the media, we found a specific and significant increase in glutamate when the tissue was exposed to hypoxia and reoxygenation. We then probed the reason to the mechanism of this release. There are five glutamate transporters within the human body (EAAT1-5), interestingly, 3 of which are only found in the placenta, further highlighting the importance for the regulation of glutamate during pregnancy. We used pharmacological interventions to block these transporters, DL-TBOA, a glutamate transporter antagonist, and DHA, a specific EAAT2 blocker. The results found that DHA being specific to only one transporter was not efficient in blocking the effects on the dendrites. However, DL-TBOA's actions being non-specific, was found to considerably rescue the dendrite lengths.

We hope that our findings and future work could lead to a potential therapy, by inhibiting the effects of glutamate, so that it does not pose a risk to the developing foetus. By understanding the mechanism of release, we aim to pave the way in developing a drug that is able to offer protection to the developing foetus and to reduce the risk of causing the onset of neurological disorders.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD108

Effect of increased corticospinal excitability by quadripulse transcranial magnetic stimulation to the primary motor cortex on the spinal inhibitory circuit

N. Matsuda[1], F. Kaneko[2], E. Shibata[1] and T. Kimura[1]

[1]Graduate School of Health Sciences, Sapporo Medical University, Sapporo, Japan and [2]Second Division of Physical Therapy, Sapporo Medical Univercity, Sapporo, Japan

Ia reciprocal inhibition and presynaptic inhibition are related to motor control. The effect of corticospinal excitability to on the spinal inhibitory circuit is studied by repetitive transcranial magnetic stimulation (rTMS). However, a relationship between corticospinal excitability and spinal inhibitory circuit has not been considered sufficiently. In recent years, quadripulse transcranial magnetic stimulation (QPS) has attracteds attention as a new technique to induce neural plasticity. QPS induce to increases a corticospinal excitability more effectively than does rTMS. The aim of this study was to clarify the relationship between corticospinal excitability and inhibition of the H- reflex. In Experiment 1, control H-reflex of the flexor carpi radialis (FCR) was induced by stimulation of the median nerve, and the test stimulus intensity was modulated so that the H-reflex was 20% of M max. To assess the Ia reciprocal inhibition and presynaptic inhibition, we applied conditioning stimulation to the radial nerve. The intensity of conditioning stimulation was set to 90% intensity of the M-wave threshold. The interstimulus interval (ISI) was set at 0-5,10,12,14,16,18,20,25,or 30 ms. The conditioned H-reflex was normalized to control H-reflex (% control amplitude). ISI-Ia was set to the minimum % control amplitude from ISI of 0 to 5 ms, in the same way ISI-presynapse was determined from ISI of 10-30 ms. In Experiment 2, the motor evoked potential (MEP) amplitude and H-reflex of the FCR were measured. To measure the conditioned H-reflex, we adopted the ISI-Ia and ISI-presynapse. QPS was performed for 30 minutes. QPS intensity was set to 90% of the motor threshold. We measured the H-reflex and MEP amplitudes twice before QPS (pre QPS-1, pre QPS-2) and every 20 minutes after QPS (post QPS-0, post QPS-20, post QPS-40, post QPS-60). The ratio of % control amplitude to pre QPS-1 was calculated (% pre1 amplitude). A one-way repeated measures analysis with time period as a factor was used to determine the effect of QPS on MEP amplitude and % pre1 amplitude ($p<0.05$). Dunnett multiple comparisons were performed as post hoc tests ($p<0.05$). In Experiment 1, The average of ISI-Ia was 4.5 ms and the average of ISI-presynapse was 20 ms. In Experiment 2, the MEP amplitude in post QPS-0 increased significantly compared with that in pre QPS-1 ($p=0.01$). The % pre1 amplitude of ISI-presynapse in post QPS-0 decreased significantly compared with that in pre QPS-2 ($p=0.021$). Although the differences were not statistically significant, the MEP amplitude in post QPS 20 increased and the % pre1 amplitude of ISI-presynapse in post QPS 20 decreased. These experimental results suggested that increased corticospinal excitability and increased presynaptic inhibition at the spinal level occurred in parallel.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD109

Prenatal hypoxia-ischemic affects neurons distribution in ventral tegmental area and nucleus accumbens, modifying memory in rats

I.M. Sab, M.M. Ferraz, C.M. Sequeira, M.R. Ferraz, T.M. Brunini and A. Mendes Ribeiro

Departamento de Farmacologia e Psicobiologia, State University of Rio de Janeiro, Rio de Janeiro, Brazil

Prenatal hypoxia-ischemia (HI) is one of the major causes of mortality and chronic neurological diseases in newborns that can evoke permanent effects such as attention deficit hyperactivity disorder (ADHD), epilepsy and cerebral palsy. These damages are associated with a delay in neural development and death of neurons. Some of the cognitive deficits may be due to impairments in mesolimbic pathway. The ventral tegmental area (VTA) to the nucleus accumbens (NAc) pathway is involved in reward, attention, motivation and learning. Nitric oxide (NO) is a gas with many physiological functions, such as vasodilatation and neurotransmission, and it is produced by the oxidation of L-arginine through NOS, using NADPH-diaphorase (NADPH-d) as the electron donor. The aim of our study was to investigate the effects of prenatal HI on NO production in NAc and VTA by NADPH-d technique, a specific histochemical marker for NOS in the brain, and the effects on the motor and habituation by the open field test (OFT). HI was induced by clamping the uterine arteries of pregnant rats (Wistar) for 45 minutes, anesthetized intraperitoneally with Avertin® (2,2,2-Tribromoethanol, 250-500 mg/kg), on the 18th day of gestation (HI group). In the other group of females the surgery was the same, but without clamping the arteries (SHAM group - SH). Three groups were examined in behavior tests: HI, SHAM and CTRL (nom-manipulated group). The motricity and habituation of the pups in P90 were analyzed by OFT on 2 consecutive days. For NADPH-d histochemistry technique, rats from both groups (HI and SH) were intracardially perfused with saline and paraformaldehyde, and the brain was coronally sectioned. The experimental procedures were approved by the Institutional Animal Care and Use Committee (CEA/051/2009) and were conducted in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals. Data were compared with a one-way ANOVA, expressed by mean± SEM, and significance level was set at 5%. HI animals (n=16) did not show difference in motor behavior from first (37.1 ± 4.9) to second day of the test (37.8 ± 4.0), but a decreased activity was observed in SH (52.6 ± 6.0 on 1st day, 41.5 ± 6.8 on 2nd day, n=15) and CTRL (59.2 ± 5.8 on 1st day, 40.9 ± 5.4 on 2nd day, n=16) groups. There was no difference in motricity between groups. HI animals showed a decreased number of NADPH-d positive neurons (216±66.36 in NAc; 150±16.7 in VTA, n=3) compared to SHAM (358±119.9 in NAc; 274±48.42 in VTA, n=3) group (preliminary data). Our findings showed that HI impairs habituation but not the motor activity, and also affects NADPH-d-positive neurons distribution in NAc and VTA.

Altered brain morphology in a mouse model of mental retardation

K.K. Gill, P. Kangesu, J.G. Jefferys and A.D. Powell

Neuronal Networks, University of Birmingham, Birmingham, UK

Altered brain morphology in a mouse model of mental retardation

Mental retardation (MR) affects 2-3% of the population; those due to X-linked mutations are a common cause of moderate to severe MR. *OPHN1* (*Ophn*-1 in mice) is one of the genes implicated in X-linked mental retardation (XLMR), encoding oligophrenin-1, a RhoGAP protein. Loss of function mutations affect Rho GTPase-dependent signalling pathways and alter actin cytoskeleton dynamics which are important for many neuronal functions, including morphogenesis and neuroepithelial development. Structural abnormalities, namely, abnormal cerebral ventricles typically associated with hydrocephalus, have been shown in brains of MR patients with *OPHN1* mutations and *Ophn*-1 null mice. A systematic study has been conducted to explore alterations in brain anatomy in *Ophn*-1 mice. *Ophn*-1 mice (male 15-30g, 6 week old (n=6 for both genotypes) and 3 month old (*Ophn*-$1^{+/y}$ n=8 and *Ophn*-$1^{-/y}$ n=6)) were anaesthetised by I.P. injection of medetomidine (1mg/kg) and ketamine (76mg/kg). Values are expressed as mean ± S.E.M, analysed by ANOVA or Student's t-test. To investigate the impact of loss of oligophrenin-1 on cerebral ventricles, ventricular volumes were analysed. Lateral ventricles were larger in *Ophn*-$1^{-/y}$ mice than *Ophn*-$1^{+/y}$ mice at 6 weeks of age (26.2±10.5 mm^3 and 3.81±0.44 mm^3; respectively; p=0.002) and 3 months of age (7.78±2.54 mm^3 and 3.42±6.99 mm^3; respectively; p=0.02). Lateral ventricle dilatation was associated with a reduction in motor cortex thickness (6 weeks: *Ophn*-$1^{-/y}$ 0.91±0.05 mm and *Ophn*-$1^{+/y}$ 1.09±0.03 mm; p=0.016 and 3 months: *Ophn*-$1^{-/y}$ 0.94±0.03 mm and *Ophn*-$1^{+/y}$ 1.04±0.02 mm; p=0.04) without alteration in somatosensory, auditory and ectorhinal cortices. Hippocampal volume was similar in *Ophn*-$1^{+/y}$ and *Ophn*-$1^{-/y}$ mice (7.38±1.40 mm^3 and 9.29±0.7 mm^3; respectively; p=0.23), neither the thalamus area (15.78±0.91 mm^2 and 13.46±0.69 mm^2; respectively; p=0.07) nor total brain area (51.8±1.6 mm^2 and 46.9±3.05 mm^2 respectively; p=0.18) were affected.

This study demonstrates brain malformation in *Ophn*-$1^{-/y}$ mice, primarily expansion of the lateral ventricles, which may be due to loss of oligophrenin-1 expression in ependymal cells, chorial villi or endothelium. Thus, this could result in impairments in cilia function, ependymal proliferation, abnormal production/absorption of cerebral spinal fluid or obstruction of cerebral aqueduct and/or fourth ventricle. How the ventriculomegaly and reduction in cortical thickness contribute to the cognitive deficits remains to be explored.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD111

NADPH oxidase 4-derived reactive oxygen species mediate the activation of adaptive antioxidant pathways in early diabetic retinas of db/db mice

M. He, H. Pan, C. Xiao and M. Pu

Anatomy, Peking Univ Hlth Science Ctr, Beijing, China

Recent studies suggest that oxidative stress plays a major role on retinal dysfunction in diabetes. The Nrf2/ARE antioxidant pathway has been found to be adaptively activated to counteract increased oxidative stress. However, the activation of Nrf2/ARE pathway has not been studied in the retina of the genetic type 2 diabetic animal model, db/db mice. The present study is to investigate the oxidative status and the activation of Nrf2/ARE antioxidant pathway in retinas of db/db mice. Male db/db C57BLKS/J mice aged at 8, 12, and 20 wks were used in this study. Age-matched male heterozygous db/m littermates were used as control. Animals were enucleated under anesthesia induced with ketamine and xylazine (80 mg/kg+10 mg/kg; intraperitoneally) and isolated retinas were prepared for reactive oxygen species (ROS) detection, immunohistochemistry, and western blotting analysis. All experiments were performed in accordance with Peking University guidelines for animal research and the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research. ROS generation was detected by dihydroethidium (DHE) assay, the expression of NADPH oxdase-4 (Nox4) and heme oxygenase-1 (HO-1) were examined by immunohistochemistry and western blotting.

ROS generation in the retinas of db/db mice increased at 8 wks and continued to progress at 20 wks of ages, compared to age-matched db/m mice (8 wks: dm: 9.67±0.84; db: 22.71±4.74, p<0.01, n=5; 20 wks: dm: 8.11±0.56; db: 21.13±3.71, p<0.01, n=5). However, the increased expression of Nox4 was only observed in the retina of 8 wks (dm: 10.80±1.23; db:17.10±5.37, p<0.01, n=5), but not 20 wks db/db mice compared to age-matched db/m mice. Meanwhile, in comparison with age-matched db/m mice, the expression of HO-1, an Nrf2-mediated antioxidant, was also increased in the retinas of db/db mice aged at 8 wks (dm: 9.68±1.17; db: 17.35±1.13, p<0.001, n=5), but not at 20 wks.

In conclusion,the antioxidant pathway was adaptively activated to counteract hyperglycemia-induced oxidative stress to maintain the redox status in early stages of the diabetic retina (8 wk). As diabetes developed, the antioxidant capacity was damaged by the continuous hyperglycemia and oxidative stress.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD112

Investigating the role of interneurons in epileptic high frequency activity

G. Morris[1], P. Jiruska[2], W. Chang[1], A.D. Powell[1] and J.G. Jefferys[1]

[1]Neuronal Networks, University of Birmingham, Birmingham, UK and [2]Department of Developmental Epileptology, Institute of Physiology, Academy of Sciences of Czech Republic, Prague, Czech Republic

Temporal Lobe Epilepsy is the most common form of epilepsy – a neurological disorder characterised by abnormal excitation and synchronisation of neuronal networks. High frequency

activity (HFA) is defined as network activity with frequency of over 100 Hz and is a biomarker for the epileptic hippocampus. The underlying mechanism is unknown, but it is hypothesised that interneurons, which are capable of firing action potentials (APs) at frequencies in the HFA range, could synchronise local pyramidal cell activity. High frequency interneuronal firing imposes synchronous IPSPs upon on a population of pyramidal cells, creating temporal windows in which they can fire. This could lead to synchronised high frequency population events. Using the VGAT-Venus A strain of rats that selectively express the fluorescent Venus protein in interneurons, we have examined the role of hippocampal interneurons in the genesis of HFA.

Adult VGAT-Venus A rats were anaesthetised with 0.24mg/kg medotomidine and 58.2mg/kg ketamine via I.P. injection before transcardial perfusion with sucrose ACSF, and 300 μm horizontal brain slice preparation. Extracellular recordings were made from stratum pyramidale (SP) in hippocampal region CA3b. Interictal-like discharges (ILDs) were induced by superfusion of the slices with high potassium (9mM). Following induction of ILDs, whole-cell patch clamp recordings were made from interneurons, irrespective of location, which were identified using fluorescence microscopy. Data is given as the mean±SEM.

Superfusion of high potassium generated ILDs (frequency = 0.72±0.04Hz; n=11), on which HFA (190.6±9.8 Hz; n=10) was superimposed. Interneurons were divided into four categories, as defined by their firing pattern. Group 1 neurons fired throughout ILDs and correlated with HFA (mean max. firing frequency = 207.5; n=2), whilst group 2 neurons fired throughout ILDs but were not correlated with HFA (182.50±20.4 Hz; n=4). Group 3 neurons fired a single AP on each ILD (n=2) whereas group 4 neurons fired randomly except for 2-3 APs at the onset of each ILD (120±31.8 Hz; n=3). Those neurons whose activity correlated with HFA were found in SP and stratum oriens and those which fire single APs were found in SP and stratum radiatum. Interneurons which are capable of maintaining HFA frequency firing, but do not correlate with HFA, were found throughout the layers of the hippocampus.

These results show that a sub-population of interneurons correlate with HFA and are candidates for pacing this activity. Pharmacological or electrophysiological manipulation of candidate cells has the potential to affect epileptic field activity by reducing the pathological synchronisation of pyramidal cell activity.

PCD113

Functional connections between the ventrolateral periaqueductal grey and cerebellum – a role in fear behaviour?

J.J. Crook, S. Koutsikou, E.V. Earl, J. Leith, R. Apps and B.M. Lumb

Physiology and Pharmacology, University of Bristol, Bristol, UK

Activation of neurons in the ventrolateral periaqueductal grey (vlPAG) matter has been shown to be associated with the expression of freezing responses to conditioned fear (1). These responses are reduced following lesions of the vlPAG, indicating that this structure plays an essential role in the freezing response to conditioned fear (2).

Previous anatomical studies have demonstrated pathways from the vlPAG to the cerebellum (3,5). Data are presented here which suggest that such a functional connection, via the inferior olive, plays a role in the expression of conditioned freezing behaviour.

Electrical stimulation of the vlPAG in anesthetised male Wistar rats (Sodium Pentobarbital; 60mg.kg$^{-1}_{ip}$) was found to evoke climbing fibre field potentials in lateral lobule VIII of the cerebellar vermis. The functional significance of this climbing fibre mediated connection was investigated in relation to the finding that chemical stimulation of the vlPAG significantly increases hindlimb-evoked H-reflex amplitude (average increase = 45.2±11%, n=16, P<0.001, Repeated measures ANOVA with Newman-Keuls post-hoc test) in alphaxalone-anesthetised male Wistar rats (Alfaxan; 25mg.kg^{-1}.hr$^{-1}_{iv}$)*.

It was hypothesised that the cerebellum supports this descending effect upon spinal a-motoneurone excitability, which may be linked to the increased muscle tone associated with freezing behaviours. It was found that cerebellectomy (n=4) or neurotoxic lesion (n=4) of the caudal inferior olive abolished the effect of vlPAG stimulation upon H-reflex amplitude.

In another set of rats localised lesions of connections to/from vermal lobule VIII, using the toxic tracer cholera toxin b-subunit-saporin (CTb-Sap) (4), were made under ketamine/medetomidine anaesthesia (Vetalar 50mg.kg$^{-1}_{ip}$ and Domitor 300μg.kg$^{-1}_{ip}$). In these animals (n=12) fear-conditioned freezing was significantly disrupted (P<0.001, Mann-Whitney test) compared to sham controls (n=10), despite appearing otherwise normal in a battery of motor and affective behavioural tasks. The same CTb-Sap treated animals were subsequently alphaxalone-anesthetised (n=6) as previously and the effect of vlPAG stimulation upon H-reflex amplitude found to be abolished. Changes in freezing behaviour as a function of H-reflex facilitation were plotted for individual animals. Consistent with the concept of H-reflex excitability being a proxy measurement for muscle tone underlying freezing behaviour, a positive correlation between the two was found (r^2= 0.75, P < 0.05, Linear regression).

In summary, these data indicate that vermal lobule VIII of the cerebellum plays an important role in the expression of vlPAG mediated freezing behaviour.

PCD114

Chronic neuropathic pain is alleviated by the highly specific iNOS inhibitor, 1400W

C.A. Staunton, L. Djouhri, R. Barrett-Jolley and S. Thippeswamy

Musculoskeletal Biology, University of Liverpool, Liverpool, UK

Chronic neuropathic pain may result from nerve injury and is refractory to currently available analgesic therapies. It is a debilitating pain condition and one that involves numerous complex underlying mechanisms that are poorly understood.
Following nerve injury, astrocytes and microglial cells become active leading to the synthesis of neurotoxic mediators and prolonged Inducible Nitric Oxide Synthase (iNOS) transcription. Such mediators alongside excessive levels of nitric oxide (NO) have been shown to correlate with an increase in pain severity and provoke ectopic neuronal cell activity. This hypersensitivity leads to the formation of peripheral and central sensitization (1-3).
We used a well established model of neuropathic pain, L5-Spinal Nerve Axotomy (L5-SNA) (4), which was carried out on Wistar rats under deep gaseous anaesthesia (2% isoflurane, 2L/min O2 and NO2). Two dosing regimens of a high selective iNOS inhibitor, N-(3-(Aminomethyl) benzyl) acetamidine dihydrochloride (1400W), or equal volume of vehicle were administered. We examined the effects of iNOS inhibition on two parameters used to characterise pain behaviour in humans; heat hyperalgesia (HH) and mechanical Allodynia (MA). Baseline behaviour was recorded prior to surgery and drug treatments and was continued for 7-14days post L5-SNA. Data are expressed as mean ±SEM. Statistical significance was calculated using either a Mann-Witney U t-test or a 2-way repeated measure ANOVA with Bonferroni's post tests, as appropriate.
Following L5-SNA and prior to drug interventions, both MA (27±0.6g to 18±0.7g, n=16) and HH (17±0.5s to 9±1s, n=16) were markedly reduced indicating a significant increase in pain levels $p<0.0001$).
When 1400W was administered 18hr post surgery, we observed increases in both HH and MA thresholds, indicating a significant decrease in pain levels (n=9; $p<0.05$). The greatest significant increase in MA following 1400W was observed at 74hr post surgery (22.4±0.8g for 1400W, n=9, compared to 15.6±0.9g for vehicle, n=7; $p<0.001$). For HH, 162 hr post surgery, the largest increase caused by 1400W was observed (15.7±0.4s for 1400W, n=9, compared to 7.2±0.7s for vehicle, n=7; $p<0.001$). However, when 1400W was administered 7days post L5-SNA, no effect was observed with 1400W at any time point post-L5 SNA (n=5 per treatment group).
The in vivo behavioral testing results strongly suggest that iNOS plays a key role in the hypersensitivity associated with trauma-induced NP during early stages of nerve injury. The results from this study indicate that 1400W has the ability to affect some analgesia, but became ineffective once chronic pain had fully established. We conclude that iNOS inhibiting drugs may have potential future use in neuroprotection and medical analgesia.

Characterization of recurrent laryngeal nerve function in rats

I. Naggar, N. Mor, K. Nakase, P. Zolkind, J.B. Silverman, K. Sundaram, M. Stewart and R. Kollmar

SUNY Downstate Medical Center, Brooklyn, NY, USA

The recurrent laryngeal nerve (RLN) is a branch of the vagus nerve that controls the movement of the vocal folds and arytenoid cartilages. Since it is damaged in 4-10% of thyroid surgeries, a better characterization of its function may aid in finding ways to repair the consequent vocal fold paralysis after damage. To this end, we developed methods to measure RLN function and vocal fold movement in rats under normal conditions, after nerve crush or cut, and upon RLN stimulation in rats. Rats were anesthetized with urethane 1.5 mg/kg intraperitoneally. Right RLN activity was recorded, along with electrical activity of the posterior crico-arytenoid and thyro-arytenoid muscles. A microsuspension laryngoscope was fashioned to visualize the arytenoid cartilages, and the deviation of the cartilages from the midline on video served as a quantitative measure of vocal fold function. Breathing was assessed by recording changes in resistance over a piece of conductive rubber wrapped around the thorax. Recordings from the above techniques were taken simultaneously during normal vocal fold function and after nerve crush or cut. Average waveforms of a single respiratory cycle during normal function and after nerve injury were calculated for each recording. The RLN was stimulated at 1, 2, 5, 10, 20, and 50 Hz with 1-millisecond pulses under normal and nerve injury conditions. A total of 31 adult rats were used in these experiments. Under normal conditions, we found rhythmic firing in the RLN that correlated in time with electromyogram (EMG) activity, vocal fold movement, and breathing. Cutting or crushing the right RLN resulted in normal breathing, but cessation of RLN and EMG activity, as well as paralysis of the ipsilateral arytenoid near the midline position. Stimulation of the distal RLN under normal and cut conditions caused arytenoid twitches that occurred upon each pulse in the 1-10 Hz range. At 20 or 50 Hz, the arytenoid moved to or stayed at the midline during stimulation. The development of quantitative techniques to study RLN function is an important step towards validating a rat model for RLN lesions. Normal RLN activity causes opening and closing of the arytenoids, but overstimulation of the RLN may overpower the adductor muscles and cause midline paralysis of the vocal folds. Our results have implications for the study of RLN regeneration after injury, as nerve impulses occurring after re-innervation may be similar to indiscriminate RLN stimulation.

Localization of cortical areas activated by visual memory task using functional magnetic resonance imaging

A. Sokolov[1], V. Fokin[1], E. Aleksandr[1] and S. Vorobyev[2]

[1]Radiology, Medical Military Academy, Saint-Petersburg, Russian Federation and [2]Neurology, Medical Military Academy, Saint-Petersburg, Russian Federation

Purpose: To localize cortical areas activated by visual memory tasks by the mean of functional magnetic resonance imaging (fMRI).
Methods: We used 1.5 T MR-scaner and BOLD-method (Blood Oxygenation Level Dependent), based on distinctions of magnetic properties of hemoglobin. We studied 27 healthy volunteers (20-32 year old). All of them passed MMSE, FAB, CES-D, attention and memory tests. There were done anatomical and fMRI fast imaging technique: echo planar imaging (EPI), whole brain scan (36 slices) matrix 64x64, 3.7 second. Fast imaging technique on modern MR-scanners with ≥ 1.5 T provides precise statistical maps of oxygenation increase with high spatial resolution. SPM8 software package was used for fMRI assessment and statistical analysis. For test stimuli we used series of 12 not related images for "baseline" and 12 images with 6 presented before for "active". Stimuli were presented 3 times with reduction of repeated images to 4 and 2.
Results: the investigation showed bilateral activity of anterior cingulate gyrus in 90% cases. In 70% cases activity was evidenced in parahippocampal gyrus (bilateral – 20%, left parahippocampal gyrus – 70%). We also noted activation of superior frontal gyrus (Brodman area 6 – BA6) in 45% cases, BA 21, 37, 38 in 40% cases.
Conclusion: our data are well co-coordinated with neurophysiologic and clinical findings that several brain areas are involved in realization of visual memory tasks. Visual memory is provided by integrative processes in brain cortex. These data will be able to use in clinical practice in patients with cognitive disorders.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Repeated exposure to novel spatial arrangement of objects: impact on hippocampal-dependent learning and synaptic plasticity

. Amaro-Leal, A.J. Carmo, I. Rocha and D. Cunha-Reis

Laboratório de Função Autonómica Cardiovascular, Unidade de Fisiologia Clínica e Translacional, Instituto de Medicina Molecular, Universidade de Lisboa, Lisboa, Portugal

It was recently demonstrated that exposure to novel configurations of objects in familiar environments enhances long-term depression (LTD) in vivo (1). LTD is an important cellular physiological process involved in memory reformulation and memory pathway regeneration. Recently we developed a cognitive training program aiming to impair cognitive decline in pathologies leading to saturation of synaptic function. Rats undergoing this 3-week training were shown to express enhanced LTP evoked by theta-burst stimulation (five or ten 100Hz bursts, 4 stimuli, separated by 200 ms) and depotentiation induced by low frequency stimulation (LFS, 1Hz, 15min) in the CA1 area of hippocampal slices obtained from trained rats.
Male Wistar rats (4 weeks-old at the beginning of training) were exposed for two weeks to three objects always presented in a new spatial configuration. Objects were placed inside wholes at the corners of an 80x80cm square arena (holeboard). Exposure either to objects in a fixed configuration or absence of objects were used as control. Behaviour during the training sessions was evaluated by addressing exploratory activity (nose-pokes, rearings and total distance travelled). In the final day of training all animals were exposed to objects in a new configuration. The impact of this training program in hippocampal-dependent spatial learning was evaluated using the radial-arm maze test. The latency to find each of the three baited arms, number of wrong arm entries and re-entries in previously visited baited arms were determined.
During training, all animals showed increased exploratory activity and decreased general exploration of objects (nose-pokes). In the final day, the animals exposed to this situation for the first time showed increased general exploration of objects (nose-pokes). Animals that were submitted to the training program (n=9) and matched controls experiencing repeated exposure to objects kept in a fixed configuration (n=9) showed decreased latency to find all baited arms in the radial arm maze when compared to animals trained in the absence of objects (n=9). All these groups performed better in the radial arm maze when compared to animals that were never exposed to the holeboard (n=8). When tested one week after the end of radial arm training, trained rats were more efficient ($P<0.05$, One-Way ANOVA) in finding the baited arms (radial arm recall test) suggesting that they have better retention of memories. Altogether, this suggests that training routines based on these aspects of novelty exposure may have a significant impact on cognitive performance in spatial learning tasks. This may be useful in cognitive recovery in neurological diseases involving synaptic pathology such as temporal lobe epilepsy.

PCD119

Auxiliary KChIP4a suppresses voltage-gated A-type K+ current through ER retention and promoting closed-state inactivation of Kv4 channels

Y. Tang, J. Zhou, Y. Lu, P. Liang, L. Lei, X. Bian and K. Wang

Peking University, Beijing, China

In the brain and heart, auxiliary KChIPs coassemble with pore-forming Kv4 α- subunits to form a native channel complex and regulate the expression and gating properties of Kv4 currents as well as membrane excitability. Among the KChIP1-4, KChIP4a exhibits a unique N-terminus that is known to suppress Kv4 function, but the underlying mechanism for Kv4 inhibition remains unknown. In this study, using approaches of confocal imaging, biochemistry and electrophysiology, we identified the hydrophobic and aliphatic residues 12-17, LIVIVL within the KChIP4a N-terminus, that function as a novel ER retention motif to reduce surface expression of Kv4-KChIP channel complex. The ability of LIVIVL motif to retain Kv4 proteins is transferable and depends on its flanking location, but not buried

in the middle of protein sequence. Interestingly, adjacent to the ER retention motif, the residues 19-21 (VKL motif) directly interact with Kv4.3 to enhance closed-state inactivation (CSI) and lead to Kv4.3 current inhibition. Because that auxiliary KChIPs can alter biophysical and physiological properties of Kv4 channels by regulating subunit composition of native Kv4 channel complex, we then analyzed the expression profile of two KChIP4 splice variants KChIP4a and KChIP4bl that have opposite effects on Kv4 function in rat dorsal root ganglion (DRG) neurons under pain conditions. Our findings show that KChIP4a mRNA was down-regulated in L4-5 DRG neurons 7 days after spinal nerve ligation in rats that received chloral hydrate (0.3 g/kg, intraperitoneally) before operation. Taken together, our findings reveal two distinct mechanisms by which KChIP4a suppresses Kv4 function through ER retention and promoting CSI. Differential regulation of auxiliary KChIPs expression in DRG neurons are likely involved in development of pathological pain conditions.

A novel compound targeting Kv7.2/3 channels relieves inflammatory and neuropathic pain

A. Peretz, E. Patrich, P. Kornilov, N. Menaker and B. Attali

Tel Aviv University, Tel Aviv, Israel

M-channels generate sub-threshold, non-inactivating voltage-gated K+ currents that play an important role in controlling neuronal excitability. In our quest to target neuronal M-type K+ channels, encoded by Kv7.2/Kv7.3 subunit assembly, we previously designed novel diphenylamine carboxylates that are powerful Kv7.2 channel openers or blockers. Recently, we designed a Kv7.2 channel opener, NH29, which was found to stabilize the Kv7.2 channel open state by interacting with its voltage sensing domain (VSD). Using the same structural framework, we designed a novel gating-modifier molecule, NH34, to test its activity on neuronal excitability and probe its potency in vivo on inflammatory and neuropathic pain. In transfected CHO cells, NH34 significantly increased Kv7.2 currents, by producing a hyperpolarizing voltage shift of the activation curve and slowing deactivation kinetics (EC50 = 17.5 μM). Interestingly, two S4 mutants, R198A and R207W significantly decreased the opener potency of the drug, suggesting that NH34, like NH29, may interact with the VSD of Kv7.2 channels. Results indicated that NH34 preferentially acts as an opener of Kv7.2 and Kv7.3 homomeric and heteromeric channels. NH34 was ineffective on Kv7.4 and Kv7.5 channels but produced a significant inhibition of TRPV1 cation channels. Patch-clamp intracellular recording of CA1 pyramidal neurons from 2 weeks-old rat hippocampal slices showed that NH34 reduced the spike discharge frequency evoked by injection of depolarizing current. Data from hippocampal slices also revealed that NH34 significantly depressed the slope of field EPSPs and the fiber volley amplitude recorded extracellularly in the CA1 pyramidal region following stimulation of the Schaeffer collaterals. NH34 reduced the frequency of evoked spike discharge in dorsal root ganglion neurons. In vivo, NH34 (3-30 mg/kg p.o) significantly relieved the hyperalgesia evoked by mechanical pressure of the paw in a rat model of inflammatory pain (Complete freund adjuvant). Similarly, NH34 (3-30 mg/kg p.o) was very efficient in alleviating the hyperalgesia evoked by mechanical pressure or cold allodynia in a Seltzer rat model of neuropathic pain. In all, the data suggest that NH34 is a very promising drug template for treating inflammatory and neuropathic pain.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD121

Cyclin-dependent kinase 5 (Cdk5) regulates TRPV1 membrane trafficking through phosphorylating KIF13B

Y. Zhang, B. Xing, Y. Yang, J. Du and Y. Wang

Neuroscience Research Institute, Peking University Health Science Center, Beijing, China

TRPV1 (transient receptor potential vanilloid 1) is a key molecule involved in the development of peripheral sensitization, which is believed to be the peripheral mechanism of pathological pain. Phosphorylation/dephosphorylation regulation plays a critical role in TRPV1 sensitization/desensitization. Multiple protein kinases, such as protein kinase A, protein kinase Cε, CaMKII (calmodulin-dependent kinase II) and Cdk5 (cyclin-dependent kinase 5), contribute to this process. Here, we reported an alternative way of functional regulation of TRPV1 by Cdk5, independent of the direct phosphorylation of TRPV1. The main findings are as follows:
(1) TRPV1 can associate with KIF13B (kinesin-3 family member 13B) FHA domain. Knock down of endogenous KIF13B expression resulted in a significant decrease of the surface expression of TRPV1 in primary cultured DRG (dorsla root ganglion) neurons.
(2) *In vitro* kinase assays showed that Cdk5 phosphorylated the KIF13B-FHA domain at Threonine-506.
(3) Inhibition of Cdk5 activity decreased threonine phosphorylation of the KIF13B-motor FHA domain and the number of TRPV1-KIF13B-motor FHA complexes in CHO cells stably expressing TRPV1 (TRPV1-CHO cells) transfected with GFP-KIF13B motor FHA domain plasmids.
(4) Transmembrane TAT-T506 peptide inhibited TRPV1 surface expression in DRG neurons.
(5) Intrathecal delivery of the TAT-T506 peptide inhibited TRPV1 sensitization after inflammation and alleviated heat hyperalgesia behaviors in CFA-induced inflammatory pain models in rats.
Conclusions:

Regulation of the membrane trafficking of TRPV1 by Cdk5 through phosphorylating KIF13B contributes to inflammatory heat hyperalgesia. TAT-T506 might be a potential candidate for analgesic drug development.

Insulin modulates GABAA channels-mediated inhibition in rat hippocampal and amygdala neurons

Z. Jin, Y. Jin, S. Korol and B. Birnir

The Division of Molecular Physiology and Neuroscience, Department of Neuroscience, Uppsala University, Uppsala, Sweden

GABA (gamma-aminobutyric acid) regulates neuronal excitability and network activity by activating GABAA channels that generate phasic and tonic currents. The pancreatic hormone insulin, in addition to its critical role in peripheral glucose regulation, has effects on neuronal excitability and memory functions. Hippocampus and amygdala, both important components of the limbic system participate in the memory formation. We have previously shown that insulin can enhance the GABAA mediated tonic conductance in rat hippocampal CA1 neurons (Jin Z, et al., 2011). The aim of this study is to investigate 1) if insulin receptor is expressed in the rat and human amygdala 2) the effect of insulin on GABAA channels-mediated inhibition in rat hippocampal and amygdala neurons. Quantitative RT-PCR was run on total RNAs isolated from rat and human post-mortem amygdala. Standard whole-cell and single channel recordings were performed on hippocampal and amygdala slices were prepared from postnatal 16-22 days old Wistar rats and incubated with ACSF (artificial cerebrospinal fluid) or low physiological concentration of insulin. The mRNA transcript for insulin receptor was detected in both rat (n=3) and human (n=12) amygdala samples. In the rat amygdala, the insulin receptor was expressed in both the central nucleus and the basolateral nucleus. The incubation of 1nM insulin increased GABAA-mediated tonic currents in rat hippocampal CA1 neurons (n=24) and reduced the action potential firing frequency (n=13). The enhanced tonic current is partially carried by alpha5, gamma2 containing GABAA channels. The insulin-induced GABAA channels have very high-affinity (pM) with novel pharmacological profile. Our results suggest GABAA-mediated tonic conductance regulate basal neuronal excitability when it is prominently expressed.

Brain temperature is a critical determinant of neuronal excitability through TRPV4 activation

K. Shibasaki[1], K. Yamada[2], H. Miwa[1], M. Tominaga[3] and Y. Ishizaki[1]

[1]Gunma University Graduate School of Medicine, Maebashi, Japan, [2]Hirosaki University Graduate School of Medicine, Hirosaki, Japan and [3]National Institute for Physiological Sciences, Okazaki, Japan

Physiological brain temperature is an important determinant of brain functions, and it is well established that changes in brain temperature dynamically influence hippocampal neuronal activity. We previously revealed that the thermo-sensor TRPV4 (activated above 34°C) is activated by physiological brain temperature in hippocampal neurons and thereby controls their excitability in vitro (J. Neurosci. 2007, Shibasaki et al.). Here, we examined whether TRPV4 regulates neuronal excitability through its activation by brain temperature in vivo. We developed an original device to cool local brain temperature to inactivate TRPV4. The cooling treatment clearly demonstrated that constitutive TRPV4 activation was occurred in mouse brain, and we found that hippocampal theta-frequency electroencephalogram (EEG) activities in TRPV4KO mice during wake periods were significantly reduced compared with those in WT mice. Furthermore, slice patch clamp recordings from dentate gyrus of hippocampus revealed that WT neurons further depolarized compared with TRPV4KO neurons. Depending on the differences of the resting membrane potentials, WT neurons had smaller fEPSPs and higher firing than KO neurons at 35°C (above TRPV4 activation), however, the differences were abolished at 30°C (less than TRPV4 activation). Taken together, for the first time we reveal that TRPV4 is an important transducer that converts brain temperature into neuronal electrical excitability in mammals.

PCD125

Trafficking of AMPA receptors in dorsal horn neurons during persistent pain: the changes in synaptic and extrasynaptic receptor pools

O. Kopach, A. Sotnik, P. Belan and N. Voitenko

Bogomoletz Institute of Physiology, Kiev, Ukraine

AMPA receptors (AMPARs) mediate fast excitatory synaptic transmission and play a critical role in synaptic plasticity in the CNS. In adult neurons, most AMPARs have low Ca2+ permeability due to GluR2 subunit expression. Cumulative evidence indicates that AMPAR subunit composition is not static and subject to change during activity-dependent plasticity. Here, we studied how the trafficking of AMPARs is changed in dorsal horn (DH) neurons of spinal cord during persistent pain produced by peripheral inflammation.

Persistent peripheral inflammation was induced by complete Freund's adjuvant (CFA, 100 μl), injected subcutaneously into the plantar side of one hind paw of the deeply isoflurane-anesthetized rats. The animals were used in accordance with protocols that were approved by the Animal Care and Use Committee at the Bogomoletz Institute of Physiology and were consistent with the ethical guidelines of the National Institutes of Health and the International Association for the Study of Pain. AMPAR functioning was investigated using whole-cell patch-clamp recording combined with Ca2+ imaging.

We found that peripheral inflammation increases the functional expression of Ca2+-permeable AMPARs in both the synaptic and extrasynaptic membranes of DH neurons. Peripheral inflammation promotes internalization of GluR2 subunits from the synapses of DH neurons during the maintenance period of CFA-induced persistent inflammatory pain (Park et al., 2009). At the same time, a dramatic increase in the functional expression of GluR1-containing Ca2+-permeable AMPARs was observed in the extrasynaptic plasma membrane in lamina II DH neurons. This increase occurred only in SG neurons characterized by intrinsic tonic firing properties, but not in those exhibiting a strong adaptation (Kopach et al., 2011).

Altogether, our results demonstrate that persistent inflammation increases the number of Ca2+-permeable AMPARs in both the synaptic and extrasynaptic membranes and their proportion within the entire AMPARs population in DH neurons. That leads to increased Ca2+ influx in the neurons resulting in increased neuron excitability and altered synaptic efficacy during persistent inflammatory pain.

[1]Department of Medical Science, Korea University, Ansan, Gyeonggi, Republic of Korea and [2]Translational Research Institute for Incurable Diseases, Korea University College of Medicine, Ansan, Gyeonggi, Republic of Korea

Sensory transient receptor potential (TRP) ion channels present in DRG nerve termini and skin keratinocytes serve a crucial role in detection of environmental harmful stimuli. Little is known about endogenous molecules that negatively control these TRP activities. Resolvins are anti-inflammatory and pro-resolving lipid molecules naturally generated during inflammatory processes. We asked whether D-series resolvins (RvDs) modulate the sensory TRP channel activation. We examined the effects of 17(S)-RvD1 and 17(R)-RvD1 on sensory TRPs using calcium imaging and whole cell electrophysiology experiments with a HEK cell heterologous expression system, cultured sensory neurons and HaCaT keratinocytes. Changes in agonist-specific acute nociceptive behaviors (licks, flicks and flinches) and TRP-related mechanical and thermal pain behaviors were also checked with or without inflammation. As a result, 17(S)-RvD1 targeted multiple TRP channels while 17(R)-RvD1 specifically acted on TRPV3. 17(S)-RvD1 inhibited TRPA1, TRPV3 and TRPV4 at nanomolar and micromolar levels. Consistent decreases in acute pain indices by local administration of 17(S)-RvD1 were also detected. Peripheral treatment of 17(S)-RvD1 significantly prevented mechanical and thermal hypersensitivity in inflamed tissues. For 17(R)-RvD1, TRPV3-specific in vitro and in vivo responses were suppressed upon its application. The administration of 17(R)-RvD1 reversed thermal hypersensitivity caused by inflammation. A molecular mechanism of such inhibition appears to be a shift in voltage-dependence of TRP channels. In conclusion, RvDs are potent endogenous sensory TRP channel inhibitors. The result implicates that our body has an internal antinociceptive potential with endogenous TRP-regulating lipids. This finding may also help understand pain mechanisms involving TRP interactions with pro-resolving substances.

Identifying ligand induced conformational changes of human P2X1 with voltage clamp fluorometry

A.G. Fryatt and R.J. Evans

Department of Cell Physiology and Pharmacology, University of Leicester, Leicester, UK

P2X receptors are a distinct family of ATP-gated trimeric cation channels involved in a wide array of physiological processes. Recent advances have been made to understanding the molecular structure and function of these ion channels, including

the generation of crystal structures of zebrafish P2X4 in both ATP-free and ATP-bound states. However, the structures give snapshots of the conformation of the receptor and do not address the time-course of conformational changes following agonist binding, channel opening, desensitization or agonist unbinding. To address these questions we used voltage clamp fluorometry to study human P2X1 receptors by introducing single cysteine point mutations along the subunit interface at residues around the cysteine rich head region (K138C, E181C), adjacent to the agonist binding site (N284C, K190C) and linking the binding site to the transmembrane portions (D320C, P196C, I62C).

Voltage clamp fluorometry allows the simultaneous measurement of channel current and the fluorescence of labelled mutant cysteine residues to detect changes in receptor conformation. In this study cysteine mutant human P2X1 receptors were expressed in *Xenopus* oocytes and labelled with 2-((5(6)-Tetramethyl-rhodamine)carboxylamino)ethyl Methanethiosulfonate (MTS TAMRA). MTS TAMRA labelled each of the single cysteine point mutants detailed above but did not label the wild type P2X1 receptors. Additionally labelling with MTS TAMRA had no effect on agonist evoked currents, showing that binding of the fluorescent probe did not inhibit channel function. ATP application had little or no effect on fluorescence at D320C, P196C, I62C and E181C mutants however decreases in fluorescence were recorded at K138C, N284C and K190C mutants (approximately 5%, 10% and 15% decrease respectively). These decreases in fluorescence returned to baseline levels following removal of ATP, however the time-course of this recovery appeared dependent on the cysteine mutant. This suggests that there are temporally distinct conformational changes in different parts of the receptor.

A DMD-based multicolor irradiation system for the optogenetic analysis of neural circuits

S. Sakai[1,2], T. Mishima[1,2], T. Ishizuka[1,2] and H. Yawo[1,2]

[1]Graduate School of Life Sciences, Tohoku University, Sendai, Japan and [2]JST, CREST, Tokyo, Japan

The brain consists of many types of neurons which make a complex network. The brain's network performance has been investigated through the analysis of its input–output relationship using electrodes. Recently, optical stimulation methods using a photosensitive ion channel, such as channelrhodopsin-2 (ChR2) from *Chlamydomonas reinhardtii*, has been developed as a powerful tool for the investigation of neural circuits *in vivo* and *in vitro*. Neurons can also be inactivated by light-driven Cl^- or H^+ pumps, such as halorhodopsin (NpHR) and archaerhodopsins (Arch, ArchT).

To manipulate neuronal activity positively or negatively with desired spatiotemporal patterns, the irradiation system has to be optimized. Spatial light modulators based on the digital mirror device (DMD) is an ideal tool for patterned photostimulation because each micro-mirror can be turned on and off at high frequencies up to several kHz (Sakai et al., 2012). Here, we improved the multicolor irradiation system using a DMD-based mercury lamp projector and a multiband-pass optical filter in combination. It is expected that ChR2 is activated by the filtered blue light whereas ArchT is activated by the filtered yellow light. To test this, we recorded the activity of a neuron, which expressed both ChR2 and ArchT, in the hippocampal slice under whole cell patch clamp. The activity was switched up and down simply with the changes of irradiating colors. Our multicolor irradiation system enables one to manipulate neuronal activity with desired spatiotemporal patterns. In the dentate gyrus (DG) of hippocampus, a hilar mossy cell (HMC) receives excitatory inputs convergently from a group of granule cells (GCs) and sends excitatory output divergently to another group of GCs. Based on this anatomical feature HMCs would regulated the dynamic state of hippocampus through positive feedback association with GCs. Here, using optogenetics and the DMD-based irradiation system, we tested whether the magnitude of HMC activity is dependent on the spatiotemporally patterned inputs. Hippocampal slices were prepared from a Thy1.2-ChR2-*Venus* transgenic rat line in which GCs are expressing ChR2 (Ji et al., 2012). Whole cell patch clamp recordings were made from HMCs, which is identified by the electrophysiological characteristics and the morphology. Under current clamp, spontaneous action potentials were observed at low frequency. However, bursts of high-frequency action potentials were often generated in synchronous with rhythmical irradiation of whole DG at 10 Hz. The bursting activity continued for 10-40 s after cessation of irradiation. On the other hand, the activity of HMC was rather inhibited when the granule cell layer was selectively irradiated with the same rhythm. It is suggested that the bursting activity of HMC is dependent on the spatiotemporal pattern of GC inputs.

Selective changes of AMPA, NMDA and Kainate receptor subunit mRNAs in the hippocampus and orbitofrontal cortex but not in prefrontal cortex of human alcoholics

A.K. Bhandage[1], Z. Jin[1], I. Bazov[2], O. Kononenko[2], E.R. Korpi[3], G. Bakalkin[2] and B. Birnir[1]

[1]Neuroscience (Molecular Physiology), Biomedical Center, Uppsala University, Uppsala, Sweden, [2]Pharmaceutical Bioscience (Biological Research on Drug Dependence), Biomedical Center, Uppsala University, Uppsala, Sweden and [3]Pharmacology, Institute of Biomedicine, University of Helsinki, Helsinki, Finland

Glutamate is the main excitatory and γ-aminobutyric acid (GABA) is the main inhibitory transmitter in the human brain. Drugs that affect the glutamatergic or the GABAergic signaling systems will alter the normal balance regulating neuronal excitability. The brain is one of the main targets of alcohol. Ethanol, the active molecule in alcoholic beverages, targets both glutamate and GABA-gated ion channels. We have examined the expression of glutamate channel subunit mRNAs in human post-mortem hippocampal dentate gyrus (HP-DG), orbitofrontal (OFC), and dorsolateral prefrontal cortex (DL-PFC) of individuals suffering from alcohol dependence and have compared the results to brain samples from individuals without alcohol dependence. HP-DC, OFC and DL-PFC samples from 21 controls and 19 individuals with chronic alcohol dependence were included in the study. Total RNA was isolated and assayed using the method of quantitative RT-PCR as described

(Jin et al., 2011). Statistical analysis was carried out using SigmaPlot and SigmaStat analysis software. Shapiro-Wilk normality test was used to examine the normality of data distribution. The differences between the control and alcoholic groups were analysed by one-way ANOVA with Bonferroni post hoc test for normally distributed data and by non-parametric Kruskal-Wallis ANOVA on ranks with Dunn's post hoc test for not normally distributed data. A significant level was set to $p < 0.05$. Out of the 16 glutamate receptor subunits, mRNAs encoding two AMPA (2-amino-3-(3-hydroxy-5-methyl-isoxazol-4-yl)propanoic acid) receptor subunits: GluA2, GluA3; three kainate receptor subunit : GluK1, GluK2, GluK5 and six NMDA (N-Methyl-D-aspartate) receptor subunits: GluN1, GluN2A, GluN2B, GluN2C, GluN2D, GluN3A in the HP-DG region were significantly increased. In the OFC, mRNA encoding the NMDA subunit GluN3A was increased. In the DL-PFC no changes in mRNA levels were detected between controls and alcoholics. Alcohol consumption clearly alters the expression of genes encoding the glutamate channels in a brain area-specific manner. Our laboratory has shown previously that genes encoding GABA-A receptors are altered in the HP-DG and the OFC from alcoholics (Jin et al, 2011). Whether changes in one neurotransmitter system drives changes in the other or if they change independently remains to be resolved.

A P2X receptor from the model cnidarian *Hydra*: expression in a unique cell type

S. Hanmer, W. Wilkinson, P. Kemp and W. van der Goes van Naters

School of Biosciences, Cardiff University, Cardiff, N/A, UK

P2X receptors are ATP-gated ion channels with a number of roles in humans and other vertebrates. To understand the full range of physiological functions served by this receptor family, we are investigating P2X receptors in model invertebrates. *Hydra*, a member of the cnidarian phylum, is thought to be a modern proxy for the first organisms to have evolved a defined nervous system. Considering the important physiological and pathophysiological functions of P2X receptors in higher organisms, understanding P2X receptor signaling in non-mammalian phyla may allow us to uncover new functions that the family serves and further understand the evolutionary origins of purinergic signaling.

A P2X receptor from *Hydra vulgaris* was bioinformatically identified and subsequently cloned and sequenced. Following heterologous expression in human embryonic kidney 293 cells of a synthesized construct of the P2X receptor, with codon usage matched to human usage, we have used whole-cell voltage-clamp electrophysiology to study its pharmacology. Extracellular ATP application results in a concentration-dependent increase in inward current with a mean EC_{50} of 123.8 ± 21.8 μM (n = 8 cells; SEM) with a Hill coefficient of 1.3. AMP, ADP, dATP, UTP, α,β-methylene ATP and β,γ-methylene ATP all failed to evoke currents at 1 mM. The broad-spectrum antagonists PPADS and suramin (both at 0.1 mM) had little or no effect on ATP-induced currents, with the compounds Brilliant Blue G and Phenol Red also having no effect. Co-application of the P2X4 receptor modulator ivermectin at 3 μM with 0.1 mM ATP potentiated currents by approx. 40%. Ion substitution experiments reveal that the receptor is permeable to K^+ ions (P_K/P_{Na} = 1.75 ± 0.22, n = 11) and Ca^{2+} (P_{Ca}/P_{Na} = 1.64 ± 0.18, n = 6), but largely impermeable to the inorganic cations $Tris^+$ (0.24 ± 0.03, n = 6) and $NMDG^+$ (0.08 ± 0.02, n = 8). The receptor is Cl^- impermeable (P_{Cl}/P_{Na} = 0.02 ± 0.007, n = 9). From this, the *Hydra* P2X receptor displays a rank order of permeability to ions as follows: $K^+ \geq Ca^{2+} > Na^+ > Tris^+ >> NMDG^+ > Cl^-$, consistent mammalian homologues.

A custom polyclonal antibody was raised against a peptide corresponding to part of the *Hydra* P2X receptor C-terminus. Whole polyp immunohistochemistry using the antibody suggests that the receptor is expressed in the phylum-specific nematocytes. Specifically, the P2X receptor appears to be localised to the nematocyst capsule wall and not to the harpoon-like inner structure used to capture prey, or to the nematocyte cell in which the nematocyst is embedded. The internal pressure within the nematocyst capsule used to expel the internal harpoon is in the MPa range (Nüchter *et al*., 2006) and we hypothesize that the P2X receptor may play a role in the osmotic potential that underlies this. The current focus of the study is to investigate this hypothesis through RNAi mediated knockdown of the receptor.

Regulation of TREK1 two pore domain potassium channels by amitriptyline

E. Al-Moubarak, E.L. Veale and A. Mathie

Medway School of Pharmacy, University of Kent, Chatham Maritime, UK

TREK1, two pore domain potassium (K2P) channels are responsible for background currents that regulate neuronal excitability. Deletion of TREK1 has previously been shown to result in a depression-resistant phenotype in mice (Heurteaux et al. 2006). In this study we investigated the effect of the tricyclic antidepressant, amitriptyline, on TREK1 channels. Additionally, amitriptyline is used for relief of neuropathic pain and TREK-1 is also involved in pain perception (Alloui et al. 2006). tsA-201 cells were transiently transfected with wild type and mutated K2P channels. The whole cell patch clamp technique was used to obtain current recordings. Homology models for TREK1 were constructed using Modeller. Amitriptyline was docked to these models using the MOE program.

Amitriptyline (50 μM) significantly inhibited WT TREK1 channel current by 77.4 ± 3.7 % (n=9). While the inhibitory effect of amitriptyline was reversible, on wash, it was often followed by an over-recovery of current to above the baseline level. We have previously investigated the effect of the antidepressant, citalopram, on TREK1, and found that it inhibited the channel. Subsequently we identified a number of amino acids in both the pore region and transmembrane domains M2 and M4 of

TREK1 that were important for its effect (Al-Moubarak et al. 2013). Interestingly, mutations of several amino acids, T142A, L289A and T251A, which reduced the effectiveness of citalopram had no effect on the observed inhibition by amitriptyline. Other mutations, L169A and I167A had no effect on inhibition by either compound. Mutation L174A (in the M2 transmembrane domain of TREK1), however, significantly reduced inhibition by both citalopram (Al-Moubarak et al 2013) and amitriptyline (50 μM, 49.0 ± 3.1 %, n=6, $p < 0.05$). As previously found for citalopram, the E306A gain of function mutation completely prevented inhibition by amitriptyline. Docking of amitriptyline into the TREK1 homology model, guided by the obtained electrophysiology results, predicts a different binding profile for amitriptyline compared to citalopram.

Thus we have shown that amitriptyline is a potent inhibitor of TREK1 potassium channels. This action may contribute to the therapeutic usefulness of this compound in both the treatment of depression and pain.

TRPV4 and KCa: The model couple?

C.H. Feetham[1], N. Nunn[1,2], R. Lewis[1] and R. Barrett-Jolley[1]

[1]Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, UK and [2]Institute of Translational Medicine, University of Liverpool, Liverprool, UK

Cardiovascular disease is an increasing problem in the UK, resulting in over 159,000 deaths each year. Cardiovascular disease has been linked to disturbed osmosensing, known to effect sympathetic activity altering blood pressure (BP) and heart rate (HR)[1]. The hypothalamus is responsible for maintaining plasma osmolality within a narrow range (~290-300mOsm)[2]. However, the mechanisms involved have yet to be established. The paraventricular nucleus (PVN) of the hypothalamus is thought to have a role in osmoregulation; hypertonic solutions increase electrical activity of PVN neurones[3]. Recent studies implicate the transient receptor potential vanilloid channel (TRPV4) and calcium activated potassium channels (KCa) as possible candidates for osmosensing [4].

Using a combination of in vivo, in vitro and in silico we have investigated a possible functional coupling of TRPV4 and KCa in PVN cardiovascular control neurone regulation in response to osmotic challenge. Mice were anaesthetized intraperitoneally with urethane-chloralose (1.4-2.2mg/kg-7-11μg/kg). BP was measured by arterial cannulae and compounds applied by intracerebroventricular (ICV) injection. Cellular mechanisms were investigated using the NEURON simulation environment and experimentally by cell-attached patch-clamp recording in mouse PVN hypothalamic brain slices. Results are given as mean±SEM; in vivo and in vitro significances were assessed by two-way ANOVA with post-hoc Tukey comparison and Student's paired t-tests respectively.

ICV injection of hypotonic saline led to a rapid decrease in BP, whereas isotonic saline had no effect (-9±2mmHg vs. -2±1mmHg; n=6; $p<0.01$). These decreases in BP were abolished by the selective TRPV4 inhibitor RN1734 (-1±1mmHg; n=6).

Using action currents to indicate action potential frequency in PVN brain slice experiments, we established that the osmotic effect on action potential frequency is dependent upon both TRPV4 channels (hypotonic: 70±14% reduction vs. hypotonic with RN1734: 45±15%; n=6; $p<0.05$) and small conductance KCa (SK) (hypotonic: 79±10% reduction vs. hypotonic with the SK channel inhibitor UCL-1684: 37±7%; n=5; $p<0.01$), but no significant effects of the intermediate and large conductance KCa channel inhibitors TRAM-34 and iberiotoxin. In order to verify the presence of TRPV4 within the parvocellular PVN, single channel activity was recorded. A population of ion channels was identified with a mean slope unitary conductance of 57±7pS and reversal potential of -5±3mV (n=6); indicative of a non-selective cation channel. This channel activity was seen in 50% of patches (8/16), with a mean open probability (Po) of 0.1±0.0 at -40mV. Po increased by 48±9% (n=4) upon addition of the TRPV4 agonist 4αPDD.

These results strongly suggest that central osmolality changes modulate the cardiovascular system by functional coupling of TRPV4 and small conductance KCa channels in the parvocellular PVN.

Recombinant α9α10 nicotinic cholinergic receptors depend on extracellular Ca2+ to reach maximum activation

J.C. Boffi, P. Plazas, M. Lipovsek, E. Katz, B. Elgoyhen and B. Elgoyhen

Instituto de investigaciones en Ingeniería Genética y Biología Molecular "Dr. Héctor N. Torres", Ciudad Autonoma de Buenos Aires, Argentina

The activation of α9α10 nicotinic receptors in cochlear hair cells can ameliorate acoustic trauma. Therefore, maximized α9α10 receptor activation may favor the prevention of noise-induced hearing loss. Hence, understanding the conditions in which α9α10 receptors reach maximum activation could have a potential therapeutic use in noise-induced hearing loss.

In this work we aimed to characterize how extracellular Ca2+ affects the activation of recombinant α9α10 receptors expressed in X. laevis oocytes under two-electrode voltage-clamp. Previous work from our lab suggests that the homomeric α9 receptor reaches maximum activation at trace con-

centrations of extracellular Ca2+ and is blocked by higher concentrations (IC50 = 100±10 μM, n = 3). We now show that the α9α10 receptor, as opposed to homomeric α9, reaches its lowest maximal currents (at saturating acetylcholine) at trace levels of extracellular Ca2+ (50±15% of maximal currents at physiological 1.8 mM Ca2+; n = 4) and its maximal activation at Ca2+ concentrations close to 0.1mM (260±55% of maximal currents at 1.8 mM Ca2+; n = 5). Furthermore, increasing extracellular Ca2+ concentrations reduces the receptor's EC50 dose dependently (trace Ca2+: EC50 = 54±4 μM, n = 7; 1.8 mM Ca2+: EC50 = 13±2 μM, n = 8).

This differential dependency upon extracellular Ca2+ suggests that the α10 subunit provides the structural determinants. In order to delineate these structural determinants, we constructed chimeric α10-α9 subunits. Receptors with chimeric α10 subunits bearing the α9 extracellular and the α10 transmembrane and intracellular domains reached maximal activation at trace levels of extracelular Ca2+ (190±20% of maximal currents at 1.8 mM Ca2+; n = 5). The inclusion of α9 transmembrane regions facing the extracellular domain (the TM2-TM3 loop and extracellular segment of TM1) in the chimeras further boosted the activation at trace extracellular Ca2+ (390±40% of maximal currents at 1.8 mM Ca2+; n = 4). Altogether, our results suggest that extracellular Ca2+ greatly affects α9α10 receptor activation and that the structural determinants of this effect are located at the interphase between extracellular and transmembrane domains of the α10 subunits, a region known to be responsible for channel gating.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD134

GABA-A channel subunit expression in cell lines derived from human glioblastoma

O. Babateen[1], Z. Jin[1], A. Bhandage[1], B. Westermark[2], K. Forsberg-Nilsson[2], L. Uhrbom[2], A. Smits[1] and B. Birnir[1]

[1]Department of Neuroscience, Uppsala University, Uppsala, Sweden and [2]Department of Immunology, Genetics and Pathology, and Science for Life Laboratory, Uppsala University, Uppsala, Sweden

Gliomas are the most common form of primary brain tumors with an overall incidence of about 4 - 5 per 10^5 persons. There is growing evidence for a widespread role of the neurotransmitter γ-aminobutyric acid (GABA) in the growth regulation of many cell types, including neuronal stem cells and perhaps tumor stem cells. Recently we showed that human brain tumors express GABA-A receptors subunits that are generally down-regulated in glioblastomas (Smits et al, 2012). We further showed that there was a correlation between GABA-A channel subunits and patient survival. Whether tumor cells that are equipped with functional GABA-A channels maintain proliferative activity upon in physiological concentrations of GABA may depend on which *subtype* of GABA-A channels are activated. We have now examined 8 glioblastoma derived cell-lines and examined which GABA-A subunits are expressed and then, selected one cell line to study in detail the functional and pharmacological properties of the GABA-A channels expressed. We used the method of RT-PCR for determining the subunits expressed, immunocytochemistry to identify cellular location of subunits and the whole-cell patch-clamp technique to record GABA-activated currents. Our results show that the eight different cell lines all express GABA-A receptor subunits but the type of subunits that are expressed varies. Cell line U3047 expressed α1, α2, α3, α5, β2, β3, δ, γ3 and θ GABA-A receptors subunits mRNAs and was selected for studies of properties of the GABA-A receptors expressed in glial/tumor cells. Immunocytochemistry demonstrated expression of the α3 and β3 proteins. GABA concentrations ranging from 1 to 1000 μM were applied to the cells and gave a half-maximal concentration of current activation (EC50) of 10 μM. The current response to 10 μM GABA was enhanced by 1 μM diazepam and 50 μM propofol, modulators of GABA-A channels. The currents were inhibited by the GABA-A channels antagonists SR-95531 (100 μM) and picrotoxin (100 μM). Our results show that the GABA-A receptors in the glioblastoma cell line U3047 are functional and respond to classical agonists and antagonists of GABA-A receptors. The profile of the subunits expressed is similar to what we reported in glioblastoma tumors from humans (Smits et al., 2012). We propose that the cell line can be used as a model system to study how GABA signaling affects tumor development.

PCD135

Relation between Ia and motoneuron responses induced by vibratory stretches in a cat

M. Mizote

Teikyo Heisei University, Toshima-ward, Tokyo, Japan

Primary endings were classified into three types by vibration threshold (1976) and a spike of motoneuron was elicited by acceleration sensitive Ia impulses (1993). The reports suggested that motoneuron is activated by Ia on which different types of intrafusal fibers are selectively induced by different vibratory stretch phases. Four cats were anesthetized with an initial intraperitoneal dose of 10% urethane and 1% chloralose (4cc/kg). Subsequent doses, as required, were given intravenously via a catheterized cubital vein. 10cc/kg of 10% urethane was given intravenously at the end of experiment. Left triceps surae muscle of cats were dissected free from surrounding tissues, while blood supply was kept intact. All other nerves in the left hip and leg were cut except nerves of the muscle. A cat was fixed on a frame mounted securely on an animal tablet and the calcaneus was attached firmly by a metal. The dorsal and ventral roots between L6 and S1 were exposed by the conventional 1aminectomy. Thin afferent and efferent filaments were hooked on each pair of electrodes at about 20mm from their entry into the spinal cord and motoneuron activity was recorded by antidromic electric stimulations of motor nerve. An afferent fiber (over 80m/s) was identified as a spindle ending Ia by their behavior during twitch contraction of the muscle elicited by stimulating its nerves. Impulses of single Ia and intracellular neuron activities were recorded simultaneously while tendon of medial or lateral gastrocnemius muscle or soleus muscle was stretched by 100Hz vibration of amplitude 100μm for 0.5 sec every 2 sec and vibration was repeated 5 times. The muscle was contracted by electric single shock stimulations before stretches. Ia impulses were classified into three types corresponding to a sensitive cyclic phase of sinusoidal stretch at which Ia impulses were elicited. Impulse

of acceleration sensitive Ia was discharged at initial phase of vibratory stretch and elicited a motoneuron spike. Velocity sensitive and displacement sensitive Ia impulses were driven while the muscle was stretched in 37 cycles. Latency of velocity sensitive Ia impulses from the vibratory stretches was 4.26±0.05ms and latency of displacement sensitive Ia was 4.92±0.05ms in 37 cycles. All of EPSPs and initial serial 4 spikes of motoneuron were driven by Ia impulses which was induced by 100Hz vibration. But spikes of motoneuron appeared intermittently every 2 or 3 Ia impulses except initial 50ms during 500ms vibration. It is suggested that velocity sensitive Ia impulses elicit motoneuron spikes rapidly in early period when muscle is stretched but motoneuron activity is inhibited gradually by some reflexive inhibitory mechanism as stretches are repeated although physical property of primary endings is not changed during vibration.

Renal denervation decreases alpha 1 adrenergic receptor protein in the renal cortex of rabbits with chronic heart failure

A. Schiller, K.K. Haack, P.L. Curry and I.H. Zucker

University Nebraska Medical Center, Omaha, NE, USA

Chronic heart failure (CHF) is a disease characterized by an overactive sympathetic nervous system. The kidney is especially vulnerable to this adaption and responds with a decrease in mean renal blood flow (MRBF). To assess any possible alpha-1 adrenergic receptor (A1ADR) mediated contributions to this response we instrumented male New Zealand White rabbits with ventricular pacing leads, surgically removed the renal nerves from one kidney and implanted radiotelemetry to record mean arterial pressure (MAP). To perform these surgeries rabbits were anesthetized with a combination of Ketamine (35 mg/kg), Rompun (5.8 mg/kg) and atropine sulfate (0.01 mg/kg) given IM and followed by Forane gas anesthesia (0.5-3.0%). CHF was induced by rapid ventricular pacing at 380 bpm and validated by echocardiography. Values are means ± S.E.M., compared by an unpaired t-test. In rabbits with CHF (n = 5) we found that removing the renal nerves (n =5) significantly increased MRBF (23.3 ± 3.7 vs. 34.1 ± 2.3, $P < .05$) at resting MAP compared to rabbits with CHF and intact renal nerves (n = 5). In order to assess contribution of A1ADR stimulation in MRBF control, 100 mg/kg phenylephrine (A1ADR agonist) was infused IV at 0.25 ml/min. At 100 mmHg MRBF in CHF rabbits remained decreased compared to CHF rabbits without renal nerves (13.1 ± 0.9 vs. 21.9 ± 2.3 intact and denervated, respectively, $P < 0.5$). At the completion of the study the kidneys were removed and native membrane proteins were extracted from cortical tissue. Levels of A1ADR receptor were determined by standard western blot technique. Intact rabbits with CHF expressed significantly higher levels of A1ADR (5.7 ± 1.5; A1ADR/total protein) compared to CHF rabbits without renal nerves (1.8 ± 0.3, $P < .05$). These data suggest that chronic removal of the renal nerves in animals with CHF contributes to increases in MRBF, in part, by down-regulation of AD1ADR in the kidney.

Analgesic and anti-inflammatory effects of honey is modulated by alpha-1 adrenergic antagonist

B.V. Owoyele and K. Ajomole

Department of Physiology, University of Ilorin, Ilorin, Nigeria

Honey is used variously as food, flavour, energy source and medicine. Its medicinal effects continue to be subjects of research. Such investigations include the effects of honey on wound healing, inflammation and pain (1,2). We previously reported its anti-inflammatory and nitric oxide inhibitory effects (2). Therefore, the present study was designed to investigate whether tamsulosin an alpha 1 blocker has effect on the anti-inflammatory and analgesic effects of honey. Rats used for both analgesic and anti-inflammatory studies were divided into five similar groups. These groups comprises of five rats each. Group A and B received saline and indomethacin (5mg/Kg) respectively, while group C received tamsulosin (3μg/kg) only, group D received honey (200 mg/Kg) and tamsulosin, group E received honey (600mg/Kg) and tamsulosin. All drugs were administered orally, pain was accessed chemically using the formalin paw licking model and thermally using the hot plate latency assay. Acute inflammation was accessed using carrageenan induced paw oedema. Values are means ± S.E.M. and statistical analysis was by ANOVA. The results showed that tamsulosin demonstrated analgesic effects in the formalin model by reducing the licking time in the early phase from 96.40±9.27 to 43.40±8.49s ($p<0.05$) and in the late phase from 79.0±8.26 to 46.20 ± 10.78s ($p<0.05$). It also enhanced the analgesic effect of honey in this model especially in the late phase for the 200 mg/Kg (control: 79.0±8.26 vs honey: 13.60± 2.34s, $P<0.05$) . However, both honey and tamsulosin did not produce analgesic effect in the hot plate test. In the anti-inflammatory study, tamsulosin did not produce anti-inflammatory effect but it abolished the anti-inflammatory effect of honey when administered together. The findings from this study show that alpha 1 adrenoceptor has the capacity to enhance the analgesic effect of honey in chemically induced pain but it inhibits its anti-inflammatory effects. On the other hand honey may be promoting its anti-inflammatory effects partly by stimulating alpha 1 adrenoceptor. Therefore, caution should be taken if subjects are receiving alpha-1 adrenergic blockers concurrently with honey administration especially if honey is been administered for the treatment of inflammatory conditions.

Electrophysiological study of voltage-gated ion channels in photoreceptors and bipolar cells in the human retina

E. Miyachi[1], F. Kawai[1], M. Ohkuma[1] and M. Horiguchi[2]

[1]Department of Physiology, Fujita Health University School of Medicine, Toyoake, Japan and [2]Department of Ophthalmology, Fujtia Health University School of Medicine, Toyoake, Japan

The photoreceptors and bipolar cells in the vertebrate retina were considered non-spiking neurons. However, we showed that human photoreceptors can generate sodium action potentials in response to membrane depolarization (Kawai *et al*, 2001). In this study, we performed physiological and molecular biological analyses to confirm the presence of the sodium channel in photoreceptors and bipolar cell in the human retina. A small piece of retina was excised from each of 15 adult patients with a fresh retinal detachment during the surgical procedure to reattach the retina. In the standard vitreous surgery to reattach a detached retina, the fluid between the detached retina and the retinal pigment epithelium is removed through an artificial retinal hole that is made during surgery. To make the artificial hole, a small piece of retina (diameter 1 mm) had to be exercised, and this piece was used in our experiment. The estimated time between retinal detachment and surgery was 2 days. In all cases, functional recovery of the retina occurred after surgery, indicating that there was no severe pathology of the retina. All experiments were performed in compliance with the guideline of the Declaration of Helsinki and the ethics committee of Fujita Health University. All patients were informed of the purpose of the surgery and the necessity of removing the retinal tissue, and signed informed consent to allow the use of the tissue for these experiments. The SCN2A, the type II sodium channel ($Na_v1.2$) transcript, was observed in photoreceptors and bipolar cells by single-cell RT-PCR analysis. Under voltage-clamp conditions, depolarizing voltage steps induced fast transient inward currents, which were inactivated within 5 ms and blocked by a voltage-gated sodium channel blocker tetrodotoxin, in several bipolar cells, as well as rods and cones. These results indicate that human photoreceptors and bipolar cells express $Na_v1.2$ voltage-gated sodium channels, and suggest that the sodium channels may serve to amplify the release of the neurotransmitter when membrane potential is depolarized. We also observed the hyperpolarization-activated current, the h current (I_h), in human rods. Dopamine reversibly decreased the amplitude of the I_h induced by hyperpolarizing voltage steps. The D2 dopamine agonist inhibited I_h, but the D1 agonist had no effect. Dopamine-induced reduction of I_h amplitude was blocked by the D2 dopamine antagonist. These results suggest that dopamine reduced I_h through a D2 receptor and that dopamine slows the recovery phase of responses to light stimuli by inhibiting I_h in human rods. We consider that I_h may contribute to preventing visual flickering by inhibiting the generation of spontaneous Na^+ spikes in human photoreceptors.

PCD142

Salicylate enhances depolarization suppression of excitation in cartwheel neurons from the dorsal cochlear nucleus of the rat

J. Zugaib and R.M. Leao

Physiology, University of São Paulo, Ribeirão Preto, SP, Brazil

Intoxication by sodium salicylate induces tinnitus in both humans and experimental animals. Tinnitus, in most cases, is caused by central mechanisms leading to hyperactivity of some central auditory regions, in special the fusiform neurons of the dorsal cochlear nucleus (DCN) in the brainstem. One hypothesis for the origin of hyperactivity is an unbalance of the inhibitory and excitatory neurotransmission in auditory areas. Salicylate inhibits the enzyme cyclooxygenase 2 which takes part in the oxidative degradation of endocannabinoids. Here we are testing the hypothesis that salycilate interferes with endocannabinoid mediated synaptic plasticity in the DCN. For this we tested the effect of sodium salicylate on the phenomenon of depolarization suppression of excitation (DSE) in parallel fibers (PF) synapses on glutamatergic fusiform and glycinergic cartwheel neurons of the DCN, which is mediated by endocannabinoids. Brain slices were prepared from 18 to 22 days old Wistar rats, and glutamatergic neurotransmission was elicited by stimulating the (PF) with a bipolar electrode, in the presence of picrotoxin and strychnine to block inhibitory neurotransmission. Post-synaptic currents were recorded at -80 mV in whole-cell voltage clamp. DSE was produced by a depolarization to 0 mV with duration of 0.5, 1, 2 and 4 seconds. As reported in mice DSE was stronger in cartwheel than in fusiform neurons (maximum DSE at 4 seconds: cartwheel 41 ± 5%; fusiform 21 ± 5%. N = 19 and 12 respectively. P = 0.0002, 2-way ANOVA). Incubation of the slices with sodium salicylate (NaSal, 1.4 mM) for at least 1 hour before the recording did not affect the PF-evoked EPSC amplitude either in cartwheel (control: -414 ± 60 pA; NaSal: -756 ± 207 pA; n=12 and 18 respectively, p=0.08, t-test) and fusiform neurons (control: -454 ± 104 pA; NaSal: -404 ± 66 pA; n=8 and 10 respectively. p=0.68, t-test). However, salicylate enhanced the DSE in cartwheel neurons significantly ($p<0.05$, 2-way ANOVA; n=9) but not in fusiform neurons. Maximum DSE after 4 seconds depolarization in cartwheel neurons was not affected by salicylate, but was attained earlier after 2 seconds depolarization (control 26 ± 5 %; NaSal: 43 ± 7%; p = 0.05, t-test). Acute applications of salicylate produced similar changes in the DSE profile of cartwheel neurons but again did not affect DSE in fusiform neurons. We conclude that sodium salicylate in concentrations similar to found in the cerebrospinal fluid after tinnitus-inducing salicylate intoxication is able to enhance DSE in DCN's cartwheel neurons. Since cartwheel neurons produces feed forward inhibition onto fusiform neurons, an increased DSE can weakens inhibition during high frequency trains of firing from the PF and can contribute for generating hyperactivity in the fusiform neurons after salicylate intoxication.

PCD143

Comparative study on the dopaminergic D_1 and D_2receptor modulation of the electroretinographic responses in the dark-adapted frog retina

E. Popova and P. Kupenova

Physiology, Medical University, Sofia, Bulgaria

Dopamine plays an important role in visual function and retinal sensitivity control. Its actions are mediated through two subfamilies, D_1- and D $_2$-class receptors that are positively and negatively linked to adenylyl cyclase, respectively. However, the data about the specific D_1- and D $_2$-class receptor contribution to retinal responses to light increments and decrements (ON and OFF responses, respectively) are contradictory. A possible explanation might be that many of the results were obtained using non-selective dopamine antagonists and within a limited stimulus intensity (I) range. In this work, the effects of selective blockade of D_1-class receptors by 10 μM SCH 23390 and D $_2$-class receptors by 40 μM sulpiride applied in isolation or in combination on the intensity-response (V - log I) functions of the electroretinographic (ERG) ON (b-wave) and OFF (d-wave) responses were studied. The electroretinograms were obtained from dark-adapted frog eyecup preparations (Rana ridibunda; for details see Popova and Kupenova, 2009). By using a very wide range of stimulus intensities (11 log units, $I_{max} = 6 \times 10^8$ quanta. s^{-1}. μm $^{-2}$), we obtained both rod- and cone-dominated responses. During the isolated D_1-class receptor blockade by SCH 23390, the amplitude of both the b- and d-wave was increased (Two-way ANOVA $p<0.000001$, $n=10$). During the isolated D_2-class receptor blockade by sulpiride, a significant enhancement of the b- and d-wave amplitude was seen in the lower intensity range, where rod-dominated responses were obtained (Two-way ANOVA, $p<0.00003$, $n=11$). The amplitude of the two waves was, however, diminished in the higher intensity range (It > -5), where cone-dominated responses were obtained (Two-way ANOVA, $p<0.0000002$). A similar effect on the b-, but not d-wave amplitude was seen during the combined application of SCH 23390 and sulpiride. The d-wave amplitude was enhanced over the whole except for the highest intensity range (It > -3.5) during the combined D_1 and D_2 receptor blockade ($n=15$). The results obtained indicate that the endogenous dopamine has an overall inhibitory action on the rod-mediated ERG ON and OFF responses, but its action on the cone-mediated responses shows clear ON-OFF asymmetry. It is excitatory upon the ON responses, but inhibitory upon the OFF responses except for those in the highest intensity range. Participation of different types of dopamine receptors (predominantly D_2-class for the ON versus D_1-class for the OFF response) is probably responsible for this difference.

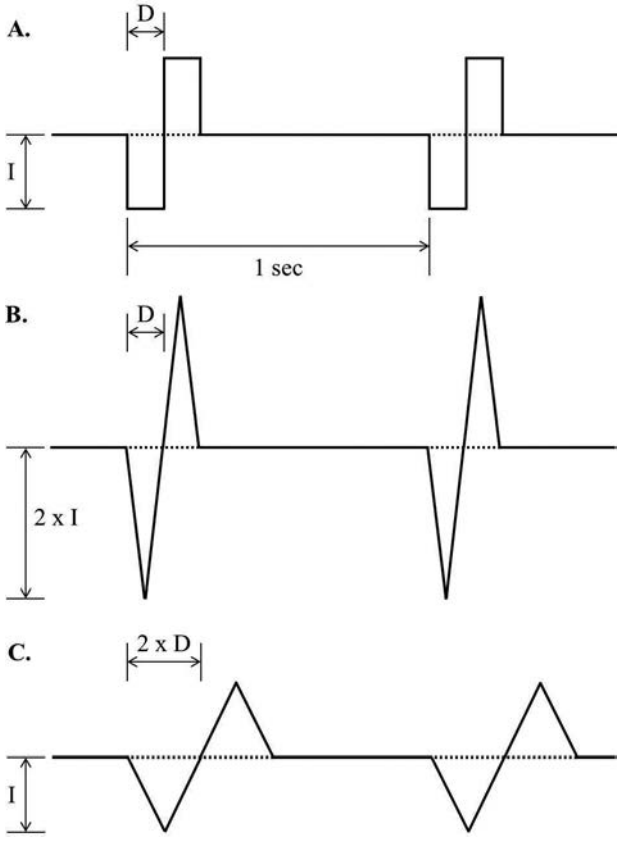
Comparison of rectangular pulse and triangular pulse on evoking retinal ganglion cell responses in retinal degenerated (*rd1*) mice

Y. Goo[1,2], K. Ahn[1,2], W. Lee[1,2] and J. Kim[1,2]

[1]Physiology, Chungbuk National University School of Medicine, Cheongju, Republic of Korea and [2]Nano Artificial Vision Reserch Center, Seoul, Republic of Korea

Retinal prosthesis has been developed for the patients with retinitis pigmentosa (RP) and age related macular degeneration (AMD), and is regarded as the most feasible method to restore vision [1-2]. Extracting optimal electrical stimulation parameters for the prosthesis is one of the important prerequisites for the success of retinal prosthesis. Previously, we proposed the optimal stimulation parameter range (e.g. amplitude, duration) for evoking retinal ganglion cell (RGC) responses using rectangular pulse shape in wild-type and *rd1* mice [3]. Traditionally, rectangular pulse shape has been the choice for neural stimulation. Not much attention has been paid to alternative pulse shapes. Therefore, we investigated pulse shape effect on evoking RGC responses. The well-known animal model for RP, *rd1* (*Pde6b* ^{rd1}) mice [4] at postnatal 8 weeks and after were used. From the *ex-vivo* retinal preparation, retinal patches were mounted on planar 8x8 microelectrode array (MEA), ganglion cell layer down onto the MEA mimicking the epiretinal prosthesis configuration. While applying current stimulus through one channel of MEA, retinal waveforms were recorded with remaining channels of MEA. Biphasic-charge balanced current pulses in the form of cathodic phase-1st and anodic phase-2nd were applied once per second (1 Hz, x 50). We tested 3 different pulse shapes with same charge; 1) biphasic rectangular pulse (I: intensity, D: duration), 2) biphasic triangular pulse with double intensity (2xI, D), 3) biphasic triangular pulse with double duration (I, 2xD). For intensity modulation, duration of the pulse was fixed to 500 μs and the intensities of the pulses were modulated from 5 to 40 μA. For duration modulation, pulse amplitude was fixed to 30 μA and the pulse durations were modulated from 60 to 500 μs. The electrically-evoked RGC spikes was defined as positive when the number of RGC spikes for 400 ms after stimulus was 1.3 times higher than that for 400 ms before stimulus in post-stimulus time histogram. RGC responses were well modulated both with rectangular and triangular pulse by varying the amplitude and duration of the pulse. Amplitude modulation shows that RGC response is preferentially activated by biphasic triangular pulse with double duration especially with 5 and 10 μA amplitude ($p<0.001$). Duration (D) modulation shows that RGC response is preferentially activated by triangular pulse with double duration especially with 60 and 100 μs ($p<0.001$), while triangular pulse with double amplitude is most efficient at 200 μs pulse duration ($p<0.001$). Now, we are comparing the stimulus threshold among three different pulse shapes in this study.



A. Rectangular pulse, B. Triangular pulse with intensity doubled, C. Triangular pulse with duration doubled.

Localization of the chemokine receptor XCR1 in rat spinal and nucleus caudalis (Vc) trigeminal dorsal horn: A novel regulator of nociception?

I. Obara[1,2], C. McDonald Wood[1], M. Singh[1], F.M. Boissonade[3] and A.E. King[1]

[1]School of Biomedical Sciences, University of Leeds, Leeds, UK, [2]School of Medicine, Pharmacy and Health, University of Durham, Durham, UK and [3]Deptartment of Oral and Maxillofacial Medicine and Surgery, University of Sheffield, Sheffield, UK

Chemokines are expressed by immune cells and cause monocyte extravasation at a site of tissue injury. They are divided into 4 families; CC, CXC, C and CX3C. There is evidence for involvement of several chemokines in pain mechanisms, notably CX3CL1, CCL2 and CX3C (Old & Malcangio, 2012). Their role is not fully understood but they are linked to mechanisms of neuron-glia communication and altered excitability of pain pathways following neuropathic or inflammatory injury (Ren & Dubner, 2010). Lymphotactin (XCL1), the only member of group C, is chemotactic for lymphocytes and mediates its effects via its cognate receptor XCR1. The role of lymphotactin and XCR1 in nociception and pain is unknown. We have used immunohistochemistry to characterize expression of XCR1 within nociceptive areas of the adult rat spinal and trigeminal dorsal horn (DH).

All procedures were carried out in accordance with UK Home Office legislation. Under irreversible anaesthesia (pentobarbital, 50 mg/kg i.p.) and after transcardiac perfusion-fixation, the spinal trigeminal nucleus caudalis (Vc) of the caudal brainstem and spinal cords were removed from rats (Wistar, 28 days). Brainstem (caudal to obex) and spinal cord (cervical and lumbar) transverse sections (30 μm) were cut and processed for immunofluorescence visualization of XCR1 either alone or in co-labelling studies with the vesicular glutamate transporters VGLUT 1 or VGLUT2 which mark glutamatergic synaptic terminals. Confocal imaging of spinal cord sections revealed intense labelling for XCR1 within nociceptive DH laminae I and II. Similarly, intense XCR1 labelling was localized to the most superficial layers of Vc and was also within the spinal trigeminal tract (STt). The diffuse pattern of labelling was indicative of an axonal or fibre localization rather than in cell bodies. In double-labelling studies with either VGLUT1 or VGLUT2, labelling for XCR1 in either spinal or Vc DH overlapped extensively with VGLUT2 in superficial layers whereas VGLUT1 staining was distributed to deeper regions with little evidence of overlap. This pattern of staining infers that XCR1 may be expressed on either the terminals of excitatory DH interneurons or small diameter nociceptive primary afferents, putatively A-delta or C-fibre subtypes in these two CNS regions (Todd et al., 2003).

Taken together, these observations reveal, for the first time, the expression of XCR1 within structures that are key areas in the transmission and subsequent modulation of nociceptive signals that give rise to both acute and chronic pain. These data may have important implications for the role of novel chemokines in the pathogenesis of chronic pain, including trigeminal oro-facial pain.

PCD146

The cooperation of sustained and phasic inhibitions regulates the sensitivity to interaural time difference cue in the nucleus laminaris of birds

R. Yamada[1,2], H. Okuda[2], H. Kuba[1,3], E. Nishino[2], T.M. Ishii[2] and H. Ohmori[2]

[1]Department of Cell Physiology, Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Department of Physiology and Neurobiology, Kyoto University, Kyoto, Japan and [3]JST PRESTO, Saitama, Japan

Sensing the interaural time difference (ITD) of a sound is crucial in localizing the sound source particularly for low-frequency sounds. However, the range of ITD that animals experience is quite small and inhibitory synapses are proposed to be signi-

ficant in enhancing the ITD sensitivity. In birds, neurons in nucleus laminaris (NL) detect the coincidence of bilateral excitatory inputs from the cochlea nucleus and change their firing rate as a function of the ITD. Sound-intensity-dependent inhibition from superior olivary nucleus (SON) is known to have sustained effects in NL neurons and control the gain of coincidence detection, which makes the ITD sensitivity of NL neurons tolerant to strong-intensity sound. Here, we found a time-dependent phasic inhibition in chicken brain slices that follows the excitatory inputs from ipsilateral cochlea nucleus, sharpens coincidence detection and may enhance ITD sensitivity in low-frequency NL neurons. Coronal brainstem slices were obtained from post-hatch chickens and whole-cell recordings were made from NL neurons. The electrical stimulation to the ipsilateral projection fibers generated a polysynaptic IPSC that followed EPSC with 1~2 ms latency in the low-frequency NL neurons. These IPSCs were elicited even when SON was dissected out. GABA-positive small neurons are distributed in and near the NL and generated IPSCs in NL neurons when photoactivated by a caged glutamate compound. These results suggest that these GABAergic neurons are interneurons that mediate phasic inhibition to the NL neurons. Consistently, these IPSCs have fast decay kinetics that is attributable to the α1 subunit of GABAA receptor, the expression of which dominates in the low-frequency region of the NL. Model simulations demonstrate that phasic IPSCs narrow the time window of coincidence detection and increase the contrast of ITD-tuning during the low-level excitatory input. These effects of phasic inhibition are prominent in the ITD-tuning of low-frequency sound. Furthermore, cooperation of the phasic and sustained inhibitions effectively increases the contrast of ITD-tuning over a wide range of excitatory input levels. We propose that the complementary interaction between phasic and sustained inhibitions is the neural mechanism that regulates ITD sensitivity for low-frequency sound in the NL.

VEGF165b attenuates hyperglycaemia-induced sensitisation of neuronal TRPA1 activation: implications for diabetic neuropathy

R.P. Hulse[1,2], H. Riaz[1], P. Singhal[1], D.O. Bates[1,2] and L.F. Donaldson[1]

[1]Physiology and Pharmacology, University of Bristol, Bristol, UK and [2]Microvascular Research Laboratories, University of Bristol, Bristol, UK

Diabetes is becoming a significant burden on global health care systems due to the onset of associated complications. A large proportion of diabetic patients develop neuropathy leading to chronic pain [1] as a result of glucose toxicity, which directly damages neurons. The transient receptor potential ankyrin 1 (TRPA1) channel has a fundamental role in the development of diabetic neuropathy resulting in pain and sensory neuronal loss in rodents [2]. We have demonstrated that vascular endothelial growth factor (VEGF) 165b has neuroprotective actions, and that systemic treatment of diabetic rats with the VEGF165b prevented development of diabetic neuropathy (enhanced nociception and loss of cutaneous nerve terminals) in vivo [3]. We therefore tested the hypothesis that TRPA1 activity in sensory neurons was altered by hyperglycaemia, and that VEGF165b could modify this.

Immortalised embryonic dorsal root ganglion cells [4] were incubated in neurobasal medium for 48hrs and differentiated by 24hr incubation in 75μM forskolin. Cells were then incubated in experimental media for 24hrs (+ 75 μM forskolin) as follows; normal neurobasal media (control), neurobasal media + additional 30mM glucose (hyperglycaemia); neurobasal media + 30mM glucose + VEGF165b (2.5nM) or neurobasal media + 30mM mannitol (osmotic control). Cells were loaded with fluo4 for 1hr at 37oC, and agonist-induced increases in intracellular calcium measured in response to 100μM allyl isothiocyanate (AITC; TRPA1 agonist).

Hyperglycaemia increased total AITC-induced calcium increase (0.92+0.068 fold change.s n=10; mean+SEM of area under curve) compared to control (0.43+0.20 fold change.s vs glucose n=10 $p<0.01$ one way ANOVA with post Bonferroni). No change was seen in the presence of 30mM mannitol (0.37+0.092 fold change.s). Treatment of cells with VEGF165b under hyperglycaemic conditions attenuated the response to AITC compared to hyperglycaemia alone (hyperglycaemia 0.92+0.068 fold change.s vs. hyperglycaemia + VEGF165b 0.33+0.16 fold change.s, $p<0.05$ n=4 Kruskal Wallis with Dunns multiple comparison).

These data demonstrate that agonist-activation of TRPA1 is enhanced by hyperglycaemia in vitro, and that this can be attenuated by treatment with the growth factor isoform VEGF165b. TRPA1 has been shown to contribute to diabetic neuropathy (neuronal loss and pain). We propose that VEGF165b may attenuate the consequences of diabetic neuropathy including nerve terminal loss and pain, through inhibition of hyperglycaemic sensitisation of TRPA1.

Electrophysiological characteristics of GABAergic neurons and localization of calcitonin receptor-like receptor in the mouse trigeminal subnucleus caudalis

S. Kuwana[1], Y. Hosokawa[2], T. Sugita[3], N. Umezawa[3], A. Matsumoto[3], H. Arisaka[3], K. Yoshida[3] and S. Sakuraba[3]

[1]Department of Physiology, Faculty of Health Sciences, Uekusa Gakuen University, Chiba City, Japan, [2]Department of Anesthsiology, Kitasato University School of Medicine, Sagamihara City, Japan and [3]Division of Anesthesiology, Department of Clinical Care Medicine, Kanagawa Dental College, Yokosuka City, Japan

The trigeminal subnucleus caudalis (SpVc) plays a crucial role in relaying inputs from the primary nociceptive afferents within the orofacial area to higher brain centers. In the SpVc, the central endings of most of primary afferents are located and release excitatory neurotransmitters and neuropeptide such as glutamate, substance P and calcitonin-gene related peptide (CGRP) in response to noxcious stimuli, which can lead excitation in the second-order nociceptive neurons (Sessle et al., 2000). We showed previously that GABAergic neurons densely distributed in the SpVc using the glutamic acid decarboxylase (GAD) 67-green fluorescence protein (GFP) knock-in neonatal mice (Kuwana et al., 2006). In the present study, we investigated the electrophysiological characteristics of GABAergic

and non-GABAergic neurons, and the relationship between localization of CGRP receptors (calcitonin receptor-like receptor, CRLR) and GABAergic neurons in the SpVc of GAD67-GFP knock-in mice. The mouse was deeply anesthetized with diethyl ether and the brainstem was isolated. We recorded activities of GFP-positive (GABAergic, n=20) and GFP-negative (non-GABAergic, n=33) neurons by whole-cell patch clamp technique in the sagittal slice of brainstem attaching the trigeminal nerve rootlet. Electrical stimulations to the trigeminal nerve rootlet evoked excitatory postsynaptic potentials (EPSPs) in most of cells from both groups (20 GFP-positive and in 31 GFP-negative neurons). On the other hand, inhibitory postsynaptic potentials (IPSPs) were not frequently evoked especially in GFP positve neurons (3 in GFP-positive and 13 in GFP-negative neurons). In morphological study, most GFP-positive neurons had multipolar-shaped somata (n=8/10) while GFP-negative neurons had bipolar (n=5/10) or triangular (n=5/10) somata. However, there is no difference in the size of neurons between groups. These data show that GABAergic neurons characterized by multipolar-shaped somata in the SpVc received exclusively excitatory postsynaptic inputs in response to electrical stimulation. Furthermore, we investigated the localization of CRLR by immunohistochemical technique in the SpVc. The CRLR-immunoreactions appeared in about 30% of GFP-positive neurons and some GFP-negative neurons of the SpVc, suggesting that the CRLR-immunoreactive neurons are second-order of nociceptive neurons in the SpVc. Therefore, we conclude that the excitatory synaptic input to GABAergic neuron may be induced by glutamate and CGRP because the primary afferent terminals containing glutamate form synapses with the dendrites of GABA neurons (Iliakis et al., 1996).

PCD149

An illusion of grasping your own finger

S. Gandevia[1,2], L. Walsh[1,2], A. Butler[1,2] and M. Héroux[1,2]

[1]Neuroscience Research Australia, Randwick, NSW, Australia and [2]University of New South Wales, Randwick, NSW, Australia

Accurate movement requires the CNS to use proprioceptive information about the joints of the body, the interrelations between body parts and knowledge of which parts belong to the body. Muscle spindle signals can contribute to determine which parts 'belong' (Walsh et al. J Physiol 2011: 589, 2009). With vision excluded, 20 subjects estimated the perceived vertical distance between the test right index finger and their left index finger when positioned ~12 cm apart. Subjects selected a line from a chart containing multiple vertically oriented lines varying from 0 to 20 cm in length. The subject's left index finger and thumb were located near a realistic artificial finger or were positioned by an experimenter to grasp the artificial finger. Studies were repeated with and without digital nerve blocks.

Perceived vertical spacing was 8.2 [6.0, 10.0] (median [IQR]) cm with no grasp of the artificial finger, and this was significantly less than the absolute distance of 12 cm ($p<0.05$). Perceived spacing diminished markedly during the passive grasp of the artificial finger (4.0 [2.0, 8.0] cm, $p<0.05$). Some subjects reported that they were holding their own right index finger, showing evidence of ownership over the artificial finger. This 'finger grasp' illusion was similar if the test index finger was anaesthetised. However, in separate experiments, the 'finger grasp' illusion was not present when the grasping left index and thumb and the test right index finger were anaesthetised ($p>0.05$), or when the artificial finger was replaced with a piece of wood ($p>0.05$).

In conclusion, passive tactile inputs which are consistent with holding a real finger are able to induce a sense of ownership of an artificial finger. These inputs can change the central representation of the body and the perceived position of the hands.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD150

Spatial- and motion selectivity of population responses in primate area MT

S.C. Chen[1,2], J.W. Morley[3] and S.G. Solomon[4,2]

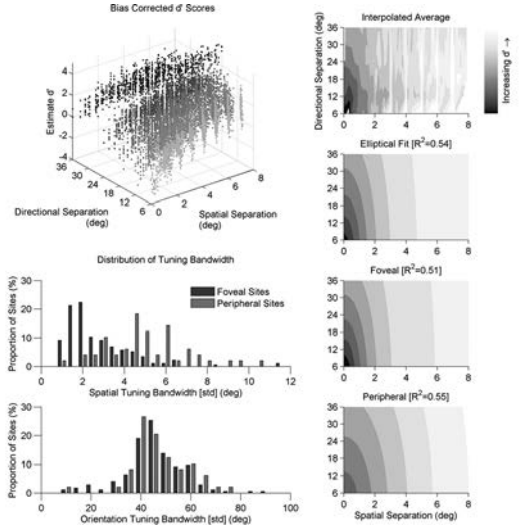
[1]School of Medical Sciences, University of Sydney, Sydney, NSW, Australia, [2]ARC Centre of Excellence in Vision Science, Sydney, NSW, Australia, [3]School of Medicine, University of Western Sydney, Campbelltown, NSW, Australia and [4]Institute for Behavioural Neuroscience, University College London, London, UK

Neurons in primate visual cortical area MT show precise visuotopic organisation and are known to be highly sensitive to motion direction. It is generally thought that the large receptive fields of these neurons make them incapable of providing precise signals for spatial position. The spatial precision of neuronal populations depends, however, on both receptive field size and the extent of overlap in receptive fields. Here we directly compare spatial- and motion selectivity of area MT by measuring from populations of MT neurons.

Recordings were made in area MT from marmosets (Callithrix jacchus) (n=3). The animals were anaesthetised throughout the duration of the experiment (induction: 12 mg/kg Alfaxan, i.m., maintenance: 6-12 μg/kg/hr sufentanil, i.v.) and artificially ventilated through a tracheostomy. Muscular paralysis was then used to prevent eye movements (0.3 mg/kg/hr pancuronium bromide, i.v.). Level of anaesthesia was established by continuous monitoring of EEG and ECG; anaesthesia was taken as dominance of low frequencies (< 5Hz) in EEG and absence of changes in EEG/ECG during application of noxious stimuli (paw pinch). A craniotomy was made and an electrode array (10x10) implanted in and around area MT in one hemisphere of the animal. The visual stimulus was a white disc moving along each of several possible linear trajectories at 20 °/s. Multi-unit activity at each electrode was counted in 0.05 s bins. Linear support vector machines (SVM) were used to establish whether neural activity in area MT was able to discriminate between pairs of spatial locations up to 8° apart, along trajectories that differed in motion direction by up to 36°. Dis-

criminability depended on a combination of both factors. An elliptical surface fit to the data indicates that for moving objects an average 1.69° (±.04, 95%CI) difference in spatial position was as discriminable as a 30° change in motion direction. Tuning curve width of these neurons was on average 3.2° (±2.0, s.d.) in space and 45.7° (±12.1, s.d.) in motion direction. Receptive fields of neurons in area MT are smaller when close to the fovea, and the performance of the SVM paralleled this. Near the fovea, a separation of 1.48° (±.06, 95%CI) was required, and in the periphery a separation of 2.13° (±.27, 95%CI) was required, to match performance for a 30° change in motion direction.

We conclude that populations of neurons in area MT provide signals for spatial position that are as precise as the signals they provide for motion direction. In addition our analyses show that while neurons show broad tuning for spatial position and motion direction, overlap in these dimensions allows precision in the population response. We speculate that the combination of broad tuning and high overlap is an efficient mechanism for simultaneous encoding of multiple dimensions of visual analysis.



Discrimination (d') depended on a combination of spatial and directional separation. An elliptical fit was used to describe the relationship. The elliptical ratio depended on the eccentricity of the visual space, related to the difference in receptive field sizes.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD151

Visual evoked potential in primary open angle glaucoma patients

B. Paudel[1], M. Jha[2], B. Badhu[3], N. Limbu[4] and D. Thakur[5]

[1]Basic and Clinical Physiology, BP Koirala Institute of Health Sciences, Dharan, Nepal, [2]Physiology, Kathmandu University School of Medical Sciences, Kavre, Nepal, [3]Ophthalmology, BP Koirala Institute of Health Sciences, Dharan, Nepal, [4]Basic and Clinical Physiology, BP Koirala Institute of Health Sciences, Dharan, Nepal and [5]Basic and Clinical Physiology, BP Koirala Institute of Health Sciences, Dharan, Nepal

Visual evoked potential (VEP) is used to assess the functional integrity of the visual pathway. We studied VEP and other ophthalmic variables in clinically diagnosed primary open angle glaucoma (POAG) patients (n=20 eyes) and compared with health controls (n=40 eyes) with an objective of whether POAG causes any neuro-ophthalmic damage. Their age ranged from 38 to 74 years. Pattern reversal (checker board) VEP latency and amplitude; and refractive error, cup disc ratio, intraocular pressure, automated visual field pattern, visual acuity, and foveal visual sensitivity were recorded. The patients were on beta blocker (timolol) for intraocular pressure control. The patients with history of head injury or stroke, on drugs that might affect VEP, secondary glaucoma, diabetes mellitus, media opacity, amblyopia, aphakia, strabismus, high myopia or refractive error, macular degeneration, maculopathy, age-related macular degeneration, non-glaucomatous optic abnormality, & any retinal disorder other than due to glaucoma were excluded from the study. The study was approved by the institute ethical committee. Since some of the variables were not normally distributed Mann-Whitney U test was used to compare the cases and controls. The variables are expressed as mean and standard deviation. Both the groups were comparable in terms of BMI (23.27±1.82 vs. 22.1.47, kg/m sq., p=NS). In POAG cases, the refractive error (3.51±1.88 vs. 1.88±1.11, D, p<0.001), cup disc ratio in percentage (66.00±16.98, vs. 28.50±5.80, p<0.001), intraocular pressure (19.55±2.08 vs. 11.65±1.64, mmHg, p<0.001) and automated visual field pattern standard deviation (4.13±6.96 vs. 1.64±0.45, dB, p<001) were significantly more than in controls. However, the visual acuity (0.41±0.29 vs. 1.00±0.01, p<001), foveal visual sensitivity (25.92±6.88 vs. 33.48±1.75, dB, p<0.001), and automated visual field mean deviation (-9.63±10.59 vs. 0.07±1.54, dB, p<0.001) were significantly less in cases than in controls. Among VEP variables, pattern reversal latency of N145 ((149±15.75 vs. 137.52±15.20, ms, p<0.01) was more in cases than in controls. The amplitudes (microV) of pattern reversal VEP of N45 (1.97±0.35 vs. 2.47±0.58, p<0.001), P100 (3.09±0.46 vs. 6.07±1.44, p<0.001) and of N145 (2.21±0.58 vs. 4.45±1.99, p<0.001) were less in cases as compared to controls. It is concluded that primary open angle glaucoma caused marked deterioration in visual functions including prolongation of VEP latency and reduction in amplitude.

All the patients and the control volunteers of the study.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD152

Coupling between apical inner hair cells of the adult mouse cochlea

A.M. Garcia de Diego[2], P. Sirko[2] and J. Ashmore[1,2]

[1]Neuroscience, Physiology & Pharmacology, UCL, London, UK and [2]UCL Ear Institute, UCL, London, UK

The mammalian cochlea contains a population of sensory cells, inner hair cells (IHCs), which act as the input cells to the auditory system. The IHCs signal to the auditory system through ribbon synapses, each cell having multiple release sites onto single auditory neurites. It is generally thought that the sharp neural tuning seen in single fibres in hearing animals reflects the selectivity of individual IHCs. Using a preparation which allows recording from adult hair cells, rather than immature systems more conventionally used, we have employed a fluorescent probe to investigate calcium signalling at the IHC synapse by using simultaneous multiphoton confocal imaging and cell recording.

Cochlear inner and outer hair cells were visualised in the intact isolated temporal bone from mice aged between P25 and 10 months. Animals were killed by rapid cervical dislocation in accordance with UK legislation and guidelines. The apical cochlea was opened to reveal the 10-15 kHz cochlear region with the cells placed in identifiable positions and orientation. The tectorial membrane was removed to allow recording and the chamber was superfused with (in mM) Na, 140; Ca, 1.3; K, 4; Cl 147, hepes 10, phosphate 0.7 to pH 7.3 at room temperatures. Cells were recorded in the whole cell tight seal mode, the pipette including 0.5, 5 or 10 mM EGTA and 0.25 mM OGB5N. Cs was used to reduce large outward currents to less than 1.5 nA at 0 mV.

These recordings showed distinct calcium entry sites, 'hotspots', when the IHC was depolarized to 0 mV from -60 mV. The kinetics of the Ca rise and fall often slowed with extended recording time over 10 mins. After OGB5N loaded for 3-5 mins it was also often found that a proportion of neighbouring cells appeared to be fluorescently loaded. Up to 9 adjacent cells could be found filled with OGB5N. Recording time constants in such cases exceeded the single cell values and could be modelled on the assumption that the cells were electrically coupled with an intercellular resistance of less than 10 megohms. Calcium responses imaged in such coupled IHCs showed that the kinetics generally differed from that of the recorded cell, suggesting that the coupling did not permit the movement of large Ca buffers between cells.

The present data thus indicate that adult IHCs can be coupled. The extent of the observed coupling would not significantly degrade the frequency selectivity of individual auditory nerves, at least in low frequency fibres, but may increase the signal/noise ratio in the pathways leading from the apical cochlea.

Antinociceptive and anti-inflammatory effects of essential oil of Nepeta pogonosperma Jamzad et Assadi in Wister rats

T. Ali[1,2], M. Javan[2], A. Sonboli[3] and S. Semnanian[2]

[1]Physiology, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh, [2]Physiology, Tarbiat Modares University, Tehran, Islamic Republic of Iran and [3]Biology, Shahid Beheshti University, Tehran, Islamic Republic of Iran

Concerning the variability of effectiveness of essential oils from different species of Nepeta genus on CNS including analgesia, this study was designed to evaluate antinociceptive and anti-inflammatory effects of essential oil of Nepeta pogonosperma Jamzad et Assadi (NP). Air-dried aerial parts of NP were hydrodistillated and GC-MS analysis of obtained essential oil was conducted. Total 24 male Wister rats (225±25gm) were taken care according to international guidelines on use of laboratory animals and studied. Experimental rats received 50, 100 and 200mg/kg of NP essential oil and control rats received equal volume (2ml/kg) of normal saline intraperitoneally (n=6/group). Antinociception was assessed by tail flick test (D'Amour and Smith, 1941) followed by formalin test (50 μl of 2% formalin, subcutaneously) using a modification of original formalin test protocol (Dubisson and Dennis, 1997). Euthanasia was done by di-ethyl ether (99%, 10-12ml) followed by decapitation (Zschenderlein et al. 2011) and anti-inflammation was measured by water plethysmometry (Fereidoni et al. 2000). Data were mean±SEM and analyzed by ANOVA with Tukey's post-hoc test. NP essential oil consisted of 4aα,7α,7aα nepetalactone (14.5%) and 1,8 cineole (31.2%) mainly. In tail flick test, 50mg/kg (10.25±8.06 vs. 11.04±5.9%) did not produce any analgesia, but 100 (26.99±2.79%; p<0.01) and 200 (43.98±7.73%; p<0.001) mg/kg reduced pain significantly. In early phase of formalin test, all doses reduced jerking frequency/5min (50mg/kg=78.66±20.67; 100mg/kg=64.5±15.47; 200mg/kg=30.83±7.16; control=201.33±14.01; p<0.001, in all doses), flexing seconds/5min (50mg/kg=62.5±20.24; 100mg/kg=65.33±18.31; 200mg/kg=50.5±21.14; control=148±21.57; p<0.05, p<0.05, p<0.01, respectively) and licking seconds/5min (50mg/kg=28.83±17.97; 100mg/kg=23.66±7.56; 200mg/kg=4.33±3.94; control=82±8.95; p<0.05, p<0.001, p<0.001, respectively). Again, in late phase of formalin test, all doses reduced jerking frequency/5min (50mg/kg=45.79±7.54; 100mg/kg=34.42±7.75; 200mg/kg=38.48±7.08; control=112.03±10.53; p<0.001, in all doses), flexing seconds/5min (50mg/kg=60.59±21.53; 100mg/kg=76.07±27.69; 200mg/kg=40.94±26.19; control=224.06±20.43; p<0.001, p<0.01, p<0.001, respectively) and licking seconds/5min (50mg/kg=12.83±3.22; 100mg/kg=18.46±4.78; 200mg/kg=5.66±1.66; control=33.03±3.83; p<0.01, p<0.05, p<0.001, respectively). Moreover, all doses reduced paw edema in % of control (50mg/kg=0.21±0.04, nonsignificant; 100mg/kg=0.13±0.02, p<0.01; 200mg/kg=0.2±0.03, p<0.05). This study reveals that NP essential oil may minimize both acute and chronic forms of nociception and may have potent role against inflammation.

Effect of vitamin B12 on pain and inflammation in Long Evans rats

M. Imtiaz, N. Begum and T. Ali

Physiology, Bangabadhu Sheikh Mujib Medical University, Dhaka, Bangladesh

Concerning the analgesic and anti-inflammatory effects of combination of Vitamin B12 with other B Vitamins or traditional drugs, this study was designed to evaluate the effect of Vitamin B12 alone on nociceptive pain, inflammatory pain and inflammation. Total 24 male Long Evans rats (225±25gm) were taken care according to international guidelines on use of laboratory animals and divided into two groups. Single supplemented rats (n=12) were intraperitonialy treated with a single dose of 15 mg/kg B12 (n=6) or equal volume (15 ml/kg) of normal saline (n=6). Similarly chronic supplemented rats (n=12) were divided into normal saline (n=6) and B12 (n=6) groups with same dose and route of treatment per day for consecutive 7 days. Analgesia was assessed by warm water (±55 degree

Celcius) tail immersion test (Steinmiller and Young 2007) followed by formalin test (50 μl of 2% formalin, subcutaneously) using a modification of the original formalin test protocol (Dubisson and Dennis, 1997). Euthanasia was done by di-ethyl ether (99%, 10-12ml) followed by decapitation (Zschenderlein et al. 2011) and anti-inflammation was measured by water plethysmometry (Fereidoni et al. 2000). The data were expressed as mean±SEM and analyzed by independent sample 't' test. The single supplementation of vitamin reduced the nociceptive pain (%MPE=4.56±1.05 vs. 4.27±1.59; jerking frequency/5min in early phase=89±3.79 vs. 101.5±4.40; flexing+licking duration in seconds/5min in early phase=247.33±10.62 vs. 260.33±6.93) nonsignificantly, inflammatory pain (jerking frequency/5min in late phase=69.28±2.40 vs. 75.44±1.26, p<0.001; flexing+licking duration in seconds/5min in late phase=277.57±2.16 vs. 288.85±2.59, p<0.01) and inflammation (ml of edema volume=0.16±0.02 vs. 0.23±0.02, p<0.01) significantly. Similarly, chronic B12 supplementation reduced the nociceptive pain (%MPE=7.08±1.3 vs. 3.85±1.55; jerking frequency/5min in early phase=86.5±3.42 vs. 87.5±5.75; flexing+licking duration in seconds/5min in early phase=243.5±7.1 vs. 260.17±6.16) nonsignificantly, inflammatory pain (jerking frequency/5min in late phase=64.07±2.07 vs. 84.65±2.45, p<0.001; flexing+licking duration in seconds/5min in late phase=275.89±1.88 vs. 289.91±1.77, p<0.01) and inflammation (ml of edema volume=0.11±0.02 vs. 0.23±0.02, p<0.01) significantly. In addition, in all study variables a better trend of decrement was found in the chronic supplementation. The study reveals that vitamin B12 may possess effective role against nociceptive and inflammatory pain, as well as inflammation, and chronic supplementation may be better useful than the acute one.

Kinesthetic perception based on integration of motor imagery and afferent inputs from antagonistic muscles with tendon vibration

E. Shibata[1,2] and F. Kaneko[3]

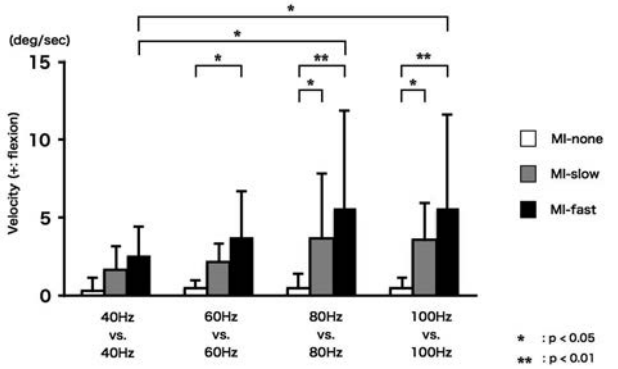
[1]Graduate School of Health Sciences, Sapporo Medical University, Sapporo, Japan, [2]Shinoro Orthopedic Hospital, Sapporo, Japan and [3]Second Division of Physical Therapy, Sapporo Medical University, Sapporo, Japan

The perceptual integration of afferent inputs from two antagonistic muscles, or the perceptual integration of afferent input and motor imagery are related to the generation of a kinesthetic sensation. However, it has not been clarified how, or indeed whether, a kinesthetic perception would be generated by motor imagery if tendon vibrations induced afferent inputs from two antagonistic muscles. The purpose of this study was to investigate how a kinesthetic perception would be generated by motor imagery during co-vibration of two antagonistic muscles at the same frequency.

Sixteen healthy subjects participated in this experiment. All subjects provided informed consent for participation in this study. Illusory movements such as wrist flexion or extension were evoked by tendon vibration. The left wrist flexor and extensor muscles were vibrated according to 4 patterns such that there was no difference between the two vibration frequencies (flexor vs. extensor: 40 Hz vs. 40 Hz, 60 Hz vs. 60 Hz, 80 Hz vs. 80 Hz, and 100 Hz vs. 100 Hz). The subjects imaged wrist flexion movement (MI-slow, MI-fast) simultaneously with tendon vibration. After each trial, the perceived movement sensations were quantified on the basis of the velocity and direction of the ipsilateral hand-tracking movements. Two-way ANOVA with a simple main effects test was used to test the effect of the "imagery" factor and "frequency" factor on the average velocities ($p < 0.05$).

When the difference in frequency between the wrist flexor and the extensor was 0 Hz, practically none of the subjects perceived such movement. However, during motor imagery, the velocity of the perceived movement was higher than the velocity without motor imagery. There was a significant main effect of motor imagery and vibration frequency (Imagery: $F = 11.115$, $p < 0.0005$, Frequency: $F = 6.837$, $p = 0.014$). The interaction between the vibration frequency and condition of motor imagery was also significant ($F = 3.818$, $p = 0.040$). A post-hoc test revealed that the velocity was significantly increased during 60Hz-MI-fast compared to 60Hz-MI-none, 80Hz-MI-slow and 80Hz-MI-fast compared to 80Hz-MI-none, and 100Hz-MI-slow and 100Hz-MI-fast compared to 100Hz-MI-none. Furthermore, that velocity was significantly increased during 80Hz-MI-fast and 100Hz-MI-fast compared to 40Hz-MI-fast.

The result of the current research showed that the imagined movement direction was perceived during motor imagery with co-vibration of two antagonistic muscles, even though the subjects experienced no kinesthetic perception by co-vibration of two antagonistic muscles at the same frequency without imagery. Furthermore, the kinesthetic perception resulting from these integrations of vibration and motor imagery differed with the imagined movement velocity and the vibration frequency.



Average (±S.D.) illusory movement velocity with four different frequency during MI-fast, MI-slow, and MI-none.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD156

Interplay between mast cells, 5-HT and TRPA1 in sensory signalling from the GI tract: Influence of ageing

Y. Yu, L. Nocchi, A. Rust, C. Keating, W. Jiang and D. Grundy

Biomedical Science, University of Sheffield, Sheffield, UK

TRPA1 is expressed on sensory neurons supplying the gastrointestinal (GI) tract and contributes to both normal mechanosensitivity and nociception [1, 2]. TRPA1 is also expressed in enterochromaffin (EC) cells leading to the release of serotonin [3], which has the potential to sensitize sensory nerve endings. Mast cell can also contribute to hypersensitivity [4]. We hypothesise therefore that there is a complex interplay between EC cells and mast cells, which serves to amplify TRPA1 signalling. Since sensory signaling from the GI tract diminishes with age [5] we further hypothesise that these modulating interactions are attenuated in aged mice.

All experiments were performed on adult (3 month) or aged (24 month) male C57/BL6 mice in accordance with UK Home Office regulations. Afferent discharge was recorded from mesenteric nerves innervating a 2 cm segment of jejunum. The TRPA1 selective agonist allyl-isothiocyanate (AITC) was bath applied (1mM) at 50-minute interval and resulted in a reproducible afferent response. Treatment with cromolyn sodium (100 μM) or granisetron hydrochloride (30 μM) 15 minutes prior to the second application of AITC was used to determine contribution of mast cells and 5-HT3 receptors to AITC response. Data are expressed as mean afferent discharge frequency ± SEM and analysed using Students t-test. Quantitive RT-PCR was performed (in duplicate) using specific probes for mouse TRPA1 and 5-HT3 receptor on RNA isolated from DRGs and jejunum wall of aged and control mice. Data are expressed as fold change (aged vs. control) with > 2-fold change taken as significant.

The increase in afferent discharge in response to AITC was significantly attenuated by cromolyn (72.5 ± 21.3 vs. 32.7 ± 9.8, $P<0.05$, paired t-test, N=6), suggesting that mast cells mediators amplify TRPA1 signalling. The response to AITC was also significantly inhibited by 30 μM granisetron (72.4 ± 15.4 vs. 21.3 ± 5.4, $P<0.05$, paired t-test, N=5) indicating a role for endogenous 5-HT, possible from EC cells. In aged mice, responses to AITC at a range of concentration were all significantly attenuated (100 μM: 19.9 ± 3.6 vs. 6.8 ± 3.4, $P<0.05$; 300 μM: 47.2 ± 10.2 vs. 15.7 ± 5.9, $P<0.05$; 1mM, 74.9 ± 7.3 vs. 28.8 ± 9.7, $P<0.01$; unpaired t-test, N=5). Expression of TRPA1 in the DRG and jejunum were not significantly different in young and aged mice (DRG, 1.58, N=5; jejunum, -1.42, N≥6), while 5-HT3B was significantly down regulated in jejunum (-2.11, N≥6) but not DRG (-1.06, N=4), which might contribute to the attenuation of TRPA1 signalling with ageing. This data suggests that there is an interplay between mast cells, EC cells and TRPA1 channels that might include both direct effects at the level of the sensory nerve terminal and amplification following the release of 5-HT and other inflammatory mediators. These mechanisms may be attenuated with ageing.

PCD157

Study of the effect of excitability change in the primary motor cortex on the sensitivity of kinesthetic perception

M. Okawada[1], F. Kaneko[2], E. Shibata[1], N. Aoki[2] and N. Matsuda[1]

[1]Graduate School of Health Sciences, Sapporo Medical University, Sapporo, Japan and [2]Second Division of Physical Therapy, Sapporo Medical University, Sapporo, Japan

Information from muscle spindles is important for kinesthetic perception. In a previous study, the contralateral primary motor cortex (M1) and primary sensory cortex (S1) were activated when kinesthetic illusion was induced by tendon vibration. Therefore, it appears that a brain neural network (e.g., M1, S1) may contribute to the pathway of the kinesthetic feelings. The purpose of this study was to study the effect of excitability change in M1 on the sensitivity of kinesthetic perception. Two experiments were performed in this study. Nine healthy right-handed male volunteers participated in the experiments, with 7 of 9 subjects taking part in each experiment. Each experiment consisted of two sessions that were at least a week apart. Participants received quadripulse transcranial magnetic stimulation (QPS), in which each train consisted of four magnetic pulses separated by an interstimulus interval of 5 msec (QPS-5), or Sham in each session. In experiment 1, the motor evoked potential (MEP) was recorded to evaluate M1 excitability. In experiment 2, the movement detection threshold was measured to examine the sensitivity of kinesthetic perception. MEP amplitude and movement detection threshold were recorded two times before QPS-5 or Sham (pre-1, pre-2) and at 0, 15, 30, 45, and 60 min after QPS-5 or Sham (post-0, post-15, post-30, post-45, and post-60). The ratio of MEP amplitude and movement detection threshold against pre-1 were calculated. Two-way ANOVA was used to test the effect of the "CONDITION" factor (SEP-5, Sham) and "TIME" factor (pre-2, post-0, post-15, post-30, post-45, post-60) on the MEP amplitude and movement detection threshold. For the factors that yielded significant main effect and interaction, we performed post hoc pair-wise comparisons with Bonferroni correction ($p < 0.05$). In MEP amplitude, there was a significant interaction between CONDITION and TIME factors. Post hoc test results revealed that MEP amplitude increased significantly after QPS-5. On the other hand, there was no effect of Sham on the MEP amplitude. In the movement detection threshold, there was a significant interaction between the CONDITION and TIME factors. Post hoc test results showed that the movement detection threshold decreased significantly after QPS-5.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Ontogenetic plasticity of the metabolic apparatus and electrical properties of *Calliphora vicina* photoreceptors

J. Rudolf, A. Meglič, G. Zupančič and G. Belušič

Department of Biology, Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia

The physiology of neural tissue is greatly shaped by information processing efficiency vs. energy cost trade-offs. A good model for studies of energy demands with respect to sensory performance is the insect eye due to its relatively simple repetitive structure and easiness of genetic manipulation (e.g. Niven et al., 2007). In our study we examined the metabolic and electrical properties of *Calliphora vicina* (white-eyed strain chalky) photoreceptors with respect to their ontogenetic plasticity.
We employed *in vivo* spectrophotometric measurements (Zupančič, 2003) to asses the metabolic activity of mitochondria in blowfly photoreceptors. By analyzing the differential absorption spectra recorded from the eyes under normoxic and anoxic conditions we estimated the dynamic range of redox states of electron transport chain components (haems in cytochromes: a, a_3, b and c). We found that the range of redox states increased with post-eclosion age in all studied haems. The largest change was found in the first week. We attributed the change mostly to the changes in cytochromes' (Cyt) concentration, which we confirmed by biochemical analysis of the Cyt c content in isolated retinal mitochondria in flies of different age. The results were in good agreement with our spectrophotometric measurements, showing a 5-fold increase in Cyt c concentration in the first two weeks post eclosion.
Long-term light adaptation profoundly influenced the performance of mitochondria. The changes in haems' dynamic redox range were significantly smaller in dark-bred animals (e.g. 2.9-fold increase for haem c in the first two weeks) compared to animals bred under 12/12h day/night cycle (4.8-fold increase).This implies that lower metabolic load results in smaller ontogenetic changes in the metabolic capacity of the photoreceptors.
The maintenance of ion gradients over the membrane was shown to be the primary energy sink in the insect photoreceptors (Laughlin et al., 1998). Thus, we expected the plasticity of photoreceptors' electrical properties to follow a similar ontogenetic time course as the one observed in the mitochondrial apparatus. We employed single electrode voltage- and current-clamp to compare the electrical parameters (cell resistance and capacitance) of blowfly photoreceptors at different age and rearing conditions. We observed significant differences in resting cell capacitance between age groups with a peak at 2 weeks after eclosion, but small changes in the resting conductance of photoreceptor cells.
Our findings indicate the existence of relevant age related changes in both studied aspects of the photoreceptor's functionality.

A comparison of medial prefrontal cortical activity during micturition in the awake and anaesthetised rat

R. Mason[2], G. Fenton[2], C. Spicer[2] and Y. Mbaki[1]

[1]School of Biomedical Sciences, University of Nottingham Malaysia Campus, Selangor Darul Ehsan, Malaysia and [2]School of Biomedical Sciences, University of Nottingham UK Campus, Nottingham, UK

Anatomical and imaging studies have implicated the involvement of the medial prefrontal cortex (mPFC) and thalamus in micturition control. The present in vivo electrophysiological study, investigates (i) the contribution of the mPFC and thalamus in the control of micturition in the anaesthetised female rat, compared with (ii) the role of the mPFC in "executive decision making" in the micturition behaviour of the awake-behaving rat.
(i) Female Sprague-Dawley rats (230-280g; n = 6) were initially anaesthetised with isoflurane (50%N_2O:50%O_2) and then maintained with urethane (1.2 g kg^{-1}, i.v.). Multiple single-unit and local field potentials (LFPs) were recorded simultaneously from the mPFC and thalamus using microelectrode arrays (MEAs). Bladder contractions were monitored and evoked by infusion (0.1 ml min^{-1}) of saline into the bladder. (ii) Awake-behaving studies were conducted on female Sprague Dawley rats (230-280g; n = 2) and male Lister-hooded rats (350-400g; n = 4) receiving MEA implants. Combined electrophysiological and video recordings were undertaken to monitor micturition on a daily basis over a number of weeks; on completion the individuals were anaesthetised and prepared in order to monitor saline-evoked bladder as above. All experiments were performed, in accordance with the Animals (Scientific Procedures) Act 1986 UK.
Multiple single-unit and LFP activity correlated to bladder contractions following saline infusion were identified within the anterior cingulate gyrus of the mPFC and thalamus in the anaesthetized female rat. In the awake-behaving study comparisons were made between pre- and post-void conditions and demonstrated altered LFP activity in power spectral density and partial-directed coherence (PDC) analysis.
This electrophysiological study demonstrates the involvement of the mPFC and thalamus in the control of micturition in the rat, and revealed a disparity in response reflecting anaesthetic state.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

ERK/MAPK in the spinal cord is involved in pain hypersensitivity in a mouse model of type 2 diabetes

H. Cao[1], X. Xu[2], H. Chen[2] and L. Xu[2]

[1]Institute of Neurobiology, Fudan University, Shanghai, Shanghai, China and [2]Department of Endocrinology, Wuxi People's Hospital, Nanjing Medical University, Wuxi, Jiangsu, China

Painful diabetic peripheral neuropathy (PDPN) is a common complication of diabetes mellitus [1]. The painful symptom becomes a major factor in decreased quality of life for patients with diabetes, while it is lack of effective treatments. The aim of the present study is to investigate the changes of pain thresholds in the early stage of diabetes in db/db mice, an animal model of type 2 diabetes mellitus [2], and the underlying mechanisms. Diabetic mice (db/db) and non-diabetic littermates (wild type, WT) of C57BLKS strain were used in present study. Body weight, blood glucose and behavioral responses to various stimuli were measured every week in db/db mice and the non-diabetic littermates mice (WT) at 4-12 weeks of age. The mechanical and thermal threshold was measured by probing von Frey hairs (von Frey, Stoelting, USA) and Hargreaves' tests, respectively [3]. Western blot was used to measure the expression of phosphorylated and total ERK1 and ERK2, GAPDH as well. Mice were deeply anesthetized by 25% urethane (1.5g/kg body weight) before tissue collection for Western blot analysis. We found that (1) db/db mice, with a leptin receptor null mutation, are characterized by obese and hyperglycaemic; (2) db/db mice were hypersensitivity to mechanical and thermal stimuli at early stage of diabetes; (3) phosphorylations of ERK1 and pERK2, but not total ERK in the spinal cord from db/db mice are significantly increased as compared with that from wild-type mice; (4) at the age of 8 weeks, db/db mice showed increased pain hypersensitivity in the formalin test. In parallel, the expressions of pERK1 and pERK2 were largely increased in the ipsilateral spinal cord of diabetes after formalin injection. Our results indicated that activation of ERK may be a potential molecular mechanism involving in the pain hypersensitivity in type 2 diabetes.

Increased A-nociceptor-evoked Fos expression in a functionally distinct subdivision of midbrain periaqueductal grey in a rat model of inflammatory pain

J. Mendes Gomes, M. Hsieh, L.F. Donaldson and B.M. Lumb

Physiology and Pharmacology, University of Bristol, Bristol, UK

Specific patterns of survival (defence) behaviours that are coordinated by the different functional columns of the midbrain periaqueductal grey (PAG) may be triggered by A- and C-nociceptive inputs that have different behavioural significance, in that they mediate 'first' and 'slow' pain respectively, and have different roles in the initiation and maintenance of chronic pain. It is of considerable importance therefore to determine to the columnar organisation of A- and C-nociceptor inputs in normal animals and in animal models of chronic pain.

Our previous studies[1,2] have shown that, in uninjured animals, inputs arising from these different fibre types target different regions of the PAG: C-fibre inputs target the ventrolateral column of the PAG (VL-PAG) and A-nociceptor inputs, the dorsolateral/lateral column (DL/L-PAG). This current study was designed to determine the activation of different regions of the PAG following either A- or C-nociceptor stimulation in an area of secondary hyperalgesia in a rat model of inflammatory arthritis.

Arthritis was induced by injection of Freund's Complete Adjuvant into the left knee joint under brief isoflurane/O2 anaesthesia (2% in O2). Animals (4-6/group) were re-anaesthetised 7 days later (halothane (2% in O2), alfaxan maintenance (i.v. 25.mg.kg.h-1) and either C- or A-nociceptors preferentially activated respectively, by slow (2.5°C.s-1, 30-55°C) or fast (7.5°C.s-1, 30-57°C) contact heating of the left hindpaw dorsum (area of secondary hyperalgesia). Some inflamed rats did not receive any stimulation (control group). Two hours after stimulation, animals were perfuse fixed and brains processed immunocytochemically for visualisation of Fos-like immunoreactivity (FLI). Fos-positive PAG neurones were counted (Image J, NIH) and their locations assigned to the different functional columns of the PAG throughout its rostrocaudal extent.

FLI was greater in caudal than rostral PAG in stimulated and control animals. Hindpaw A-nociceptor stimulation increased FLI in the caudal right (contralateral) L-PAG but in no other area, in arthritic rats. These results demonstrate that caudal L-PAG activation is greater in response to A-nociceptor input from the area of secondary hyperalgesia than in inflamed unstimulated rats. These data may indicate that processing of 'first' pain in L-PAG is enhanced in secondary inflammatory hyperalgesia.

Intracranial recording of the primary motor and somatosensory activity during kinesthetic perception

F. Kaneko[1] and Y. Kubota[2,3]

[1]Second Division of Physical Therapy, Sapporo Medical University, Sapporo, Japan, [2]Department of Neurosurgery, Asakadai Central General Hospital, Saitama, Japan and [3]Department of Neurosurgery, Tokyo Women's Medical University, Tokyo, Japan

Several studies have demonstrated that the sensorimotor areas were associated with kinesthetic perception. Specific contrasts were shown that the perception of an illusory movement in the right wrist joint was specifically related to activation in the left premotor, sensorimotor, and parietal cortices as well as in bilateral supplementary motor and cingulate motor areas. In previous studies, cerebral activity during kinesthetic perception was demonstrated, but the inhibitory or facilitatory effect of those cerebral activity has not been clarified. In the current study, we had an oppotunity to record the cerebral activity directly in a patient with epilepsy, so this research was done to show the cerebral activity in the sensorimotor areas associated with kinesthetic perception. A 14-year-old male with intractable epilepsy participated in this study. Informed consent for study participation was obtained from the patient and his parents before the experimental procedure was performed, as required by the Helsinki Declaration. The patient underwent intracranial electrodes implantation to identify the epileptogenic zone. The following study was carried out 10 days after the implantation of the electrodes. During the study, no epileptiform discharge was observed by an epileptologist on the electroencephalogram (EEG) recorded from the intracranial electrodes. Cerebral activity was recorded during the performance of 5 kinds of task, including resting. The main task was to apply the tendon vibration to the wrist joint flexors and/or extensors, to induce a kinesthetic illusory feeling. To induce an illusory feeling of moving in the extensional direction, we stimulated the flexors with 50-Hz (F50 condition) or 100-Hz (F100 condition) vibration. We also induced the illusion of flexion by stimulating the flexors with 100-Hz vibration and the extensors with 50-Hz vibration (F100-E50 condition). On the other hand, there was no illusory feeling when the 50-Hz or 100-Hz vibration was applied to both flexors and extensors (Non-50, Non-100). Negative peak values for the channel of the primary motor area depended on the amount of differences in vibration frequency between flexors and extensors. The highest peak value was recorded during the F100 condition (-82.1 μV), and the lowest value was observed under the Non-100 condition (-45.2 μV). Time frequency analysis revealed that signals around 10 Hz increased after the beginning of vibration in the channel of the primary motor cortex, while the signals around 10 Hz were suppressed in the channel of the primary somatosensory cortex. An EEG signal around 10 Hz indicated a different trend between the channels for the motor cortex and the somatosensory cortex. The cerebral activity reported in this study was recorded from only one patient; however, the recordings provided very unusual and noteworthy data.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD163

Movement deficits of patients presenting with cerebellar degeneration during precise auxometric finger movements

D.F. Kutz[1], D. Timmann[2] and F.P. Kolb[1]

[1]Institute of Physiology, University of Munich, Munich, Germany and [2]Department of Neurology, University of Duisburg-Essen, Essen, Germany

Question: In his famous work on patients presenting acute with cerebellar injuries Gordon Holmes demonstrated that some exemplary patients with unilateral damage (N=3) showed a delayed start of auxometric finger movements as well as incomplete force production [1]. The aim of this study was to investigate these results in more detail.
Methods: Patients presenting with cerebellar lesions (N=9, age: 51.6 years) and age and sex matched subjects (N=9, age: 51.3 years) performed a sequence of precise auxometric finger movements with a custom-made dynamometer. The apparatus consists of a hinge (58 mm legs) kept open by a leg spring at an angle of 11°. The spring had a constant of 39.4 Nmm/° resulting in a force range of 8.7 N (initial value) to 16.2 N (maximal value). Subjects had to squeeze the hinge each time a 1 kHz tone (duration: 2 s) was presented. Trial intervals varied randomly between 10 – 15 s. During each trial the tone was presented twice with a constant inter-stimulus interval of 2 s. Mean values for reaction time (RT) and movement time (MT) of both hands were compared statistically. During the procedure electro-myographic activity (EMG) of the thenar muscle (TH) and first dorsal interosseus muscle (FDI) were recorded.
Results: In the patient group (CBL), RT and MT of the two movements in the sequence were significantly increased (both $p < 0.05$) compared with the control group (CTRL), regardless of the hand in use. Interestingly, for the right hand RT and MT of the second movement were clearly reduced (both $p < 0.05$) compared with the first movement (RT: 435 vs. 355 ms, MT: 374 vs. 250 ms, respectively) in CBL, indicating an improvement of movement performance when timing is predictive. The EMG-onsets of FDI were significantly later in CBL than in CTRL. Detailed analysis revealed that the mean EMG-onset asynchronicity between TH and FDI was significantly greater in CBL (right hand 72 ms, left hand 131 ms) than in CTRL (right hand 30 ms, left hand 25 ms), suggesting better co-ordination of the muscles around the thumb joint in CTRL.
Conclusions: Patients presenting with cerebellar degeneration have more difficulties in starting precise auxometric finger movements. This may be, in part, due to a limited co-ordination of co-acting muscles around a joint. Nevertheless, they can improve in performing simple movements when timing remains predictive, because of a fixed interval.

Impact of birth order on child development in a rural community, India

S. Sadat Ali[1], S.S. Goudar[2] and D. Sm[3]

[1]Department of Physiology, Dr. B R Ambedkar Medical College, Bangalore, Karnataka, India, [2]Department of Physiology, Jawaharlal Nehru medical College, KLE University, Belgaum, Karnataka, India and [3]Pediatrics, Jawaharlal Nehru medical College, KLE University, Belgaum, Karnataka, India

Objective: To assess the impact of birth order on child development among preschool children. Design and method: A cross sectional study was conducted through anganwadi schools among 530 children at three years staying in a rural community in a Primary health centre area, to assess the developmental delay using screening tool, Ages and stages questionnaire (ASQ). Then, these children were correlated and analysed for birth order in the family with their global development. The study was approved by Institutional Ethics Committee for Human Subjects Research. Chi-square test was used to compare categorical variables. Differences were considered significant at P<0.05 level. Results and conclusions: The prevalence of global developmental delay assessed by ASQ was 19.8%. [1] A majority of the children (85.8%) were from joint family and majority (81.5%) were of 1st and 2nd birth order. In the present study, ASQ score for personal social skill was low for a child who stayed with fewer number of children at home as against those who stayed with more number of children (P=0.07), though not statistically significant. The gross motor development was better in 1st and 2nd order children compared to higher order and this showed a statistically significant change (P=0.04). The rest of the domains didnot show any significant correlation. The results of the present study showed that there was a trend towards higher ASQ scores from higher birth order to lower birth order.

Mechanisms of calcium independent but voltage dependent secretion (ciVDS) and calcium dependent secrtion (CDS) in somata of primary sensory neurons

C. Wang[1,2], X. Zhang[1,2], X. Wu[1,2], Z. Chai[1,2], P. Hou[3], H. Liu[3], Y. Liu[3], T. Liu[1,2], Y. Wang[1,2], B. Liu[1,2], C. Zhang[1,2], W. Guo[1,2], S. Wang[1,2], X. Zhang[1,2], J. Ding[3] and Z. Zhou[1,2]

[1]Peking University, State Key Laboratory of Biomembrane and Membrane Biotechnology and the Center For Life Sciences, Beijing, China, [2]Peking University, Institute of Molecular Medicine, Beijing, China and [3]Huazhong University of Science and Technology, School of Life Sciences, Wuhan, China

The somata of primary sensory neurons, including dorsal root ganglion (DRG) neurons and mesencephalic trigeminal nucleus (MeV) neurons, release neurotransmitters and neuropeptides. In addition to the conventional Ca2+-dependent secretion (CDS), Ca2+-independent but voltage-dependent secretion (ciVDS) also occurs in the somata of isolated DRG neurons (Zhang et al., 2002; Liu et al., 2011) and brain slice MeV neurons (Zhang et al., 2011). Electrical stimulation induces both CDS and ciVDS, which differ in size and are coupled with different types of endocytosis contributed by ciVDS and CDS, respectively. However, it is unclear whether they use a common vesicle pool, so we investigated the relationship between the vesicle pools of CDS and ciVDS. DRG neurons were isolated from Wistar rats (male, ~ 60 g) treated with 0.6 ml/100 g 25% urethane. Membrane capacitance recording and photolysis of a caged-Ca2+ compound showed that, in low external Ca2+ solutions, the depolarization-induced exocytosis contained two (fast and slow) phases, which were contributed by ciVDS and CDS respectively. Depletion of the CDS readily-releasable pool using photolysis did not affect the ciVDS. When the ciVDS and CDS vesicle pools were depleted by electrical stimulation, the pools had different sizes. Their kinetics of exocytosis-coupled endocytosis were also different. Thus, ciVDS and CDS used different vesicle pools in somata of primary sensory neurons.

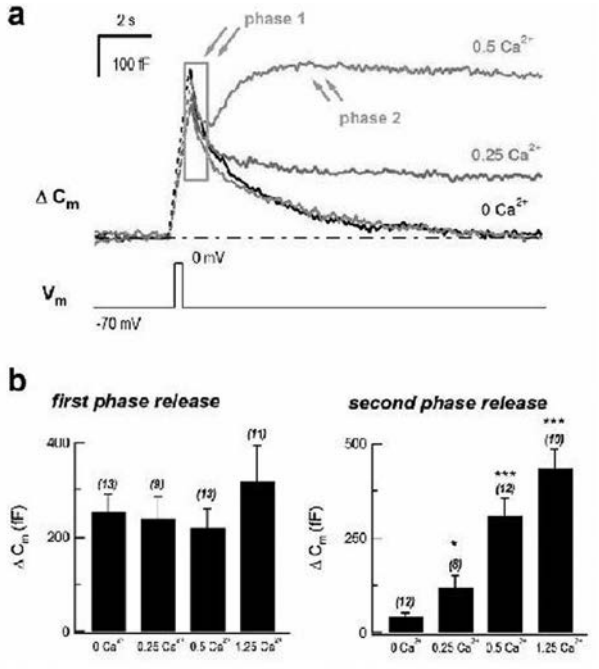

Figure 1. The first phase of exocytosis was CIVDS in low external Ca^{2+} solution. a, Representative traces of depolarization induced C_m response of a DRG neuron in different concentration of external Ca^{2+} solutions. The first phase (phase 1) was indicated in grey blank rectangle, the second phase was indicated by phase 2. **b,** Summary graph of peak of ΔC_m response of first phase and second phase in different external Ca^{2+} solutions. Modelling mechanotransduction in primary sensory endings

T.J. Suslak[1,2], G.S. Bewick[3], J.D. Armstrong[1] and A.P. Jarman[2]

[1]Doctoral Training Centre in Neuroinformatics and Neural Computation, University of Edinburgh, Edinburgh, UK, [2]Centre for Integrative Physiology, University of Edinburgh, Edinburgh, UK and [3]Institute of Medical Sciences, University of Aberdeen, Aberdeen, UK

Mechanotransduction is a process fundamental to life. It underpins a variety of sensory modalities from hearing to blood pressure regulation. However, the molecular components of the mechanosensory mechanisms in primary sensory endings are poorly understood. Experimental approaches to solving this problem are long and laborious. Therefore, a theoretical approach was proposed as an efficient means to circumventing this process.

A mathematical, biophysical model of mechanosensory endings was implemented, which reproduced existing experimental data of the receptor potential of the mammalian muscle spindle primary ending. This probabilistic model combines mathematical representations of different ion channel types to produce an output which is the predicted receptor potential of the sensory ending, given the presence of specific ion channels. The model outputs the tension-dependent electrical response of the receptor, given a stretch stimulus. The parameters required for this model identify the necessary molecular entities required for this behaviour to occur.

The dbd (dorsal bipolar dendritic) neuron in D. melanogaster larvae fulfils a similar role to the muscle spindle in mammals. Electrophysiological data was obtained from these neurons via whole-cell patching. It was shown that the dbd neuron can respond to both electrical and mechanical stimuli, but that these responses are noticeably distinct. Furthermore the stretch-evoked data obtained from these receptors was equivalent to that predicted by the model, demonstrating a cross-taxa correlation between the behaviour of neurons in this class.

This finding enables simple genetic assays to be carried out in D. melanogaster to ascertain the identity of molecules which are involved in primary mechanotransduction at the sensory terminal. A simple bioinformatics search has yielded a shortlist of candidates which fulfil the criteria of the model predictions. These can now be experimentally tested in a simple and direct approach.

PCD167

Role of the cerebellum in descending control of nociception

N. Weerasinghe, B.M. Lumb, R. Apps and J.C. Murrell

Physiology and Pharmacology, University of Bristol, Bristol, UK

The cerebellum is critically involved in motor control; however there is evidence to indicate that it also has a role in nociceptive processing. Previous studies suggest a dual role, whereby stimulation of the anterior lobe of the cerebellum invokes antinociception (1-3), and posterior lobe stimulation invokes pronociception (4,5). However, these data are difficult to interpret with respect to (i) somatic nociceptive pathways as they investigated visceral nociception and (ii) precise localisation of the origin of descending control as previous studies utilised electrical stimulation of the cerebellum, where current spread to neighbouring structures, activation of fibres of passage and antidromic activation are important confounds. The aim therefore of the present study was to investigate modulation of somatic nociception in rats following activation of the anterior (lobule V) and posterior (lobule VIII) lobes of the cerebellum using DL Homocysteic acid (DLH), an excitatory amino acid that allows cerebellar activation to be restricted to target neurons thereby overcoming some of the limitations of electrical stimulation. Rats were initially anaesthetised with

halothane (2-3% in 0_2) delivered by face mask and maintained with a continuous infusion of alfaxalone (25mg/kg/hour i.v). EMG was recorded from the biceps femoris while pinching the ipsilateral hindpaw. The change in mechanical withdrawal threshold (the force required to elicit an EMG response) and magnitude of EMG activity at threshold was assessed following injection of either DLH (0.1M) or an equivalent volume of saline into lobule VIII (n=8 and n=7 respectively), or lobule V (n=4 and n=5 respectively) of the cerebellar cortex. Values are mean ± SEM compared by paired t test. Pronociception was observed following lobule VIII stimulation, indicated by a statistically significant decrease on average of 23% in mechanical withdrawal threshold following DLH injection (from 56.5 ± 5.0 g/mm^2 to 43.2 ± 4.3 g/mm^2, P=0.0038). There was also a statistically significant facilitation on average of 63% in EMG activity (from 0.007 ± 0.002 v/s to 0.012 ± 0.002 v/s, P= 0.0077). In contrast, there was no statistically significant change in mechanical withdrawal threshold or EMG activity following DLH administration into lobule V or after injection of saline in either lobule VIII or V. These data indicate that stimulation of the anterior and posterior lobe of the cerebellum has a differential effect on nociceptive processing, which may be explained by activation of different cerebellar modules. However, recording EMG responses does not discriminate between effects due to modulation of sensory and/or motor components of the spinal pathways activated by the noxious stimulus. Further experiments will therefore investigate cerebellar modulation of sensory input by making recordings from dorsal horn neurons.

Development of fluorescent and biotinylated agonists for a novel glutamate receptor in mechanosensory terminals

S. Watson[1], C. Zanato[1], S. Dall'Angello[1], R.W. Banks[2], I. Greig[1], M. Zanda[1] and G.S. Bewick[1]

[1]School of Medical Sciences, University of Aberdeen, Aberdeen, UK and [2]School of Biological & Biomedical Sciences, University of Durham, Durham, UK

Mechanotransduction by proprioceptive sensory organs, such as muscle spindles, is poorly understood. We recently reported that stretch releases glutamate from synaptic-like vesicles within spindle terminals, and activates a non-canonical mGluR (Bewick et al, 2005) coupled to phospholipase D (PLD), modulating afferent firing. In further investigations into this receptor's pharmacology, ligands selective for classical mGluRs were screened for their ability to alter stretch-evoked spindle firing. We now report on the development of a fluorescent and a biotinylated agonist. These agonists will be in the key in the next stages of the investigation, isolating the receptor using a pull-down/precipitation assays. Nerve-muscle preparations were excised from humanely killed (Schedule 1, ASPA, 1986) adult male Sprague-Dawley rats. Spindle discharges during 1mm stretch-and-hold cycles were compared with and without drug. Differences in mean firing frequencies were evaluated by two-way ANOVA with Bonferroni post test (sig. threshold P=0.05). Four compounds were found to increase afferent firing; kainate (1 μM, n = 7, P = 0.01) quisqualate (1 μM, n = 8, P = 0.05), t-ADA (1 μM, n = 9, P = 0.05) and L-CSA (0.1 μM, n = 7, P = 0.05). NBQX, a kainate and AMPA receptor antagonist, had no effect on afferent firing when applied alone (n= 4) or in combination with kainate (n = 7), adding further evidence that classical kainate or AMPA ionotropic receptors are not responsible for the increase in stretch-induced afferent firing with application of kainate. In addition PCCG-13 was able to attenuate the effect of kainate (n = 4) suggesting kainate is acting on the PLD-coupled mGluR. Kainate was used as the parent compound in the synthesis of click-chemistry amenable (Kolb et al, 2001) analogues; ZCZ49, ZCZ50 and ZCZ90. Only ZCZ90 retained activity in the system, increasing afferent firing at 1 μM (n = 7, P = 0.01). From this fluorescent (ZCZ172) and biotinylated (ZCZ180) versions were synthesised. Both retained activity, increasing afferent firing at 10 μM (n = 8, P = 0.001) and 1 μM (n = 8, P = 0.01) respectively. These data show kainate is a useful base ligand for the development of tools to isolate and further characterise this intriguing receptor.

PCD169

Spinal mu and delta opiate receptors differentially modulate a-nociceptor processing in primary and secondary inflammatory hyperalgesia in rats

M. Hsieh, L.F. Donaldson and B.M. Lumb

School of Physiology and Pharmacology, University of Bristol, Bristol, UK

Delta and mu receptors (DOR & MOR) are differentially expressed by A- and C-nociceptors, and are hypothesised to differentially modulate mechanical and thermal nociceptive behaviours respectively[1]. A- and C-nociceptors can be preferentially activated by controlled contact heating[2], allowing identification of the nociceptor population driving nociceptive changes, with no confound of different stimulus modalities. Neurons in the superficial dorsal horn (dh) process C-nociceptor inputs from the area of primary hyperalgesia. This is hypoth-

esised to activate lamina I projection neurons, higher centres, and descending control pathways, which contribute to central sensitisation leading to enhanced responses of dh neurons to A-nociceptor input in secondary hyperalgesia. We hypothesised that sensitised responses to specific A- and/or C-nociceptor inputs, rather than to stimulus modalities (mechanical/thermal) are differentially controlled by MOR/DOR in inflammatory hyperalgesia.

1° & 2° inflammatory hyperalgesia were induced by injection of Freund's Complete Adjuvant into dorsal hindpaw and knee joint respectively under brief isofluorane anaesthesia (2-4% in O_2). After 7 days, animals were re-anaesthetised (halothane 2-4% in O_2, alfaxan maintenance (25.mg.kg^{-1} i.v.)) and DAMGO (MOR agonist 12 pmol/20μl) and SNC80 (DOR agonist 120 nmol/20μl) given intrathecally in inflamed or control animals. Withdrawal thresholds were determined in response to preferential activation of C- or A-nociceptors with contact heat stimulation, and to mechanical stimulation of the hindpaw.

MOR and DOR agonists both inhibited A- and C-nociceptor evoked-responses in all groups (control, 1° & 2° hyperalgesia). SNC80 had a significantly greater effect on A-nociceptor-withdrawal thresholds in 2° hyperalgesia compared to controls, and a significantly smaller effect on A-nociceptor-evoked responses on 1º hyperalgesia (control, 8.6±0.4°C.hr; 1°, 5.9±0.6°C.hr; 2°, 13.2±1.4°C.hr; AUC mean±SEM, p<0.01). DAMGO had equivalent effects on preferential A- and C-nociceptor thermal stimulation under all conditions, but significantly increased withdrawal thresholds in response to mechanical stimuli in 2º but not 1º hyperalgesia compared to controls (control, 11.6±4.5°C.hr; 2°, 35.9±9.6°C.hr; p < 0.05). SNC80 had a greater effect on mechanical stimuli than DAMGO in all animals (p<0.05), but effects were equivalent in hyperalgesic and control animals.

These results suggest that both MOR and DOR can modulate both unmyelinated and myelinated nociceptive inputs. DOR may have a greater contribution to the processing of A-nociceptor inputs in thermal 1° and 2° hyperalgesia than MOR, and MOR may be more important in modulation of responses to mechanical stimulation in 2° hyperalgesia.

Sacral neuromodulation facilitates anal canal evoked potentials but not median nerve evoked potentials in the primary somatosensory cortex in a rat model

J. Evers[1], R.P. O'Connell[1,2] and J.F. Jones[1]

[1]School of Medicine and Medical Science, University College Dublin, Dublin, Ireland and [2]Centre for colorectal disease, St. Vincent's Hospital Dublin, Dublin, Ireland

Introduction

Faecal incontinence (FI) may follow pudendal nerve injury sustained during childbirth. Sacral neuromodulation (SNM) is a treatment option for FI, when conservative treatment has failed.

The mechanism of action of SNM is yet unclear. However SNM may augment anal sensation via afferent somatosensory fibres, as small sensory fibres are more susceptible to damage than the larger motor fibres. This study investigates, how fore paw, hind paw and anal canal evoked cortical potentials (EPs) are affected by SNM in an animal model.

Methods

Six female virgin Wistar rats (body mass: 230g–270g) were used. Experiments were carried out in accordance to protocols approved by the UCD Animal Ethics Research Committee and licenced by the Irish Department of Health and Children. Experiments were performed under urethane anaesthesia (1.5g.kg-1, i.p.) and vital signs were stable throughout. A craniotomy was performed over the right primary somatosensory cortex. A 32 channel multi-electrode array, placed extra-durally, recorded EPs created by electrical anal canal stimulation, left tibial nerve stimulation and left median nerve stimulation. SNM was performed utilizing a concentric needle electrode placed in the left first sacral foramen. Stimulation parameters were 10Hz, 15V and 1ms pulse duration for 3min. EPs before and 10 and 40min after SNM were compared for each location. Values are expressed as mean ± sem; the criterion for statistical significance was P<0.05.

Results

EPs consisted of one upward deflection and a small less marked downward deflection (Figure 1). Anal canal EPs had a latency of 11.5ms±0.73ms and amplitude of 18.8μV±3.56μV; tibial nerve EPs 9.0ms±0.42ms and 32.6μV±5.17μV; median nerve EPs 8.4ms±1.1ms and 21.5μV±3.79μV. SNM induced an increase in the maximal amplitude of 50% in anal canal and tibial nerve EPs, but not in median nerve EPs (Figure 2). A two-factor (location and time) repeated measures ANOVA showed that this result was highly significant (location factor: P<0.0001).

Conclusions

S1 neuromodulation causes facilitation of afferent fibre input of the same spinal segmental level but not higher segmental level. This study provides evidence that SNM selectively restores sacral inputs and may improve cortical awareness of the anorectum. The finding that a limb nerve input is also augmented may serve as a surrogate marker of the efficacy of SNM. This fact also suggests that percutaneous posterior tibial nerve stimulation, a novel treatment for FI, may share a similar mechanism to SNM.

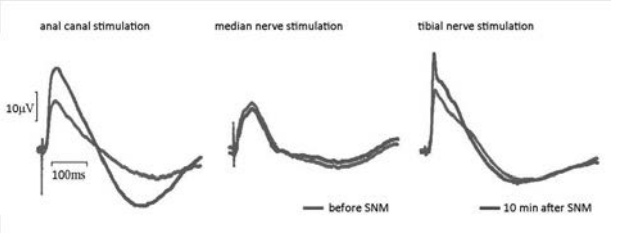

Figure 1 Mean triggered EPS of group data before and 10 min after SNM.

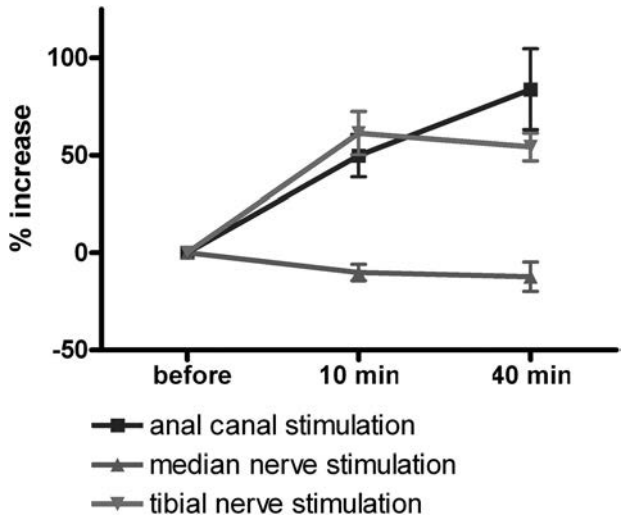

Figure 2 Percent increase of the maximal amplitude 10 and 40min after application of SNM.

PCD171

EP3 receptor activation in the ventrolateral periaqueductal grey facilitates nociceptive spinal reflexes in the normal and arthritic rat

R. Drake, L. Leith, B. Lumb and D. Lucy

University of Bristol, Bristol, UK

Descending controls on spinal nociception, particularly descending facilitatory pathways from the midbrain periaqueductal grey (PAG), play major roles in the initiation and maintenance of chronic pain, and are important determinants of the pain experience. A better understanding of these systems may inform the development of more effective chronic pain treatments. Prostaglandin receptors EP1-4 in the ventrolateral periaqueductal grey (vlPAG)1 contribute to acute inflammatory pain and in nerve injury vlPAG EP1 receptors contribute to tonic descending facilitation in naïve and injured rats2.
Inflammatory arthritis was induced in male rats under brief isoflurane anaesthesia (2% in O2) by left knee intra-articular injection of Freund's complete adjuvant (100μl/1mg.ml-1). Naïve animals were used as controls. After 7 days, rats were re-anesthetised with halothane (3% in O2) and maintained on alfaxan infusion (i.v. 25mg.kg.h 1). Bipolar steel wire electrodes were placed in the bicep femoris of the left hind limb to record electromyographic activity, and a micropipette positioned stereotaxically in the left PAG. A and C nociceptors were preferentially activated by application of fast (7.5°C.s-1) or slow (2.5°C.s-1) rates of contact skin heating applied to the dorsal surface of the left hind-paw3 respectively. Withdrawal thresholds to A- and C-nociceptor stimulation (interstimulus interval 8 min) were determined before and after delivery of drug/vehicle into the PAG by pressure ejection.
There was a prolonged secondary (hindpaw) hyperalgesia 7 days after induction of inflammation, indicated by a reduction in A- but not C-nociceptor withdrawal thresholds (naïve vs. arthritic A-nociceptor thresholds: 57±1oC vs 54±1.2oC . p<0.0001 unpaired t test. n=16 naïve, 18 arthritic). In naïve animals EP3 receptor antagonism (GW671021B 250nM/200nl) in the vlPAG increased C- but not A-nociceptor evoked-reflexes. In contrast in secondary hyperalgesia, EP3 receptor antagonist increased A-nociceptor responses (AUC GW A-nociceptor effect vs AUC Vehicle A-nociceptor effect: 352.1±85.0oC.min vs 116.8±26.10oC.min. p<0.0357 Mann Whitney. n=5 for GW, n=3 for Vehicle.) with minimal effect on C-nociceptor reflexes. Inflammatory knee joint arthritis produces secondary hyperalgesia of the hind paw involving sensitisation of A- but not C-nociceptor-evoked spinal reflexes. Blockade of prostaglandin EP3 receptors in the vlPAG predominantly modulates A-nociceptor withdrawals in the hyperalgesic state but selectively alters C-nociceptor reflexes in the normal rat. In the transition to chronic inflammatory pain, descending EP3 receptor-mediated facilitation from vlPAG switches from C-nociceptor facilitation in naïve rats to A-nociceptor facilitation in inflammatory secondary hyperalgesia.

Mechanically elicited evoked potentials: A physiological approach to assessment of anorectal sensory pathways

E.V. Carrington[1,2], J. Evers[1], M.S. Scott[2], C.H. Knowles[3], R.P. O'Connell[1,4] and J.F. Jones[1]

[1]School of Medicine and Medical Science, University College Dublin, Dublin, Ireland, [2]GI Physiology Unit, The Wingate Institute of Neurogastroenterology, Queen Mary, University of London, London, UK, [3]National Centre for Bowel Research and Surgical Innovation, Queen Mary, University of London, London, UK and [4]Centre for Colorectal Disease, St. Vincent's Hospital Dublin, Dublin, Ireland

Introduction
Normal defaecation is dependent upon activation of anorectal mechanoreceptors, which respond to pressure and stretch. Evoked potentials (EPs) have been used to interrogate these pathways but are typically recorded in response to non-physiological electrical stimuli, known to directly depolarise nerve fibres without receptor activation. However, the use of a mechanical stimulus should provide a more physiological assessment of these pathways. This study compared EPs elicited via mechanical and electrical stimulation of the rat anal canal.
Methods
In fourteen anaesthetised (urethane i.p., 1g/kg) female Wistar rats (body mass 180 - 270g) mechanical and electrical EPs were recorded using a 32 channel multi-electrode array placed over the right primary somatosensory cortex. Stimulations for electrically elicited EPs were applied with a 2mm anal plug electrode (1Hz, 1ms, 10V) and mechanical stimuli via an interdental brush placed on a rotating stepper motor (1Hz, 1ms, 15o rotation). Response latency, response amplitude and activated spatial extent (expressed as an index) were evaluated. A P value of <0.05 was considered to be statistically significant.
Results
Mechanical and electrical EPs were recorded successfully in all animals. Mean maximal response amplitude (electrical 25.9μV (SD 22.2) vs. mechanical 19.3 μV (12.6)) and onset latency

(electrical: 13.8ms (2.6) vs. mechanical: 14.2 ms (2.2)) were similar (Student's t-test P = 0.25 and P = 0.62). Cortical location and waveform profile were also similar. An activated spatial extent index was significantly lower for mechanical stimulation (2.1 (1.4) vs. (4.5 (2.4), Mann-Whitney U-test P = 0.0015). Figure 1 illustrates this in one animal as a colour map encoding the maximal amplitude for each channel.

Conclusions

To the authors' knowledge these are the first mechanically elicited anal EPs recorded in animals. Cortical responses to mechanical stimulation appear to be more focal, a finding which may reflect more selective activation of ascending sensory pathways. Mechanical EPs may prove useful in the further exploration of treatments that modulate the neuronal control of defaecation such as sacral nerve stimulation.

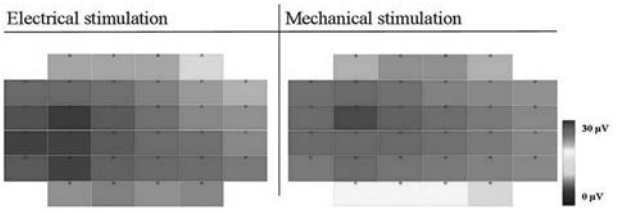

Figure 1 Representative colour maps encoding the maximal amplitude in each channel for electrical and mechanical anal canal stimulation.

PCD173

The descending noradrenergic system spatially restricts and temporally delays the onset of A-fibre mediated heat hypersensitivity in a model of neuropathic pain

S. Hughes, T. Pickering and B. Lumb

University of Bristol, Bristol, UK

Previous work from our laboratory has studied the functional roles of distinct types of nociceptors in acute pain processing [1, 2]. We have demonstrated that descending control can differentially modulate A- vs C-fibre evoked responses and we have shown that thermal nociception is under tonic regulation by descending noradrenergic control [3]. However, the different roles these nociceptors have in the development of heat hyperalgesia during chronic pain states and the changes descending control are poorly understood. Here we have investigated the descending noradrenergic control of A- and C-heat nociceptor evoked responses during the development of neuropathic hyperalgesia. Wistar rats (300-350g) had tibial nerve transection (TNT) under ketamine (50mg/kg) and medetomidine (300μg/kg) recovery anaesthesia [4]. Subsequently heat ramp withdrawal experiments were performed at day 3-5 or day 19-21 post-TNT under alphaxalone (9 - 15mg.kg-1.h-1 i.v.) anaesthesia. Fast (7.5°C/s) or slow (2.5°C/s) rates of skin heating were applied to the dorsal hindpaw to preferentially activate A- or C-heat nociceptors, respectively. EMG withdrawal response thresholds were recorded from the biceps femoris. A 32 gauge intrathecal catheter was inserted at the L5-L6 interspace for administration of yohimbine (α2-AR antagonist, 30μg) or clonidine (α2-AR agonist, 15μg). Changes in dopamine-beta-hydroxyalse (DBH) immunoreactivity were analysed at days 19-21. Data are expressed as mean withdrawal thresholds ± SEM or %DBH immunoreactivity analysed using either t-test or one-way ANOVA with Bonferroni's post tests. Following TNT animals showed substantial A- but not C-fibre evoked ipsilateral hyperalgesia by day 21 (TNT: A-fibre: day 3 55.2±0.7°C vs day 21 47.8±0.9°C P<0.001 n=5) when compared to sham. Intrathecal yohimbine revealed sensitivity of A- but not C-fibre evoked responses at day 3 (control 55.2±0.7°C vs 51.6±0.6°C post yohimbine P<0.001 n=4). Once hyperalgesia had developed (by day 19) yohimbine had no further sensitising effect on A-fibre responses however intrathecal clonidine increased A-fibre thresholds to beyond cut off (>58°C, P<0.01, n=3). Yohimbine was without effect in sham animals (n=3). Interestingly, yohimbine revealed contralateral heat hypersensitivity mediated by A- but not C-fibres at days 19-21 (A-fibre: 54.6±0.8°C to 49.0±0.8°C P<0.01, n=5). By days 19-21 there was a loss of DBH-ir in the ipsilateral L4-L6 spinal cord when compared to sham (n=3).These data demonstrate that descending pontospinal noradrenergic tone preferentially modulates, both temporally and spatially, the development of fast, prickling, heat hypersensitivity mediated by A-fibres following a loss of descending noradrenergic innervation to the lumbar region.

Whisker photostimulation evokes barrel cortical response of ChR2 transgenic rat

T. Honjoh[1], A. Sumiyoshi[2], Y. Yokoyama[1], Z. Ji[1], T. Ishizuka[1], R. Kawashima[2] and H. Yawo[1]

[1]Graduate School of Life Sciences, Tohoku University, Sendai-shi, Japan and [2]Institute of Development, Aging and Cancer, Tohoku University, Sendai-shi, Japan

In one of thy1.2-channelrhodopsin 2 (ChR2)-Venus transgenic rat lines, W-TChR2V4, the ChR2 was expressed in the mechanoreceptive subpopulation of trigeminal ganglion neurons which innervate whisker follicles. It is thus well expected that a whisker-related sensory perception should be induced by the photostimulation of their follicles.

To test this, the barrel cortex responses were examined using electrophysiological recordings and functional magnetic resonance imaging (fMRI). Under anesthesia with urethane (1.3g/kg i.p.), the whiskers were trimmed and connected with optic fibers of which other endings were connected to LEDs. Pulsative irradiation of blue LED light was used as a test and that of red LED light as control.

We found that the blue light irradiation of whisker follicles evoked enhanced unit activities as well as a local field potential in the barrel field of contralateral somatosensory cortex whereas the red light did not. The blue light irradiation also induced blood oxygenation level-dependent (BOLD) and cerebral blood volume (CBV) responses in the barrel field of con-

tralateral somatosensory cortex. It is suggested that the optogenetic whisker stimulation could activate the whisker-barrel cortical pathway of mechanoreceptive signaling. This method would facilitate to study how the spatio-temporal pattern of the whisker mechanoreception would be integrated in the cortex.
All animal procedures were conducted in accordance with the guiding principles of Physiological Society of Japan and NIH.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD175

Effect of tetrahydrobiopterin deficiency on hyperoxia-induced vascular damage in the retina

K.S. Edgar[1], N. Matesanz[1], T.A. Gardiner[1], Z.S. Katusic[2] and D.M. McDonald[1]

[1]Centre for Vision & Vascular Science, Queen's University Belfast, Belfast, N. Ireland, UK and [2]Anesthesiology and Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic, Rochester, MN, USA

Purpose: Neovascularisation is a serious complication of several retinal diseases including diabetic retinopathy and retinopathy of prematurity. In these diseases an oxidative insult damages the endothelium leading to vascular closure, tissue ischaemia and the eventual abnormal neovascular response that characterizes these diseases. Endothelial nitric oxide synthase (eNOS)-derived nitric oxide (NO) plays an important role in maintaining vascular integrity, normal eNOS function, however is dependent upon the cofactor tetrahydrobiopterin (BH4) whose deficiency plays a pivotal role in the reduced NO bioavailability observed in diabetic vascular disease. We have previously shown that eNOS is dysfunctional in hyperoxia-induced vascular damage in a model of oxygen induced retinopathy (OIR). Thus, here our aim was to investigate the effect of hyperoxia-induced vascular closure in BH4 deficient mice (hph-1).
Methods: BH4 levels in retinas, aortas and lung samples were analyzed by HPLC analysis. Normal vascular development was confirmed by lectin staining of retinas from postnatal day 7 (P7) animals. For OIR, animals were exposed to 75% oxygen for 5 days from P7 to P12 and returned to room air. Eyes were collected at various time points between P12 and P17 and vascular preservation and ischaemia-induced growth quantified by B simplicifolia isolectin staining of retinal flat mounts. Avascular, normal vascular and neovascular areas were quantified using image analysis software. NO production was quantified by NOS activity assay in the presence and absence of BH4. In situ superoxide and peroxynitrite were quantified by DHE, DCF and nitrotyrosine immunoreactivity.
Results: BH4 levels in hph-1 retinal samples were significantly lower than wild-type litter mate controls and comparable to levels observed in aorta and lung samples. All BH4 levels were further reduced following in vivo hyperoxia treatment. Surprisingly, despite evidence of reduced retinal BH4 levels, hph-1 animals were partially protected from hyperoxia-induced damage which correlated with reduced reactive oxygen and nitrogen species production. In contrast, in response to ischaemia hph-1 animals displayed a significantly reduced neovascular response.
Conclusions: Our results show that BH4 deficient hph-1 animals are protected from hyperoxia-induced vasodegeneration. However, the attenuated angiogenic drive observed in these animals suggests a reduced ability to respond to ischaemic insult.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD177

Hypothalamic Gαi2 proteins: A central molecular mechanism that counters the development of salt-sensitive hypertension

R.D. Wainford and J.T. Kuwabara

Pharmacology & Experimental Therapeutics, Boston University, Boston, MA, USA

Aim: We have demonstrated up-regulation of hypothalamic paraventricular nucleus (PVN) Gαi2-proteins is required to suppress norepinephrine (NE) mediated sodium retention during high salt intake in the Sprague-Dawley rat (1, 2). In these studies we examined the role(s) of PVN Gαi2 proteins in the pathophysiology of salt-sensitive hypertension in Brown Norway (BN), Dahl salt-resistant (DSR), Dahl salt-sensitive (DSS) and congenic DSSBN8 (3) rat strains.
Methods: BN, DSR, DSS or DSSBN8 rats were maintained on a normal (NS-0.4% NaCl) or high (HS-8% NaCl) diet for 21-days. Additional groups of intact and bilateral renal denervated (RDNX) DSR and DSS rats received a 21-day i.c.v. infusion of a scrambled (S) or a Gαi2 targeted oligodeoxynucleotide during high salt-intake. MAP was continuously recorded by radiotelemetry. 24h sodium balance, plasma NE, Fractional excretion of sodium (FENa) and PVN Gαi2 protein levels were determined after 21-days on a NS or HS diet (N=8/group ± SEM).
Results: HS-intake did not alter MAP, increased FENa and suppressed plasma NE in BN, DSR and S infused DSR rats (Δplasma NE [nmol/L]; BN -32±4, DSR -35±3, DSR S -33±5, $P<0.05$). HS-diet evoked a site-specific increase in PVN Gαi2 protein levels in salt-resistant BN, DSR and S infused DSR rats (4.8, 4.2 and 3.9-fold respectively, $P<0.05$) but not in hypertensive DSS rats. Oligodeoxynucleotide-mediated CNS Gαi2 protein down-regulation evoked hypertension (MAP [mmHg]; DSR S HS 98±4 vs. DSR Gαi2 HS 124±3, $P<0.05$), sodium retention and elevated plasma NE content (plasma NE [nmol/L]; DSR S HS 75±8 vs. DSR Gαi2 HS 108±7, $P<0.05$) in DSR rats and profoundly exacerbated DSS hypertension (MAP [mmHg]; DSS S HS 155±5 vs. DSR Gαi2 HS 178±5, $P<0.05$). RDNX prevented the development of hypertension (MAP [mmHg]; DSR Sham RDNX HS Gαi2 128±4 vs DSR RDNX HS Gαi2 97±4, $P<0.05$), sodium retention and sympathoexcitation in DSR rats and prevented the exacerbation of DSS hypertension. BN chromosome 8 substitution restored salt-induced PVN specific Gαi2 protein up-regulation (3.6-fold, $P<0.05$), attenuated the development of salt-sensitive hypertension (MAP [mmHg]; DSS HS 159±4 vs. DSSBN8 HS 138±3, $P<0.05$) and global sympathoexcitation (plasma NE [nmol/L]; DSS HS 98±6 vs. DSSBN8 HS 65±6, $P<0.05$) in DSSBN8 vs. DSS rats.
Conclusion: Up-regulation of PVN Gαi2 protein-gated pathways represents a conserved central molecular mechanism that suppresses renal nerve-dependent NE mediated sodium reabsorption to maintain a salt-resistant phenotype. We speculate PVN Gαi2 protein-gated regulation of NE secretion influences renal NCC expression (4) to maintain salt-resistance. SNP's in the GNAI2 gene correlate with human hypertension (5) suggesting the translational potential of our mechanistic studies.

Water and sodium intake by hyperosmotic rats treated with moxonidine into the lateral parabrachial nucleus depends on the activation of central cholinergic mechanisms

C.F. Roncari, R.B. David, P.M. De Paula, D.S. Colombari, L.A. De Luca Jr., E. Colombari and J.V. Menani

Department of Physiology and Pathology, Dentistry School, UNESP, Araraquara, Sao Paulo, Brazil

Recently it was demonstrated that plasma hyperosmolarity, a classic dipsogenic stimulus, can also facilitate sodium intake if inhibitory mechanisms are deactivated by the injections of moxonidine (α_2-adrenoceptor/imidazoline receptor agonist) into the lateral parabrachial nucleus (LPBN). It has also been suggested that water intake induced by plasma hyperosmolarity depends on the activation of central cholinergic mechanisms. Therefore, in the present study, we investigated whether central cholinergic mechanisms are important for water and sodium intake by hyperosmotic rats treated with moxonidine into the LPBN. Male Holtzman rats (290-310 g, n = 9) were anesthetized with ketamine (80 mg/kg of body weight) and xylazine (7 mg/kg of body weight) subcutaneously and stainless steel guide-cannulas were implanted into the lateral ventricle (LV) and bilaterally into the LPBN. Five days after the brain surgery, the animals received an intragastric load of 2 M NaCl (2 ml) and an injection of saline or atropine (muscarinic antagonist; 20 nmol/1 μl) in the LV. Forty-five minutes later, the animals received bilateral injections of vehicle or moxonidine (0.5 nmol/0.2 μl) into the LPBN. Water and 0.3 M NaCl intake was measured for 2 h starting 15 min after LPBN injections. Results are reported as mean ± SEM. Two-way ANOVA using treatments and times as factors followed by Newman–Keuls tests was used for comparisons. Bilateral injections of moxonidine into the LPBN of hyperosmotic rats that received saline in the LV significantly increased water (13.0 ± 4.4 ml/2 h, vs. vehicle: 6.9 ± 1.0 ml/2 h, $p < 0.05$) and 0.3 M NaCl intake (18.6 ± 5.2 ml/2 h, vs. vehicle: 0.2 ± 0.1 ml/2 h, $p < 0.05$). The pre-treatment with atropine into the LV abolished water (0.7 ± 0.3 ml/2 h, $p < 0.05$) and 0.3 M NaCl intake (1.3 ± 0.4 ml/2 h, $p < 0.05$) induced by hyperosmolarity combined with moxonidine injected into the LPBN. The results suggest the involvement of central cholinergic muscarinic mechanisms on water and sodium intake by hyperosmotic rats treated with moxonidine injected into the LPBN.

PCD179

The combined administration of natriuretic peptides (ANP and CNP) in the lateral ventricle modulates the fluid intake in response to sodium depletion and water deprivation

L. Margatho, B. Fortes de Morais, L. Elias and J. Antunes-Rodrigues

School of Medicine of Ribeirao Preto-USP, Ribeirao Preto, Brazil

The physiological actions of the natriuretic peptides are first modulated by interactions with their receptors. The NPR-A receptor recognizes the atrial natriuretic peptide (ANP) and the NPR-B receptor shows specificity for the natriuretic peptide type-C (CNP). In this study we investigated the effects of combined injections of ANP or CNP in the lateral ventricle (LV) on water and 0.3M NaCl intake in rats submitted to 24 h of sodium depletion or water deprivation. Methods and Results: Male Wistar rats (250–300 g, n = 5-8) with sham or stainless steel cannulas implanted into the lateral ventricle (AP= 0.8 mm caudal to bregma; L=1.2 mm lateral to midline and V=4 mm bellow dura mater) were used. All surgical procedures were performed under ketamine (80 mg/kg of body weight) combined with xylazine (7 mg/kg of body weight) anesthesia. Water and 0.3 M NaCl intake was induced by water deprivation (the rats had water bottles removed from the cages with free access to food for 24 h) or sodium depletion [the rats received a subcutaneous injection of the diuretic Furosemide (20 mg/kg,0.2 ml/kg) followed by access to sodium deficient diet and water for 24 h]. ANP (1 μg/5 μl) or CNP (1 μg/5 μl) were injected consecutively in the LV with a range interval of 10 min. Sham rats received only vehicle in the LV. At the end of the injections, two glass burettes with 0.1 ml divisions containing 0.3 M NaCl or water were offered to rats and the intake was measured every 15 min for 1h. Values are means ± S.E.M., compared by ANOVA. Results: Lateral ventricle injection of ANP plus CNP reduced 0.3 M NaCl intake in response to water deprivation (1.4 ± 0.4 ml vs. sham: 5.3 ± 1.5 ml, p = 0,01) and sodium depletion (3.2 ± 1.2 ml vs. sham: 8.0 ± 2.5 ml, $p < 0,05$) without changes on water intake. Also, CNP plus ANP reduced 0.3 M NaCl intake (1.8 ± 0.5 ml) only in response to water deprivation. There were no changes on sodium intake in rats previously treated with CNP plus ANP in the LV and subjected to sodium depletion. This last result shows that the previous injection of CNP was able to inhibit the inhibitory effect of ANP on sodium intake. A decrease in water intake was observed when CNP plus ANP were administered into the LV in response to water deprivation (3.7 ± 1.4 ml vs. sham: 16.8 ± 4.5 ml, $p < 0,05$) and sodium depletion (0.5 ± 0.2 ml vs. sham: 1.6 ± 0.5 ml, $p < 0,05$). Conclusion: In rats subjected to intra- or extracellular thirst, the results are pioneers in demonstrating an inhibitory modulation of the ANPergic pathway on the CNPergic path in rats previously treated with ANP plus CNP in the LV reducing sodium appetite; as well as the previous injection of CNP plus ANP reducing water intake.

Adrenomedullin-induced modulation of calcium channels in osteoblasts

T. Endoh[1], H. Kobayashi[2], M. Tazaki[1] and K. Sueishi[2]

[1]Dept of Physiol, Tokyo Dental College, Chiba, Japan and [2]Dept of Orthodont, Tokyo Dental College, Chiba, Japan

Adrenomedullin (ADM) is a 52-amino-acid peptide originally isolated from a human pheochromocytoma. It is structurally and functionally related to calcitonin gene-related peptide (CGRP) and belongs to the amylin peptide family. Voltage-dependent calcium channels (VDCCs) serve as crucial mediators of membrane excitability and many calcium-dependent functions such as growth of bone, regulation of proliferation, enzyme activity and gene expression. The purpose of this study was to investigate the effects of ADM on VDCCs currents in osteoblasts using a patch-clamp recording method. Murine osteoblastic MC3T3-E1 cells were cultured at 37 C in a 5%(v/v) CO2 atmosphere with alfa-modified minimal essential medium. Fabricated recording pipettes (2-3 M ohm) were filled with the internal solution of the following composition (in mM): 150 CsCl, 5 EGTA, 10 D-glucose, and 10 HEPES. The pH was adjusted to 7.3 with CsOH. Extracellular solution was a solution containing the following (in mM): 115 BaCl2 and 20 HEPES. The pH was adjusted to 7.4 with TEA-OH. Application of 1 micro M ADM rapidly and reversibly facilitated barium current from minus 49 pA to minus 127 pA (159% facilitation). Application of 0.1 micro M ADM rapidly and reversibly facilitated barium current from minus 78 pA to minus 93 pA (19% facilitation).

Apical KCNN4c channel regulated by Epac1 signaling affect epithelial Cl- secretion in diarrhea

I.A. Sheikh[1], R. Sinah[2], D. Nag[2], H. Koley[2], M.K. Chakraborty[1] and M.H. Kazi[1]

[1]Pathophysiology, National Institute of Cholera & Enteric Diseases, Kolkata, West Bengal, India and [2]Microbiology, National Institute of Cholera & Enteric Diseases, Kolkata, India

KCNN4 (IK) is a calcium activated potassium (K) channel. However, its role in diarrhea and regulation by Epac1 in cAMP stimulation is unknown. By RT-PCR and Western blot, we dentified KCNN4 expression in mouse intestine and human intestinal cell line. We hypothesized that apical KCNN4 was involved in diarrhea and regulated by Epac1 associated signaling. Depletion of Epac1 protein and apical addition of TRAM-34, a specific KCNN4 inhibitor significantly abolished cAMP stimulated Cl secretion and apical K conductance IK(ap) in T84 cells. We studied the current-voltage relationships in basolaterally permeabilized monolayers treated with 8-pCPT-2'-O-Me-cAMP in a symmetric K ion concentration. The presence of an inwardly rectified, Ca-activated K channel was evident in T84WT cells, whereas 8-pCPT-2'-O-Me-cAMP was not able to activate this inwardly rectified current in Epac1 knock down (Epac1KDT84) cells. Furthermore, addition of KCNN4 channel specific activator, 1-EBIO to intact wild type (T84WT) cells resulted 44±5 μA/cm2 rise in Isc while in Epac1KDT84 cells and T84WT + TRAM 34, 1-EBIO enhanced Isc was only 5±1 μA/cm2 and 4 ± 3 μA/cm2 respectively. Reconstructed confocal image in the X-Z plane of T84Epac1KD monolayers revealed redistribution of KCNN4c proteins into sub-apical intracellular compartment. We compared the surface amount of KCNN4c in these cells that Epac1 depleted cells have ~83% lower surface membrane expression of KCNN4c compared with T84WT cells. The role of Epac1-Rap1 signaling in endogenous regulation of KCNN4 was further assessed in T84 cells by Rap1 activation assays. FSK and 8-pCPT-2'-O-Me-cAMP induced GTP-loading of Rap1 in T84WT cells. To better understand the specific involvement of Rho-A and Rho-associated kinase ROCK in KCNN4 regulation in intestinal Cl secretion, Isc and IK(ap) was measured in T84WT cells. Finding that both Rho-A and ROCK kinase inhibitors significantly reduced FSK stimulated Isc as well as IK(ap). To explore the therapeutic potential of Epac1 regulated signaling of KCNN4c channels, we tested the effect of Rap1a inhibitor GGTI-298, ROCK inhibitor H1152 or KCNN4c inhibitor TRAM-34, in a closed loop mouse model. Our result demonstrated Epac1-Rap1-Rho-A-ROCK signaling lead to the alleviation of diarrhea by recruiting KCNN4c to the apical membrane which has important therapeutic value in diarrhea

PCD182

Interleukin-1β reduces K^+ channel activity through phosphorylation processes mediated by protein kinase C in human kidney proximal tubule cells

K. Nakamura, Y. Komagiri and M. Kubokawa

Department of Physiology, School of Medicine, Iwate Medical University, Yahaba, Iwate, Japan

It is well known that proinflammatory cytokines, such as interleukin-1β (IL-1β), interferon-γ (IFN-γ), tumor necrosis factor-α, induce cell injury in various organs, including kidney. Some investigators reported that changes in K^+ channel activity contributed to the renal tubular cell injury during ischemia or endotoxemia (1, 2). Thus, it is possible that the proinflammatory cytokines may cause cell injury partly by modulating K^+ channel activity in the kidney. However, little information was available regarding the effects of cytokines on activity of renal K^+ channels. In cultured human kidney proximal tubule cells purchased from Lonza (Walkersville, MD, USA) which isolated these cells under informed consent, an inwardly rectifying K^+ chan-

nel with an inward conductance of 40 pS was most frequently observed under the control condition (3). We have reported that IFN-γ possessed an acute stimulatory effect and a delayed suppressive effect on activity of this 40 pS K^+ channel (4). In this study, we investigated the effect of IL-1β on activity of the 40 pS K^+ channel in cultured human proximal tubule cells, using the patch-clamp technique and Fura-2 Ca^{2+} imaging. Values are means±S.E.M., compared by ANOVA. In cell-attached patches, IL-1β (15 pg/ml) significantly reduced channel activity to 33±9 % of the control (n=10, p<0.01) in a few minutes. This acute suppressive effect was blocked by an IL-1 receptor antagonist (IL-1ra, 20 ng/ml), suggesting that the effect of IL-1β was mediated by its specific receptor. An inhibitor of protein kinase C (PKC), GF109203X (500 nM), also blocked the acute suppressive effect of IL-1β. In inside-out patches, effects of phorbol 12-myristate 13-acetate (PMA) and PKC were examined in the presence of ATP (1 mM) and Ca^{2+} (1 μM). While PMA (500 nM) alone had no appreciable effect, the subsequent addition of PKC (1 U/ml) reduced channel activity to 21±6 % of the control (n=6, p<0.01). Since it has been reported that phospholipase C (PLC) plays important role in activation of PKC by providing diacyl glycerol and inositol 1,4,5-triphosphate which in turn causes Ca^{2+} release from the intracellular store (5), we next examined the effect of a PLC inhibitor, neomycin, on the acute suppressive effect of IL-1β in cell-attached patches. Neomycin (300 μM) completely blocked the suppressive effect of IL-1β. Finally, we examined whether IL-1β would actually increase intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$). The Fura-2 Ca^{2+} imaging revealed that IL-1β transiently caused a 1.5±0.2-fold increase in $[Ca^{2+}]_i$ (n=9, p<0.01). In accordance with the patch-clamp experiments, this increase in $[Ca^{2+}]_i$ was blocked by IL-1ra or neomycin. These results suggested that the acute suppressive effect of IL-1β on activity of the 40 pS K^+ channel in cultured human kidney proximal tubule cells would be dependent, at least in part, on the PKC-mediated phosphorylation processes.

Determination of the oligomeric assembly and intramolecular distances in the TRPV1 ion channel via FRET measurements

L.D. Islas, V. De la Rosa and G. Rangel

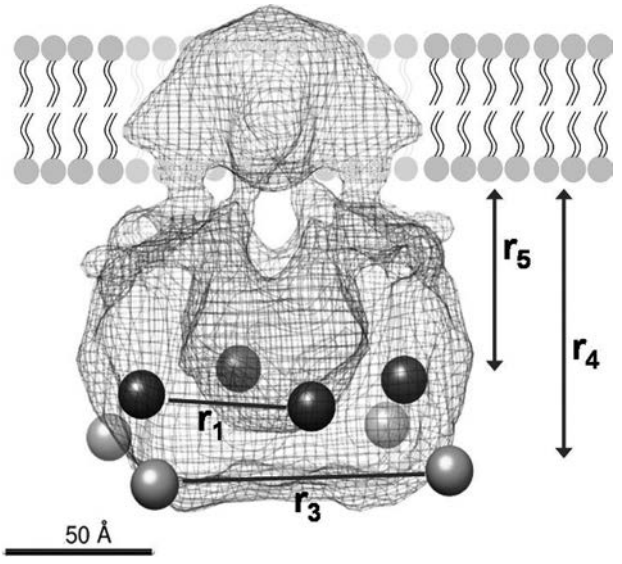
Physiology, UNAM, School of Medicine, Mexico City, DF, Mexico

The TRPV1 channel is an important molecular detectors of irritating compounds, elevated temperatures and other stimuli such as extracellular pH and divalent cations. Since these channels are regulated by several other compounds involved in signaling pathways related to pain and inflammation, their study has relevance in the clinical field. In spite of their obvious physiological importance, relatively little is known of their structure and molecular organization. TRP channels have so far been refractory to traditional structural analyses, such as X-ray protein crystallography and NMR. Among the structural approaches to date, there exists a low resolution structure determined by cryo-electron microscopy (Moiseenkova-Bell et al., 2008) and at least to molecular homology models based on the available structures from Kv channels.

As an alternative approach, we have undertaken determinations of the oligomeric state and inter and intra subunit distances of the TRPV1 ion channel, using FRET (Fluorescence Resonance Energy Transfer) measurements.

We have constructed several fluorescently-tagged channels using the pair of fluorescent proteins(FPs) eCFP/eYFP, were the fluorescent proteins have being inserted in the N- and/or C- termini of the protein. By means of co-expressing different combinations of these constructs in HEK 293 cells, we measured apparent FRET efficiencies using a spectral-FRET method (Zheng et al. 2002). We were able to determine that the most likely number of subunits in the functional TRPV1 channel is four. The distances between FPs at the C- termini are shorter than the distances between N- termini. This suggest that the N- termini are located in the periffery of the C-termini. We have also used FRET between a non-fluorescent membrane probe and the YFP constructs to determine the distance between the C and N termini and the plane of the membrane.

These experiments provide us with a glimpse of the possible gross molecular architecture and organization of the TRPV1 channel. The distances are consistent with both N and C termini being intracellular and forming a large mas of the channel. Some of our measurements are summarized in the figure below.



The FRET-determined positions of the N- termini (light spheres) and C-termini (dark spheres) mapped into the available electron density of TRPV1 obtained by (Moiseenkova-Bell et al., 2008).

Expression of exogenously transfected ROMK K^+ channel activity favors the polarized apical membrane of cultured M1 collecting duct cells

M. Kubokawa[1], K. Nakamura[1], T. Mayanagi[2] and K. Sobue[2]

[1]Department of Physiology, School of Medicine, Iwate Medical University, Yahaba, Japan and [2]Department of Neuroscience, Institute for Biomedical Science, Iwate Medical University, Yahaba, Japan

Potassium secretion along the renal collecting duct plays a key role in the body fluid potassium homeostasis. ROMK K^+ channels (Kir1.1) cloned from rat kidney by Hebert's group (1) are the major candidate for the route of this secretion. To date, several investigators have demonstrated the regulation of functional expression of transfected ROMK K^+ channels in various cells (2, 3, 4). However, little is known about the affinity of the functional expression of ROMK K^+ channels to the specific cell membrane. Recently, we have cloned ROMK1 (Kir1.1a) K^+ channel and examined the exogenous expression of the cloned ROMK1 fused with EGFP in polarized and non-polarized membranes of cultured mouse collecting duct (M1) cells. We used two types of cellular conditions in culture. One was single M1 cells on conventional glass dishes, and the other was confluent M1 cells on membrane inserts to expose the polarized apical membrane of the cells. Visual expression of ROMK-EGFP in the cells was confirmed with a fluorescent microscope, and the functional expression was examined using the cell-attached and the whole-cell modes of the patch-clamp technique. Values are mean ± S.E.M., compared by ANOVA. Without the exogenous transfection, ROMK-like K^+ channel has not been detected in both single and confluent cells. The lack of intrinsic ROMK in M1 cells was also confirmed by Western blot. The current identical to ROMK1 K^+ channel was observed in the ROMK-EGFP-expressing M1 cells in both single cells on glass and confluent cells on membrane inserts in cell-attached patches. Although no appreciable difference in fluorescence intensity and the localization of ROMK-EGFP was observed between the two conditions, there was a significant difference of the frequency of the ROMK current acquisition. Namely, active ROMK1 K^+ channels were detected in 67.9 % of the confluent cells and in 15.6 % of single cells. Numbers of active ROMK1 K^+ channels in individual patch-membranes of the confluent cells and the single cells were 2.21±0.44 (n=28) and 0.40±0.17 (n=45), respectively, indicating that expression of ROMK1 K^+ channel activity in the confluent cells is significantly higher than that in the single cells in cell-attached patches ($p<0.01$). Moreover, whole-cell current of the single cells with transfected ROMK-EGFP was not affected by K^+ channel blocker, Ba^{2+} (2 mM), but that of the confluent cells with ROMK-EGFP was markedly attenuated by Ba^{2+}. From the above data, it is strongly suggested that the exogenously transfected ROMK1 K^+ channel has a high affinity to the polarized apical membrane to express its activity in cultured M1 cells. The factor for this affinity remains to be investigated.

PCD185

Mathematical modelling of unique subconductnace level states in heteromeric Kir4.1/Kir5.1 channels from Xenopus tropicalis

L. Shang

School of Medical Sciences, University of Bradford, Bradford, UK

Ion channels are proteins which sit in the membrane of every cell in the body and control the flow of positively charged ions such as sodium and potassium into and out of the cell. The traditional view is that an ion channel exists in one of two stochastic states i.e. open or closed. However, this is challenged by the observation of intermediate conductance, or 'subconductance', states in a number of ion channels, including several potassium (K+) channels. It has previously been shown that heteromeric XTKir4.1/XTK5.1 channels are a model system for observing the usually short-lived subconductance levels [1]. These particular channels exhibit long-lived subconductance states and that an ortholog of Kir5.1 from Xenopus tropicalis causes a dramatic change in the frequency and duration of these substates. It is theorised that these sublevels correspond to the movement of the individual subunit which form the channel.

In this study we used the different pieces of available software [2-4] to details the kinetic analysis on this model system, based on my experimental data gathered using single channel recording [Fig1,2].

Figure 1 Single-channel recording of the rat Kir4.1-Kir5.1 channel. The S1 and S2 subconductance states are visible in an expanded trace on the right.

Figure 2 Left Hand Panel: Single channel currents from the X.tropicalis XTKir4.1/XTKir5.1 heteromeric channel showing the extended duration of the S1 sublevel state. Right Hand Panel: This long S1 sublevel duration is also observed with the ratKir4.1 subunit therefore the difference is due to the presence of the XTKir5.1 subunit. In both dimers all four conductance levels are visible.

For the measurement of subconductance states in all type of channels we used the threshold-crossing method, amplitude histograms and HMM (Hidden Markov Model) analysis. Single-channel events were analyzed first by idealizing the recording into closed and open dwells, and then fitting histograms of dwell times with mixtures of exponential functions that reflect the dwells in various states using Clampfit 9.2 and HJCFIT software. To ensure the unambiguous detection of brief sublevel events and comparison of sublevel durations we will use QuB analysis software.

A combination of amplitude histograms and dwell time analysis under different analysis software have been compared and contrasted to build a mathematical model to show how many sublevel states exist is formed and to gain some insight into its mechanism.

PCD186

TRPC1/C6 and STIM/Orai channels may regulate cell cycle progression of bone marrow stromal cells

J. Ichikawa and R. Inoue

Department of Physiology, Fukuoka University School of Medicine, Fukuoka, Japan

Ca^{2+} influx induces various physiological events such as contraction, exocytosis, gene expression, and cell growth and death. Transient receptor potential (TRP) and store-operated Ca^{2+} (SOC) channels are the representative of non-voltage-gated Ca^{2+} entry channels, and serve as major Ca^{2+} entry routes for non-excitable cells. Many reports indicate that Ca^{2+} influx through these channels is causally associated with cell cycle progression or growth, but the mechanism underlying it seems to vary depending on the cell type.

To question how the proliferative potential and cell cycle progression of adult stem cells are controlled is an attractive theme for regenerative medicine and bioengineering, but the implication of non-voltage-gated Ca^{2+} entry channels therein is poorly elucidated. In this study, we investigated the roles of TRP and STIM/Orai channels on cell cycle progression of bone marrow stromal cells (BMSCs) from adult rat which include mesenchymal stem cells. Cultured BMSCs were synchronized in G_1, S, G_2 or M phases, and the mRNA levels of respective TRPC and STIM/Orai subtypes were assessed by the quantitative real-time PCR. In the S phase, the expression levels of TRPC1, STIM and Orai were significantly enhanced. On the other hand, that of TRPC6 was greatly reduced in the S phase and significantly enhanced in the G_1 phase. In experiments measuring the intracellular Ca^{2+} concentration with Fura 2, SOC-mediated Ca^{2+} influx, which was evoked by thapsigargin or cyclopiazonic acid, was inhibited by 1μM Gd^{3+}. The Ca^{2+} influx was significantly enhanced in the S phase. Gd^{3+} (1μM), SKF96365 or pyrazole compound (Pyr2) suppressed cell proliferation. To seek a role of TRPC6 channels for cell cycle progression, we evaluated the resting membrane potential (RMP) of cells using a voltage-sensitive dye $DiBAC_4(3)$ or by the current-clamp mode of patch clamp technique. siRNA knockdown of TRPC6 expression but not of TRPC1 produced a significant negative shift of RMP. RMP in the S phase was deeper than in the other cell cycle stages. From these observations, we speculate that TRPC6 channels may work as a modulator of RMP thereby controlling the driving force for Ca^{2+} influx in the S phase. Cell cycle analysis by the flow cytometry revealed that siRNA knockdown of TRPC1, TRPC6 or STIM/Orai expression differentially affected the distribution of cell cycle stages. The fraction of cells residing in the G_0/G_1 phase was increased by siRNA of STIM/Orai but decreased by siRNA of TRPC1 or TRPC6. siRNA of TRPC6 significantly increased the fraction of cells in the G_2/M phase. To elucidate these observations more explicitly, the correlation between cell cycle-regulating molecules such as cyclins and the functions of TRPC1/C6 and STIM/Orai will need to be investigated.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD187

Inhibition of TRPM7 by oxidative stress is dependent on intracellular magnesium

H. Inoue[1], T. Murayama[2] and M. Konishi[1]

[1]Physiology, Tokyo Medical University, Tokyo, Japan and [2]Cellular and Molecular Pharmacology, Juntendo University Graduate School of Medicine, Tokyo, Japan

TRPM7 is a non-selective cation channel which permeates Ca^{2+} and Mg^{2+} and plays important roles in fundamental cellular functions, including Mg^{2+} homeostasis, proliferation, migration, and viability. In various cell types, it has been reported that during whole-cell patch-clamp recordings, low $[Mg^{2+}]_i$ conditions induced activation of cationic currents called magnesium inhibited cation (MIC) currents, which is considered to be endogenous TRPM7 currents. We previously demonstrated that MIC currents were activated by lowering $[Mg^{2+}]_i$ under the whole cell recordings and inhibited by hydrogen peroxide in white adipocytes isolated from mice (ref.1). In the present study, we investigated whether or not hetelorogously overexpressed murine TRPM7 is inhibited by oxidative stress as endogenous MIC currents. First, to clarify if the molecular identity of MIC channel was TRPM7, shRNAs for human TRPM7 were introduced to HEK293T cells which express MIC currents similar to that in white adipocytes. Introduction of shRNAs for human TRPM7 reduced both the expression of MIC currents and TRPM7 mRNA to ~30% of control cells. Thus TRPM7 might be responsible for MIC currents. Next murine TRPM7 variants 1 and 2 were cloned from mouse white adipose tissue and then tetracycline-inducible HEK293 cell lines for each variants were established. Under the whole-cell recordings, both veriant 1 or 2 of TRPM7 showed similar properties to endogenous MIC currents in white adipocytes and HEK293T cells; outward rectification in the presence of extracellular divalent cations, liner I-V relationships in the absence of extracellular divalent cations, and inhibition by 2-aminoethoxydiphenil borate (100 or 200μM) and N-methyl maleimide (100 μM). On the other hand, hydrogen peroxide (500 μM) could not inhibit TRPM7 currents when Mg^{2+} was eliminated from intracellular solutions in both of variants of TRPM7. However when $[Mg^{2+}]_i$ was added to the intracellular solution, TRPM7 currents were inhibited by hydro-

gen peroxide concentration dependently. The inhibition was irreversible during whole-cell recordings. From these results, it is suggested that oxidation of TRPM7 or its regulatory proteins by hydrogen peroxide inactivate TRPM7, possibly by sensitizing it to intracellular Mg^{2+}.

Serotonin-specific reuptake inhibitor (SSRI) enhances anoctamin 6 (ANO6) calcium activated Cl^- channel activity

H. Kim[1], Y. Kim[1], M. Lee[2] and J. Nam[1]

[1]Physiology, Dongguk University College of Medicine, Gyeongju, Gyeongsangbukdo, Republic of Korea and [2]Pharmacology, Yonsei University College of Medicine, Seoul, Republic of Korea

Ca^{2+}-activated Cl^- channels (CaCCs) control diverse functions in several physiological processes. Recently, anoctamins (ANOs) have been identified as a family of putative Cl^- channels, and ANO1 and ANO2 have been identified as essential components of the CaCCs. (1) However, the role of other members of the ANO family in generating Cl^- currents by increasing the intracellular Ca^{2+} concentration is still a debatable matter. Recently, a study showed that ANO6 generates a small-conductance Ca^{2+}-activated nonselective cation current. (2) In addition, ANO6 has been linked to phosphatidylserine exposure in platelet apoptosis and platelet activation. However, other studies have shown ANO6 as an essential component of the outward-rectifying Cl^- channels or CaCCs. (3,4) It is therefore unclear whether ANO6 belongs to the family of CaCCs or to a family of proteins with heterogeneous functions. Serotonin-specific reuptake inhibitors (SSRIs) are widely used antidepressants that primarily act as selective serotonin reuptake inhibitors, and they inhibit various ion channels, including voltage-activated K^+ channels, two-pore K^+ channels, and CaCCs. In particular, ANO1 is sensitively inhibited by fluoxetine. (1) Using the whole-cell patch-clamp technique, we examined the effects of SSRIs, including fluoxetine, paroxetine, and sertraline, on cloned human ANO6 expressed in HEK293 cells. We identified that ANO6 can produce calcium-activated Cl^- currents that have low sensitivity to calcium ions. (EC_{50}: 29.9 ± 2 μM, n=5) Surprisingly, in contrast to ANO1, SSRI enhances ANO6 currents in a concentration-dependent manner. However, these mechanisms need to be elucidated in the future.

PCD189

Membrane-dependent activation of the bile acid-sensitive ion channel (BASIC), a DEG/ENaC channel expressed in the liver

D. Wiemuth, A. Schmidt and S. Gründer

Physiology, RWTH Aachen, Aachen, Germany

The physiological function of members of the DEG/ENaC family of ion channels ranges from Na^+-reabsorption over pH-sensing and neuronal transmission to mechanosensation and the sensation of taste. As diverse as their physiological functions are their modes of activation. Constitutively active channels like the epithelial Na^+ channel (ENaC) and proton-sensitive channels like the acid-sensing ion channels (ASICs) are found in this ion channel family as well as mechanosensitive channels like MEC-4 and peptide-gated channels like Hydra Na^+ channels (HyNaCs).

The bile acid-sensitive ion channel (BASIC) adds another layer of diversity to the DEG/ENaC family. It is expressed in cholangiocytes, the epithelial cells lining the bile ducts and strongly activated by bile acids. Both, physiological function and the mode of activation are not known so far. Bile acids are negatively charged, amphiphilic derivatives of cholesterol that affect structure, curvature and fluidity of membranes. They could activate BASIC either indirectly by interfering with the membrane or directly in a ligand-like manner by binding to the channel. We addressed this question by employing a pharmacological approach and used molecules, which are known to affect biological membranes. Crenating agents like trinitrophenol (TNP) and cup-forming molecules like chlorpromazine (CPZ) were applied to Xenopus oocytes expressing BASIC or co-applied with bile acids. Interestingly, the anionic TNP had a stimulatory effect when co-applied with bile acids or when applied alone at millimolar concentrations while the cationic CPZ displayed an inhibitory effect when co-applied with bile acids. Other membrane active substances like anionic or cationic tensides also affected the activity of BASIC. These data point towards a mechanism of activation, where the membrane is modulated and BASIC functions as a sensor for this modulation. In addition to the pharmacological approach we are using a chimeric approach with ASIC1a, a related but bile acid-insensitive channel, in order to define the domains of BASIC that are crucial for sensing membrane modulation induced by bile acid. Taken together our data will help to understand the events leading to the activation of the DEG/ENaC channel BASIC.

PCD190

A gate-coupled expansion of the cytoplasmic pore of mammalian inward rectifier potassium channels

A. Inanobe[1], A. Nakagawa[2] and Y. Kurachi[1]

[1]Department of Pharmacology, Osaka University, Graduate School of Medicine, Suita, Japan and [2]Osaka University, Institute for Protein Research, Suita, Japan

Inward rectifier potassium (Kir) channels comprise transmembrane and cytoplasmic domains. Various cytoplasmic regulators associate with the cytoplasmic domain to control the

gate at the transmembrane domain. Despite increasing knowledge about its structure, it remains unclear how conformational change in the cytoplasmic domain couples to the gate. To approach this question, we focused on 2 spatially adjacent residues, Glu236 and Met313, of G protein-gated Kir channel subunit Kir3.2, whose side chains face the cytoplasmic pore when it is in a closed state. These 2 residues reside on adjacent β-strands which form a β-sheet. Since the cytoplasmic pore appeared to expand its inner diameter during gating, it could be speculated that effect of mutations reflects conformational changes surrounding these residues. We introduced mutations into either of residues, expressed them with m2-muscarinic receptor in Xenopus oocytes and measured the acetylcholine (ACh)-dependent potassium currents. Mutants at Glu236 tended to shift dose-response curves to the rightward direction. On the other hand, mutations at Met313 tended to render the concentration-dependent curve with shallow slope. These results suggest that, even though 2 β-strands lie adjacent in the closed state, both strands shift differently during gating. One of the Glu236 mutants showed the malconduction and the constitutive activity. In crystal structure of the mutant, the residue introduced contacts with main chains of the adjacent subunits. These results strongly suggest that the Kir channels change the inner diameter of the cytoplasmic pore during gating, and the strands differently contribute to pore expansion to control of Kir channel gating.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD191

Contribution of Orai-STIM to histamine-induced store operated Ca^{2+} entry and functional coupling with Ca^{2+}-activated K^+ channels in Chondrocytes

M. Inayama[1], Y. Suzuki[1], H. Yamamura[1], S. Ohya[2] and Y. Imaizumi[1]

[1]Molecular and Cellular Pharmacology, Nagoya City University, Graduate School of Pharmaceutical Sciences, Nagoya, Aichi, Japan and [2]Department of Pharmacology, Kyoto Pharmaceutical University, School of Pharmacy, Kyoto, Kyoto, Japan

In articular cartilage inflammation, histamine release from mast cells enhances cytokine production and matrix synthesis, and also promotes cell proliferation of stimulated chondrocytes. The response to histamine H1 receptor stimulation induces Ca^{2+} release from endoplasmic reticulum (ER) through inositol trisphosphate (IP3) production in chondrocytes. The depletion of Ca^{2+} in the ER may trigger the opening of plasma membrane store operated Ca^{2+} entry (SOCE) channels. Activation of Ca^{2+}- activated K^+ (K_{Ca}) channels due to rise of $[Ca^{2+}]_i$ produces membrane hyperpolarization, which may enhance Ca^{2+} entry through SOCE channels in chondrocyte.
The present study was undertaken to reveal the functional impact of functional coupling between KCa and SOCE channels in the regulation of $[Ca^{2+}]_i$ in chondrocytes in responses to store depletion using OUMS-27 cells, as a model of chondrocytes derived from human chondrosarcoma.
Application of histamine induced a significant $[Ca^{2+}]_i$ rise and synchronized membrane hyperpolarization, and both effects were mediated by H1 receptor activation. The histamine-induced membrane hyperpolarization was attenuated to approximately 50% by large conductance K_{Ca} (BK) channel blockers, and further reduced by intermediate (IK) and small conductance K_{Ca} (SK) channel blockers (Funabashi, et al.). The $[Ca^{2+}]_i$ rise induced by application of 2.2 mM Ca^{2+} after store depletion by thapsigargin in Ca^{2+} free solution (SOCE) was enhanced and inhibited by 2-APB at low (5 μM) and high (30 μM) concentrations, respectively. RT-PCR analysis suggests that the molecular basis of SOCE channel may be Orai-STIM combination (Orai1, Orai2, STIM1 and STIM2). The SOCE was significantly reduced by application of siRNA of Orai1.
The movement of STIM1-YFP following store depletion and subsequent punctual co-localization with Orai1-CFP were visualized using total internal reflection fluorescence microscopy (TIRFM). The expression of mutant (E106Q) Orai1 in OUMS-27significantly decreased histamine-induced $[Ca^{2+}]_i$ rise than in the control. K_{Ca} channel activation by $[Ca^{2+}]_i$ rise contributed to the sustained Ca^{2+} entry through SOCE channels, presumably via the predominant combination of Orai1 and STIM1.
The functional coupling between K_{Ca} channel and SOCE channel plays substantial roles as a positive feedback mechanism for the sustained $[Ca^{2+}]_i$ rise following stimulations. The sustained $[Ca^{2+}]_i$ rise may enhance cytokine production and matrix synthesis, and also promote cell proliferation of stimulated chondrocytes.

PCD192

Effects of local anaesthetics on ion channels of canine articular chondrocytes

M. Wegg[1], R. Lewis[1], A. Mobasheri[2] and R. Barrett-Jolley[1]

[1]Musculoskeletal Biology, University of Liverpool, Liverpool, UK and [2]University of Nottingham, Nottingham, UK

Local anaesthetics (LAs) are routinely injected into joints at high concentrations during joint surgery [1], although consistent findings show local anaesthetics are chondrotoxic [2,3]. Studies have shown that LAs modulate both potassium and sodium channels, but the mechanism of cell chondrotoxicity is not known. In previous studies, we have shown that both transient receptor potential (TRP) channels and epithelial sodium channels (ENaC) exert a profound effect over chondrocyte cellular volume control and therefore interaction with these channels could potentially also be toxic [4, 5]. In this study we investigate whether any of a range of LAs modulate either ENaC-like channel activity and/or that of a TRP-like non-specific cation (NSC) conductance.
Articular chondrocytes were isolated from canine stifle joints using standard procedures [4] from dogs euthanatized for unrelated veterinary reasons under local Ethical Approval. Standard physiological HEPES buffered saline solutions (150mM NaCl/5mM KCl) were included in both patch pipette and bath solutions. Membrane potentials were corrected for junction potential calculated using JPCalc (University of New South Wales, Auz). Ion channel activity was recorded in cell–attached mode. LAs were added to the patch pipette solution at typical clinical concentrations as follows: 20mM prilocaine, 35mM mepivacaine, 70mM mepivacaine and 15mM bupivacaine. Statistical tests were performed with Minitab (PA, USA).

We first characterised an NSC single channel conductance, g of 43±13pS (n=14), sensitive to gadolinium III (75±9% reduction of open probability with 100μM), with a reversal potential (Vrev) of 1±9mV (n=14) and an ENaC-like ion channel (8.2±2.6pS, n=5) with Vrev 75±9mV (n=5) near to the predicted ENa of 85mV. The NSC channel was seen in 14/20 patches under control conditions, and the ENaC-like channel seen in 5/20 patches. Following exposure of the cells to each of the LAs there were no significant (ANOVA), changes in Vrev or g of the NSC channel (20mM prilocaine:-2±9mV, 45±9pS, n=4; 35mM mepivacaine 5±10mV, 65±16pS, n=9; 70mM mepivacaine 5±2mV, 31±5pS, n=6; 15mM bupivacaine 5±5mV, 67±25pS, n=6). However, this conductance was seen significantly more frequently in the presence of mepivacaine and bupivacaine ($p<0.05$, $p<0.01$ respectively; one sample sign test), but not prilocaine. No ENaC-like channel activity was detected in the presence of any of the local anaesthetic treatments used.

This data shows that at the concentrations used routinely in clinics, local anaesthetics have profound effects on a chondrocyte ion channel activity. Future studies will be directed at establishing whether these acute ion channel effects do mediate decreases in chondrocyte survival.

Expression of TRP channels in isolated single Merkel cells from hamster oral mucosa

M. Soya[1,2], H. Kuroda[1,2], A. Kawaguchi[1,2], M. Sato[1], U. Sobhan[1], M. Tazaki[3], T. Ichinohe[2] and Y. Shibukawa[1,3]

[1]Oral Health Science Center hrc8, Tokyo Dental College, Chiba, Japan, [2]Department of Dental Anesthesiology, Tokyo Dental College, Chiba, Japan and [3]Department of Physiology, Tokyo Dental College, Chiba, Japan

Sensory receptors throughout the body, including those in the oral epithelium, produce sensation in response to stimulation. Merkel cells (MCs) in the oral mucosa constitute a distinct cell population localized at the border between the epidermis and the dermis, and are believed to form part of an MC-neurite complex with myelinated Aβ-neurons which acts as a mechano-electric transducer. Transient receptor potential (TRP) channels, which constitute a large and functionally versatile family of cation-permeable transmembrane proteins, are mainly considered to be polymodal cell sensors involved in various cellular functions, including thermo/mechano/osmo-sensitivity. In rat footpad, these channels were found to be sensitive to mechanical and osmotic stimulation. The localization and physiological role of TRP channels in oral mucosal MCs, however, remain to be clarified. We isolated quinacrine-positive single MCs from hamster oral mucosa to investigate the expression, localization, and activity of TRP channels by immunohistochemical analysis and measurement of intracellular free Ca2+ concentration ([Ca2+]i) using fura-2 fluorescence. Intense immunoreaction for cytokeratin 20 (CK20), which co-localized with quinacrine fluorescence, was observed in the acutely isolated MCs. Both CK20 and quinacrine are used as specific markers to identify MCs. Intense immunoreactions for TRP vanilloid subfamily members (TRPV)-1, TRPV2, and TRPV4, and TRP ankyrin subfamily member (TRPA)-1 and TRP melastatin subfamily member (TRPM)-8 were observed on quinacrine-positive MCs. Transient increases in [Ca2+]i were osmo-dependently observed by application of hypo-tonic solution (140 to 300 mOsm/L). These [Ca2+]i increases were inhibited by TRPV1, TRPV2, TRPV4, or TRPA1 channel antagonists, but not by TRPM8 channel antagonist. In the presence of extracellular Ca2+, TRPV1, TRPV2, TRPV4, or TRPA1 channel agonists induced an increase in [Ca2+]i in MCs, but not in the absence of extracellular Ca2+. The present results indicate that hypotonic solution-induced membrane stretch activates TRPV1, TRPV2, TRPV4, and TRPA1 channels, and suggest that these channels play a key role as molecular sensors in the sensory transduction process in either MCs or MC-neurite complexes.

Role of membrane cholesterol and lipid rafts in cellular mechanotransduction and actin remodeling

V.I. Chubinskiy-Nadezhdin, Y.A. Negulyaev, S.Y. Khaitlina, T.N. Efremova and E.A. Morachevskaya

Russian Academy of Sciences, Institute of Cytology RAS, St.Petersburg, Russian Federation

Cholesterol is a major lipid component of mammalian cells which regulates dynamical and physical properties of the plasma membrane. Lipid rafts are cholesterol- and sphingolipid-enriched regions of membrane that are implicated in various cellular responses. Considering the major impact of cholesterol in the mechanical properties of lipid bilayer, the role of lipid rafts and their integrity in regulation of cellular mechanotransduction is of peculiar interest.

Cholesterol-depleting treatment of cells with methyl-beta-cyclodextrin (MbCD) significantly suppressed the activation of mechanosensitive (MS) stretch-activated ion channels in human myeloid leukemia K562 cells. Particularly, the open state probability (Po) of MS channels significantly decreased (Po=0.08±0.03 after MbCD treatment vs. 0.28±0.03 in control) whereas the minimal level of stimulus, that was needed for channel activation increased (70 80 mm Hg after MbCD vs. 30 40 mm Hg in control). Atomic force microscopy revealed

the increase of plasma membrane stiffness after cholesterol depletion. The observed alteration of mechanical properties of the membrane and the inhibition of MS channels after MbCD treatment could not be explained by the change of dynamic properties of lipid bilayer after cholesterol sequestration. We hypothesized, that this effect was mediated by actin cytoskeleton rearrangement after lipid raft disruption. The disruption of rafts was confirmed by fluorescent staining of lipid raft marker GM1 ganglioside. Importantly, fluorescent data revealed the formation of F-actin network in K562 after cholesterol depletion. Importantly, the high level of MS channel activity in cholesterol-depleted cells was fully restored after F-actin disruption with cytochalasin D or latrunculin B. Experiments on different cell lines showed that the effect of cholesterol depletion on actin organization is determined by the initial state of microfilament system in the cell. Particularly, in cultured normal BALB/3T3 fibroblasts that characterized with highly developed microfilament system, the cholesterol depletion resulted in actin disassembly and reduction of stress fibers. On the contrary, in transformed 3T3B-SV40 fibroblasts, containing low amount of fibrillar actin, MbCD treatment induced intensive formation of stress fibers and increased cell spreading. Thus, the functional impact of cholesterol depletion and lipid raft disruption on actin cytoskeleton can be determined by an initial balance of fibrillar and globular actin. Cholesterol-regulated actin rearrangement may affect different signaling processes in living cells, including cellular mechanotranduction. Particularly, the assembly of F-actin network in K562 cells after cholesterol depletion increases the stiffness of plasma membrane and thus inhibits MS channel activity.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD195

Altered expression of two-pore domain potassium (K_{2P}) channels in cancer

S. Williams, A. Bateman and I. O'Kelly

Faculty of Medicine, University of Southampton, Southampton, UK

Ion channels have been implicated in both the behaviours of cancer cells and the development of cancer. Potassium channels (KCh) play fundamental roles in cell behaviours linked to cancer progression, including proliferation, migration and apoptosis. One family, the two-pore domain (K_{2P}) KCh are of particular interest since when functionally expressed these channels are constitutively active. Of the 15 K_{2P} family members, 4 channels; K_{2P}2.1, K_{2P}3.1, K_{2P}9.1, K_{2P}5.1, are reported to show expression and functional implications in cancer. Supporting the hypothesis that alterations to K_{2P} channels expression or function may play a role in cancer progression and that targeting these channels may lead to novel therapies.

To determine the expression of the KCNK genes, encoding the K_{2P} channels, in a range of cancer types we used the online cancer microarray database, Oncomine (www.oncomine.org). Each gene was examined across 20 cancer types, comparing mRNA expression in cancer to normal tissue. Searches were performed using threshold criteria (p-value < 0.05, fold change > 2, gene rank percentile < 10%) so that positive analyses for altered expression were above these. mRNA expression of K_{2P} channels were also examined in human cancer cell lines by RT-PCR.

Significantly overexpression of K_{2P} channels was observed in a range of cancers including breast, leukaemia and lung. The data highlights K_{2P} channels with overexpression in a range of cancers; K_{2P}1.1, K_{2P}3.1, K_{2P}12.1. More cancers and channels showed underexpression rather than overexpression, suggesting that underexpression of K_{2P} channels may be important in cancer. Six K_{2P} channels have a wide underexpression pattern across the cancer types examined; K_{2P}1.1, K_{2P}3.1, K_{2P}5.1, K_{2P}6.1, K_{2P}7.1, K_{2P}10.1. There was significant underexpression of K_{2P} channels in a wide range of cancer types; brain, colorectal, gastrointestinal, kidney, lung, melanoma, oesophageal. Three K_{2P} family members; K_{2P}4.1, K_{2P}16.1, K_{2P}18.1 did not show altered expression in cancer.

Using RT-PCR we examined the expression of K_{2P}3.1 mRNA in cancer cell lines and found expression in breast, lung and kidney cell lines. K_{2P}9.1 mRNA was also identified in several cancer cell lines including brain, breast, colorectal, and oesophageal. K_{2P}15.1 mRNA has been detected in all cancer cell lines examined to date.

K_{2P} channels alter cell resting membrane potential therefore altered expression in cancer cells would change this potential and influence the activity of other ion channels causing behavioural consequences. K_{2P} channels also show sensitivity to physiological stimuli including pH, oxygen tension and glucose concentration; physiological parameters which are disrupted in the tumour microenvironment. This information will be instrumental towards understanding the role of K_{2P} channels in cancer progression.

PCD196

Voltage-gated Na^+ channels contribute to depolarised membrane potential in the MDA-MB-231 human breast cancer cell line

M. Yang and W.J. Brackenbury

Biology, University of York, York, UK

Voltage-gated Na^+ channels (VGSCs) initiate and conduct action potentials in excitable cells. Functional VGSCs are also present in cells from a number of cancers. Inhibiting Na^+ current (I_{Na+}) reduces cancer cell migration and invasiveness (Brackenbury, 2012). We previously reported that phenytoin, an antiarrhythmic agent, inhibits I_{Na+} in human MDA-MB-231 breast cancer cells, thus reducing migration and invasion (Yang *et al.*, 2012). Membrane potential (V_m) is finely tuned in cellular activities such as proliferation and differentiation. Cancer cells possess depolarised V_m (Marino *et al.*, 1994), which favours cell cycle progression (Sundelacruz *et al.*, 2009). Here, we used whole-cell current clamp to study the involvement of VGSCs in regulating V_m of MDA-MB-231 cells. Cells were firstly perfused with standard physiological saline solution (PSS) for 60s, followed by a 'test' PSS for 150s, and finally a wash-out step with standard PSS for a further 150s. V_m values (sampled at 100Hz) within the last 5, 15, 30 and 60s in each of the 3 stages were analysed using ANOVA followed by Tukey *post-hoc* tests. Values are mean ± SEM. We firstly replaced extracellular Na^+ with choline in the PSS. Na^+ depletion reversibly hyperpolarised the V_m by ~10mV (Table 1). We next tested if VGSCs are involved in V_m regulation by applying 10 μM phenytoin in the PSS. Phenytoin hyperpolarised the V_m by ~3mV

while the drug carrier 75μM NaOH had no effect (P=0.98). The effect of phenytoin was thus more subtle than Na^+ depletion. Interestingly, after washing out phenytoin, the V_m did not recover (Table 2). We conclude that (1) Na^+ conductance contributes to the depolarised V_m in MDA-MB-231 cells, and (2) phenytoin partially inhibits the Na^+-mediated V_m depolarisation in a non-reversible manner. Given that depolarised V_m is a hallmark of malignancy (Sundelacruz *et al.*, 2009), we propose that Na^+-mediated V_m regulation may play a role in cancer progression.

Extracellular ATP arrests the adaptive reaction in mouse eggs subjected to hypotonic stress

M. Pogorelova[1,2] and V. Pogorelova[1]

[1]Institute of Theoretical and Experimental Biophysics RAS, Pushchino, Russian Federation and [2]Biological Department, Moscow State University, Moscow, Russian Federation

Cell volume homeostasis is particularly critical for early preimplantation development [1]. The ability to regulate cell size first appears in the oocyte after ovulation is triggered [2]. The nature of the regulatory mechanisms governing the volume changes in the mature oocyte during regulatory volume decrease (RVD) is not clear. Volume-sensitive organic osmolyte-anion channel or VSOAC is known to be involved in RVD in most somatic cells. It was shown that VSOAC-like channel may also participate in egg volume regulation [3]. The most important property of VSOAC is the open-channel block by millimolar concentrations of extracellular ATP [4]. The aim of this study was to investigate the external ATP influence on kinetics of mouse metaphase II (MII) oocyte osmotic response under hypotonic stress.

Eggs (MII oocytes) were obtained from 8-10-week-old SHK female mice. The females were superovulated by an i.p. injection of 10 IU of Folligon (Intervet, Holland) followed by an i.p. injection of 5 IU of human chorionic gonadotropin (hCG, Intervet, Holland) 46-48 hs later. The MII oocytes were flushed from excised oviducts of sacrificed by cervical dislocation animals 14 hs after hCG administration. The hypotonicity was created by replacing 140mM NaCl in Dulbecco`s solution with 70mM NaCl. Eggs were exposed for 90 minutes in the hypotonic conditions. The similar procedure was employed for Dulbecco`s containing 5 mM ATP (Sigma, USA). Osmotic adaptation in single oocyte has been studied employing the direct measurement of cell volume with the quantitative microtomography [5]. Egg volume was determined with laser scanning microscopy followed by three-dimensional reconstruction (3-DR). The keeping of the intact volume of mature mouse oocyte was based on freeze-drying technique. After cryofixation in liquid propane and subsequent low-temperature dehydration the cell was immediately immersed in the Epon medium. The monolayer of freeze-dried embedded oocytes was examined with a laser scanning microscope (Leica DM2500, Germany). Using 532-nm laser a gallery of optical slices of mouse oocyte was collected in Z-direction with deepness step of 1 μm thick. 3-DR was performed in the 3ds max medium. All results are presented as means ± S.D., compared by Student's *t*-test.

Our data indicate that hypoosmotic incubation for 20 minutes resulted in the swelling peak of oocyte volume of 221±15 pl *vs.* initial level of 121±13 pl, p<0.05. After 90 minute exposure the cell volume was recovered to 174±24 pl *vs.* 213±17 pl in hypotonic Dulbecco`s with ATP, p<0.05.

In the given research it was shown that mouse MII oocytes are capable of RVD. The recovery is pronounced but not completed at 90 minutes. RVD in mouse eggs is inhibited by external ATP of 5mM. This finding suggests the involvement of the VSOAC-like mechanism in osmotic response of mature oocyte to hypotonic stress.

STIM and Orai proteins regulate store-operated calcium entry and NADPH oxidase activity in primary human monocytes

S. Saul, B. Pasieka, D. Conrad, G. Schwär, R. Kappl, B. Niemeyer and I. Bogeski

Biophysics, Saarland University, Homburg, Saarland, Germany

In the innate immune defense, professional phagocytes such as neutrophils, monocytes and macrophages play an important role in clearance of pathogenic intruders and in triggering the adaptive immune system. Monocytes invade tissues as a result of chemokine attraction wherein they differentiate into macrophages and dendritic cells and act as first line of host defense.

Store-operated calcium entry (SOCE) through calcium release activated calcium (CRAC) channels composed of Orai1-3 and STIM1 and 2 proteins is implicated in a plethora of cellular functions. While a major role for CRAC channels was revealed especially in T cells and neutrophils, it is presently not known if and what role Orai and STIM proteins play in human monocytes.
For efficient immune response, monocytes need to generate high amounts of oxidants upon encounter with an antigen. Hence, we investigated the role of Orai and STIM isoforms on reactive oxygen species (ROS) production, Ca2+ homeostasis, and the effects of their interplay for monocyte function. Expression analysis using qRT-PCR showed the presence of all CRAC channel components in human monocytes, with comparatively high Orai3 and STIM2 levels. To determine the interplay of SOCE and ROS production, monocytes were activated by internal Ca2+ store depletion using thapsigargin or bacterial products (fMLF). To determine the specific contribution of a particular CRAC channel component in monocyte SOCE we used small interfering RNA gene silencing. Our measurements showed a significant contribution of Orai1 and STIM1 and, in contrast to other phagocytes, also Orai3 and STIM2 proteins. Not unexpectedly, NADPH-oxidase 2 (NOX2) was identified as the main enzymatic source of ROS in monocytes, which showed a clear dependency on not only internal Ca2+ concentration, but also on SOCE. To determine the dependency of NOX2 on Ca2+ and thus Orai and STIM, we analyzed quantitative and temporal parameters of ROS generation using fluorescent dyes and electronic paramagnetic resonance (EPR) spectroscopy. Down-regulation of Orai1, STIM1 and STIM2 expression levels resulted in altered kinetics and a decrease in ROS production. Contrary to these results, lower levels of Orai3 led to enhanced SOCE and consequently increased ROS production.
We demonstrate the existence of a regulatory feedback loop between Orai channels and NOX2 enzymes essential for monocyte function. Based on our preliminary data we are currently investigating the contribution of Orai and STIM proteins in monocyte migration and invasion and phagocytosis.

Synergistic activation of the human bile acid-sensitive ion channel (hBASIC) by chenodeoxycholic and deoxycholic acid

C.M. Lefèvre, S. Gründer and D. Wiemuth

Institute of Physiology, Aachen, Germany

The human bile acid-sensitive ion channel hBASIC is a member of the DEG/ENaC gene family. According to the main site of expression, the intestinal tract, hBASIC was initially named hINaC (human intestinal Na^+ channel), BASIC from mouse and rat were named BLINaC (brain liver intestine Na^+ channel) as they were additionally found in brain and liver. Based on their sensitivity for bile acids, INaC/BLINaC were recently renamed BASIC. Furthermore immunohistochemical data suggest that the channel is strongly expressed in cholangiocytes, the epithelial cells of the bile ducts. Despite the high degree of sequence identity between hBASIC and its orthologs from mouse and rat, the pharmacological and electrophysiological features vary drastically between these channels. While mBASIC is a constitutively open channel, hBASIC and rBASIC are almost completely blocked by physiological concentrations of extracellular Ca^{2+}. Consequently removal of Ca^{2+} opens the channels. rBASIC is strongly activated by the bile acids chenodeoxycholic acid (CDCA) and hyodeoxycholic acid (HDCA), which are both present in murine bile. When co-applied, CDCA and HDCA cause a synergistic activation of the channel. In contrast, hBASIC is strongly activated by CDCA but only weakly by HDCA and co-application caused no synergistic effect. However, only CDCA but not HDCA is present in human bile. Therefore we extended our study to bile acids present in the human bile acid pool and applied the most common human bile acids CDCA, cholic acid (CA) and deoxycholic acid (DCA) individually and in combination. Interestingly DCA activates hBASIC as potently as CDCA and a synergistic activation could be observed when co-applied. Additional removal of extracellular Ca^{2+} during the application of bile acids leads to increased current amplitudes without changing the amplitude relationship. Thus, removal of extracellular Ca^{2+} and bile acids displayed a synergistic effect on hBASIC activity. In summary human and rat BASIC differ in their sensitivity for different bile acids. Furthermore they show a preference for bile acids present in the respective species-specific bile acid pool, supporting the hypothesis that BASICs may have co-evolved to match the bile acid prevalence of different species.

PCD200

Lipid rafts as regulators of P2X7 receptor and pannexin-1 signalling

L. Robinson and R. Murrell-Lagnado

Department of Pharmacology, University of Cambridge, Cambridge, UK

The ATP-gated P2X7 receptor is a low affinty cation channel which mediates a range of responses, from cell proliferation to cell death, and is a key regulator of the inflammatory response. Emerging evidence supports an important role for lipid rafts in the regulation of P2X7 receptor signalling, but the mechanism of this regulation is not yet understood (Garcia-Marcos et al., 2006; Barth et al., 2007; Gonnord et al., 2009). Lipid rafts are regions of the plasma membrane enriched in cholesterol and sphingolipids which provide specialised platforms for the organisation of signalling pathways, and by dynamic remodelling can directly modulate signal transduction.
We have evidence that disrupting lipid rafts enhances P2X7 receptor-mediated large pore formation, as measured by dye uptake. Dye uptake, measured using confocal microscopy, is predominantly mediated via the P2X7 receptor but following cholesterol depletion, the enhanced kinetics of dye uptake appears to involve the pannexin-1 hemichannel. Inhibitors of pannexin-1 can block this increase and so can the non-specific caspase inhibitor, Z-VAD-FMK. To investigate targeting of the P2X7 receptor and pannexin-1 to lipid rafts we have separated cellular components on a discontinuous sucrose gradient by ultracentrifugation following their heterologous expression in either HEK293 cells or TSA 201 cells. Both proteins appear in the light lipid raft fractions although not exclusively. This targeting can be manipulated by the co-expression of either wild type or a dominant negative mutant of caveolin-1 and by stomatin. Interactions between these proteins are being investigated by co-immunoprecipitation experiments and FRET as are the effects on P2X7 receptor—pannexin-1 signalling.

PCD201

Evaluation of the role of pH in cancer cell proliferation

U. Bose, C. Allegrucci, C. Rauch, C. Tufarelli and R. Khan

University of Nottingham, Derby, UK

Objective: A common feature of tumours is a shift in cellular metabolism generating a high acid load in the tumour microenvironment. In addition, hypoxia contributes to the exacerbation of tumour extracellular acidosis. The potential toxic effects of low extracellular pH (pHe) are counteracted by cellular mechanisms including potassium channels and the H^+/K^+ ATPase proton pump. We hypothesize that regulation of pH of the tumour microenvironment affects cancer cell proliferation through pH sensitive membrane proteins. The present study was aimed at investigating the effect of pH and cellular pH regulating mechanisms on proliferation of the SKOV3 and MG63 cell lines.

Materials and method: Ovarian cancer (SKOV3) and osteosarcoma (MG63) cell lines were cultured media of Extracellular pH (pHe) ranging from 6 to 7.5 . Cells were also maintained at 3% O2 to induce a low pHe and to compare their response to alterations in pHe in normoxia. Cell proliferation and cell viability assays were performed in the presence and absence of drugs known to inhibit the H^+/K^+ATPase proton pump (omeprazole), EAG channel (E-4031) and the pH-sensitive potassium channel, TASK3 (methanandamide) over 24 and 72 hour time-points using MTS cell proliferation assay. Data was compared using one-way ANOVA. All experiments were repeated thrice.

Result: The SKOV3 and MG63 cells showed an increased rate of proliferation after culturing for 72 hours in pH 6.0 compared with pH 7.5 ($p<0.05$). E-4031 and methanandamide at 0.1 μM increased cell death by 35% and 20% respectively in SKOV3 and MG63 cells after 72 hours in pHe 6.0 in comparison to pHe 7.5 ($p<0.05$). Omeprazole at 10 μg/ml significantly decreased cell proliferation of MG63 cells within 24 hours at a pHe of 6.5 in comparison to cells treated with omeprazole at pHe 7.5 ($p<0.05$).

Discussion and Conclusion: Inhibitors of potassium channels and proton pumps elicited a variable response from proliferation experiments with MG63 and SKOV3 cell lines. A change in pHe influenced proliferation, indicating dependence on cellular pH regulating systems and membrane protein. The presence of these pH regulating systems often works in correlation with change in cellular metabolism owing to altered intracellular pH and pHe. Further investigation is required to understand the fundamentals of pH regulatory systems to meet the challenge of targeting tumour metabolism and acidosis as an anti-cancer therapy.

PCD202

The role of P2X7 receptor C-terminal in trafficking and targeting to the plasma membrane

M. Brunet, L. Robinson, M. Shridar and R. Murrell-Lagnado

Pharmacology, Cambridge University, Cambridge, Cambridgeshire, UK

The P2X7 receptor (P2X7R) is a ligand-gated non-selective cation channel activated by extracellular ATP. With prolonged ATP exposure the receptor pore dilates to accommodate larger cations up to 900Da and this promotes cell death. P2X7 receptors are not always found at the plasma membrane; cell- and species-dependent differences in its trafficking have been reported (1). These differences range from the receptor being predominantly intracellular to predominantly at the cell surface. Determinants of P2X7R trafficking have been identified within its uniquely long cytoplasmic tail, but mechanisms that regulate its trafficking remain poorly understood (2). P2X7 receptors are predominantly expressed in immune and epithelial cells in physiological conditions but are up-regulated in many other cell types in pathophysiological conditions. An example is fibroblasts, where up-regulation of P2X7R contributes to lung, kidney and pancreatic fibrosis (3,4,5). We are interested in the regulation of P2X7R in fibroblasts and the role of caveolin-1 in this regulation. Heterologous expression of P2X7R in fibroblast cell lines was surprisingly toxic compared to other epithelial cell lines. There was a correlation between toxicity and levels of caveolin-1 expression and over-expression of caveolin-1 in HEK293 or HeLa cells increased cell death associated with P2X7R expression. Increased expression of caveolin-1 increased targeting of P2X7R to lipid rafts, as measured by fractionation on a sucrose density gradient. To study the role of the P2X7R C-terminus in trafficking and targeting, we generated chimeras in which the C-terminal tail (Ct) of either rat or human P2X7 was fused downstream of the transmembrane region of CD8 alpha. Human P2X7R shows much greater ER retention than rat P2X7R. Expressed in HeLa cells, immunocytochemistry combined with flow cytometry showed that CD8a is expressed at the plasma membrane (pm) whereas the rat Ct chimera shows pm expression but more endoplasmic reticulum (ER) retention and the human Ct chimera, much greater ER retention. In the REF52 fibroblast cell line a different distribution was observed. The Ct chimeras were much more efficiently trafficked to the pm than in HeLas. This increased trafficking could explain the greater toxicity of P2X7R in these cells. Unlike CD8 a, which is excluded from lipid rafts, the P2X7 Ct chimeras showed targeting to the light raft fractions. There were two molecular mass species of the Ct chimeras consistent with a post-translational modification. Only the higher mass species was targeted to the raft fractions; this targeting was disrupted by coexpression of a dominant negative mutant of caveolin-1.

Role of TRPV6 calcium channels in proliferation of human T lymphocytes

V.N. Tomilin, Y.A. Negulyaev and S.B. Semenova

Institute of Cytology RAS, St.Petersburg, Russian Federation

The calcium influx plays a key role in processes of activation, proliferation and cytokine synthesis in human T lymphocytes. Although the calcium currents in blood cells are well studied, the molecular identity of ionic channels involved in such an important process as T-cell activation and normal/pathological cell proliferation remains elusive. Several members of transient receptor potential (TRP) channel family were shown to play a role in changes of [Ca2+]in in blood cells, however the properties and expression profiles of these channels in human lymphocytes are not yet fully determined. In our previous study, using RT-PCR and Western blot analyses we have shown the expression of TRPV6 (transient receptor potential vanilloid type 6) channels in Jurkat T- cells and in normal human blood lymphocytes (HBLs), isolated from the peripheral blood of healthy volunteers. Moreover, it was found that the levels of mRNA and protein expression of TRPV6 were significantly higher in malignant T-cells than in quiescent HBLs. In this study we performed electrophysiological and immunofluorescent experiments to reinforce our hypothesis that TRPV6 channels could be involved in human blood lymphocytes proliferation. We used outside-out patch-clamp recordings to search for TRPV6 channels in quiescent lymphocytes, phytohemagglutinin (PHA)-treated (48h) lymphocytes and Jurkat cells. TRPV6 single channels recording was assessed in divalent free solution at negative membrane potential (-70 mV), and the channels activity was reduced in presence of nonselective inhibitor of TRPV6 channels, Ruthenium Red (IC50=10μM). Overall, single TRPV6 channel activity was obtained in 77% (17 out of 22) of outside-out patches in Jurkat cells; in 83% (5 out of 6) of outside-out patches in PHA-treated HBLs; and in 40% (2 out of 5) of outside-out patches in quiescent HBLs. Next, immunofluorescence method was employed to examine the TRPV6 channel density and subcellular distribution in these cells. Immunofluorescence signal was detected on the plasma membrane of T- cells and HBLs and the intensity of the signal was substantially higher in Jurkat and PHA-treated HBLs than in quiescent HBLs. Thus, both electrophysiological and immunofluorescence data showed that TRPV6 channel activity and TRPV6 channel density are significantly higher in transformed lymphocytes (Jurkat) compared to quiescent lymphocytes. Moreover number of TRPV6 channels increases after activation of HBLs to proliferation. In whole, present findings suggest a potential role of TRPV6 in normal and/or pathological proliferation of human blood lymphocytes. We hope that in the future, TRPV6 can be considered as a potential molecular marker for early diagnosis of T-cells malignancy.

PCD204

Propylamine activates and blocks ELIC channels

A. Marabelli, R. Lape and L.G. Sivilotti

University College London, London, UK

Prokaryotic channels, such as ELIC and GLIC, give key structural information for the Cys-loop superfamily. ELIC, a cationic channel from Erwinia chrisanthemi, is suitable also for single channel recording because of its high conductance (> 80 pS) (Zimmermann and Dutzler, 2011). Here we report on the kinetic properties of recombinant ELIC channels expressed in HEK293 cells.

Single channel currents elicited by the full agonist propylamine (0.5-50 mM) were recorded from outside-out patches at -60 mV and analysed by maximum likelihood direct global fitting of kinetic schemes to the idealized data (HJCFIT program; Colquhoun et al 2003). Several mechanisms were tested and their adequacy was judged by comparing the predictions of the best fit obtained with the experimental open/shut time distributions and the dose response curve. The fitted model had to account also for the time course of macroscopic propylamine-activated currents, elicited by fast theta-tube applications (50-600 ms, 1-50 mM, -100 mV).

Other Cys-loop channels, such as glycine receptors, activate via a pre-opening intermediate ('flip' model, Burzomato et al., 2004) and, when fully liganded, open with high efficacy to a single open state. In contrast with that, ELIC open time distributions at saturating propylamine showed more than one component. Thus, more than one open state must be accessible to the fully liganded channel. The `primed` model (Mukhtasimova et al., 2009) allows that by including more than one fully liganded intermediate. The best fit of this type of model showed that ELIC maximum open probability (99%) is reached when three molecules of agonist have bound to the channel. The overall efficacy of the fully liganded branch was 130 ± 20 (n = 3 sets; c.f. 20 for $\alpha1\beta$ glycine channels; Burzomato et al., 2004). The microscopic affinity for the agonist was seen to increase as the channel activated, from a resting state value of 6.2 ± 0.6 mM to 0.19 ± 0.11 mM (n = 3 sets) for the partially activated intermediate state.

Macroscopic responses to propylamine had a monoexponential rising phase (time constant of 33 ± 4 ms at 10 mM, n= 16 patches), but a complex off-relaxation. This was notable for the presence of an almost instantaneous rebound current at the end of the application. The amplitude of this rebound current (normalized to the peak of the agonist current itself) increased with increasing propylamine concentration to reach 10% at 50 mM, but was voltage independent. We will present evidence that the rebound current is due to the relief of a low affinity, voltage-independent propylamine block of the open ELIC channel. The decay phase of the agonist currents (from the peak of the rebound current) appeared to be sigmoidal (e.g. two exponential components with amplitudes of opposite sign) and this time-course was well-described by the 'primed' mechanism fitted to the single channel records.

PCD205

Dose-dependent effects of Angiotensin-(1–7) on the NHE3 exchanger and the [Ca2+]i in *in vivo* proximal tubule

R.C. Castelo-Branco[1], D. Leite-Dellova[2] and M. Mello-Aires[1]

[1]Department of Physiology and Biophysics, University of São Paulo, São Paulo, São Paulo, Brazil and [2]Department of Basic Sciences, University of São Paulo, São Paulo, São Paulo, Brazil

The acute direct action of Ang-(1-7) on net bicarbonate reabsorption ($JHCO_3^-$) was evaluated by stationary microperfusion of *in vivo* middle proximal tubules of rat kidney, using H ion-sensitive microelectrodes. The mean control value of $JHCO_3^-$ is 2.82 ± 0.078 nmol. cm^{-2}. s^{-1} (50) and Ang-(1-7) (10^{-12} or 10^{-9} M) into luminally perfused tubules causes a significant decrease [to 1.80 ± 0.21 nmol. cm^{-2}. s^{-1} (52) and 1.11 ± 0.119 nmol. cm^{-2}. s^{-1} (78), respectively] but Ang-(1-7) (10^{-6} M) increases it to 5.09 ± 0.46 nmol. cm^{-2}. s^{-1} (70). A779 [10^{-6} M; an Ang-(1-7) receptor Mas antagonist] alone increases the $JHCO_3^-$ to 3.68 ± 0.394 nmol. cm-2. s-1 (64); these data indicate that in the basal situation intratubular Ang-(1-7) inhibits $JHCO_3^-$. However, A779 prevents the inhibitory and the stimulatory effects of Ang-(1-7) in $JHCO_3^-$. S3226 (10^{-6} M; an inhibitor of NHE3 isoform of Na^+/H^+) alone decreases the $JHCO_3^-$ to 1.56 ± 0.168 nmol. cm^{-2}. s^{-1} (53), does not affect the inhibitory effect of Ang-(1-7) and changes its stimulatory effect on an inhibitory effect [1.98 ± 0.358 nmol. cm-2. s-1 (47)]. So, our results indicate that the biphasic dose-dependent effect of Ang-(1-7) on $JHCO_3^-$ is mediated by the Mas receptor and via NHE3. The mean control value of cytosolic free calcium ($[Ca^{2+}]_i$), monitored by FURA-2-AM, is 101 ± 2 nM [6 (n° of tubules; each tubule is the average of 10 areas)] and Ang-(1-7) (10^{-12}, 10^{-9} or 10^{-6} M) causes a transient (3 min) increase of it [to 252 ± 8 nM (5), 203 ± 3 nM (6) or 153 ± 8 nM (5), respectively]. A779 alone increases the $[Ca^{2+}]_i$ to 126 ± 2 nM (5) but impairs the stimulatory effect of Ang-(1-7) all doses. The results are compatible with stimulation of NHE3 by a moderate increase in $[Ca^{2+}]_i$ with Ang-(1-7) (10^{-6} M) and its inhibition by large increase in $[Ca^{2+}]_i$ with Ang-(1-7) (10^{-12} or 10^{-9} M). Our findings are the opposite of those found for the biphasic dose-dependent effect of Ang II on the Na^+/H^+, since several studies indicate the stimulation of the Na^+/H^+ with low doses of Ang II by a small increase in $[Ca^{2+}]_i$ and inhibition of the Na^+/H^+ with high doses of Ang II by a large increase in $[Ca^{2+}]_i$. It is therefore reasonable to assume that, in the intact animal, the interaction of the opposite dose-dependent effects of Ang-(1-7) and Ang II on the Na^+/H^+ and $[Ca^{2+}]_i$ may represent an important physiological regulation in terms of intra- and extracellular volume and/or pH changes.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Regulation of glomerular filtration rate by canonical transient receptor potential 6 in glomerular mesangial cells

R. Ma, Y. Ding, C. Smedley, B. Zhu, Y. Wang, M. Ding and S. Chaudhari

University of North Texas Health Science Center, Fort Worth, TX, USA

Glomerular mesangial cells (MCs) regulate glomerular filtration rate (GFR) by regulating effective filtration surface area. Canonical transient receptor potential (TRPC) 6 is a Ca2+ permeable cation channel and playa an important role in renal physiology and pathophysiology. We have recently demonstrated that TRPC6 was expressed in MCs and modulated MC contractile function. The aim of the present study was to determine whether and how TRPC6 in MCs can regulate GFR. GFR in mice was estimated using a two-compartment clearance model. 5% FITC-inulin (3.74 μl/g body weight) was retroorbitally injected under anesthetized state and blood samples were periodically collected from the tail vein under the conscious state. GFR in rats was evaluated based on the plasma inulin clearance during intravenous infusion of 1% FITC-inulin at a rate of 1 ml/h/100 g BW. Blood samples were collected from the left common carotid artery and urine samples were collected from either the bladder or the urether under the anesthetized state (pentobarbital, 50 mg/kg BW, i.p). In vivo knockdown of TRPC6 in rat kidneys was achieved by injection of shRNA constructs against rat TRPC6 via the left renal artery under anesthetized state. Ca2+ imaging was employed to assess intracellular Ca2+ level. Furthermore, MC contractile response was assessed by measuring a change in the planar surface area of MCs in response to Ang II. We found that GFR in TRPC6 knockout mice (881 ± 238 μl/min, n=6) was remarkably elevated compared to wild type mice (177 ± 61 μl/min, n=7) (P<0.01, Student t-test). In rats, acute infusion of Ang II significantly reduced GFR (1.2 ± 0.1 vs. 0.7 ± 0.1 ml/min/100 g BW, before vs. after Ang II, n=8, P<0.05, paired t-test). However, the Ang II response was abolished by knockdown of TRPC6 in kidneys. Immunohistochemistry showed that MCs were the predominantly transfected glomerular cells. Consistently, the GFR of the transfected kidney significantly decreased by Ang II when transfected with control vectors (0.53 ± 0.21 vs. 0.33 ± 0.21 ml/min/100 g BW, before vs. after Ang II, P<0.05, paired t-test, n=5), but did not have a significant change when transfected with shRNA against TRPC6. There were no significant differences in blood pressure and renal blood flow between TRPC6-knocked down and control rats. Furthermore, Ang II-stimulated Ca2+ entry was significantly inhibited in MCs isolated from TRPC6 knockout mice and in human MCs with TRPC6 knocked down. Moreover, the Ang II-stimulated contraction was significantly suppressed in TRPC6 deficient mouse MCs. These results suggest that TRPC6 channel is an important component regulating GFR by modulating MC Ca2+ signaling and contraction.

Real-time electrochemical detection of endogenous substance release in freshly isolated perfused kidney

O. Palygin[1], V. Levchenko[1], D.V. Ilatovskaya[1,2], T.S. Pavlov[1], R.P. Ryan[1], A.W. Cowley[1] and A. Staruschenko[1]

[1]Physiology, Medical College of Wisconsin, Milwaukee, WI, USA and [2]Institute of Cytology RAS, St. Petersburg, Russian Federation

The structural and functional heterogeneity of the kidney and fast transient changes in signaling molecules present a tremendous experimental challenge to study variety of functional processes in whole organ. Extracellular nucleotides such as adenosine, 5'-triphosphate (ATP) are essential local signaling molecules in many organs including the kidney. Goal of this study was to develop quantitative approach for detection of hydrogen peroxide (H_2O_2) and ATP in freshly isolated whole organs. We established and described a novel approach to measure acute concentrations changes in endogenous substances in the freshly isolated perfused kidney. This method is based on using enzymatic microelectrode biosensors and utilizes standard amperometry technique. In addition to measurements of basal levels of H_2O_2 and ATP, this technique allows rapid detection of purinergic signaling, and immediately provides observation of changes and fluctuations in ATP concentration in freshly isolated organs during vehicle or drug perfusion. The real time changes in ATP and H_2O_2 concentrations in response to angiotensin II (Ang II), a pluripotent peptide hormone of the renin-angiotensin system, were measured. Freshly isolated kidneys of the Sprague Dawley (SD) or Dahl salt-sensitive (SS) rats were flushed with 1 μM Ang II under constant laminar perfusion. For these experiments rats were anesthetized with isoflurane inhalation and the surgical procedure was performed on a temperature controlled table. The kidneys were perfused through the distal aorta with a HBSS to clear blood from the organs. The flushing was continued for 2-3 min until the kidneys were completely blanched, then the animal was euthanized by pneumothorax. The left kidney was then removed and aorta ligated above the renal artery for the consequent perfusion. After surgery, the flushed kidney with catheterized renal vessels was placed into the bath solution and swathed to the silicone resin to avoid movement during perfusion. Dual simultaneous amperometric recordings were made with the biosensors detecting ATP and H2O2 levels. Biosensors were obtained from Sarissa Biomedical Ltd (Coventry, UK). Ang II perfusion produced a rapid simultaneous release of both ATP and H_2O_2 in the kidney cortex. Substance release rate and total integral release were also estimated. Controls with AT_1 receptor antagonist losartan and catalase revealed specificity of used biosensors. Renal cortex interstitial H_2O_2 concentration was also determined in SS rats fed low or high salt diets by traditional microdialysis and analyzed with Amplex red to compare these two approaches. The data indicate that SS rats have increased levels of H_2O_2 compared to SD rats, especially when fed a high salt diet. Furthermore, Ang II induced ATP and H_2O_2 release, which can stimulate arteriolar vasoconstriction or effect renal tubular transport in the kidney, and this effect is also enhanced in SS rats. In conclusion, current method is a unique powerful approach for substance release detection during pathological or normal conditions in whole organs including the kidney.

Acute effects of angiotensin II on TRPC6 channels in the podocytes of the freshly isolated glomeruli

D. Ilatovskaya[1,2], V. Chubinskiy-Nadezhdin[1], Y. Negulyaev[1] and A. Staruschenko[2]

[1]Institute of Cytology RAS, St. Petersburg, Russian Federation and [2]Medical College of Wisconsin, Milwaukee, WI, USA

Genetic studies have led to the identification of proteins playing a crucial role in glomerular slit-diaphragm signaling and maintenance of podocyte integrity. Particularly, the gene encoding transient receptor potential canonical channel 6 (TRPC6) was identified as the genetic basis for an autosomal dominant form of focal segmental glomerulosclerosis (FSGS). A key role for podocytes in the pathogenesis of proteinuric diseases has been established since the injury of these cells leads to proteinuria and foot process effacement. Interstitial angiotensin II (Ang II) is found to be a key mediator of renal inflammation and fibrosis in chronic nephropathies. It was shown that expression of Ang II and its receptors (ATRs) is increased in patients with progressive glomerulopathies; what is more, Ang II application can increase intracellular calcium, and members of the TRPC-family channels emerged as prime candidates for this raise.

The goal of this research was to define the signaling mechanisms mediating the effect of Ang II on TRPC6 channels in the podocytes and to study the potential capabilities of ATRs inhibitors in the treatment of FSGS. To address this aim we established a new approach allowing to measure ion channels activity and calcium concentration changes in the freshly isolated decapsulated glomeruli. We examined the effects of Ang II on intracellular Ca^{2+} concentrations in intact podocytes of the rat glomeruli. Changes in intracellular Ca^{2+} stimulated by 100 nM and up to 10 μM of Ang II in the presence or absence of thapsigargin or 100 μM TRPC inhibitor 2-APB were measured in Fura-2AM loaded podocytes of the intact glomeruli. Depletion of internal Ca^{2+} stores with thapsigargin did not affect cell activation by Ang II, but 2-APB totally blocked calcium flux. This therefore allows hypothesizing that TRPC channels in the podocytes mediate calcium influx in response to Ang II.

Western blotting and IHC staining revealed that TRPC1, 3 and 6 are expressed in the Sprague Dawley rat glomeruli. Single channel electrophysiological analysis with patch-clamp demonstrated that 100 nM Ang II acutely activates native TRPC-like channels in the podocytes, as well as TRPC6 channels transiently overexpressed in CHO cells together with the ATR1; the detected effect was mediated by changes in the channel open probability.

The ability of podocytes to precisely regulate intracellular Ca^{2+} plays a central role in glomerular diseases, therefore, manipulating Ca^{2+} levels by inhibiting TRPC channels or their activators may be a useful strategy for treating patients with FSGS. In this study we provide evidence of Ang II-dependent activation of TRPC6 channels in podocytes, which might play a significant role in the development of kidney diseases.

The mouse calcium sensing receptor of the intercalated cell type B in the collecting duct may contribute to alkali secretion via stimulation of pendrin during dietary calcium loading

Y. Yasuoka[1], Y. Sato[2], H. Nonoguchi[3] and K. Kawahara[1]

[1]Physiology, Kitasato University, School of Medicine, Sagamihara, Japan, [2]Molecular Diagnostics, Kitasato University, School of Allied Health Sciences, Sagamihara, Japan and [3]Internal Medicine, Kitasato University, Medical Center, Kitamoto, Japan

Background: Urinary acidification and polyuria regulated by stimulation of calcium sensing receptor (CaSR) may reduce the risk for urolithiasis caused by hypercalciuria (Renkema KY *et al.* 2009). However, expression level of CaSR, localized at the basolateral membrane of intercalated cell type B (IC-B) in the mouse kidney collecting duct (CD), was unexpectedly decreased during metabolic acidosis caused by NH_4Cl-loading (Yasuoka Y *et al.* 2011). Thus, we further investigated a role of the CaSR for the Ca and pH metabolism in the kidney using a combination of functional and molecular biology technique. Methods: C57BL/6J mice (male, 10 weeks) were subjected to (1) normal (1%) Ca diet (control, n=6), (2) high (2.5%) Ca diet (calcium (CaX) loading, n=6), and (3) NH_4Cl-loading (2.5%) diet (acidosis, n=6). For blood analysis, heparinized blood, collected from the carotid artery of mice anesthetized with 1.5% isoflurane, was analyzed as usual. Values are means ± SE., compared by Student's *t*-test. Results: The level of blood [Ca^{2+}] remained in normal ranges even after administration of CaX and NH_4Cl for 28 and 6 days, respectively. Blood pH of CaX-loading mice was also unchanged (7.37 ± 0.02), whereas that of NH_4Cl-loading mice significantly decreased (7.25 ± 0.02, $P < 0.005$) compared with control (7.38 ± 0.01). Urinary [Ca^{2+}] of CaX- and NH_4Cl-loading mice was significantly increased (6.2 ± 0.1 mg/dl ($P < 0.05$) and 12.1 ± 0.9 mg/dl ($P < 0.005$), respectively), compared with control (5.6 ± 0.4 mg/dl). Urinary pH of CaX- and NH_4Cl-loading mice was significantly lower (6.07 ± 0.07 ($P < 0.005$) and 5.96 ± 0.03 ($P < 0.005$), respectively) than control (6.48 ± 0.04). When mice were kept with NH_4Cl for 6 days, the expression of H-ATPase, carbonic anhydrase (CA) XII and anion exchanger (AE) 1 increased, whereas the levels of the transient receptor potential vanilloid 5 (TRPV5), CaSR, and pendrin expression were decreased. On the other hands, the expression levels of all these molecules were markedly increased by CaX-loading. Interestingly, NH_4Cl-loading increased cell height of IC-A in CDs and CaX-loading increased it at both IC-A and IC-B. All these results suggest that hypercalciuria, reduced reabsorption of Ca^{2+} due to acidosis-induced downregulation of TRPV5 at the distal convoluted tubule (DCT), may stimulate acid secretion of IC-A and alkali secretion of IC-B in parallel, probably due to an activation of CaSR of IC-B through unknown mechanisms. Conclusions: CaSR of IC-B may contribute to alkali secretion to prevent urolithiasis in the mouse kidney collecting duct during dietary surplus Ca loading.

Identification and characterization of a new promoter regulating expression of Slc4a10 in rat kidney, and localization of Slc4a10 proteins in renal tubules

D. Wang, Y. Liu, Y. Guo, D. Jiang, Z. Xie and L. Chen

Department of Biophysics and Molecular Physiology, Key Laboratory of Molecular Biophysics of Ministry of Education, Huazhong University of Science & Technology School of Life Science & Technology, Wuhan, Hubei Province, China

The electroneutral Na-coupled HCO3– transporter NBCn2, encoded by SLC4A10, plays critical roles in intracellular pH regulation and transepithelial HCO3– movement. In human, dysfunction of SLC4A10 is associated with multiple pathological conditions, including complex epilepsy, mental retardation, autism spectrum disorders, as well as dysmorphic features. We have previously demonstrated that Slc4a10, under the control of two distinct promoters, is capable of expressing two groups of NBCn2 variants differing in the extreme amino termini (Nt), one starting with "MEIK" (the first four residues of the Nt), and the other, "MCDL". In rat, MEIK-NBCn2 is specifically expressed in the central nervous system, whereas MCDL-NBCn2 is predominantly expressed in the kidney.

In the present study, by 5'-rapid amplification of cDNA ends and cDNA cloning, we identified from rat kidney a third new promoter located between the two previous ones in Slc4a10. From this new promoter, two types of Slc4a10 transcripts can be produced, one encoding a protein identical to the previous MCDL-NBCn2. The other lacks exon 3, thus could in theory produce a new type of NBCn2 with a truncation at the Nt. The genomic sequences of the three promoters, including P1 expressing MEIK-NBCn2, the new P2 expressing MCDL- plus the Nt-truncated-NBCn2, and P3 expressing MCDL-NBCn2, were cloned and analyzed by luciferase reporter assay. Among the three promoters, P2 showed the highest activity in human embryonic kidney cells HEK293, while P3 showed just basal activity. Our data are consistent with the notion that MCDL-NBCn2 is expressed under the control of promoter P2 in the kidney. By immunocytochemistry with anti-MCDL-NBCn2, NBCn2 was predominantly localized in the cortex of rat kidney. Surprisingly, a higher magnification view showed that NBCn2 was localized at the apical membrane of epithelial cells in renal tubules, likely the proximal segments. The physiological role of NBCn2 in the kidney remains to be addressed.

Our study is important for the field of acid-base transport. Firstly, disclosing the promoters of Slc4a10 represents a critical step forward towards understanding the mechanism underlying the regulation of tissue-specific expression of Slc4a10. Secondly, the characterization of the promoters could also be important for studying the differential regulation of Slc4a10 expression in response to acid-base stress in different tissues. Finally, our finding about the cellular localization of NBCn2 in the kidney might impact our understanding of the molecular mechanism involved in the acid-base transport in renal tubules.

Histological analysis of quercetin effects on cisplatin-induced acute renal failure in rats

S. Hiranyachattada[1], P. Muangnil[1], P. Boonyoung[2] and P. Kirirat[2]

[1]Physiology, Prince of Songkla University, Hatyai, Songkhla, Thailand and [2]Anatomy, Prince of Songkla University, Hatyai, Songkhla, Thailand

The remarkable side effect of cisplatin, a cytotoxic agent in cancer treatment, is acute renal failure which limited its clinical uses. An increase in free radicals has been shown to play an important role in this renal pathogenesis. Our previous studies have shown a significant increase in renal melondialdehyde level on day 3 along with a marked reduction in renal blood flow, glomerular filtration rate and urinary Na+ and K+ excretion on day 3 and day 7 after cisplatin (7.5 mg/kg i.p.) injection in rats. The number of survived animals and the degree of renal damage assessed by clearance technique have been improved with quercetin, a strong antioxidant, co-treatment. In this study, we used histopathological scoring analysis of glomerular and tubular lesions on day 3, 7 and 14 after 7.5 mg/kg cisplatin i.p. injection in rat to strengthen our prior data. The protective effects of oral administration of quercetin, 50 mg/kg, twice 24 hr and 10 min, before cisplatin injection were thoroughly determined. Experiments were performed in male Wistar rats, 200-300 g. The number of rats in each sub-groups were between 5-11. All experimental rats were maintained and handled according to the approval of the Prince of Songkla University Animal Ethics Committee. On the day of experiment, the animals were anesthetized with 60 mg/kg pentobarbitone sodium, i.p., then, the kidneys were retrograde perfused and isolated. Each kidney was longitudinal cut into two pieces and fixed in 10% buffer neutral formalin for 24 hrs before further process. The embedded renal tissues were sectioned at 6 μm thick ribbon and stained with hematoxilin and eosin. Glomerular injury was defined according to the percentage of glomerular atrophy in the renal cortex whereas renal tubular injury grading was defined by the percentage of nuclear swelling, pyknosis and karyorrhexis and tubular dilatation in renal cortical and outer strip of outer medullary area. Intraluminal hyaline cast formation was also randomized graded in both cortex and medulla. Both glomerular and tubular lesions were classified into five grades according to the degree of damage incremently. It is found that the oral co-administration of quercetin with cisplatin injection blunted the progressive lesions of glomerular atrophy, tubular dilatation and intraluminal hyaline cast formation observed on day 7 and 14 but blunted the tubular nuclear damage observed on day 3, 7 and 14. These effects were indicated by the significant reduction in the number of rat with higher lesion grades. It is noticed that one of the mechanisms responsible for the renal protective effect of quercetin in cisplatin- induced acute renal failure rats is via glomerular and tubular structural remodeling.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Introduction Altered cell proliferation is critical to the progression of neoplastic disorders such as cancer and polycystic diseases. Identifying new potential therapeutic agents to target cell proliferation may therefore provide improved treatments for these disorders. Here, we used the simple, tractable biomedical model *Dictyostelium* to investigate the molecular mechanism of naringenin, a dietary flavonoid with antiproliferative and chemopreventive actions *in vitro* and in animal models of carcinogenesis [1,2]. **Methods and Results** *Dictyostelium discoideum* cells (wild type Ax2) were grown in liquid culture. Naringenin inhibited *Dictyostelium* growth, but not development, after 48-96 hours with an EC50 of 50-100 μM. Screening of a library of random gene knockout mutants identified a mutant (*pkd2-*) lacking the polycystin-2 protein (DDB_G0272999) that was resistant to the effect of naringenin (200 μM, 21 days) on growth and random cell movement. Naringenin (100 μM) reduced cell growth by 37% in wild type cells at 48 and 72 hours, but had no significant effect in the gene knockout mutant *pkd2-*. Polycystin-2 is a divalent cation channel, where mutations in the protein give rise to type 2 autosomal dominant polycystic kidney disease [3]. We therefore translated these results to a mammalian kidney model and grew Madin-Darby Canine Kidney (C7) cells in culture and as cysts in a collagen matrix [4]. Data are expressed as mean ± SEM from 3 independent experiments. Naringenin inhibited MDCK cell growth as measured by neutral red and SRB protein assay with an EC50 of 28 ± 1 μM and inhibited cyst growth with an EC50 of 3-10 μM. Levels of polycystin-2 protein were knocked down to 56 ± 5% after 24 and 48 hours by siRNA in this model. Polycystin-2 knockdown increased the EC50 value for naringenin in MDCK cells to 65 ± 1 μM. Cysts were larger following polycystin-2 knockdown compared to untransfected controls and resistant to the same concentration of naringenin: e.g. 10 μM naringenin: control 0.84 ± 0.03 mm^2; polycystin-2 knockdown 1.44 ± 0.07 mm^2; 30 μM naringenin: control 0.65 ± 0.01 mm^2, polycystin-2 knockdown 1.18 ± 0.06 mm^2. Metformin (10 μM), an activator of AMP-activated kinase and inhibitor of mTOR, reduced the size of both control and transfected cysts equally. **Conclusion** The antiproliferative actions of naringenin in *Dictyostelium* and mammalian kidney cells suggested a conserved effect of naringenin on cell growth mediated by polycystin-2. Further studies will determine if naringenin is a drug candidate for the treatment of ADPKD where polycystin-1 is lost but polycystin-2 is intact [5].

PCD213

Sialylation of N-glycan stimulated by protein kinase C (PKC) increases urea transporter UT-A1 activity

G. Chen, X. Li and J.M. Sands

Physiology, Emory University, Atlanta, GA, USA

The protein abundance of the UT-A1 urea transporter in kidney inner medulla (IM) is dramatically increased under diabetic conditions, particularly the highly glycosylated 117 kDa form of UT-A1. This change is consistent with the increase in urea permeability in the perfused rat inner medullary collecting duct (IMCD). In diabetes the diacylglycerol (DAG) - protein kinase C (PKC) pathway is activated. It is not known whether and how the elevated DAG and activated PKC pathway contribute to the increased kidney IMCD urea permeability under diabetes conditions. In this study, diabetic animal model was induced in SD rats by tail vein injection of streptozotocin (62.5 mg/kg BW). At 14 day, kidney IM was dissected and cell plasma membrane was isolated by sucrose gradient ultracentrifugation and used for lectin pullown. Diabetes causes significant UT-A1 glycan changes of increased sialic acid as demonstrated by sambucus nigra lectin (SNA) pulldown assay. We then investigated the role of PKC in UT-A1 protein expression. Treatment of 2 μM PDBu, the protein kinase C (PKC) activator, significantly increases UT-A1 protein abundance in UT-A1 MDCK cells. The glycan structure change of UT-A1 was examined using sugar-specific binding lectins. Interestingly, activation of PKC markedly increases UT-A1 glycan sialic acid. Rat kidney IMCD suspensions were prepared and treated with 2 μM PDBu for 4 h. Activation of PKC by PDBu specifically increased UT-A1 sialylation from kidney IMCD. Functionally, increased UT-A1 sialylation has enhanced urea transport activity when the UT-A1 MDCK cells were incubated with 2 mM sialic acid for 24 h. Our study suggests that activation of DAG- PKC pathway may participate in elevated tubular urea reabsorption by increasing UT-A1 sialylation, which plays an important role to prevent the osmotic diuresis caused by glucosuria under diabetic conditions.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD214

The membrane cytoskeletal crosslinker ezrin is essential for the regulation of phosphate and calcium homeostasis

R. Hatano[1], E. Fujii[1], H. Segawa[2], K. Mukaisho[3], M. Matsubara[4], K. Miyamoto[2], T. Hattori[3], H. Sugihara[3] and S. Asano[1]

[1]Molecular Physiology, Ritsumeikan University, Kusatsu, Japan, [2]Molecular Nutrition, University of Tokushima Graduate School, Tokushima, Japan, [3]Pathology, Shiga University of Medical SciencesSchool, Otsu, Japan and [4]Molecular Medicine, Tohoku University School of Medicine, Sendai, Japan

Ezrin is an actin-binding protein that crosslinks between the plasma membrane proteins (adhesion proteins, transporters, channels) and actin cytoskeleton. It is involved in microvilli formation, membrane fusion and protein trafficking. Ezrin is highly expressed in stomachs, small intestines, and kidney. In the kidney, it is mainly localized at brush border membrane (BBM) of proximal tubules, where phosphate (P_i) is reabsorbed by Na^+/P_i cotransporters. There, ezrin is reported to be associated with a major Na^+/P_i cotransporter, Npt2a, through a scaffolding protein, Na^+/H^+ exchanger regulatory factor (NHERF) 1. In the present study, we focused on the physiological role of ezrin in the renal Pi reabsorption and duodenal Ca^{2+} absorption by using ezrin knockdown (*Vil2*$^{kd/kd}$) mice in which expression of ezrin was down-regulated as low as 7% compared with wild-type (WT) mice (Tamura et al. 2005). We found that *Vil2*$^{kd/kd}$ mice exhibited hypophosphatemia and hypocalcemia. The reduced plasma concentration of P_i was attributed to the defective urinary P_i reabsorption. Immunofluorescence staining revealed that cell surface expression of Npt2a and NHERF1 was impaired in the kidney of *Vil2*$^{kd/kd}$ mice. Immunoblotting also revealed that the Npt2a and NHERF1 expressions at the BBM fractions of proximal tubules were markedly reduced in the kidney of *Vil2*$^{kd/kd}$ mice. On the other hand, urinary loss of Ca^{2+} was not observed in *Vil2*$^{kd/kd}$ mice. Plasma concentration of 1,25-dihydroxyvitamin D was elevated following reduced plasma Pi level, and mRNA level of vitamin D-dependent TRPV6 Ca^{2+} channel was increased in the duodenum of *Vil2*$^{kd/kd}$ mice. However, the expression of TRPV6 at apical membrane was disturbed in *Vil2*$^{kd/kd}$ mice due to ezrin knockdown. *Vil2*$^{kd/kd}$ mice also exhibited osteomalacia. Bone mineral density in tibiae was significantly lowered in the adult and young *Vil2*$^{kd/kd}$ mice compared with WT mice. These results strongly suggest that ezrin is required for the regulation of systemic P_i and Ca^{2+} homeostasis in vivo.

Mechanoprotection by Polycystins against Apoptosis Is Mediated through the Opening of Stretch-Activated K2P Channels

R. Peyronnet[1], E. Honoré[2] and F. Duprat[2]

[1]Heart Science, National Heart & Lung Institute, Harefield, Middlesex, UK and [2]Institut de Pharmacologie Moléculaire et Cellulaire, UMR CNRS 7275, Université de Nice Sophia Antipolis, Valbonne, France

How renal epithelial cells respond to increased pressure and the link with kidney disease states remain poorly understood. Pkd1 knockout or expression of a PC2 pathogenic mutant, mimicking the autosomal dominant polycystic kidney disease, dramatically enhances mechanical stress-induced tubular apoptotic cell death. We show the presence of a stretch-activated K+ channel dependent on the TREK-2 K2P subunit in mouse proximal convoluted tubule epithelial cells (isolated cells were obtained following the protocol described in Barriere et al. 20031). Our findings further demonstrate both on isolated cells and on the whole kidney in vivo, that polycystins protect renal epithelial cells against apoptosis in response to mechanical stress, and this function is mediated through the opening of stretch-activated K2P channels. Thus, to our knowledge, we establish for the first time, both in vitro and in vivo using mouse model, a functional relationship between mechanotransduction and mechanoprotection. We propose that this mechanism is at play in other important pathologies associated with apoptosis and in which pressure or flow stimulation is altered, including heart failure or atherosclerosis.

Upregulation of NOX4 mediates TGFβ-induced apoptosis in mouse podocyte

R. Das, S. Xu, X. Quan, S. Cha, I. Kong and K. Park

Physiology, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea

Podocytes are terminally differentiated, actin-rich epithelial cells present on the glomerular basement membrane and critical for glomerular filtration process. Podocyte injury leads to onset of chronic renal diseases characterized by proteinuria. Elevated level of TGFβ in pathogenic condition is associated with podocyte damage ultimately resulting in apoptosis and detachment. The underlying mechanism of apoptosis, however, remains not clearly understood in these cells. We investigated pathogenic mediators for proapoptotic effects of TGFβ in cultured immortalized mouse podocytes. TGFβ induced podocyte apoptosis was mediated by elevated level of reactive oxygen species (ROS) which was blocked by N-acetyl-cystein, an antioxidant. Exogenous TGFβ1 selectively increased the expression of only Nox4, excluding other NADPH oxidase (NOX) enzymes. Consistent with Nox4 upregulation, the total NOX activity was higher in TGFβ1-treated podocytes. TGFβ1 enhanced total ROS and elicited apoptosis indicated by the increased number of apoptotic nuclei and elevated level of cleaved caspase-3. These changes by TGFβ1 were blocked by SB431542 and DPI, a potent inhibitor of Type I TGFβ receptor and a selective inhibitor of NADPH oxidases, respectively. Knock-down of Nox4 by siRNA (siNOX4) treatment blocked TGFβ1-induced ROS production and caspase activation. In podocyte, Nox4 was localized to mitochondria as it co-localized with mitochondrial protein Cox1. TGFβ1 elicited mitochondrial membrane depolarization which was recovered by siNOX4 or DPI treatment. In addition, siRNA for smad2 or smad3 reduced Nox4 in transcript and protein level, total ROS generation, and cleaved caspase-3 activation. These results suggest that TGFβ-induced activation of Smad2/3 is responsible for Nox4 up-regulation, and ROS production by NOX4 closely participates in TGFβ-induced apoptosis via mitochondrial dysfunction which might be a crucial mechanism for the development and progression of proteinuric glomerular diseases including diabetic nephropathy.

PCD217

Sinaling pathways involved in the rapid biphasic effect of aldosterone on Na+/H+ exchanger in IRPTC cells

D.C. Leite-Dellova[1], G.K. Fonseca[2], M. Oliveira-Souza[3] and M. Mello-Aires[3]

[1]Veterinary Medicine, University of Sao Paulo, Pirassununga, Sao Paulo, Brazil, [2]Basic Sciences, University of Sao Paulo, Pirassununga, Sao Paulo, Brazil and [3]Physiology and Biophysics, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil

We demonstrated that the rapid nongenomic dose-dependent biphasic effect of aldosterone on Na+/H+ exchanger in proximal tubule is compatible with stimulation of this exchanger by small increases in intracellular calcium concentration ([Ca2+]i) (at 10-12 M aldosterone) and inhibition due high increases in [Ca2+]i (at 10-6 M aldosterone) (Leite-Dellova et al, 2008); however, the signaling pathways involved in these effects are still unknown.The purpose of this study is researching the involvement of the mineralocorticoid receptor (MR), glucocorticoid receptor (GR), extracellular signal-regulated Kinases 1 and 2 (ERK1/2), adenosine 3`,5`-monophosphate (cAMP) and protein kinase C (PKC) in the aldosterone rapid effects on the Na+/H+ exchanger and [Ca2+]i of proximal tubule. The hormonal effects on intracellular pH (pHi) and [Ca2+]I were investigate in immortalized proximal tubule cells of rats (IRPTC), using fluorescence microscopy and the probes BCECF-AM (3 μM) and FURA 2-AM (5 μM), respectively. The values shown are means ± S.E.M. and the comparisons are made by ANOVA ($p < 0.05$). The pHi recovery rate (pHirr), after cellular acidification with a NH4Cl pulse, was 0.24 ± 0.011 pH units/min (N=8). EIPA (20 μM; Na+/H+ exchanger inhibitor) and HOE 694 (5 μM; NHE1 specific inhibitor), but not S3226 (1 μM; NHE3 specific inhibitor), cause a decrease in pHirr (63% and 59%, respectively). The mean baseline [Ca2+]i was 100 ± 4 nM (N=10). Aldosterone (10-12 M; 2 min preincubation) increases the pHirr (50%) and the [Ca2+]i (63%), but aldosterone (10-6 M; 2 min preincubation) decreases the pHirr (46%) and increases the [Ca2+]i (132%). RU 486 (1 μM; GR inhibitor),

PD 98059 (15 μM) and U0126 (15 μM) (ERK1/2 inhibitors), Cheleritrine (1 μM) and Stausporine (10-5 M) (PKC inhibitors) abolish the effects of aldosterone on pHirr and [Ca2+]i. Eplerenone (10-5 M, MR inhibitor) and 8Br cAMP (10-5 M; cAMP analogue) do not alter these parameters. The present results confirm our previous data indicating that the rapid biphasic (stimulatory/inhibitory) effect of aldosterone on NHE1 is associated with the rapid stimulatory dose-dependente effect of aldosterone on the [Ca2+]i. The observed effects of aldosterone on pHirr and [Ca2+]i occur via GR (data consistent with GR detection in IRPTC cells by RT-PCR and Western blot) and are mediated by ERK1/2 and PKC signaling pathways and seem to be independent of MR and cAMP.

Keywords: aldosterone rapid effects, NHE1, pHi, intracellular calcium

PCD218

An antatomically-unbiased approach for analysis of renal BOLD magnetic resonance images

R.I. Menzies[1], A. Zammit-Mangion[2], M.A. Jansen[1], D.J. Webb[1], J.J. Mullins[1], J.W. Dear[1], G. Sanguinetti[2] and M. Bailey[1]

[1]Centre for Cardiovascular Sciences, The University of Edinburgh, Edinburgh, UK and [2]The School of Informatics, The University of Edinburgh, Edinburgh, UK

Oxygenation defects may contribute to renal disease but pO_2 is difficult to measure. Microelectrodes offer quantitative but localised measurements and are invasive. A global "map" of pO_2 can be obtained post-mortem by immunohistochemical detection of pimonidazole adducts. This is non-quantitative and insensitive. BOLD MRI provides an alternative for longitudinal measurement of oxygen gradients. However, post-acquisition data analysis often relies on manual selection of region(s) of interest, which excludes from analysis significant quantities of biological information and is subject to selection bias.

We applied k-means clustering as an anatomically unbiased analytical approach, clustering individual voxels on quantitative nearness of the R2* signal. This quantitative similarity does not necessarily imply close anatomical association of voxels or compartmentalization within a given region of the kidney.

Scans were performed on anesthetized (2% Isofluorane) F344 rats (n=6) using a 7T MRI scanner. A birdcage volume coil and a 4-channel phased array surface coil were used for radio frequency transmission and signal reception, respectively. We employed two complementary strategies to affect R2*. Acutely, we administered acetylcholine IV; chronically we infused via osmotic minipump angiotensin II (60ng/min) over a 3-day period, after which rats were rescanned.

Data (mean ± SE) were analysed by RANOVA. In control rats, low R2* clustering was located predominantly within the cortex and higher R2* clustering within the medulla (70.96±1.48 versus 79.00±1.50; 3 scans per rat; n=6; P<0.01) consistent anatomically with a cortico-medullary oxygen gradient. An IV bolus of acetylcholine caused a transient reduction of the R2* signal in both clustered segments (P<0.01), which was nitric oxide dependent. Chronic infusion of angiotensin II disrupted the cortico-medullary gradient, producing less distinctly segmented mean R2* clusters (71.30±2.00; versus 72.48±1.27; n=6; NS). The acetylcholine-induced attenuation of the R2* signal was abolished by chronic angiotensin II infusion, consistent with reduced nitric oxide bioavailability.

In summary, we have developed an anatomically unbiased method for the assessment of renal function by BOLD MRI, employing signal analysis to remove errors inherent in manual ROI selection. This method offers a global insight into intrarenal oxygenation and the dynamic response of R2* to acetylcholine can provide information relating to renal NO bioavailability.

PCD219

The effects of Angiotensin 1-7 on renal haemodynamics

W.E. Osman, E.J. Johns and A.F. Ahmeda

Physiology Department, UCC, Cork, Ireland

The renin angiotensin system (RAS) is involved in the regulation of renal function and cardiovascular homeostasis. The actions of the vasoconstrictor and anti-natriuretic factor angiotensin II (Ang II) are well described, however, recently the discovery of a second isoform of angiotensin converting enzyme which generates angiotensin 1-7 (Ang1-7) has generated further interest in this peptide. Studies to date suggest that Ang1-7 opposes the effects of Ang II, that is it is vasodilator and has diuretic properties. This study investigated the effects of Ang 1-7 on regional renal haemodynamics in animals of different dietary sodium intakes to stimulate or suppress the endogenous RAS.

Three groups (n=6), 250-300g, of male Wistar rats fed a normal salt (NS) [0.3% Na+], high salt (HS) to suppress the RAS [3% Na+], or low salt (LS) to stimulate the RAS [0.03% Na+] diet for three weeks, were anaesthetised with 1 ml i.p. chloralose/urethane (16.5/250 mg/ml, respectively).

The right femoral vein and artery were cannulated for infusion of saline (154 mM NaCl) at 3 ml/h, anaesthetic supplementation (0.05 ml every 30 min), and measurement of arterial blood pressure and heart rate.

The left kidney was exposed via a flank incision, placed in a holder and a small cannula was inserted 4.5 mm into the corticomedullary border (CMB) for infusion of saline or Ang1-7 at 1.0 ml/h.

Two Laser-Doppler microprobes were inserted 1.5 and 4.0 mm into the kidney to measure cortical (CP) and medullary (MP) blood perfusion. 90 minutes were allowed for recovery from the surgery followed by baseline recording, and then infusion of the Ang (1-7) at two different doses (low, 15ng/min and high, 50ng/min) into the CMB for 40 min. At the end of experiments the rats were killed with an overdose of anaesthetic.

Data, presented as mean ± SEM, were subjected to the Student's t-test and significance taken at P<0.05.

Baseline recordings for CP and MP in NS were 227±50PU and 98±12PU, in HS were 313±48PU and 132±20PU and in LS were 293±40PU and 123±9PU, respectively.

Infusion of Ang 1-7 at low and high doses increased CP in all groups (15±5% and 7±3% in NS, 9±2% and 18±10% in HS, and 9±2 and 1±3% in LS; P<0.05).
MP increased significantly (P<0.05) only following the infusion of the low dose on both normal and high salt fed rats by 10± 3% and 8±3%, respectively. In LS group, where RAS is activated and Ang II is at a high level, the MP remained unchanged at both doses.
These results indicate that Ang 1-7 caused a vasodilatory effect on the renal microvasculature, expressed as an increase in blood perfusion, which was much more evident in the cortical region but could not be related to the level of dietary sodium intake. Ang 1-7 caused a similar vasodilation in the medullary region except when the RAS was suppressed by the high salt intake when no effect could be demonstrated.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD220

Cell signaling responses in rabbit renal proximal tubules exposed to acute acid-base disturbances

L. Skelton and W.F. Boron

Physiology and Biophysics, Case Western Reserve University, Cleveland, OH, USA

Acute exposure of rabbit proximal tubule suspensions (PTs) to acid-base disturbances alters ErbB1 and ErbB2 tyrosine phosphorylation. Here we examine whether Src (which can transactivate ErbB1/2) or proteins downstream of ErbB1/2 are involved in the CO_2/HCO_3 signaling cascade. New Zealand White rabbits were euthanized under anesthesia using ~10ml intravenous 5% pentobarbital sodium. PTs were purified from rabbit renal cortex using a method similar to Doctor RB *et al.* (1998), modified for rabbit. We exposed purified PTs for 5 or 20 min to: *HEPES* (i.e., HEPES/pH 7.40); *Butyrate* (HEPES/pH 7.10 + 20 mM butyrate);*EGF* ('HEPES' + 10 nM EGF); *Physiological* CO_2/HCO_3 (5% CO_2/22 mM HCO_3/pH 7.40); *respiratory acidosis* (RAc; 10% CO_2/22 mM HCO_3/pH 7.10); *compensated RAc* (10% CO_2/44mM HCO_3/pH 7.40); *metabolic acidosis* (MAc; 5% CO_2/11 mM HCO_3/pH 7.10), *respiratory alkalosis* (RAlk; 2.5% CO_2/22 mM HCO_3/pH 7.70), or *metabolic alkalosis* (MAlk; 5% CO_2/44 mM HCO_3/pH 7.70) +/- PD168393, an ErbB family inhibitor. We probed lysates with phospho-specific (p) antibodies to ErbB1/ErbB2, Src, ERK1/2 (p44 & p42), and PLCγ1. PTs exposed to RAlk for 5 min exhibited a decreased ratio of Src-pY-416 (kinase-activating) to Src-pY-527 (kinase-inactivating). Concurrently ErbB1-pY845 (Src-transactivated) fell. RAlk or MAlk for 5 min reduced pERK1/2 levels compared to the other treatments; PD168393 inhibited only p44 after MAlk. At 5 min, butyrate, RAc, or Compensated RAc reduced PLCγ1-pY-783; at 20 min, pY for butyrate and RAc remained low. In conclusion, rabbit PTs exhibit acid-base–dependent signaling responses in pathways up- and downstream from ErbB1/2, and these signals evolve over time.

PCD222

Cleavage of SPAK kinase by kidney-enriched protease(s)

N. Markadieu[1], P.A. Welling[2] and E. Delpire[1]

[1]Anesthesiolgy, Vanderbilt University Medical School, Nashville, TN, USA and [2]Physiology, University of Maryland Medical School, Baltimore, MD, USA

The Ste20 kinases SPAK and OSR1 regulate Na^+ transport in the distal nephron. Western blot analysis of kidney lysates revealed the presence of multiple SPAK fragments in the kidney medulla, which are thought to have inhibitory effects on OSR1 in the thick ascending limb of Henle [1, 2]. The nature of these fragments is still not completely understood. Based on a 49 kDa band size found in multiple tissues, we proposed earlier that translation also starts at an alternative methionine, resulting in a shorter protein sometimes called SPAK2 [3]. Analysis of Expressed Tag Sequences databases also revealed the presence of a shorter SPAK transcript consistent with a 34 kDa protein (KS-SPAK) [2]. Here, we demonstrate using a C-terminal anti-SPAK antibody that mouse kidney lysate cleaves in a dose- and time-dependent manner a fusion protein consisting of GST followed by full-length SPAK. The incubation results in five to seven proteolytic fragments with two of the fragments having sizes compatible with SPAK2 and KS-SPAK. We further confirm that thrombin, which protease site is located at the end of GST, produces only one fragment of a larger molecular size. When we used equal protein amounts from lysates prepared from mouse brain, spleen, liver, and kidney, we only observed the cleavage pattern with kidney, indicating that the protease(s) is/are enriched in this tissue. We demonstrate that the cleavage is resistant to aprotinin (2.5 μM), leupeptin (40 μM), PMSF (3 mM), and EDTA (5 mM), indicating inefficacy of traditional protease inhibitors. The cleavage was also resistant to pepstatin (1-10 μM), and CuSO4 (1 mM) or doxycycline (200 μM), potentially eliminating cathepsins and metalloproteases as possible proteolytic enzymes. We show, however, that the cleavage was sensitive to DTT, as proteolysis was significantly reduced with 1 mM of the reducing agent and completely eliminated at 10 mM. This observation indicates that the protease is stabilized by di-sulfide bridges. The protein cleavage occurred over a wide temperature range (4ºC – 45ºC), but was impaired at 55ºC and eliminated at 65ºC and higher temperatures. Finally, we tested SPAK cleavage over a wide pH range (pH 5.5 – 9.5) and made the following observation: the proteolysis leading to the higher size fragments occurred equally over the entire pH range, whereas the proteolysis leading to the smaller two fragments was significantly inhibited by basic pH and markedly activated by acidic pH. This observation indicates the possible involvement of two distinct proteases. Future work will seek to identify the amino acid sequences in SPAK targeted for proteolytic cleavage and determine the identity of the protease(s) involved.

Glucocorticoid receptor haploinsufficiency causes salt-sensitivity and dysregulation of the thiazide-sensitive Na-Cl cotransporter

J.R. Ivy[1], L.C. Evans[1], R.V. Richardson[1], P.W. Flatman[2], K.E. Chapman[1], C.J. Kenyon[1] and M.A. Bailey[1]

[1]Molecular Physiology (CVS), University of Edinburgh, Edinburgh, UK and [2]Centre for Integrative Physiology, University of Edinburgh, Edinburgh, UK

The distal convoluted tubule (DCT) plays key roles in blood pressure (BP) homeostasis. Reabsorbing up to 7% of the sodium load, DCT length changes with demand, optimizing sodium delivery into the collecting duct. The Na-Cl co-transporter (NCC) is the predominant route for apical sodium entry. Aldosterone activates NCC but the conventional paradigm of mineralocorticoid protection by 11β-hydroxysteroid dehydrogenase 2 does not apply: the enzyme is not expressed in the DCT and NCC can be regulated by glucocorticoids.
Glucocorticoid receptor (GR) heterozygous mice on a standard (0.25%) sodium diet have elevated BP and increased circulating corticosterone. We found in vivo that NCC reabsorbs ~2% of the filtered sodium load in both wild-type and GR+/- mice. When mice were a fed high salt diet (2.5%), a reduction of thiazide-sensitive transport was seen in wild type mice but not in GR+/-. Heterozygotes entered positive sodium balance ($P<0.01$, n=6, one way ANOVA) and BP increased ($P<0.05$ n=16, one way ANOVA). High sodium diet caused a moderate increase ($P<0.05$) in mRNA abundance for slc12a3, the gene encoding NCC, in GR+/-, but not in controls (n=8, Student's t-test). Surprisingly, the high sodium diet increased total expression of NCC in both genotypes and there was no difference in expression between genotypes under either dietary regimen ($P>0.05$, n=6, Student's t-test).
These data indicate that inappropriate NCC activity contributes to salt sensitive hypertension in GR haploinsufficiency. Sustained NCC activity in vivo does not correlate with protein abundance and may reflect alterations in post-translational modification (e.g. phosphorylation), protein-protein interactions or membrane trafficking.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD224

Systemic iPSs decrease kidney injury dependent on ROS-facilitated engraftment

M. Xiang, N. Li, P. Lu, L. Le, J. Quan, D. Meng, X. Wang, R. Wang, A. Chen and S. Chen

Department of physiology and pathphysiology, Shanghai Medical College,Fudan University, Shanghai, China

Aims: Induced pluripotent stem cells (iPSs) are believed to have great therapeutic potential. Treatment for acute kidney injury is challenging. Therefore, we aimed to demonstrate if iPSs attenuate acute kidney injury and the possible mechnisms.
Methods: In vivo experiments: Male C57BL/6 mice were anesthetized with an intraperitoneal injection of 4% sodium pentobarbital (Nembutal). Kidneys were exposed and subjected to right nephrectomy, followed by left renal ischemia for 50min, then resuscitated with Ringer's lactate. After operation, the mice were injected iPSs with or without 100uM NAC pre-treated. The kidney tissue and serum were collected 24 h, 48h after resuscitation. Creatinine, pathology score, cytokine expression, iPSs quantification and identification in injury kidney were detected. In vitro EC- iPSs experiments: mice glomerular endothelial cells isolated from C57BL/6 were pre-treated with MCP-1 (10 U/ml) 4h, and then added iPSs with or without NAC(100 uM) treated. Following that the adhesion and transendothelial migration of IPS were detected.
Results: In vivo study showed iPSs decreased the scores from 2.5±0.2 at 24h and 3.9±0.1 at 48h in mice receiving PBS to 1.1±0.1 and 0.25±0.1, respectively. The scores of mice receiving NAC-pretreated iPSs were in between. The serum creatinine levels to 248.14±13.66 umol/L at 24h and 280.94±9.89 umol/L at 48h. Intravenous injection of iPSs decreased serum creatinine levels to 99.54±4.65 umol/L at 24h and 93.9±4.58 umol/L at 48h . The serum creatinine level had no significant difference between mice receiving PBS and NAC-pretreated iPSs.Administration abolished the increases in the expressions of IL-6, GRO, and GM-CSF in the kidney. NAC-pretreated iPSs had the same effect as untreated iPSs. The positive cells were found in the kidney that received iPS or NAC-pretreated iPSs, but not in the mice that received PBS by FISH staining.
In vitro study showed the rate of adhesion of iPSs to MCP-1-activated GEC was significantly higher than to untreated GEC. NAC-pretreatment decreased the transendothelial migration of iPSs by 47.2%, adhesion to activated GEC by 57.1%, and adhesion to untreated GEC by 14.4%.
Innovation and conclusion: The novel findings of the present study included isogenic iPSs decreased renal ischemia/reperfusion injury. iPSs selectively homed to injured kidneys and became an integrated part of glomeruli and renal tubules in a ROS-dependent manner. Our results also showed that iPSs can be regulated by modulating either iPSs themselves or the endothelial cells of target tissue.

Extracellular nucleotides increase albumin permeability of isolated intact wistar rat glomeruli

M. Kasztan[1], A. Piwkowska[2], E. Kreft[1], R. Kowalski[1], M. Szczepanska-Konkel[1] and M. Jankowski[1,2]

[1]Department of Therapy Monitoring and Pharmacogenetics, Medical University of Gdansk, Gdansk, Poland and [2]Laboratory of Molecular and Cellular Nephrology, Mossakowski Medical Research Center Polish Academy of Sciences, Gdansk, Poland

INTRODUCTION: Renal glomeruli consist of endothelial cells, mesangial cells, acellular basement membrane and epithelial cells called podocytes. Interactions between these cells and amorphic membrane affect the glomerular barrier function. Activity of these cells is regulated by extracellular nucleotides via P2-receptors in para-/autocrine manner. These receptors are nucleotides-gated ion-channels receptors (P2X) and G protein-coupled receptors (P2Y). The expression of purinoceptors is up-regulated in some forms of chronic renal injury and inflammatory diseases characterized by increased glomerular permeability leading to development of albuminuria/proteinuria, a sign of kidney disease and independent risk factor for the progression of renal failure and for cardiovascular morbidity and mortality.
AIM: The aim of study was to investigate the effects of P2-receptors activation on glomerular-capillary permeability for albumin.
METHODS: The osmotic pumps (ALZET, model 2001, reservoir volume 200μl, pumping rate 1μl/hr) with specific and non-selective agonists of P2-receptors, 2-MeSATP (10-6M), ATP-γ-S (10-6M) or buffer were implanted subcutaneously into Wistar rats for 7 days. Afterwards pumps were removed and glomeruli were isolated by sieving technique. Isolated, affixed to a dishes coated with poly-L-lysine, glomeruli were incubated with buffer or natural nucleotides (ATP, ADP, AMP, UTP, UDP) or synthetic nucleotides (2-methylothioATP, ATP-γ-S). Glomerular-capillary permeability for albumin (Palb) was measured as a volume response of glomerular capillaries to an oncopressive medium generated by defined concentrations of albumin. Measurements were conducted using video-microscopy (Olympus IX51). Glomerular volume was derived from the area of glomerular image calculated using CellSens Dimension Software (Olympus). The reflection coefficient of albumin (Salb) was calculated as Salb = ΔVexperimental/ΔVcontrol. Palb was calculated as Palb = 1-Salb. Cultured rat podocytes were used for immunofluorescence studies.
RESULTS: Palb in control glomeruli was 0.10±0.03. 2-MeSATP and ATP-γ-S (10-6M, 10 min, 37°C) induced increase in Palb to 0.58±0.04 and 0.37±0.08, respectively. Palb in glomeruli isolated from rats in vivo exposed to 2-MeSATP or ATP-γ-S (released from osmotic pumps) were significantly increased (0.35±0.03 vs. 0.13±0.02. and 0.52±0.02 vs. 0.13±0.02, respectively). Palb in glomeruli incubated with natural agonists of P2-receptors were increased and amounted to 0.24±0.04 (ATP 10-6M, 2min), 0.34±0.04 (ADP 10-6M, 2min), 0.33±0.05 (AMP 10-6M, 2min), 0.35±0.10 (UTP 10-6M, 2min), 0.23±0.05 (UDP 10-6M, 2min), respectively. 2-MeSATP and ATP-γ-S affects cortical actin remodeling in cultured podocytes.
CONCLUSIONS: Our results suggest that activation of P2-receptors increases glomerular-capillary permeability for albumin and may be involved in pathogenesis of renal diseases.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD226

Expression of the extracellular calcium-sensing receptor, CaSR, in rat, human and mouse kidney

J. Graca[1], M. Schepelmann[2], D. Riccardi[2] and S. Price[1]

[1]AstraZeneca, Macclesfield, UK and [2]Cardiff University, Cardiff, UK

The calcium sensing receptor (CaSR) is a GPCR with a key role in the regulation of calcium homeostasis. Although the initial cloning and characterization of the CaSR in kidney was performed in 1995, discrepancy in the expression pattern within this organ and species differences have been reported by different groups. Determining the expression of the CaSR along the nephron is key to understanding the physiological role of the CaSR in the kidney.
We aimed to determine the localisation of the CaSR in rat, human and mouse kidney, using *in situ* hybridisation and immunohistochemistry methods.
In situ hybridization was carried out using a sensitive branched-DNA methodology. CaSR mRNA showed highest expression in the thick ascending limb (TAL), but was also expressed in the distal tubule (DT) and collecting duct (CD), with weaker expression in the proximal tubule (PT). For immunohistochemistry three different antibodies raised against different epitopes of the CaSR were used to determine whether the differences reported previously could be ascribed the different antibodies used. By western blotting, all the three antibodies used produced bands of the expected immunoreactivity and molecular weight for CaSR protein in mouse and rat kidney. Immunolocalisation of the CaSR was similar with the three different antibodies; generally CaSR immunoreactivity was stronger in the medulla and weaker in the cortex. Dual labelling was also carried out using antibodies against specific markers for DT (thiazide-sensitive Na+-Cl- cotransporter, NCC), TAL (Tamm-Horsfall protein) and CD (aquaporin 2), to confirm the exact nephron segments expressing the CaSR. The CaSR co-localized with CD, TAL and DT markers, with the strongest signal in the TAL.
Our data show that the CaSR exhibits the strongest expression in the TAL, and that it is also expressed in other nephron segments including the PT, CD and DT. These findings have clarified the expression pattern of the CaSR in kidney in several species, using different techniques. This work will enable the full physiological role of the CaSR in kidney to be determined.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD227

MO25β has no physiological role in electrolyte homeostasis or systemic blood pressure maintenance

K. Siew[1], P. de los Heros[2], D.R. Alessi[2] and K.M. O'Shaughnessy[1]

[1]Clinical Pharmacology Unit, Department of Medicine, University of Cambridge, Cambridge, UK and [2]MRC Protein Phosphorylation Unit, College of Life Sciences, University of Dundee, Dundee, UK

Introduction: Hypertension (HT) affects 1 in 4 age 25+ years, contributing to ~12.8% of global deaths. Thiazide diuretics are

amongst the most widely used Anti-HT drugs that reduce blood pressure (BP) by inhibition of the Na^+-Cl^- Cotransporter (NCC) in the renal distal convoluted tubule (DCT) causing salt-wasting. Genetic disorders & knockout (KO) mice targeting proteins SPAK, OSR1 or WNKs that form a cascade regulating NCC activity & expression in the DCT have also resulted in BP modulation via parallel changes in NCC function & renal Na^+ excretion. So the WNK/SPAK/OSR1 pathway represents a novel therapeutic HT target (1-3). Recently mouse protein-25 alpha (MO25α/CAB39) was discovered to be the master regulator of SPAK/OSR1; it colocalises with NCC, increases SPAK/OSR1 activity up to 100-fold independent of WNKs, facilitates SPAK/OSR1 monomer interactions & stabilises active conformations, which in turn enhance NCC activity & Na+ reabsorption (3-5). It was hypothesised that MO25 deficiency would result in a hypotensive salt-wasting phenotype, however the embryonic lethality of MO25α-KO mice has limited *in vivo* data & focus to its sister isoform MO25beta (MO25β/CAB39L). MO25β shares 79% sequence identity with MO25α, interacts similarly with substrates such as LBK1 & has high renal expression (4). Thus MO25β-KO mice were utilised to test *in vivo* effects of the MO25α paralog. Methods: Age matched C57Bl/6 MO25β-KO mice & wildtype (WT) littermates between 2-4 months were either fed a normal Na^+ diet (0.25%) or placed on a high Na^+ diet (3%) for 10 days before switching to a low Na^+ diet (0.03%) with urine collected for electrolyte analysis at 0hrs, 3hrs, 6hrs, 24hrs & 4 days post-switch. BP was measured by direct carotid manometry (MLT844, AD Instruments) under terminal anaesthesia (isoflurane 2% at 2L/min O_2). The procedure terminated with blood collection via cardiac puncture for electrolyte analysis & excision of the kidneys. Data are presented as mean ± SEM; means were compared by Student's t-test with $P < 0.05$ considered statistically significant. Results: There were no differences between KO vs. WT mean arterial pressures on normal Na^+ [80.2 ± 2.4 mmHg (n=4) vs. 79.0 ± 2.3 mmHg (n=3)] or low Na^+ diets [80.0 ± 1.2 mmHg (n=11) vs. 80.7 ± 1.1 mmHg (n=11)]. No significant differences were detected for urine or plasma levels of creatinine, Na^+, K^+, Cl^-, Ca^{2+}, Mg^{2+} or PO_4^{3-} on any diet with the one exception of Mg^{2+} on a normal Na^+ diet (see table). We therefore conclude MO25β does not play a significant role in BP or electrolyte homoeostasis *in vivo*.

Baseline Urine Electrolytes (0.25% Na^+ diet)

Iodinated contrast media induced oxidative stress and tubular necrosis in isolated thick ascending limb of rat

Z. Liu, K. Schmerbach, P. Persson, E. Seeliger, C. Kathleen, A. Patzak and M. Sendeski

Institut fuer Vegetative Physiologie, Charité-Universitätsmedizin Berlin, Berlin, Germany

Introduction: The cases of contrast induced acute kidney injury (CI-AKI) are increasing. A toxic effect of contrast media on the tubular cells is generally accepted as the key feature in CI-AKI(1,2). We investigate the hypothesis that contrast media induce tubular cell death by generating oxidative stress and reducing nitric oxide.

Methods: Male Sprague-Dawley rats were killed using isoflurane and isolated thick ascending limbs (TALs) were perfused with either vehicle solution or iodixanol. Nitric oxide bioavailability and superoxide concentration were quantificated by the fluorescent dyes DAF-FM and dihydroethidium (DHE), respectively. Propidium iodide was used to estimate the cell death rate. The expression of oxidative stress related genes and the activity of superoxide dismutase (SOD) in tubuli were investigated using a microarry and the OxiSelect kit in an ex vivo setup. DHE, DAF-FM and Propidium iodide data were compared using Brunner's test. RNA microarray and the activity of SOD data were compared by the Student's t-test.

Results: Iodixanol increased DHE fluorescence ratio (9.6±1.4%, n=7) compared to the control group (1.7±1.0%, n=8) in 4min, whereas tempol, a superoxide dismutase mimic, inhibited the increase by iodixanol. DAF-FM fluorescence intensity decreased during iodixanol treatment (-0.6±0.6%, n=7) and by nitric oxide synthase inhibitor L-NAME, whilst it increased by 1.6±0.3% in the control group within 12min (n=7). Propidium iodide intensity was significantly enhanced by iodixanol (n=8) compared to the control group (n=6) within 20min. Moreover, during total 4-hour perfusion, iodixanol increased propidium iodide intensity to 17.7±3.1%, while in control group was 7.0±1.0%. Only two of 84 investigated genes related to oxidative stress were differentially expressed in the tubuli. The SOD activity did not differ between iodixanol perfused rats and control animals.

Conclusion: The study shows that contrast media increase superoxide concentration, implying oxidative stress in TALs. Further, an impaired nitric oxide bioavailability happens due to contrast media. TAL cells are damaged by contrast media. This damage is not because of changes in the expression of oxidative stress related genes or SOD activity.

Inflammatory cytokines provokes a macrophage phenotype switch by modulation of Ivns 1abp

C. Mastora[1,2], A. Sola[2], M. Ventayol[2], S. Buenestado[2], T. Carbonell[1] and G. Hotter[2]

[1]Physiology, University of Barcelona, Barcelona, Spain and [2]Ischemia and Inflammation, IIBB-CSIC-IDIBABS, Barcelona, Spain

Macrophages are phagocytic cells involved in a number of functions that secrete a large number of cytokines, chemokines and growth factors that can activate different cell types and play a role in inflammation. Macrophages can be classically or alternatively activated, obtaining either the pro-inflammatory phenotype M1 or the anti-inflammatory phenotype M2. Inflammatory cytokines, such as TNF-a and IFN-gamma are known to provoke a M1 phenotype but the mechanism responsible are unknown.

Ivns1abp is a gene coding for a 642 amino acid protein that localizes to both the nucleus and the cytoplasm. Functioning as a homodimer, Ivns1abp associates with F-actin and, via this association, plays an important role in the organization and stabilization of the actin skeleton.

The aim of this work was to study the mechanism involved in cytokine regulation of macrophage phenotype switch. For this purpose, murine BMDMs, obtained by Swiss CD1 mice, sacrificed by an overdose of isoflurane, were cultured in presence of GM-CSF during 7 days to achieve macrophage phenotype. After this period of time macrophage overexpressing ivns1abp and control macrophages in the presence or absence of cytokines and c-myc inhibitors were cultured to evaluate cytokines, ivns1abp and c-myc production.

Results indicated that cytokines provoke a a decrease in Ivns1abp, c-myc expression, M2 cytoskeletal features and anti-inflammatory mediators (IL-10, mannose receptor), showing an increase in M1 cytoskeletal features . C-myc inhibitors provoked the same results indicating that cytokines act on c-myc to down regulate ivns1abp, anti-inflammatory mediators and cytoskeletal M2 features.

Based on these results, we conclude that cytokines trough its inhibitory action on c myc, down regulates ivns1abp expression that in turns provokes a phenotype change trough cytoskeleton stabilization.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD233

T-cell trafficking during inflammation is regulated by a novel PEPtide Inhibitor of Trans-Endothelial Migration, a pathway defective in chronic disease

M. Chimen[1], H.M. McGettrick[2], C.M. Yates[1], A. Martin[3], F. Barone[2], L.S. Walker[2], C.D. Buckley[2], G. Nash[1] and G.E. Rainger[1]

[1]School of Clinical and Experimental Medicine, University of Birmingham, Birmingham, UK, [2]School of Immunity and Infection, University of Birmingham, Birmingham, UK and [3]School of Cancer Sciences, University of Birmingham, Birmingham, UK

T-cells are recruited from the blood into extra-vascular tissues during acute inflammation. However, in chronic inflammatory diseases, an inappropriate accumulation of T-cells in the diseased tissue contributes to pathogenesis. Very little is known about the mechanisms by which T-cell trafficking is regulated during inflammation. Here we describe a unique immune regulatory peptide that imposes a tonic inhibition of T-cell trafficking during inflammation. PEPtide Inhibitor of Trans-Endothelial Migration (PEPITEM) introduces a new paradigm into the pathways that regulate the inflammatory response. We present evidence that this new pathway is compromised in chronic inflammatory diseases. We propose that loss of this regulatory pathway makes the immune system 'leaky', allowing inappropriate access of T-cells to vulnerable tissues. Lymphocyte trafficking was assessed in vitro using videomicroscopy on TNF-α/IFN-γ activated endothelial cells (EC) and lymphocytes isolated from healthy donors or patients with chronic inflammatory diseases. In vivo, lymphocyte recruitment was assessed in a model of zymosan-driven peritoneal inflammation. PEPITEM was identified using mass spectrometry. Our studies began with an interest in adiponectin, an anti-inflammatory adipose tissue-derived cytokine. Using an in vitro migration assay, we observed that the migration of human lymphocytes was dose-dependently blocked by adiponectin with an EC50=37.2nM. Adiponectin achieves its effects on T-cell migration by the induction of a novel mediator released from B-cells. Thus, the effect of adiponectin was lost when B cells are absent, but could be regained by the addition of supernatants from adiponectin stimulated B-cells. Interestingly, the B-cell derived product did not act directly on T-cells; rather, it stimulated EC to release the lipid mediator sphingosine-1-phosphate, which in turn inhibited the migration of T-cells. We used mass spectrometry to isolate a B-cell derived peptide, corresponding uniquely in the human genome to a proteolytic excision product of the 14.3.3$\zeta\delta$ protein. Synthetic PEPITEM could also effectively inhibit T-cell migration with an EC50=18.6pM. In zymosan-induced peritonitis in the mouse, T-cell recruitment was significantly increased in BABL/C mouse strain lacking B cells (Jh-/-) when compared to wild-type animals. This excess of T-cell recruitment was ameliorated by intravenous treatment with PEPITEM. Importantly, lymphocytes isolated from patients with chronic inflammatory disease (type-1-diabetes) were released from the inhibitory effects of adiponectin, but this regulatory pathway could be re-established by the addition of exogenous PEPITEM. We believe that PEPITEM and its associated pathway may have therapeutic efficacy in a number of disease scenarios.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD234

Comparison between automated inflation and manual inflation for forearm blood flow measurements made with venous occlusion plethysmography in humans

R. Junejo, F. Pavliv, C.J. Ray and J.M. Marshall

Clinical & Experimental Medicine, University of Birmingham, Birmingham, UK

Venous occlusion plethysmography has been used for over a century and is still a powerful tool for recording limb blood flow. It has been used to investigate autonomic regulation, vasodilator responses to exercise, ischemia, emotional stress and changes in body temperature, and to follow changes in endothelium-dependent responses in a number of diseases. Comparisons made between the older, air-filled plethysmographs and the more modern mercury/indium-gallium in silas-

tic strain gauges have indicated that the estimates made of limb blood flow are very similar (see Joyner et al, 2001). Recently, automated rapid inflation systems have been introduced to inflate the sphygmomanometer cuffs that are used to occlude the venous drainage, replacing the use of manual inflation. To our knowledge, there have been no direct comparisons between the blood flow measurements made with automated and manual inflation.

In an initial study on 7 male subjects (18-25 years old), forearm blood flow (FBF) was recorded by venous occlusion plethysmography, by using an automated system (E20, Rapid Cuff inflator, Hochansen Inc, USA) that inflated the cuff around the upper arm to 50mmHg. FBF was 8.4±1.1 at rest, 61.2±8.1 ml.min-1.100ml-1 immediately after 3 minutes static contraction at 60% maximum voluntary contraction (MVC) and 53.4±6.1, 45.4±7.9, 35.3±8.2, 29.8±5.4, and 20.9±3.3 ml.min-1.100ml-1 at 30s, 1, 3, 5 and 7 min respectively after contraction: FBF increased at maximum by ~7-fold. By contrast, we previously reported that in a similar group of subjects, FBF increased from 6.8±0.6 ml.min-1.100ml-1at rest, by only ~3.2 fold after static contraction at 60%MVC (Win & Marshall, 2005), suggesting the responses were much larger when recorded with automated inflation. Thus, in a separate study on 5 subjects (3F/2M; 20-30 years old), direct comparisons were made between automatic and manual cuff inflation before and following static contraction at 70% MVC for 1min. With automated inflation, FBF was 7.2±0.6 ml.min-1.100ml-1 at rest and 44.4±6.8 ml.min-1.100ml-1 immediately after, and 32.9±4.7, 26.8±3.4, 21.5±3.4, 16.9±2.9,11.6±3.4 ml.min-1.100ml-1 at 30s, 1, 3, 5 and 7 min respectively after contraction, whereas with manual inflation the corresponding values were 8.2±2.2 at rest and 32.8±5.5, 20.3±1.7, 17.8±2.7, 14.6±2.8,12.4±2.4 and 9.6±2.6 ml.min-1.100ml-1. These values were significantly different from 0-3min after contraction ($P<0.05$, repeated measures ANOVA).

Venous occlusion plethysmography underestimates limb blood flow relative to the thermodilution technique (Joyner et al, 2001). The present results indicate that automated cuff inflation gives a better estimation than manual inflation; this would have tremendous implications for use of the technique in physiological and clinical studies.

PCD235

The effect of longer cold water immersion time in the contrast bath on the skin temperature and parasympathetic activity

K. Inoue[1,2], J. Udagawa[1], N. Wakasugi[2] and K. Endo[3]

[1]Shiga University of Medical Science, Otsu, Japan, [2]Hatanaka Orthopedics, Rehabilitation Clinic, Amagasaki, Japan and [3]Institute for Frontier Medical Kyoto Univeriity, Kyoto, Japan

Recent reports suggest the relationship between the decrease in the body temperature and hypotension or the onset of diabetes mellitus, in people whose normal temperature is more than 36.5 degrees. Autonomic nervous system regulates blood flow, thermogenesis, and glucose and adipose metabolisms, therefore, it is important to keep the autonomic function adequately for preventing the circulatory and metabolic diseases. The contrast bath therapy is one of rehabilitation therapies. In usual way, the body part is immersed in warm bath for 4 minutes, then in cold bath for 1 minute, and this procedure is repeated 5 times. This therapy improves local blood circulation through vasodilatation and vasoconstriction. Furthermore, immersion of the body part in cold water activates the parasympathetic function. In this study, we examined whether or not longer immersion time in cold water improves parasympathetic function and prevents the skin temperature from decreasing. Twenty healthy subjects (10 men and 10 women: mean age 22.0±1.8 years old) with no history of any pathological condition were recruited. All subjects signed an informed consent before participating in this study. A hand was immersed for 4 minutes in cold water and for 1 minute in warm water, and this procedure was repeated 5 times in this contrast bath. The contrast bath was performed twice or three times a week and was continued for four weeks. We carried out cold immersion test in which a hand was immersed in 10 degrees of water for 16minutes before starting and after completing a series of the contrast bath. RR interval were monitored by electrocardiograph during cold water immersion test, and a high-frequency (0.30 – 0.40 Hz) RR interval variation was analyzed by FFT to quantify parasympathetic activity. After cold water immersion test, the skin temperature was immediately measured on the proximal nail fold of the index finger. Paired t-test and Scheffe's test were used to analyze the change of skin temperature and electrocardiogram, respectively.

The skin temperature did not decrease by cold water immersion test after 4 weeks of the contrast bath whereas it significantly decreased before starting the contrast bath. Moreover, parasympathetic activity significantly increased 10 minutes after cold water immersion in the test by performing 4 weeks of the contrast bath.

Present results suggest that longer cold water immersion time in the contrast bath stimulates parasympathetic nervous system, increases blood circulation in the periphery, and keeps skin temperature of the finger-tip.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Pre-cooling for endurance exercise performance in the heat: a systematic review

P.R. Jones, C. Barton, D. Morrissey, N. Maffulli and S. Hemmings

Centre for Sports and Exercise Medicine, Queen Mary University of London, London, UK

Background: Endurance exercise capacity diminishes under hot environmental conditions. Time to exhaustion can be increased by lowering body temperature prior to exercise (pre-cooling). This systematic literature review synthesizes the current findings of the effects of pre-cooling on endurance exercise performance, providing guidance for clinical practice and further research.

Methods: The MEDLINE, EMBASE, CINAHL, Web of Science and SPORTDiscus databases were searched in May 2012 for studies evaluating the effectiveness of pre-cooling to enhance endurance exercise performance in hot environmental conditions (≥28°C). Studies involving participants with increased susceptibility to heat strain, cooling during or between bouts

of exercise, and protocols where aerobic endurance was not the principle performance outcome were excluded. Potential publications were assessed by two independent reviewers for inclusion and quality. Means and standard deviations of exercise performance variables were extracted or sought from original authors to enable effect size calculations.
Results: In all, 13 studies were identified. The majority of studies contained low participant numbers and/or absence of sample size calculations. Six studies used cold water immersion, four crushed ice ingestion and three cooling garments. The remaining study utilized mixed methods. Large heterogeneity in methodological design and exercise protocols was identified. Effect size calculations indicated moderate evidence that cold water immersion effectively improved endurance performance, and limited evidence that ice slurry ingestion improved performance. Cooling garments were ineffective. Most studies failed to document or report adverse events. Low participant numbers in each study limited the statistical power of certain reported trends and lack of blinding could potentially have introduced either participant or researcher bias in some studies.
Conclusions: Current evidence indicates cold water immersion may be the most effective method of pre-cooling to improve endurance performance in hot conditions, although practicality must be considered. Ice slurry ingestion appears to be the most promising practical alternative. Interestingly, cooling garments appear of limited efficacy, despite their frequent use. Mechanisms behind effective pre-cooling remain uncertain, and optimal protocols have yet to be established. Future research should focus on standardizing exercise performance protocols, recruiting larger participant numbers to enable direct comparisons of effectiveness and practicality for each method, and ensuring potential adverse events are evaluated.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD237

Using perceived exertion to self-regulate exercise on a wheelchair ergometer in able-bodied novice participants

B.L. Savill[1,2], V. Tolfrey[3] and T. Paulson[3]

[1]Medicine, Cardiff University, Cardiff, UK, [2]Sport & Exercise Science, Loughborough Univerisity, Loughborough, UK and [3]Peter Harrison Centre for Disability Sport, Loughborough University., Loughborough, UK

Spinal cord injuries require rehabilitation programs immediately after injury. Ratings of perceived exertion (RPE) have been demonstrated as a suitable means to regulate exercise intensity for those trained in wheelchair propulsion. The use of RPE with novice wheelchair users has not been validated. Ten able-bodied males with no previous wheelchair experience (mean ± SD, age 22 ± 2 years, height 1.79 ± 0.08 m, mass 76.0 ± 12.1 kg) completed an incremental submaximal test followed by a VO2peak test on a wheelchair ergometer. In a second visit, two 12-min intermittent exercise tests of three 4-min bouts were completed at a moderate (40% VO2peak) and a vigorous intensity (60% VO2peak). On a separate day, participants completed the two 12-min tests at a self-selected intensity corresponding to the RPE noted during the second visit. During the last minute of each 4-min bout measures of VO2, HR and blood lactate concentration [La-] were recorded. Power output (PO) was measured continuously. There were differences in average VO2, %VO2peak, HR, and %HR between the Imposed and RPE-regulated Trial at a moderate ($P<0.05$) but not at a vigorous intensity ($P>0.31$) for these measures, whilst [La-] showed no difference at either intensity. There were no differences in PO between the Imposed and RPE-regulated Trial at a vigorous intensity. PO was however ~13% higher during the RPE-regulated Trial at the moderate intensity ($P \leq 0.01$). These data supports the use of RPE as a method of regulating exercise at a vigorous but not at a moderate intensity during wheelchair propulsion in novice able-bodied males. Research is needed into familiarisation with wheelchair propulsion to improve RPE accuracy at a moderate intensity, since large inter-individual differences were observed when comparing the Imposed and RPE-regulated Trial

PCD238

The role of prostaglandin and antioxidant availability on recovery from forearm ischemia-reperfusion injury in humans

S.E. Carter and M. Rakobowchuk

School of Biological Sciences, University of Essex, Colchester, Essex, UK

Endothelial dysfunction, manifesting as attenuated flow mediated dilation (FMD), following ischemia-reperfusion (IR) injury is a clinically important measure of vascular health. Antioxidants may prevent this dysfunction by scavenging reactive oxygen species, however the acute effects of oral antioxidant administration in humans are unknown. Low-flow mediated constriction (L-FMC), a further parameter of endothelial health, is largely unstudied and the mechanisms for this response are unclear. This study assessed interventions that impact FMD and L-FMC throughout an IR injury protocol. Twelve healthy subjects (5 female, 7 male) attended the lab on 3 occasions. The initial test acted as a baseline measure. Prior to subsequent visits subjects ingested either: 1) an antioxidant cocktail (300mg α-lipoic acid, 500mg Vitamin C and 200IU Vitamin E) 2 hours prior and a further cocktail (300mg α-lipoic acid, 500mg Vitamin C and 400IU vitamin E) 1.5 hours prior; or 2) 1200mg of a prostaglandin inhibitor (Ibuprofen) 1 hour prior in a blinded fashion. Endothelial function was assessed by non-invasive ultrasound of the right brachial artery. For each vascular function protocol vessel diameters were determined

throughout 5 min of forearm ischemia and 3 min after. Following a baseline measure (Pre) IR injury was induced by a 20 min upper arm occlusion. Subsequent vascular function protocols were carried out at 15, 30 and 45 min of recovery. Values are means ± SD, analysed by ANOVA. Endothelial dysfunction was evident in all three conditions. FMD was attenuated at 15 min post-IR injury (Control Pre: 5.96±3.41%; Post15: 0.67±3.26%; Antioxidant Pre: 6.90±3.83%; Post15: 0.68±2.87%; Ibuprofen Pre: 5.85±4.81%; Post15: -0.63±4.81%; $p<0.05$) but recovered by 45 min to near basal values. Antioxidant administration did not preserve FMD compared to control ($p>0.05$). The magnitude of L-FMC was augmented at 15 min compared to basal values (Pre: 1.44±0.27%; Post15: 3.75±1.73%; $p<0.05$) and recovered by 45 min. Ibuprofen administration produced the largest constrictive response and a significant time x condition interaction was observed (Ibuprofen Pre: -1.13 ±1.71%; Post15: -5.57 ±3.82%; Control Pre: -1.58 ±2.26%; Post15: -3.58 ±2.65%; interaction: $p<0.05$). Results demonstrate the presence of endothelial dysfunction following IR injury and the inability of acute oral antioxidant supplementation to preserve vascular function. Data also suggests that a lack of shear stress during occlusion combined with prostaglandin blockade magnifies L-FMC; possibly due to augmented expression of endothelin-1. Moreover, when prostaglandins are blocked their habitual role in inhibiting endothelin-1 secretion is abolished, increasing endothelin-1 bioavailability, and leading to a more pronounced L-FMC.

Effects of acute strenuous exercise on vascular endothelial cell activation

K. Fukada[1], H. Kushi[2], K. Oki[2], R. Koshizawa[2] and A. Mori[2]

[1]Graduate School of Literature and Social Sciences, Nihon University, Tokyo, Japan and [2]College of Humanities and Sciences, Nihon University, Tokyo, Japan

Introduction: Plasminogen activator inhibitor-1 (PAI-1) is a marker of vascular endothelial cell activation. The aim of this study was to evaluate whether a difference in low-density lipoprotein cholesterol (LDL-C) concentration affects the PAI-1 level during acute strenuous exercise.
Subjects and Methods: Thirteen healthy trained men aged 19 to 23 years participated in this study: 7 of these were categorized in the low LDL-C (LL) group (LDL-C concentration < 100 mg/dL), and 6 in the high LDL-C (HL) group (LDL-C concentration, 100-140 mg/dL). Venous blood samples were collected from the subjects before and after they performed the Cooper 12-min test (running as far as possible within 12 min). LDL-C concentrations were measured by direct methods using samples collected before exercise, and PAI-1 (total amount of active form, latent form, tissue plasminogen activator/PAI-1 complex) level was measured by Latex Photometric Immunoassay using samples collected before and after exercise. LDL-C concentrations in the LL and HL groups were compared using an unpaired t-test. PAI-1 levels were compared using a two-way analysis of variance (group × time) with repeated measures. Statistical significance was set at $P < 0.05$.
Results: The mean (± SE) age, height, and weight of the subjects in the LL group were 21.0 ± 0.5 years, 172.8 ± 1.7 cm, and 64.7 ± 3.0 kg, respectively, and the corresponding values for the subjects in the HL group were 20.6 ± 0.5 years, 171.0 ± 3.5 cm, and 84 ± 7.8 kg, respectively. LDL-C concentration was significantly higher in HL group (121.8 ± 4.4 mg/dL) than in the LL group (87.5 ± 2.8 mg/dL; $P < 0.05$). There was a significant difference in PAI-1 level between the LL and HL groups ($F=0.54$; $P < 0.05$). PAI-1 level before (30.4 ± 6.5 mg/dL) and after (25.2 ± 7.2 mg/dL) exercise did not change significantly in the LL group, whereas it increased significantly in the HL group (40.6 ± 7.0 mg/dL to 58.7 ± 7.8 mg/dL; $P < 0.05$). There were no significant differences in the PAI-1 levels before exercise in the LL and HL groups, whereas the levels after exercise were significantly different ($P < 0.05$).
Conclusions: It was reported that PAI-1 level does not decrease or change significantly after acute strenuous exercise. In this study, the PAI-1 level increased significantly in the HL group. Therefore, we conclude that a difference in LDL-C concentrations affects vascular endothelial cell activation during acute strenuous exercise.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD240

Comparison of Cardiopulmonary Exercise Tests for Patients with COPD and Overlap Syndrome

F. Coskun[1], A. Ertem Cengiz[1], F. Ozyener[2] and A. Ursavas[1]

[1]Chest Disease, Uludag University, Bursa, Turkey and [2]Physiology, Uludag University, Bursa, Turkey

Chronic Obstructive Pulmonary Disease (COPD) is a disease that progresses through inflammation and the main reason for morbidity in COPD is this inflammation. The rate of appearance of OS (Overlap Syndrome) and COPD together is %1 in the general public. Systemic inflammation increases the severity even more when the two diseases appear together. This is why the morbidity and mortality rates are higher with patients diagnosed with OS.
Purpose: The purpose of this study is to find out whether there is a significant difference between the cardiopulmonary exercise test results for patients with the moderate and serious form of COPD.
Method: 18 patients were subjected to Cardiopulmonary Exercise Tests (KPET) within the scope of the study. 12 of the patients were diagnosed with COPD and 6 of them with OS. A symptom-limited incremental KPET was performed using a Vmax Encore, USA device. The study was designed and carried out in accordance with principles of the Declaration of Helsinki and with approval from the Ethics Review Board of Uludag University (15th June 2010, 2010-13/2). Informed consent was obtained from all subjects.
Findings: The results of the KPET revealed that the maximum oxygen consumption (VO2max ml/kg/min) in the group of patients with COPD was 15,5 ±6,4, and 12,4±6 in the group with OS. There was no significant difference in that sense ($P>0,05$). There was also no significant difference in carbon dioxide outturn between the two groups (VCO2 L/min) ($p>0,05$). The maximum work-watt in the group of patients with COPD was 59,2±29, and 45,8±19 in the group with OS. There also was no significant difference between these results ($p>0,05$). The maximum throb of the group of patients diag-

nosed with COPD was 120±21, and 116±18 in the group with OS. The comparison of Oxygen pulse value (ml/Pulse) and maximum throb did not show any significant difference either (p>0,05). The maximum ventilation rate (VEmax-L/min) in the group of patients with COPD was 43±13, and 36,6±9,2 in the group with OS. No significant difference was found between the two groups. (p>0,05). End-tidal CO2 values and end-tidal O2 values did not show any significant difference either. When compared (p >0,05) . The respiratory quotient RQ in the group with COPD was 1,1 ±0,4 whereas in the group with OS the value was 1,1±0,4. No significant difference. The anaerobic tree-shot (AT) values in both groups were similar. No statistically significant difference was found between these two values either. (p>0,05).

Conclusion: Although the KPET values of patients diagnosed with COPD and OSD were below the general population, there were no significant differences between the two diseases.

Oxidative stress is not involved in the morphofunctional impairments of non-pregnant murine uterus caused by intense and exhaustive exercise

A.E. Costa[1], M.J. Simões[3], J.L. Silva[2] and V.L. Nouailhetas[1]

[1]Biophysics, Escola Paulista de Medicina/Universidade Federal de São Paulo, São Paulo, São Paulo, Brazil, [2]Universidade Nove de Julho, São Paulo, São Paulo, Brazil and [3]Morphology and Genetics, Escola Paulista de Medicina/Universidade Federal de São Paulo, São Paulo, São Paulo, Brazil

Intense exercise (IE) causes damage to organs and tissues such as in the gastrointestinal tract, urinary, and brain. Even though IE is associated with dysfunctions in the female reproductive system, little is known about the mechanisms underlying its effects mainly on the non-pregnant uterus. We investigated the effects of intense and exhaustive exercise (IEE) program on the isolated uterine morphology, tissue responsiveness, and oxidation markers. Female C57Bl/6 mice (20 g), 3-month old, were acclimated for 5 days, and the oestrous cycle followed by daily vaginal smears. Animals were then allocated into 2 groups: control (CT) and exercised (EX) groups. EX group performed 2-consecutive days of a daily bout of treadmill running at 85% of its maximum running velocity (MV) until animal exhaustion. MV was determined by maximal incremental test (MIT 1) performed by all animals 24-h before the beginning of IEE program. Training responses were evaluated the time each animal took to reach exhaustion (TTE) and the MV, evaluated by the second MIT (MIT 2) performed 24-h after the end of the second exercise session. CT and EX animals were in the oestrous stage at the beginning of the exercise program. Tissue morphology was evaluated by histological analysis of 4-μm HE-stained uterine slices; tissue responsiveness was evaluated through concentration-isometric contractile response curves evoked by either KCl or carbachol (CCh) (de Jalon solution, T° 37°, pH 7.4, and 0.2 g basal tension); and uterus lipid peroxidation and protein oxidation were evaluated by MDA and carbonyl concentration measurements, respectively. IEE decreased animal physical performance as it caused 32 and 29% decreases in TTE and MV, respectively (N = 60), decreased the longitudinal muscular layer (from 79 ± 2 μm to 71.1± 2 μm, N = 6, p<0.05), impaired CCh-evoked contraction (increase in EC50 from 2.8 ± 1.2 to 18 ± 3 μM, and decrease in Emax from 1.7 ± 0.3 (N = 4) to 1.0 ± 0.2 g, (N = 6), p<0.05), but caused only strong trend to impair KCl-evoked contraction (increase in EC50 from 5.7 ± 1.3 to 9 ± 3 mM, and decrease in Emax from 1.4 ± 0.2 to 1.2 ± 0.16 g, N = 4-6, p>0.05), reduced MDA concentration from 400 to 180 nmol/mL.g dry tissue (N = 5-6, p<0.05), without affecting the level of protein carbonyl (4 and 4.3 nmol/ mg protein, in CT and EX, respectively, N = 5-6, p>0.05,). Is concluded that C57BL/6 mice non-pregnant uterus is an important exercise-target, and displays important morpho-functional alterations in response to intense and exhaustive exercise which, nonetheless, are not related to signs of uterus oxidative stress, but may be well related to exercise-induced uterine dysfunction.

PCD242

Do the vascular responses to cool water immersion in young Asian males give them greater susceptibility to Non-Freezing Cold-induced Injury (NFCI) than white Caucasians?

W. Blevins[1], C.J. Ray[1], M.J. Tipton[2] and J.M. Marshall[1]

[1]Clinical & Experimental Medicine, University of Birmingham, Birmingham, UK and [2]Institute of Sport & Exercise Science, University of Portsmouth, Portsmouth, UK

Prolonged or repeated exposure to cool, wet conditions is known to induce Non-Freezing Cold-induced Injury (NFCI), sometimes known as trench foot. Susceptibility to NFCI appears to be greater in certain populations. Epidemiological studies show a greater incidence of NFCI in Afro-Caribbean populations than Caucasian populations, while being a Gurkha is protective There is also evidence amongst Indians, that Southern Indians show less pronounced cold-induced vasodilatation than High altitude natives or Gurkhas, raising the question as to whether they are more susceptible to NCFI (Imray et al 2011). Thus, in the present study, we compared the cardiovascular responses evoked by repeated immersion of the right leg in cool water at 15 degrees C between Caucasian and Asian young males (aged 20.1 ± 0.3 years, n=8 in each group). Immersion was repeated 5 times for 2-minute periods separated by 2-minute recovery periods at room temperature. The left leg was supported at near horizontal throughout.

In the Caucasians, cutaneous red cell flux (RCF), measured using laser Doppler fluximetry, fell, for eg from 8.1±1.0 to 7.5±1.3PU in the immersed foot in the 1st immersion and from

17.9±2.2 to 14.4±1.3PU in the contralateral foot and recovered well between immersions. However, in the Asians, RCF in the immersed, right foot fell during immersion from 8.0 ± 0.5 PU at baseline to 6.0 ± 0.5* PU in the 5th immersion (*: p<0.01, repeated measures ANOVA) and did not return to baseline during the recovery periods: 6.3 ± 0.8* PU immediately before the 5th immersion. Further, immersion caused a reduction in RCF in the contralateral, left foot: from 15.2 ± 1.3 PU at baseline to 12.4 ± 0.8* PU. In the Caucasians, left calf blood flow (CBF), measured by venous occlusion plethysmography, did not change significantly throughout the protocol, but in the Asians, CBF fell, reaching significance during the recovery periods from 5.4 ± 0.9 at baseline to 3.8 ± 0.5* ml.min-1.100ml-1 before the 5th immersion. These changes in blood flow in the Asians reflected increases in cutaneous and calf vascular resistance.

These data indicate that the local and reflex vasoconstrictor responses evoked by cool water immersion in cutaneous and muscle circulations of the lower limb are greater and more persistent in young Asian males, than young Caucasian males. The fact that the vasoconstriction was particularly pronounced in the immersed foot suggests an important role for local mechanisms in initiating the vasoconstriction. Exaggerated reductions of limb blood flow in Asians in cold wet conditions might be expected to lead to tissue damage through ischaemia and increase susceptibility to NFCI. Future work will concentrate on the role of locally synthesised prostaglandins in the vascular response to cold.

PCD244

Sex difference of the human brain functional connectivity related to the second to fourth digit ratio

T. Donishi[1], M. Terada[2] and Y. Kaneoke[1]

[1]System Neurophysiology, Wakayama Medical University, Wakayama, Wakayama, Japan and [2]Wakayama-Minami Radiology Clinic, Wakayama, Japan

Difference in human behavior is in part related to the prenatal brain exposure to androgen. Thus the brain functional network may vary with the magnitude of the androgen exposure, which can be estimated by the second to fourth digit ratio (2D:4D). Digit length was measured from the basal crease proximal to the palm to the tip of the digit on a photocopy of the right hand. We measured global functional connectivity of the gray matter in the human brain regions ("regional global connectivity," rCG), and examined its correlation with 2D:4D. A 3 Tesla magnetic resonance imaging system (MRI, Philips) with a 32-channel head coil was used to obtain T1-weighted anatomical and resting state functional images of the healthy subjects (103 males and 96 females, mean (SD) age was 21±2 years old for both groups). During the acquisition (a series of three 5-min sessions), subjects were asked to stay awake with their eyes closed. Preprocessing of the blood oxygenation level dependent (BOLD) signal was performed using the analysis tools in SPM8 and in-house software developed on MATLAB, which includes head motion realignment, normalization with the standard template for echo planar imaging, and spatial/temporal smoothing and noise reduction. For each voxel (6x6x6 mm) in the gray matter, cross-correlation coefficients with all other gray matter voxels were calculated and averaged to determine each voxel's rGC. The rGC values had significant relationship with 2D:4D at several regions as revealed by Pearsons's correlation coefficient (t-test, p<0.05, corrected for multi-comparison with Monte Carlo simulation). We found marked sex difference in the hippocampus and adjacent regions (parahippocampus and fusiform gyrus): in male, negative correlation was seen in the bilateral regions, while positive correlation was seen in the left side in female. Further, in female, positive correlation was found at the left supra-parietal cortex, and negative correlation at the anterior and medial cingulate cortex and the superior medial frontal cortex. Hippocampus is known to be involved in various cognitive and emotional functions, as well as memory. Recent studies demonstrate that the hippocampal volume is affected by the prenatal androgen exposure as measured by the second to fourth digit ratio (2D:4D) in female. Thus, it is likely that the hippocampus may be a key region to construct sex-related identity. Our results suggest that, in female, the low hippocampal rGC is related to personality such as dominance and aggression (known to be related to low 2D:4D). In contrast, in male, the high hippocampal rGC may be related to the risk-taking decision making, since 2D:4D is known to be inversely related to the male day traders' ability.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Preliminary methods for automated detection of fasciculations associated with motor neuron disease

P.J. Harding[1], I.D. Loram[1], N. Costen[2], N. Combes[3] and E. Hodson-Tole[1]

[1]Institute of Biomedical Research into Human Movement and Health, School of Healthcare Science, Manchester Metropolitan University, Manchester, UK, [2]School of Computing, Mathematics and Digital Technology, Manchester Metropolitan University, Manchester, UK and [3]Dpt. Clinical Neurophysiology, Royal Preston Hospital, Lancashire Teaching Hospitals NHS Foundation Trust, Preston, UK

Motor neuron disease (MND) is a devastating neurodegenerative disease. Diagnosis requires invasive, often painful, intramuscular myoelectric signal recordings from multiple body regions to identify the occurrence of electrophysiological events such as fasciculations [involuntary firing of a motor unit]. It has recently been shown that fasciculations can be seen by eye in ultrasound images collected at ~75Hz (1) and that assessment of images provides more sensitive detection than myoelectric signals in some muscles, e.g., biceps brachii (2). These studies are however based on manual, visual assessment of images to identify the occurrence of fasciculations. Here an automated, quantitative approach based on computationally tracking movement of features in collected images is assessed to determine the feasibility of using such techniques to automatically identify the occurrence of fasciculations. Development of such non-invasive, quantitative methods could facilitate earlier screening and diagnosis of suspected cases of MND.

Nine human participants completed the study. Three participants, recruited through the MND Care and Research Centre at Royal Preston Hospital [RPH], had previously been diagnosed with MND. The study was approved by authorities at RPH and

the universities local ethics committee. All participants provided informed written consent. In all participants B-mode ultrasound images simultaneously showing medial gastrocnemius [MG] and soleus [SO] were recorded. In those with MND, images were also collected from biceps brachii. The occurrence of fasciculations [localized tissue displacements lasting 0.2-1s (3)] were manually identified by two experienced operators. Features in each image were mathematically identified and tracked between images using methods described in (4). Resulting feature data were used in a mutual information [MI] analysis to provide a statistical classification of movement of tracked features between images.

Correspondence between manually identified fasciculations and spikes in the MI metric was quantified by compiling receiver operating characteristics to identify the true positive rate at which the number of false positives and true negatives were equal [HEE]. For MG/SO image sequences HEE was 87% in healthy participants and 79% for participants with MND. HEE was 81% in sequences recorded from biceps. These strong preliminary results indicate excellent potential for the development of quantitative, automated detection of fasciculations in ultrasound images. The MI metric was not sensitive to the smallest manually identified movements and was influenced by the inherent noise in collected images. Further improvements in accuracy can therefore be expected with the application of more sophisticated analysis approaches.

Exploration of functional mutations of ryanodine receptor in malignant hyperthermia

T. Yamazawa[1,4], H. Oyamada[2], T. Murayama[3], N. Kurebayashi[3], K. Oguchi[2], T. Sakurai[3], M. Iino[4] and S. Takemori[1]

[1]Department of Molecular Physiology, The Jikei University School of Medicine, Minato-ku, Tokyo, Japan, [2]Department of Pharmacology, School of Medicine, Showa University, Shinagawa-ku, Tokyo, Japan, [3]Department of Pharmacology, Juntendo University Graduate School of Medicine, Bunkyo-ku, Tokyo, Japan and [4]Department of Pharmacology, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan

Ryanodine receptors, located in the sarcoplasmic/endoplasmic reticulum (SR/ER) membrane, are required for intracellular Ca^{2+} release that is involved in a wide range of cellular functions. Malignant hyperthermia (MH) is a pharmacogenetical complication of general anesthesia resulting from abnormal Ca^{2+}-induced Ca^{2+} release (CICR) via the type 1 ryanodine receptor (RyR1) in skeletal muscles. The typical symptoms include a rapid increase in body temperature and induction of a hypermetabolic state with skeletal muscle rigidity. More than 100 mutations in the RyR1 gene have been reported in MH patients. Most of those mutations have been found in three "hot spots" regions (#1-614, #2129-2458 and #4637-4973 as the amino acid numbers) of RyR1. However, there were only a few experimental results confirming those mutations being responsible for the increment of the CICR sensitivities, since such a long cDNA of RyR1 not only required much complicated procedures for making desired mutations but also caused its low transfection efficiency of the mutant DNAs. We improved the method for making MH mutants in the cDNA of RyR1. We characterized the functional mutations on RyR1 in non-muscle cells, specifically HEK293 cells with tetracycline-regulated RyR1 expression. Rabbit RyR1 channels carrying corresponding Japanese mutations (L13R, Q155K, R163C, D166G, R533H, etc.) were expressed in HEK293 cells for functional assay. HEK293 cells were loaded at room temperature with fura-2 AM in physiological salt solution. Fluorescence images at >420nm were acquired using an inverted microscope equipped with a objective, a cooled CCD camera and a polychromatic illumination system at a rate of one frame every 1 or 2 s. It was found that R163C and Q155K mutations of the RyR1 resulted in enhanced Ca^{2+} release activity, therefore these mutations would be responsible for the MH incidence. These results suggest that exploration of the functional mutations of RyR1 is probably effective in preventive diagnosis of patients associated with MH disease.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD247

ATP release from rat skeletal muscle may involve chloride channels

L. Lu[1], J. Tu[2], W. Cai[1] and H.J. Ballard[1]

[1]Department of Physiology, Institute of Cardiovascular Science and Medicine, The University of Hong Kong, Hong Kong, Hong Kong and [2]Shenzhen Key Laboratory for Neuropsychiatric Modulation, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shen Zhen, China

ATP is released from skeletal muscle cells under basal conditions, and at higher rates during acidosis or muscle contractions. The cystic fibrosis transmembrane conductance regulator (CFTR) is involved in the stimulated ATP release, but neither inhibition of CFTR nor silencing of CFTR expression could abolish the basal ATP release. Chloride channels such as the maxi anion channel or voltage-sensitive-outwardly- rectifying (VSOR) channel are known to mediate ATP release in a number of cell types. We investigated whether chloride channels were involved in the release of ATP from rat skeletal muscle.

Using RT-PCR (n=3), rat L6 skeletal myocytes were shown to express CFTR, ClC 2, 3 and 7, and VDAC (Voltage-dependent anion channel); the maxi anion channel and VSOR, whose molecular identities are uncertain, were not tested. Whole cell chloride currents were measured in the myocytes using patch clamp: reducing the pH from 7.4 to 6.8 increased the current from 69.8 ± 8.8 to 98.6 ± 9.6 pA/pF (mean ± SEM, n=9; $P<0.05$, ANOVA) at 70 mV; this increase could be partially inhibited by the specific CFTR inhibitor, $CFTR_{inh}$-172. Addition of DIDS (100 μM) reduced the current to 16.2 ± 3.4 pA/pF at pH 7.4;

lowering the pH to 6.8 in the presence of DIDS increased the current to 25.6 ± 3.8 pA/pF (P<0.05; n=4).
Gastrocnemius muscle contractions were induced in rats anaesthetised with sodium pentobarbital (70 mg/kg i.p.) by stimulation of the sciatic nerve at 1 Hz and supramaximal voltage; the interstitial fluid was sampled using microdialysis. In the absence of drugs, muscle contractions increased the interstitial ATP from 1.4 ± 0.1 to 44.1 ± 12.8 nM (n=5); this increase was reproducible in repeated contractions in the absence of drugs. Injection of DIDS (100 μM) reduced the interstitial ATP to 0.3 ± 0.05 nM at rest and 3.8 ± 2.0 nM during contractions.
During buffer-perfusion of the rat hindquarters, infusion of lactic acid (10 mM) increased the EDL muscle interstitial ATP from 31 ± 5 to 50 ± 7 nM (n=14); addition of SITS (100 μM) to the perfusate abolished the lactic-acid-induced increase in ATP.
The ATP concentration in the medium surrounding the cultured L6 myocytes was increased from 0.6 ± 0.06 to 1.1 ± 0.08 nM (n=57; P<0.001, t-test) by the addition of 10 mM lactic acid to the medium. Addition of the maxi anion channel inhibitors gadolinium (100 μM, n=12) or sodium orthovanadate (100 μM, n=6) to the medium increased the extracellular ATP, but the acidosis-induced increase in ATP was abolished. The VSOR inhibitor, phloretin (100 μM, n=6) also increased extracellular ATP, but failed to inhibit a further increase in ATP when the pH was reduced to 6.8.
These data suggest that lowering of the pH opens both CFTR and another chloride channel, and that a chloride channel, which may be the maxi-anion channel, contributes to ATP release from skeletal muscle.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD248

Alterations in calcium handling in isolated fast fibres from speed gene knockout mice

S.I. Head[1], S.C. Chan[1], P.J. Houweling[2], R.M. Murphy[3], K.G. Quinlan[2] and K.N. North[2]

[1]School of Medical Sciences, University of New South Wales, Sydney, NSW, Australia, [2]Institute for Neuroscience and Muscle Research, The Children's Hospital at Westmead, Sydney, NSW, Australia and [3]Department of Zoology, La Trobe University, Melbourne, VIC, Australia

Background: Absence of the fast-twitch skeletal muscle Z-line protein, α-actinin-3, encoded by the ACTN3 speed gene, is associated with poorer sprinting performance in athletes and a slowing of relaxation in fast-twitch muscles of Actn3 knockout (KO) mice. Around 20% of the world's population are ACTN3 deficient. Fast-twitch muscles from KO mice display longer twitch half-relaxation times than muscles from wild-type (WT) mice. In mechanically skinned fast fibres the sarcoplasmic reticulum (SR) in fibres from KO mice load calcium more slowly than the SR in fibres from WT mice (Chan et al., 2011).
Aim: Our present study investigates the calcium kinetics of fast-twitch fibres from Actn3-KO and WT mice and SERCA pump and parvalbumin protein expression, to see whether any changes in calcium kinetics and associated SR and calcium buffering proteins can account for the previously observed effects of α-actinin-3 deficiency on whole muscle relaxation and SR calcium loading.
Methods: Mice were killed with an overdose of halothane, UNSW animal ethics approval 11/140B. Flexor digitorum brevis (FDB) muscles were dissected out and digested in collagense 1a to yield individual fibres. Fibres were plated onto a chamber placed on a Nikon inverted microscope attached to a Cairn spectrophotometer to monitor calcium transients using a photomultiplier tube (PMT). An intracellular microelectrode was used to ionophorese the free acid form of fura-2 or low affinity fura-ff to give a final concentration 5-50 μm. Fibres were electrically stimulated using a bipolar concentric electrode positioned near the neuromuscular junction. In some cases the fibre was immobilized with BTS (4-methyl-N-(phenylmethyl) benzenesulfonamide)to stop contractions
Results: In FDB fibres of α-actinin-3-deficient KO mice, the calcium transient in response to a single action potential displayed a lower peak, a slower rate of rise and a faster rate of relaxation than the calcium transients from fibres of WT mice (n=15 for KO, n=19 for WT). Interestingly it was found that KO animals have 50% higher density of SERCA protein while the amount of parvalbumin protein is unchanged. The rate of ICE (calcium release cocktail)-induced SR calcium release was higher in KO. However there does not appear to be a difference in releasable calcium. Calcium-frequency curves showed no significant differences between fibres from KO and WT mice.
Conclusions: The faster decay of the calcium transients in fibres of α-actinin-3-deficient KO mice is consistent with data showing an increased density of SERCA pumps in the SR of fibres from KO mice. However, the observations from previous studies that whole fast-twitch muscles from KO mice relax more slowly, and that SR loading is slowed in KO mice, suggest that there may be an increased calcium leakage from the SR of KO mice via the SERCA pump calcium leak pathway.

PCD249

Is the replacement of skeletal alpha-actin by cardiac alpha-actin in skeletal muscles beneficial?

J. Ochala[1], H. Iwamoto[2], G. Ravenscroft[3] and K. Nowak[3]

[1]Centre of Human and Aerospace Physiological Sciences, King's College London, London, UK, [2]JASRI, SPring8, Hyogo, Japan and [3]Centre for Medical Research, The University of Western Australia, Perth, WA, Australia

Nemaline myopathy is the most common congenital myopathy and is notably caused by mutations in the ACTA1 gene encoding skeletal alpha-actin. The main features of ACTA1 null mutations (absence of skeletal alpha-actin) are generalized skeletal muscle weakness and premature death. A mouse model mimicking this condition can be rescued by incorporating the ACTC gene into skeletal muscles and hence, by overexpressing cardiac α-actin (ACTCCo/KO). Nevertheless, muscle fibres from ACTCCo/KO animals generate less force than normal cells (-20-25%). To understand the underlying mechanisms, here, we have undertaken a detailed functional study of fibres from ACTCCo/KO. Mechanical and X-ray diffraction pattern analyses of single membrane-permeabilized fibres showed, upon maximal Ca2+ activation and under rigor conditions, lower stiffness but maintained meridional and equatorial reflections in ACTCCo/KO when compared with age-

matched wild-type animals (WT). Overall, these results demonstrate that in ACTCCo/KO, the presence of cardiac alpha-actin instead of skeletal alpha-actin alters the formation of myosin cross-bridges by finely altering the strain of individual actomyosin interaction, thus lowering muscle fibre force production. These findings provide important information that has to be taken into consideration when considering the incorporation of the ACTC gene as a therapy for ACTA1-based nemaline myopathy.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD250

Viscoelastic analysis of myosin adsorbed to gold

T. Ohno[1], M. Wagatsuma[2], M. Ichihashi[2] and A. Itoh[2]

[1]Physiology, Jikei Univ., Tokyo, Japan and [2]Research & Development Division, Ulvac, Inc, Tokyo, Japan

We observed the adsorption process of myosin to the gold surface by QCM (quartz crystal microbalance). Using the AFFINIXQN Pro (Initium, Tokyo), viscoelasticity of the myosin adsorbed to the surface of the gold electrode and its surrounding solution as a whole was estimated by the response of quartz crystal to the resonance frequency and the frequencies in the vicinity.
Samples were measured in both solution and air. The adsorbed protein volume was calculated from the data in the air.
When myosin adsorbed more sparsely than 0.2 ug/cm^2, viscoelastic change accompanied with myosin adsorption was almost the same as to the viscoelasticity of buffer except myosin. The resonance frequency falls as to weight of adsorbed myosin. This implies that myosin adsorbed at low density plays as a solid globular protein. On the other hand, when myosin adsorbed at higher density, large viscoelastic change has been obserbed. Viscoelastic analysis indicate myosin plays as a protein having viscoelasticity.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD251

Monoclonal antibodies to myosin head retard formation of rigor actin-myosin linkages in skinned rabbit psoas muscle fibers

T. Kobayashi[1], T. Abe[1], K. Kimura[1] and H. Sugi[2]

[1]Department of Electronic Engineering, Shibaura Institute of Technology, Tokyo, Japan and [2]Department of Physiology, Teikyo University, Tokyo, Japan

Muscle contraction results from cyclic attachment and detachment between myosin head in the thick filament and actin in the thin filament. According to biochemical studies on the actomyosin ATPase reaction, the myosin head (M), in the form of M • ADP • Pi, first attaches to actin (A), and exerts a power stroke, associated with release of ADP and Pi, so that at the end of power stroke, M forms rigor linkage AM with A. Upon binding with a new ATP, M detaches from A to extert a recovery stroke, associated with the reaction, M • ATP → M • ADP • Pi, and reattaches to actin. The presence of the rigor linkage AM during muscle contraction is, however, not yet proved by X-ray diffraction studies on contracting muscle fibers. To give information about formation of the rigor linkages, we examined development of rigor linkages in single skinned rabbit psoas muscle fibers in response to removal of ATP from the relaxing solution by recording changes in muscle fiber stiffness, measured by applying sinusoidal vibrations (peak-to-peak amplitude, 0.2% of L_0; 2kHz) at 20°C. If 4mM $MgCl_2$ was present in the ATP-free rigor solution, the fibers exhibited a long latent period of 40-60s until starting to develop appreciable stiffness, which then increased slowly to a peak with a half rise time of 20-30s. By the addition of three different monoclonal antibodies (against catalytic, converter and lever arm domains, respectively; Sugi et al. BBRC 405: 651-656, 2011), both the latent period and the half rise time of rigor stiffness development increased by a factor of 1.5-2. When Mg ions in the ATP-free rigor solution was removed by 10mM EDTA, The latend period for rigor stiffness development markedly decreased to 2-3s, and the antibodies had no effect on the latent period, but still increased the half rise time of rigor stiffness development by a factor of 1.5-2. The result that the rigor linkage formation is retarded by the antibodies seem to imply that, in the present experimental conditions, the rigor linkage formation requires some structural changes in the catalytic, converter and lever arm domains, so that binding of antibodies to these domains retards the rigor linkage formation. Meanwhile the antibodies had no effect on the relaxation of rigor force and stiffness when rigor fibers were returned to the relaxing solution containing 4mM ATP.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD252

Physiological finger tremor size mirrors speed of finger movement due to muscle thixotropy

C.A. Vernooij, R.F. Reynolds and M. Lakie

School of Sport and Exercise Sciences, University of Birmingham, Birmingham, UK

Human physiological finger tremor is described as an inevitable small trembling of the finger consisting of two main frequency components; one 8-12 Hz and one over 15 Hz. When the finger is extended, both of these peaks are present in the frequency spectrum, but their relative size is variable. When moving the finger, the low frequency peak is much larger and usually the high frequency peak is no longer identifiable. Our recent studies revealed a main role for mechanical resonance in generating finger tremor. In contradiction to previous beliefs, a specific neural input was not necessary. Both tremor frequencies could be explained based on a changing resonant frequency due to altered muscular stiffness with movement. How the tremor frequencies transform during the transition between posture and movement and the interaction with EMG is described here.
With ethical permission, physiological tremor of 15 healthy subjects (23.7 ± 9.9 yr, 12 male) was measured using a miniature accelerometer taped to the splinted middle finger. A retroflective laser sensor, pointed at the tip of the finger, measured finger position. A pc placed ~2 m in front of the subjects showed finger position and a target with which subjects had to align their finger position. The target started with 10 s at a comfortable static middle position of the finger which progressed into a vertically orientated sinusoidal chirp signal ranging from 0 Hz to 0.05 Hz over 50 s. Over the subsequent 60 s

the target consisted of a mirror image of the first half, ending with a 10 s static middle position (see Fig 1a). The maximum required angular velocity of the finger was 3 deg/s. Each subject was asked to repeat the 120 s trial 10 times, during which surface EMG was recorded from the extensor digitorum communis muscle (m. EDC). We calculated a wavelet transform for acceleration and rectified EMG for each trial which afterwards were averaged across trials and participants. A Pearson's correlation was computed between acceleration size and EMG size and between these measured variables and position and speed of the finger.

Unsurprisingly, EMG correlated strongly with the vertical position of the finger (r^2 = 0.84) (Fig 1, top), because more extension required more EMG. In contrast, acceleration size seemed to correlate best with the speed of the finger (r^2 = 0.72) (Fig 1, bottom), and less strongly with EMG (r^2 = 0.19). We propose that primarily the movement-related (thixotropic) character of the muscles determines the size of physiological finger tremor. With increased speed of finger movement, an increased amount of muscle tissue is moved about and the overall muscle stiffness will progressively drop. This is associated with an increase in the size of the resonance and thus finger tremor. This must cause computational difficulties in finger control when making the transition from posture to movement.

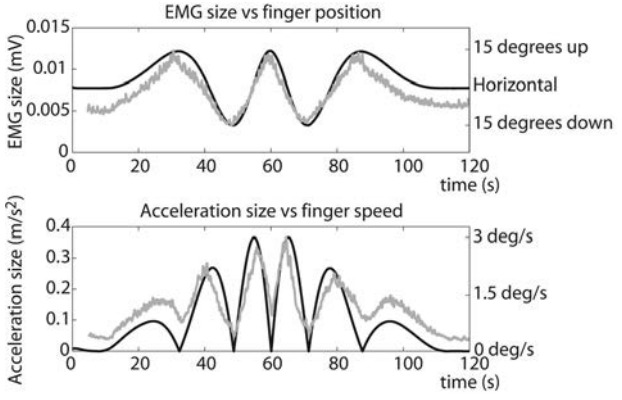

Figure 1.
Top graph: EMG size (grey) is adjusted with finger position (black).
Bottom graph: Acceleration size (grey) is adjusted with finger speed (black).

Mdx mice skeletal muscle differentiation and recovery of neuromuscular junctions after bone marrow stem cells transplantation

A.V. Sokolova[1], V.V. Kravtsova[2], N.A. Timonina[2], I.I. Krivoi[2] and V.V. Mikhailov[1]

[1]Institute of Cytology of the Russian Academy of Sciences, Saint-Petersburg, Russian Federation and [2]Saint-Petersburg State University, Saint- Petersburg, Russian Federation

Mdx mice are a model of Duchenne muscular dystrophy caused by deficiency of dystrophin. Striated muscle fibers (SMFs) of mdx mice are characterized by high level of death. As a result most SMFs of mdx mice have centrally located nuclei. Furthermore, neuromuscular junctions (NMJs) in mdx mouse are altered. Usually acetylcholine receptors (AChRs) of mdx mice are distributed as small islands in contrast to original AChRs branches of C57BL/6 mice NMJs. Our previous results showed that single intramuscular injection of C57BL/6 Lin(-) bone marrow (BM) stem cells ameliorate structure of NMJs of mdx mice SMF. 4 months after BM local transplantation total NMJs area was increased in 1.5 times due to increase of area of AChRs clusters simultaneously with increase of their number. The part of dystrophin-positive SMFs was increased from 0.5±0.1 % up to 1.8±0.4 %. We also changed mutant BM for BM of wild type. Male, 2 month old mdx mice (gift of Prof. T.A. Partridge, UK) were irradiated by X-ray in dose 3 Gy. BM cells were harvested from C57BL/6 mice (Rappolovo animal farm, St. Petersburg) killed by ether narcosis. 24 h after irradiation, mdx mice were anaesthetized with nembutal (40 mg kg-1, i.m.) and injected intravenously by BM cells. The study of m. quadriceps femoris and diaphragm was made at 2, 4, 6 month after transplantation. To localize NMJs we used tetramethylrhodamine-α-bungarotoxin (Biotium, USA) with help of Leica TCS SL confocal microscope. Values are means ± S.E.M. Experiments were performed at the animal care facility of Institute of Cytology of the RAS. We observed the increasing part of dystrophin-positive SMFs in m. quadriceps femoris mdx mice up to 27.6±6.7 % at 6 month after transplantation which was accompanied by decreasing of SMFs death from 2.2±0.6 % to 0.7±0.1 % and by accumulation of SMFs without central nuclei from 10.5±1.0 % up to 22.6±1.9 %. Similar to m. quadriceps femoris the increasing of part of dystrophin-positive SMFs was observed in diaphragm of mdx mice up to 12.0±3.2 % in 4 month after transplantation. The part of muscle SMFs without central nuclei increased from 8.4±0.6 % up to 30.4±1.5 % in diaphragm of mdx mice. The part of diaphragm NMJs with clusters of AChRs distributed as continuous branches was increased from 14±3 % up to 42.6±6 % and part of NMJs with AChRs clusters as islands was decreased from 75.8±3 % up to 53.7±6 %. Recovery of structure of NMJs was accompanied by recovery of the resting potential of the diaphragm end-plate membrane. Replacement of mutant BM stem cells for stem cells of wild type in condition of non-lethal X-ray irradiation is reason of recovery of dystrophin synthesis and of NMJs structure and function. This study was supported by Research Project #1.37.118.2011 of St. Petersburg State University, the Russian Foundation for Basic Research (#13-04-00973a).

Involvement of the lateral reticular nucleus in the suppression induced by stimulation of the red nucleus on the jaw-opening reflex

Y. Satoh[1], E. Yajima[2], K. Ishizuka[1], Y. Nagamine[2] and S. Iwasaki[1]

[1]Physiology, Nippon Dental University, Niigata, Japan and [2]Orthodontics, Nippon Dental University, Niigata, Japan

The jaw-opening reflex (JOR) can be evoked by electrical stimulation of either the low- or high-threshold afferents of the trigeminal nerve. The JOR evoked by high-threshold afferents is thought to be evoked by noxious stimulation (Lund et al., 1984). We have reported that stimulation of the red nucleus (RN) facilitated the low-threshold afferent-evoked JOR and suppressed the high-threshold afferent-evoked JOR. The effect is probably mediated by an indirect pathway, since there is little evidence for direct projections from the RN to the trigeminal motor nucleus. A possible interneuronal link in this pathway could be located within the lateral reticular nucleus (LRN).

This region has been proposed as a site engaged in the mechanisms of analgesia (Hall et al., 1982; Morton et al., 1983) and to receive contralateral projections from the RN (Flumerfelt and Gwyn, 1974). Furthermore, stimulation of the LRN suppressed the JOR evoked by noxious stimulation (Sotgiu, 1986). We therefore decided to examine whether lesion of the LRN affects RN-induced modulation of the JOR. The experiments were performed on 10 male Sprague-Dawley rats weighing 319-364 g. The rats were anesthetized with urethane and α-chloralose (500 m/kg and 50 mg/kg, respectively; i.p.), so as to maintain anesthesia at a level at which no withdrawal reflex was evoked by noxious stimulation of the paw. Arterial blood pressure was monitored to confirm the condition of the rat throughout the experiment. The test stimulation was applied to the inferior alveolar nerve (1 pulse, 0.1 ms in duration, 1 Hz) to evoke the JOR. The stimulus intensity was either 1.2 (low threshold) or 4.0 (high threshold) times the threshold. The electromyograms were recorded from the anterior belly of the digastric muscles. The conditioning stimulation (1pulse, 0.2 ms in duration, 1 Hz, 100 μA) was applied to the RN 10 or 30 ms before the test stimulation. The control JOR responses were recorded as well as the modulation induced by stimulation of the RN. The LRN lesion was made contralateral to the RN by the passage of electric current (20 μA, 2 min). The effect of the RN stimulation on the JOR was tested at the termination of lesion. At the end of each experiment, the stimulating sites were verified histologically. RN-induced facilitation of the JOR was not affected by lesion of the LRN (n=7, Wilcoxon t-test with Bonferroni correction, $P > 0.05$). On the other hand, RN-induced suppression of the JOR is significantly reduced by lesion of the LRN (n=7, Wilcoxon t-test with Bonferroni correction, $P < 0.05$). RN-induced modulation of the JOR was not affected by lesion of the outside of the LRN (n=3, Wilcoxon t-test with Bonferroni correction, $P > 0.05$).These results suggest that the suppressive effect of RN stimulation on the JOR is mediated partly by a relay in the contralateral LRN.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD255

The contractile properties of slow and fast skeletal muscles from Protease Activated Receptor-1 null mice

A. Bakker[1], S. Paran[1], P. Charles[2], M. Eleanor[2] and G. Pinniger[1]

[1]School of Anatomy, Physiology & Human Biology, The University of Western Australia, Perth, WA, Australia and [2]School of Veterinary Science, The University of Melbourne, Melbourne, VIC, Australia

Protease activated receptors (PARs) are unique G-protein-coupled receptors that are activated by proteolytic cleavage. Four PAR isoforms (PAR-1 to 4) have been identified. PARs may play an important role in skeletal muscle development, as they are highly expressed in myoblasts and myotubes in tissue culture (Mackie et al., 2008), and show marked changes in expression in muscle fibres during embryonic development (Chevessier et al., 2001). In order to increase our understanding of the role of PAR-1 receptors in muscle development, we compared the contractile properties of slow and fast skeletal muscles from PAR-1 null (P-1N) and wild type (WT) mice.
Experiments were conducted on 12 week old P-1N null (n=7) and WT littermate mice (n=5). This study was approved by the animal ethics committee of the University of Western Australia. Mice were anaesthetized by intraperitoneal injection of pentobarbitone (40mg/kg). The soleus (mainly slow twitch) and extensor digitorum longus (EDL) (fast twitch) muscles were surgically removed and connected to a force transducer system. The muscles were maintained in Kreb's mammalian Ringer solution bubbled with Carbogen (95% O2 and 5% CO2). Twitch force characteristics, the force frequency relationship and maximum specific force (force normalised to muscle cross sectional area) were determined, and the rate of fatigue and post-fatigue recovery were assessed. Muscle fibre type proportions were determined using immunohistochemistry.
The absence of PAR-1 receptors in soleus muscles resulted in a significantly greater mean peak twitch force (P-1N: 6.2 ± 0.231 N.cm-2, WT: 4.6 ± 0.392 N.cm-2, $p<0.05$) and mean twitch time to peak values (P-1N: 57.0 ± 3.0 ms, WT: 41.0 ± 1.0 ms, $p<0.05$) and produced a significant shift of the force-frequency curve to the left. In addition, the soleus muscles from the P-1N mice fatigued significantly more slowly ($p<0.05$) and exhibited a significantly faster post fatigue recovery ($p<0.05$) than muscles from WT mice. There was no difference in maximum specific force between soleus muscles from P-1N and WT mice. There was a 24% increase in the proportion of type 1fibres, and a 90% decline in the proportion of type IIb fibres in the soleus muscles from PAR-1 null mice compared to soleus controls. In P-1N EDL muscles, no significant differences were found, except for a slower rate of fatigue compared to controls.
The results of this study indicate that the absence of PAR-1 receptors significantly alters the contractile properties of skeletal muscle, especially in the predominately slow twitch soleus. The absence of PAR-1 results in a slower skeletal muscle contractile phenotype, likely due to an increase in type I and a decrease in type IIb fibre numbers. These results suggest that PAR-1 receptors may play a role in setting fibre-type proportions during skeletal muscle development.

PCD256

The impact of resveratrol and hydrogen peroxide on C2C12 myoblast regenerative cascade is dose-dependent

A. Bosutti and H. Degens

Institute for Biomedical Research into Human Movement and Health, School of Healthcare Science, Manchester Metropolitan University, Manchester, UK

Myoblast migration represents a key step in muscle regeneration following microdamage after exercise (1). Myosatellite cell fusion with the damaged myofibre and subsequent differentiation pilots muscle remodelling (2). While increased production of Reactive Oxygen Species (ROS) is crucial in exercise-induced muscle damage (3). In line with this, antioxidant supplementation, such as the polyphenol resveratrol, may suppress skeletal muscle damage and improve anti-oxidant capacity (4). However, ROS is also crucial for exercise-mediated adap-

tation and repair (5). The way at which ROS and/or resveratrol modulate myoblast function in muscle repair remains unclear.

Here, we explored the individual and combined effect of different concentrations of resveratrol (RS; 10-20-40-60 μM) and hydrogen peroxide (H_2O_2; 2-1 mM, 800-500-100-50-10μM) on non-differentiated (myoblasts) and differentiated (myotubes) mouse skeletal muscle-derived cells (C2C12). The impact of RS on myoblasts regenerative capacity was tested by assessing cell morphology, proliferation (MTS assay), migration (wound healing), sprouts formation (spheroids assay) and myotube formation and/or shrinking. In myoblasts, we tested the effect of RS plus H_2O_2 on cell migration. In 8-days differentiated myotubes we studied the impact of RS plus H_2O_2 on the oxidative capacity [succinate dehydrogenase (SDH) activity] and myosin ATPase activity and composition (total and type1-myosin). Data analysed by ANOVA in five replicates.

The effect of RS on cell mitosis (24-48h) and proliferation (72h) was dose dependent; RS 10-20μM did not show significant effects, but at higher doses (40-60μM) it impaired both cell processes ($p<0.01$). RS 10-20μM enhanced ($p=0.03$) migration and the formation of myoblast sprouts, but not cell fusion. RS 40-60μM almost blocked myoblast regenerative capacity. In parallel, low doses of H_2O_2(10-500μM) enhanced motility with the highest efficiency at 100μM, while higher doses showed damaging effects. Notably, 24h of RS pre-conditioning (10-20μM) prevented the deleterious effects of H_2O_2(1mM) and further enhanced cell migration induced by $H_2O_2$100μM.

Evidence suggests that RS may increase fibre oxidative metabolism (4). Surprisingly, we did not find any effect of RS on myotube oxidative capacity (SDH), while we found a reduction ($p<0.01$) in myosin type1-ATPase activity and increased total myosin ATPase content. Finally, H_2O_2 (1mM) induced a reduction ($p<0.01$) in total and myosin type1 ATPase activity, that was prevented by RS in a dose-dependent manner.

In conclusion, our data support the notion that low concentrations of ROS enhance myoblast regenerative capacity while it is impaired at high concentrations. High doses of anti-oxidants may also impair regenerative capacity, while low doses may abolish the detrimental impact of high concentrations of ROS on muscle regeneration.

The adaptive response of capillarisation to disuse is muscle-specific

A. Bosutti[1], M. Salamova[2], J. Rittweger[3] and H. Degens[1]

[1]Institute for Biomedical Research into Human Movement and Health; School of Healthcare Science, Manchester Metropolitan University, Manchester, UK, [2]Vegetative Anatomy, Neuromuscular Group, Charité Universitätsmedizin, Berlin, Germany and [3]Institute of Aerospace Medicine, German Aerospace Center, Cologne, Germany

Human skeletal muscle adapts to microgravity-induced disuse by atrophy and weakness, switch of fibre types (from slow to fast twitch fibres), changes in muscle energy metabolism and metabolic demand (1) and capillarisation (2). We hypothesize that a change in capillarisation precedes muscle fibre atrophy during disuse. Bed rest s a well-accepted model of either inactivity induced by deconditioning or simulated microgravity in healthy humans. There is some evidence that milk-based proteins, such as whey proteins, can act as an effective countermeasure to alleviate or attenuate the atrophy during prolonged bed rest.

Here we explored the changes in capillarisation in response to 21 days of medium-term bed rest with and without countermeasure (Whey protein diet). Muscle biopsies were taken from the soleus (SOL) and vastus lateralis (VL) muscles before (pre) and after bed rest (post) with or without whey protein supplementation (n = 5, each). Fibre types and capillaries were identified by immunohistochemical co-staining of muscle section with anti-myosin type1 and lectin. Analysis was done with the method of capillary domains (3). Statistical analysis was done by repeated measures ANOVA. Ethical approval was obtained from the local Ethics Committee and each participant provided informed consent before enrolment in the study.

Surprisingly, bed rest did neither affect fibre type composition nor fibre size in both SOL and VL muscles. Capillary density was, however, 10% less in the SOL ($p<0.01$), but not in the VL muscle after bed rest. Despite the reduced capillary density in the SOL, the heterogeneity of capillary spacing was not significantly changed in both muscles. Whey protein did not have a major effect on the impact of bed-rest-induced muscle adaptations.

In conclusion, our results show that medium-term bed rest induced a reduction in capillary density in the soleus but not in the vastus lateralis muscle. The absence of significant muscle fibre atrophy suggests that a reduction in capillary supply may precede fibre atrophy in disuse.

Temperature and 'fatigue' effects on ATP induced actomyosin dissociation kinetics

C. Karatzaferi[1] and M.A. Geeves[2]

[1]PE & Sports Science, University of Thessaly, Trikala, Greece and [2]School of Biosciences, University of Kent, Canterbury, UK

The functional characteristics of the various types of skeletal muscles, are largely dictated by the expression of class II myosin heavy chains (MyHC) isoforms; especially contraction velocity, a manifestation of the rate of actomyosin (A.M.) interaction and of ATP turnover. Higher levels of expression of a fast MyHC isoform lead to faster contraction velocity, while higher levels of expression of a slow MyHC lead to a slower contraction velocity. It has been observed that in slow myosin isoforms ADP binding to A.M is tighter than with fast isoforms, and one of us has shown that with slow isoforms multiple A.M.ADP complexes are present. The in vivo muscle temperature ranges from 34 to > 40 degrees Celsius (oC) while in extreme fatigue, pH drops and inorganic phosphate (Pi) accumulates. Still, most kinetics characterisations in the past have been done in 'standard' conditions e.g. 20oC, pH 7 and no added phosphate. Recent data by one of us highlighted the importance of investigating possible synergisms between temperature and such 'fatigue' factors which may gain different 'importance' in the different fibre types.

We thus examined the fast kinetics of ATP induced dissociation of A.M. (with and without ADP) of rabbit fast and slow myosin for a range of temperatures (from 5 to 35oC) using stopped flow to examine the effects of pH (7 vs 6.2), and Pi (0, 15 and 30 mM), individually or in combination. We also examined the temperature dependence of these 'fatigue' factors. The experimental protocol was approved by the local Animal Ethics Committee, and all the experimental procedures conformed to the UK Animals (Scientific Procedures) Act, 1986.

Temperature did not have an evident effect on ADP affinity nor did low pH seem to affect ADP affinity for the fast myosin. For slow myosin, ADP affinity weakened at pH 6.2, also at 35oC. Addition of Pi affected the two myosin typess differently, Pi competing with the ADP inhibition in fast but almost abolishing ADP inhibition in slow myosin at the higher Pi concentration. In slow myosin Pi and low pH combined affected ATP induced dissociation of A.M in the lower range of the temperatures studied.

Our results provide further evidence of distinct mechanochemical coupling between the myosin types. Results will be also discussed in relation to the effects of fatigue on velocity of contraction.

PCD260

Endogenous and maximal SR calcium content in human vastus lateralis muscle fibres is decreased with ageing

C. Lamboley[1], R.M. Murphy[2], M.J. McKenna[1] and G.D. Lamb[2]

[1]ISEAL, Victoria University, Melbourne, VIC, Australia and [2]Zoology, La Trobe University, Melbourne, VIC, Australia

A progressive decline in skeletal muscle function is part of the normal ageing process. The observed loss of specific force in aged muscle suggests that a Ca2+ dependent process may be impaired in ageing.

The muscle force production is closely related to the amount of Ca2+ released from the sarcoplasmic reticulum (SR). For this reason, it would be important to have a reliable measurement of total SR Ca2+ content ([CaT]SR) in aged human skeletal muscle fibres under physiological resting conditions. The present study examined for the first time, in individual fibres from human skeletal muscle biopsies, whether endogenous SR Ca2+ content and maximal SR Ca2+ capacity are different between young and aged healthy adults.

A muscle biopsy was taken from the vastus lateralis muscle from eleven and nine healthy young (23±0.8 yo) and old (70±0.7 yo) adults, respectively. After injection of a local anesthetic into the skin and fascia (1% lidocaine (Xylocaine)), a muscle sample was taken using a Bergstrom biopsy needle. Individual fibre segments, obtained from the biopsy, were mechanically skinned under paraffin oil so that they still contained their endogenous Ca2+ content. The total amount of Ca2+ contained in each fibre could be quantified by pre-equilibrating the fibre in a solution with a known concentration of the calcium-buffer BAPTA and then transferring the fibre to an emulsion of 1% Triton X-100 and paraffin oil (TX-oil) in order to lyse all membranous compartments and release any Ca2+ from within the fibre (Fryer & Stephenson, 1996). The total amount of Ca2+ present in the fibre can be calculated from the BAPTA concentration and the magnitude of the force response upon lysis. Furthermore, other fibre segments, prior to the TX-oil lysing, were loaded to their maximal SR Ca2+ capacity. Finally, using Western blotting, each muscle fibre was classified as type I or II according to the myosin heavy chain isoform present.

When fibres with an endogenous Ca2+ content were assayed, the endogenous [CaT]SR obtained (expressed relative to intact fibre volume) was significantly decreased in aged subjects compared to young individuals (0.58±0.01 (n=15) and 0.67±0.03 (n=8) mmol.l^{-1}, respectively, in type I fibres, and 0.62±0.02 (n=10) and 0.77±0.02 (n=15) mmol.l^{-1}, respectively, in type II fibres). By loading the SR of the fibres maximally, the study also revealed that the maximal SR Ca2+ capacity was significantly decreased in fibres of aged subjects compared to young adults (1.22±0.03 (n=12) and 1.36±0.04 (n=14) mmol.l^{-1}, respectively, in type I fibres, and 1.45±0.03 (n=11) and 1.72±0.03 (n=19) mmol.l^{-1}, respectively, in type II fibres).

The present results suggest that the appreciable decrease with ageing of the endogenous and maximal [CaT]SR in both type I and II fibres could be an important factor in muscle weakness in the elderly.

PCD261

Effect of ascorbic acid on force frequency relationship of skeletal muscle fibers in long term cold exposed Sprague Dawley rats

A. Shahid[1] and U. Khan[2]

[1]Physiology, Wah medical college, Wah Cantt, Pakistan and [2]Physiology, Al-Nafees Medical College, Islamabad, Pakistan

Background: On exposure to prolonged cold temperature, the body responds for effective heat production, both by shivering and nonshivering thermogenesis.1 Cold exposure increases the production of reactive oxygen species (ROS) which influence the sarcoplasmic reticulum Ca++ release from the skeletal muscles and affect their contractile properties.2 The role of ascorbic acid supplementation on force-frequency relationship of cold exposed skeletal muscles was evaluated in this study. Method: Ninety healthy, male Sprague Dawley rats were tagged and randomly divided into three groups of control (I), cold exposed (II) and cold exposed along with ascorbic acid supplementation (III). Rats of group I were kept at room temperature at 22±3˚C. Group II and III were given cold exposure of 8-14˚C, by keeping their cages in ice-filled tubs for 1hr/day for one month.3 Rats of group III were also given ascorbic acid supplement, as 500mg of L-Ascorbate (MERCK, research grade Cat No. 500074) in powder form mixed per liter of drinking water, for one month.4 After the study period, the rats were ether anesthetized in glass jars and then extensor digitorum longus muscle was dissected out. The muscle was placed on the muscle holder of Power Lab ADInstruments 4/26T [ML856] and force-frequency relationship in the skeletal muscle fibers was analyzed on computerized data acquisition system.5 (Fig. 1) Results: The cold exposed group II showed a significant decline in the contractile properties of skeletal muscle fibers at different frequencies as compared to the control group I (p value <0.05). In group III, however, the force was contraction was better than group II (p value <0.05). Conclusions: Chronic cold exposure delays the contractions in skeletal muscles, while supplementation with ascorbic acid prevents the decrease in force of contraction in muscles exposed to chronic cold.

PCD262

Contributions of lower muscle mass and specific force to muscle weakness in old mice

S. Ballak[1,2], H. Degens[1], A. de Haan[1,2] and R. Jaspers[2]

[1]Institute for Biomedical Research into Human Movement and Health, Manchester Metropolitan University, Manchester, UK and [2]Move Research institute Amsterdam, Faculty of Human Movement Sciences, VU University Amsterdam, Amsterdam, Netherlands

Age-related muscle wasting and weakness (sarcopenia) ultimately lead to a dependent lifestyle. The general thought is that age-related reduction in force is primarily the consequence of a loss of muscle mass, due to both loss of fibres and fibre atrophy, and to a limited extend to a reduction in specific force of the remaining muscle tissue.

To investigate the quantitative contribution of each of these factors to the age-related muscle weakness 9-month- (adult, n=9) and 25-month- (old, n=10) old male C57BL/6j mice were studied. Maximal isometric tetanic force of the m. plantaris was measured *in situ*(1). All mice received a subcutaneous injection of 0.06 ml 1% temgesic as an analgesic and 4% isoflurane, 0.1L*min^{-1} O_2 and 0.2L*min^{-1} normal air for anaesthesia (1.5-2.5% during operation). Wet muscle mass was measured directly after excision. The fibre type composition was determined by immunohistochemical staining of 10-μm sections of the muscle using antibodies, against type I, IIA, IIX and IIB, respectively. An ANOVA was used to determine age-related differences. Data are expressed as mean±SD.

The maximal isometric force of the plantaris muscle of old mice was 13% lower than that of adult mice (968±122 vs. 840±109mN; p<0.05). The m. plantaris, gastrocnemius medialis and soleus muscle masses were 5-8% lower in old than adult mice (24.2±2.3 vs. 22.4±2.4mg, 65.2±5.9 vs. 60.08±5.3, 13.3±1.0 vs. 12.2±1.3; p<0.05, respectively). Fibre number was similar in the m. plantaris of adult and old mice (Adult vs. Old: 1033±195 vs. 1109±174). A shift towards a slower phenotype was observed, reflected by a lower proportion of type IIB fibres (46.5±4.6 vs. 38.4±4.5%; p<0.05) in the older animals. Fewer than 1% type I fibres and similar proportions of type IIA and IIX fibres in adult and old mice were observed (Adult vs. Old: 26.8±4.4 vs. 30.2±5.1% and 25.6±2.9 vs. 29.1±3.4%, respectively). Although the specific force (40.94±3.72 vs. 37.58±4.31N/gr; p=0.108) did not differ significantly between m. plantaris muscles from adult and old mice, linear regression suggested that 60% of the variance of force was explained by specific force (R^2=0.598) and the other 40% by muscle mass (R^2=0.392).

The most important outcome of this study is the reduction in force generating capacity with age, accompanied by a shift towards a slower phenotype. Moreover, age-related reduction in muscle force was explained by reductions in muscle mass (40%) and s

Acute effects of curcumin on skeletal muscle contractile function

J. Lam, G.J. Pinniger and A.J. Bakker

University of Western Australia, Perth, WA, Australia

Curcumin, a component of the spice turmeric (*Curcuma longa*), has been reported to alleviate the symptoms of muscular dystrophy in *mdx* mice (Pan et al., 2008) and decrease the expression of inflammatory mediators involved in muscle injury (Epstein et al., 2012). Therefore, curcumin could provide an new avenue for the treatment of muscle disorders (Pan et al., 2008; Alamdari et al., 2009; Epstein et al., 2012). However, curcumin has also been reported to impair skeletal muscle Ca^{2+} handling (Bilmen et al., 2001; Logan-Smith et al., 2001), which could result in curcumin-induced muscle weakness. The aim of this study was to investigate the acute effects of curcumin exposure on skeletal muscle contractile function using intact and skinned fibre preparations from isolated extensor digitorum longus (EDL) muscles of the mouse.

ARC(s) mice (male, 6 week old, n=12) were anaesthetized with sodium pentobarbitone (40 mg/kg, I.P.) and intact EDL muscles were surgically removed and attached to a force transducer system. Muscles were maintained in an organ bath containing Kreb's mammalian Ringer solution, bubbled with carbogen (95% O_2 and 5% CO_2) at 25°C. The contractile properties (twitch force parameters, maximum tetanic force, force-stimulation frequency relationship and rate of muscle fatigue) were compared after a 60 minute exposure to curcumin or vehicle (0.01% DMSO). To determine the effect of curcumin on the Ca^{2+} sensitivity of the myofilaments, chemically skinned EDL fibres were exposed to highly buffered Ca^{2+} solutions of different known Ca^{2+} concentrations, in the presence of curcumin or DMSO. All values are expressed as means ± SEM.

Curcumin (15μM) significantly decreased maximum specific force in whole EDL muscles (control: 21.84±0.64 N/cm^2; curcumin: 19.07±0.57 N/cm^2, p<0.05), and shifted the force-frequency relationship to the left, with significantly greater relative forces at stimulation frequencies of 10-80Hz in the curcumin group (p<0.05). Curcumin also significantly increased the time to peak force of the twitch response (control: 17±1 ms; curcumin: 20±1 ms, p<0.05), but had no significant effect on other twitch force parameters. In addition, the rate of muscle fatigue was significantly slower in the curcumin exposed group, compared to controls (p<0.05, n=6). In skinned fibre experiments, curcumin (15μM) produced a small increase in the sensitivity of the myofilaments to Ca^{2+} (pCa_{50}: -6.26±0.05; control pCa_{50}: -6.13±0.09, p<0.05), and a marked decrease maximal force production to 52.8±10.6% of controls (p<0.05). These findings show that, at a bath concentration of 15μM, curcumin significantly decreases maximal force production in skeletal muscle, most likely via a direct effect on the force generating ability of the myofilaments. These findings have important implications for the use of curcumin as a treatment for diseases resulting in skeletal muscle weakness.

Ca^{2+}-calmodulin/calcineurin mediated signaling pathways are essential for upregulation of MHC I mRNA level in C2C12 cells

Y. Mori[1], M. Yamamoto[1], R. Hiroshima[1], T. Nakano[1] and M. Watanabe[1]

[1]Kansai Univ. of Welfare Sciences, Kashiwara, Japan and [2]Osaka Med. Coll., Takatsuki, Japan

Maintenance of skeletal muscle mass is essential for overall health, functionality and quality of life, and it is critical to elucidate the fundamental mechanisms underlying the maintenance. Skeletal muscle has been known to cause disuse atrophy during long-term recumbence and to recover by exercise. Although there are many studies about skeletal muscle regulatory factors, such as IGF-1, FGF, HGF, and IL-6, that are known to affect skeletal muscle mass, mechanism of exercise on muscle cell proliferation is still unclear. Our previous study using rat soleus muscle indicated that myosin heavy chain (MHC) and HSP 70 proteins were significantly increased by the exercise after disuse atrophy. It is well known that the mechanical stress by exercise raises intracellular calcium level in the muscle cell, therefore we examined effects of increase in intracellular Ca^{2+} on MHC I, HSP 70, and IL-6 mRNA expression level using real-time PCR method in C2C12 skeletal myoblasts. The C2C12 cells which were differentiated into myocyte in D-MEM containing 2% FBS was incubated with ionomycin in 6 or 24 hr. First, we measured MHC I mRNA level and it was significantly increased by the 6 hr incubation with ionomycin compared with control. 24 hr incubation with ionomycin significantly upregurated HSP 70 mRNA level, although 6 hr incubation with it did not affect the mRNA level. IL-6 mRNA level was significantly increased by the 6 hr incubation of ionomycin. Second, we examined the effect of IGF-1 on MHC I, HSP 70, and IL-6 mRNA expression levels. IL-6 mRNA level was significantly increased by the 24 hr incubation with IGF-1, although MHC I and HSP 70 mRNA levels were not increased. Third, we examined the effect of IL-6 on MHC I, HSP 70, and IL-6 mRNA expression levels. The mRNA levels of IL-6 and HSP 70 were significantly increased by the 24 hr incubation with IL-6, although MHC I mRNA level was not increased. Thus, it is considered that activation of Ca^{2+}-dependent signaling pathways, such as calcineurin, could act as a major factor upregulating MHC I mRNA levels. Therefore, we confirmed that effect of calcineurin inhibitor on ionomycin induced increase in mRNA level of MHC I. Ionomycin induced upregulation of MHC I mRNA level was significantly attenuated by the application of FK506. These results indicate that activation of Ca^{2+}-calmodulin/calcineurin mediated signaling pathways might have essential roles for upregulation of MHC I mRNA level.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD265

Mutation of the valosin-containing protein (VCP) decreases the fatigue tolerance of fast-twitch skeletal muscle fibres

L. Cully[1], G. Watts[1] and G. Mutungi[2]

[1]Biomedical Research Centre, University of East Anglia, Norwich, UK and [2]Department of Medicine, Norwich Medical School, University of East Anglia, Norwich, UK

Valosin-containing protein (VCP) is a member of the AAA+ (ATPases associated with diverse cellular activities) protein family that is involved in many cellular processes including cell cycle regulation, Golgi biogenesis, and the degradation of misfolded proteins1. Its mutation causes inclusion body myopathy, Paget's disease of bone and frontotemporal dementia (IBMPFD) 2. The IBM is accompanied by muscle fibre degeneration, rimmed vacuole formation and ubiquitin containing sarcoplasmic inclusions. Moreover, muscle fibres of VCPR155H/+ knock-in mice display severely swollen and abnormal mitochondria2; suggesting that they may have impaired energy metabolism. However, no studies have investigated the fatigue resistance of fast and slow muscle fibres isolated from VCP mutant mice. The primary aim of this study was to investigate the fatigue resistance of fast- and slow-twitch muscle fibres isolated from either wild type (WT) or VCP mutant mice.

Experiments were performed at 20°C on small bundles of 10-20 muscle fibres dissected from the extensor digitorum longus (EDL, a mainly fast-twitch muscle) and soleus (a mostly slow-twitch muscle) from both VCP mutant and WT mice (cross sectional diameter 340±110μm; n=14). Mice were killed according to the Animals (Scientific Procedures) Act 1986, UK and all the experiments conformed to the local animal welfare committee guidelines. The fibre bundles were mounted horizontally between two stainless steel hooks in a muscle chamber perfused with Ringer's solution prepared as previously described3. The sarcomere length (SL) was adjusted to 2.5μm and fibre bundle was allowed to equilibrate for ~20 minutes before subjection to the fatigue protocol (FP). During the FP, the fibre bundles were subjected to maximum isometric contractions once every 9 sec (for EDL) or every 4 sec (for soleus). After ~70 contractions, the stimulation rate was reduced to once every 90 sec and the fibre bundles were allowed 15-20min recovery. Only fibre bundles that recovered ≥90% of the force recorded at the start of the FP were included.

Our results show that VCP mutation decreased the fatigue resistance of fast-twitch fibres without affecting that of slow-twitch fibres, or the maximum isometric tension (Po). For example, at contraction 60 of the FP, Po declined by 39.6±16% in the fast twitch fibres isolated from the transgenic mice (n=8) but by only 2±8% in WT mice (n=2). The corresponding values in slow-twitch fibres were 9.7±2% and 10±7.6% in the WT (n=2) and transgenic mice (n=2) respectively. Our findings suggest that the effects of VCP mutation in skeletal muscle fibres may be fibre type dependent.

PCD266

Intrinsic ankle stiffness is reduced by increasing ankle sway in standing individuals

T.E. Sakanaka, R. Reynolds and M. Lakie

School of Sport and Exercise Sciences, University of Birmingham, London, London, UK

Previous research studies defined the upper and lower bound values of ankle stiffness in quiet standing [1] [2]. While freely standing on footplates, subjects were submitted to a series of small disturbances that simulated the ankle movement common to this task. In this study, for a better understanding of the muscle thixotropy property – one of the short range passive phenomena in quiet standing [4] –, in addition to the sequence of small disturbances, we applied a slow and continuous large sway to reduce muscle thixotropy's influence, and correlating it with static ankle stiffness.
The experiment was approved by the local human ethics committee and conducted in ten participants that gave a written informed consent. A servo tube motor was connected to two footplates and programmed to apply different types of stimulus to the foot, summing up to eight different conditions. Fast, small and randomly positive or negative cosine-wave type disturbances (0.2 and 0.8 deg amplitude, 140ms duration) were followed by inter stimulus intervals of 2-4 seconds of stillness, or added to a randomized continuous slow sway of a higher amplitude (2-3 deg amplitude). Subjects were asked to stand freely on top of the footplates, with eyes open or closed – assuming that without a visual reference they would sway more. Types of conditions were determined by the differences of ankle sway size that each condition would incite. Torque was measured with miniature load cells attached to the footplates. For the ankle and body sway measurements, two laser-reflex sensors were placed at the umbilicus and mid-tibia levels. The accelerometer (attached to the bottom of the left footplate), left and right torque and relative angle data (captured by a potentiometer) were used for the Savitzky-Golay filter analsysis to calculate muscle stiffness.
Despite the natural large disparities between subjects, the data suggests that ankle stiffness is inversely related to the stimulus size and body sway, indicating the decreasing effect that muscle thixotropy has on static ankle stiffness as the body sway increases.

Table 01: Correlation between combined relative stiffness (%, intrinsic ankle stiffness divided by toppling torque) and ankle sway are displayed in the table above. As the sway increases, the ankle stiffness decreases.

	Combined Relative Stiffness (%)	SEM	Ankle sway (°/s)	SEM
0.3° 07Hz: still, eyes open	73.1372	±6.2342	0.9332	±0.0368
0.3° 07Hz: still, eyes closed	68.9216	±4.9471	1.0557	±0.0569
0.3° 07Hz: with sway, eyes open	45.9292	±4.9881	2.2060	±0.1366
0.3° 07Hz: with sway, eyes closed	54.9461	±6.5305	2.4682	±0.1867
0.9° 07Hz: still, eyes open	49.4740	±4.4004	2.8414	±0.0356
0.9° 07Hz: still, eyes closed	50.5986	±3.8307	2.9371	±0.0613

Skeletal muscle myopathy in zebrafish larvae following knockdown of desmin

M. Li[1], M. Andersson-Lendahl[2], T. Sejersen[3] and A. Arner[1]

[1]Dept. of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden, [2]Dept. of Cell and Molecular Biology, Karolinska Institutet, Stockholm, Sweden and [3]Dept. of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden

Skeletal muscle was examined in zebrafish larvae, to address questions related to the function of the intermediate filament protein desmin and its role in the pathogenesis of human desminopathy. A novel approach including mechanical and structural studies of skeletal muscles from 4-6 day larvae was applied. Gut motility was studied with confocal imaging. Two desmin genes were identified in the larvae with the experession both in skeletal musclese and gut. Morpholino antisense oligonucleotides were utilized to knock down desmin. Expression was assessed using mRNA and protein analyses. Histology and synchrotron-light based small angle x-ray diffraction were applied. Functional properties were analyzed with in vivo studies of swimming behavior and with in vitro mechanical examinations of muscle. The two desmin genes normally expressed in zebrafish could be knocked down by about 50%. This resulted in a phenotype with disorganized skeletal muscles with altered attachments to the myosepta. The knockdown larvae were smaller and had diminished swimming activity. Active tension was lowered and muscles were less vulnerable to acute stretch-induced injury. X-ray diffraction revealed wider interfilament spacing. In conclusion, desmin intermediate filaments are required for normal active force generation and affect the vulnerability during eccentric work in skeletal muscles. This is related to the role of desmin in anchoring contractile units for optimal force transmission. The results also show that partial lack of desmin, without protein aggregates, is sufficient for causing skeletal muscle pathology resembling that in human desminopathy.

Supported by grants from the Swedish Research Council, the Swedish Heart Lung Foundation and a grant from the Association Française contre les Myopathies. X ray diffraction was performed at the A2 beamline in HASY-Lab, Hamburg Germany, and at the I911-SAXS beamline at Max IV Laboratory, Lund, Sweden.

PCD268

High cholesterol level and statin treatment affect the calcium homestasis of rat skeletal muscle cells

J. Vincze[1], M. Fuzi[1], A. Jenes[1], B. Dienes[1], P. Szentesi[1], P. Kertai[2], G. Paragh[3] and L. Csernoch[1]

[1]Department of Physiology, University of Debrecen, Debrecen, Hungary, [2]Department of Preventive Medicine, University of Debrecen, Debrecen, Hungary and [3]Department of Internal Medicine, University of Debrecen, Debrecen, Hungary

Statins are the most widely used drugs in the treatment of hyperlipidaemia. Their side-effects on skeletal muscle, however, have been reported with increasing frequency. Although the pathomechanism of the statin associated myopathy has been studied in detail and several theories do exist, there is still no final consensus.

To study of the effects of statin on skeletal muscle rats were fed with a special diet to achieve high blood cholesterol levels and fluvastatin was administered to them orally. Single skeletal muscle fibers were isolated enzymatically from the *extensor digitorum communis* muscles of rats. The surface membrane was permeabilized using a relaxing solution containing saponin. Cells were then loaded with Fluo-4 and imaged using a Zeiss LSM 510 META laser scanning confocal microscope to study localized calcium release events. Images were automatically analysed using the method published by Szabó LZ *et al.* (2010). All data are presented as mean±S.E.M.

Blood cholesterol levels of rats kept on a cholesterol-rich diet rose more than seven fold (from 1.5±0.1 to 10.7±2.0 mmol/L; n=15 and 16) with a dramatic increase in LDL/HDL ratio (from 0.29±0.02 to 1.56±0.17), proving that our model is usable for the study of hypercholesterolaemia. Previously published (Füzi *et al.* (2012)) elevation of the resting calcium level of adult skeletal muscle cells in both hypercholesterolemic and statin-treated rats was also accompanied by changes in the frequency of localized calcium release events (sparks). Muscle cells from statin-treated animals kept on normal cholesterol diet had higher spark frequency than cells from control animals (1.59 vs 0.88 $s^{-1}sarc^{-1}$) and cells from statin-treated animals kept on a high cholesterol diet had higher spark frequency than those from untreated hypercholesterolemic animals (1.48 vs 0.94 $s^{-1}sarc^{-1}$). Full width of half maximum values of sparks were slightly elevated and amplitude values were slightly decreased in all groups compared to the control.

Fluvastatin and rosuvastatin were also applied on rat primary cell cultures to assess their effects on in vitro proliferation an differentiation. Effects on the cytoskeletal structure of muscle cells were visualized using immunofluorescence. Skeletal muscle cell proliferation and differentiation were impaired and a decrese in the level of fibrillar actin was seen in statin-treated cultures.

The effects of statins on the calcium homeostasis, proliferation, differentiation and structure of adult and developing muscle cells may contribute to the explanation of certain adverse effects seen in clinical use.

Impact of Kv7 voltage-gated potassium channel modulators on contractile activity of myometrium from pregnant women at term

Y. Mansour[1], L.A. McCallum[1], I.A. Greenwood[2] and R.M. Tribe[1]

[1]Division of Women's Health, King's College London, London, UK and [2]Division of Biomedical Sciences, St George's University of London, London, UK

Background: Voltage gated potassium (Kv) channels play an important role in regulating resting membrane potential, and in smooth muscle are key determinants of contractile frequency. KCNQ-encoded Kv7 channels have been extensively studied in the cardiac and nervous systems due to their importance in normal physiological function. There is now an established role for these channels in smooth muscle and we have recently identified mRNA for these channels (Kv7.1-7.5), and their modulatory subunits (KCNE1-5), in pregnant human myometrium1. The aim of this study was to characterise the functional effects of a range of Kv7 activators and blockers on the contractility of myometrium from pregnant women at term ex vivo.

Methods: Myometrial tissue was obtained, with informed written consent, from pregnant women undergoing elective lower segment Caesarean section at term (> 37 weeks', not in labour) (Ethics approval number EC00/137). Spontaneous contractile activity (mean integral tension, MIT and contraction frequency) was measured in isolated myometrial strips and the effect of Kv7 inhibitors (XE991, 20 μM; Chromanol 293B, 20 μM) and activators (retigabine, 20 μM; maxipost, 20 μM; acrylamide S-1, 20 μM) determined and compared to vehicle controls (DMSO). The effect of the ERG inhibitor (dofetilide, 10 μM) was also assessed.

Results: Retigabine significantly decreased %MIT (35.98% ± 11.28 versus control 83.43% ± 5.4; n=5, $p<0.05$) and acrylamide S-1 appeared to have a more potent relaxant effect than retigabine. The pan Kv7 blocker (7.2-7.5) XE991 increased %MIT and contractile frequency (n=10) whereas the Kv7.1-specific blocker chromanol 293B (n=10) had no significant effect on MIT. Administration of maxipost had no demonstrable effect on MIT.

Conclusions: These data suggest that Kv7.2-7.5, but not Kv7.1, and ERG channels contribute significantly to the regulation of spontaneous myometrial contractions in tissues from pregnant women at term. The relaxation induced by Kv7 activators highlights a potential use of these agents for the treatment of spontaneous preterm birth.

PCD270

Flow mediated dilation is associated with endothelial cell oxidative stress in humans

A.N. Gurovich[1], J.C. Avery[2] and R.W. Braith[2]

[1]Applied Medicine and Rehabilitation, Indiana State University, Terre Haute, IN, USA and [2]Applied Physiology and Kinesiology, University of Florida, Gainesville, FL, USA

Cardiovascular diseases, including coronary artery disease and stroke, are the leading cause of death in the Western World (Rosamond et al., 2007). According to current medical theory, endothelial dysfunction is the primary cause of atherosclerosis, which is responsible for 90% of acute coronary syndrome and 80% of strokes (Mallika et al., 2007). Multiple factors affect endothelial function, but endothelial oxidative stress and low endothelial shear stress may be the most relevant (Davies, 2009, Thuillez and Richard, 2005). Flow mediated dilation (FMD) is considered a biomarker for endothelial function and brachial FMD is well correlated with coronary artery endothelial function.(Harris et al., 2010) However, the relationship between FMD and endothelial oxidative stress in vivo is still to be determined. Therefore, here we sought to determine if brachial artery FMD is associated with endothelial oxidative stress in humans. Twenty-three apparently healthy young men (25±4 yrs) with different activity background (e.g. sedentary, active recreational) underwent brachial artery FMD testing and venous endothelial cell biopsies on 2 occasions within 6 weeks. Protocol was approved by University of Florida Institutional Review Board. Immuno-fluorescence quantification was used to assess nitrotyrosine (NT), a criterion marker of endothelial oxidative stress. Values for NT expression were reported as a ratio of endothelial cell to human umbilical vein endothelial cell average pixel intensity. As shown on the figure, brachial FMD was inversely correlated with NT ($R=0.273$, $p<0.05$). The inverse relationship observed in the present study supports the hypothesis that FMD is associated with endothelial cell oxidative stress. Larger brachial dilations, relative to baseline vessel diameters, are associated with lower NT expression and vice versa. These results provide additional evidence to support the use of FMD as a non-invasive bio-marker for endothelial dysfunction.

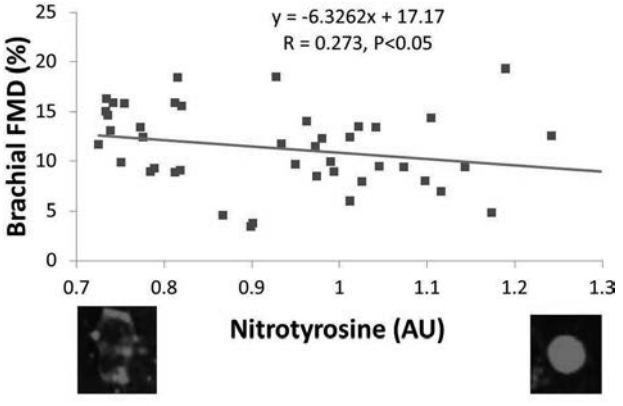

Figure: Correlation between brachial FMD (%) and Nitrotyrosine (AU).

[1]Medical Faculty Osijek, University of J.J. Strossmayer Osijek, Osijek, Croatia and [2]Clinical Hospital Center Osijek, Osijek, Croatia

Background: High pO2 responses in cerebral circulation can be altered in disease(1,2,3,4). This study aimed to determine the effects of acute hyperoxia on cerebrovascular reactivity (CVR), thromboxane B2 (TXB2, a stable metabolit of TXA2) plasma levels and systemic haemodynamic parameters in acute stroke patients(SP) and healthy volunteers(HV).
Methods: The study protocol and procedures were approved by the Ethical Committee of the Faculty of Medicine Osijek, and conformed to the standards set by the latest revision of the Declaration of Helsinki. 52 SP (age 68±6.7 yrs) with acute ischemic stroke (within 72 hours) and 52 HV (64.5±8.3 yrs) were included. Mean blood flow velocity (MBFV) in middle cerebral artery (MCA), pulsality index (IP) and resistance index (IR) were determined by transcranial Doppler before (basal), during 15 minutes (hyperoxia), and 15 minutes after the acute hyperoxia (inhalation of 100% O2 over facial mask). Systolic and diastolic blood pressure (SBP, DBP), heart rate (HR) and pO2 (measured by pulse oxymeter) were assessed at the same time points. Tromboxane B2 (TXB2) levels in venous blood samples were measured by ELISA before and immediately after hyperoxia. Mixed factorial ANOVA with repeated measures and Games-Howell post hoc test were used with logarithmic transformation; $p<0.05$ was considered significant. Data are expressed as mean±SD.
Results: Basal MBFV was significantly lower in SP(53±14) compared to HV(61±17). During hyperoxia MBFV significantly increased in SP(58±15; by 10%), while it decreased in HV(57±16; by 7%) compared to respective basal values. IP (basal=1±0.36; hyperoxia=1± 0.35; after=1± 0,40) and IR (basal=0.67±0.08; hyperoxia=0.67±0.10; after=0.66±0.08) were significantly higher in SP compared to HV (PI: basal=1±0.30; hyperoxia=1±0.35; after= 1±0.28); RI: basal=0.61±0.09; hyperoxia=0.61±0.09; after=0.60±0.08) in all 3 time points. Hyperoxia did not affect IP and IR in both groups, nor HR in SP, while HR decreased in HV (7%, $p<0.01$). SP had significantly higher SBP/DBP (basal=144±18/91±12;

hyperoxia=145±18/92±12; after=142±17/89±11) at all 3 points compared to HV (SBP/DBP: basal=129±17/83±11; hyperoxia=130±15/87±11; after=126±19/82±10). SBP/DPB significantly increased in both groups during hyperoxia compared to basal values. pO2 during hyperoxia increased in SP only (4%, p< 0.001). There was 8% decrease in TXB2 levels in SP and 4% increase in TXB2 in HV in hyperoxia, however, did not reach significance (p>0,05). TXB2 showed weak negative correlation with MBFV in both studied groups.
Conclusion:This study demonstrated paradoxical vasodilation of MCA, with decreased TXB2 in SP, and vasoconstriction with increased TXB2 in HV, suggesting the role of cyclooxygenases' metabolites mediating these changes in both, SP and HV. Hyperoxia affected haemodynamic parameters also.

Comparison of endothelial function using three non-invasive methods: flow-mediated dilation, changes in distension and changes in pulsewave velocity

A. Faulkner[1], S.E. Carter[1] and M. Rakobowchuk[2,1]

[1]School of Biological Science, University of Essex, Colchester, UK and [2]Centre for Sports Medicine & Human Performance, University of Brunel, London, UK

Endothelial function is routinely assessed by non-invasive techniques but is expensive and requires skilled technicians precluding its routine use as a clinical tool to predict cardiovascular disease risk. Commonly assessed in the brachial artery, due to access and calibre similarities to the coronary circulation, dysfunction is defined as an inability of the artery to dilate in response to reactive hyperaemia. Recently changes in carotid-radial pulsewave velocity have been suggested as an alternative method to measure endothelial function. Moreover, changes in arterial distension following reactive hyperaemia should provide similar predictive utility, but has not been evaluated. Eleven participant's (female=4) attended the laboratory on up to 4 occasions and underwent repeated vascular function protocols. Ischaemia-reperfusion injury was induced on each occasion to reduce endothelial function thus providing a range of flow-mediated dilation (FMD) values within each participant. Trials were also preceded by one of four experimental conditions to further provide a range of FMD values. Participants ingested either: 1) water ad libitum, 2) an antioxidant cocktail at 2 and 1.5 hours, 3) 1200mg Ibuprofen 1 hour prior; or 4) a combination of 2 and 3 in a blinded fashion. FMD was determined using an Aloka Alpha6 Doppler ultrasound system. Diameters were acquired at 2MHz before and after a 5-minute forearm occlusion period. The spatial resolution of diameter measurements was 0.05mm acquired using echotracking. The time delay between the R-wave of the ECG and the foot of the diameter waveform were used to calculate pulse transit time (PTT). Maximal relative change in PTT was determined as (PTTmax-PTTmin)/PTTmin x 100%. Brachial artery distension was determined on a beat-by-beat basis throughout the reactive hyperaemia period and maximal relative change was determined as (distension max-distension min)/distension min x 100%. Relationships between the three measurement modalities were determined by correlation analysis using Pearson product-moment correlation coefficient. Significance was assumed if p≤0.05. No relationship was observed between pulsewave velocity and FMD (r=-0.113, p=0.352) or absolute FMD (r=-0.003, p=0.98). Furthermore, no relationship existed between the change in brachial artery distension and FMD or absolute FMD (r=0.03, p=0.80; r=-0.006, p=0.96 respectively). The results of this study suggest that non-invasive measures of vessel stiffness changes induced by reactive hyperaemia do not represent an adequate assessment tool for measures of endothelial function within the brachial artery. Flow-mediated dilation remains the 'gold-standard' for non-invasive measurement for assessment of endothelial function.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD273

Muscular arterial stiffness is not altered by ischemia-reperfusion injury and not influenced by cyclooxygenase inhibition by Ibuprofen

A. Reed[1], S.E. Carter[1] and M. Rakobowchuk[2]

[1]Biological Sciences, University of Essex, Colchester, UK and [2]Centre for Sports Medicine and Human Performance, Brunel University, London, UK

Ischemia-reperfusion injury induces endothelial dysfunction related to oxidative stress and a lack of nitric oxide bioavailability. The non-invasive forearm ischemia-reperfusion model is commonly used to evaluate interventions to attenuate decrements in brachial artery endothelial function. To date, no study has evaluated the impact of an ischemia-reperfusion injury on the mechanics of the brachial artery, which should also be altered by this injury.
10 healthy participants (6 male, 4 female) underwent ischemia-reperfusion injury (IRI) on 2 separate visits to the laboratory. The first visit provided control measurements, in the absence of supplements. One hour prior to the second visit, participants took 1200mg Ibuprofen (cyclooxygenase inhibitor). IRI was induced by a 20 minute upper-arm supra-systolic occlusion. Measures of brachial artery stiffness were made immediately before, and then 15, 30 and 45 minutes post-IRI. Brachial artery stiffness was determined by non-invasive ultrasound assessment of arterial diameter using echo tracking software at 2MHz (Hitachi Aloka Alpha 6). Arterial perfusion pressures were measured by applanation tonometry on the contralateral radial artery. Immediately prior to each measure the tonometer was calibrated to contralateral brachial artery pressures using an oscillometric sphygmomanometer. Values are mean ± SD. Significance was assessed at 95% confidence levels using two-way repeated-measures ANOVA (SPSS v19).
Results show that IRI did not significantly change arterial compliance (Control Pre: 0.06±0.02; Post 15: 0.08±0.02; Post 30: 0.08±0.03; Post 45: 0.07±0.03; and Ibuprofen Pre: 0.07±0.03;

Post 15: 0.07±0.03; Post 30: 0.07±0.03; Post 45: 0.07±0.03 mm^2/kPa) from baseline over time or between conditions (p=0.55, p=0.65, respectively). Similarly, IRI and Ibuprofen intake had no significant effect on change in arterial diameter (p=0.93 and p=0.43, respectively) and pulse pressure (p=0.39 and p=0.97, respectively).
These data demonstrate neither detrimental effect of IRI, nor palliative effect of Ibuprofen before or after IRI, at the brachial artery. It seems that reduced nitric oxide bioavailability as a result of IRI and prostaglandin inhibition by Ibuprofen have no effect on the mechanical properties of a muscular peripheral artery such as the brachial artery in apparently healthy individuals.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Effect of hypoxia during incubation on the metabolic rate and thermal preference of 8–10-day-old chicks

K.C. Bicego[1], P.A. Velasquez[1], M.H. Fernandes[2], C.S. Scarpellini[1], M. Macari[1] and L.H. Gargaglione[1]

[1]Animal Morphology and Physiology, Sao Paulo State University, FCAV Jaboticabal, Jaboticabal, Sao Paulo, Brazil and [2]Animal Science, Sao Paulo State University, FCAV Jaboticabal, Jaboticabal, Sao Paulo, Brazil

It has been reported that thermal and non-thermal stressful stimuli early in the development may influence thermoregulation of juvenile or adult animals (Arjona et al., 1990; Soriano and Branco, 2010). Moreover, it is known that hypoxia can induce decreases in body temperature, metabolic rate and thermal preference of several species (Bicego et al., 2007; Tattersall and Milsom, 2009; Branco et al., 2010). To our knowledge, the effect of hypoxia during incubation in thermoregulation of juvenile chicks has not been investigated until now. Thus, we studied the influence of hypoxia at different phases of incubation on the metabolic rate and thermal preference of 8–10-day-old broiler chicks (Gallus domesticus). To this end, three groups of broiler eggs were distributed in a completely randomized design: normoxia for the entire period of incubation (N; 21% O2 during the 21 days), hypoxia during the first week of incubation (HI; 15% O2) and hypoxia during the last week of incubation (HL; 15% O2). After hatching, all the animals were maintained at thermoneutral zone (TNZ) up to the day of experiments. Measurements of oxygen consumption (VO2) were obtained by open-flow respirometry at (29oC), above (34oC) and below (19 and 24oC) TNZ. Thermal preference was assessed in a thermal gradient chamber. In each experiment, 6-8 animals were used per group. Values are means ± S.E.M., and the data were analyzed as a completely design with repeated measurements using the MIXED procedure of SAS version 9.2. VO2 of chicks at TNZ was lower in the HL (24.47 ± 4.33 mL.min-1.kg-1 STPD) than in HI (37.5 ± 5.03 mL.min-1.kg-1 STPD) and N (40.04 ± 4.28 mL.min-1.kg-1 STPD) groups ($p< 0.05$). Exposure to 19 and 24oC caused increases in VO2 of N and HL, but not HI, animals ($p< 0.05$). In contrast, no significant change in VO2 of all groups was observed at 34oC. In the thermal gradient, N chicks spent most part of the time (frequency of distribution) at ambient temperatures of 29-31oC and HI and HL at 24-26oC (ANOVA, $p< 0.01$). Based on the present results, we can conclude that exposure to hypoxia during the first or the last week of incubation interferes with the metabolic rate and thermal preference of 8–10-day-old chicks.

Amelioratory effect of proanthocyanidine on paraquat - induced oxidative stress, biochemical and histopathological changes in rat kidney

A.B. Jebur[1], F.M. El-Demerdash[2] and A.M. Attia[3]

[1]Ministry of Education, Baghdad, Iraq, [2]Environmental Studies, Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt and [3]Environmental Studies, Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt

Paraquat (PQ) is a highly toxic quaternary nitrogen herbicide capable of increasing superoxide anion production. The present study was carried out to evaluate the oxidative damage induced by PQ in rat kidney and its effect on antioxidant defense system and nephrotoxicity biomarkers in addition to the role of proanthocyanidin in alleviating its toxic effects. Male Wister albino rats were randomly divided into four groups of 10 each, group I served as control; group II treated with proanthocyanidin (25 mg/kg BW), group III received single dose of paraquat (PQ; 10 mg/kg BW; i.p) and group IV treated with both PQ and proanthocyanidin. Rats were orally administered their respective doses of proanthocyanidine daily for 21 days. The local committee approved the design of the experiments, and the protocol conforms to the guidelines of the National Institutes of Health (NIH). The administration of PQ caused significant elevation in lipid peroxidation (LPO) and reduction in the activities of antioxidant enzymes including superoxide dismutase (SOD), catalase (CAT) and glutathione S-transferase (GST). A significant reduction in glutathione (GSH) content was also observed. Serum urea, creatinin and lactate dehydrogenase (LDH) activity were significantly increased. Histopathological manifestations were investigated in tissues from rat kidney. As expected, PQ administration induced marked changes in the morphological structure of the kidney in PQ demonstrated animals since necrotic changes in both glomeruli and renal tubules were observed. Proanthocyanidin treatment to PQ treated rats decreased LPO level and normalized SOD, CAT and GST activities, while GSH content was increased. Also, urea, creatinin and LDH were maintained near normal level due to proanthocyanidine treatment. In addi-

tion, proanthocyanidin attenuated the morphological damages induced by PQ in the kidney tissue of experimental animals. Our results suggest antitoxic and antioxidant effects of proanthocyanidin against paraquat.

Oxidative Stress, biochemical perturbations and environmental safety in Petrochemical Industry

M.A. ElMasry[1], E.M. Salem[2], F.M. El-Demerdash[3] and H.M. Hassan[4]

[1]Environmental Studies, Institute of Graduate Studies and Research, Alexandria, Egypt, [2]Environmental Studies, Alexandria University, Institute of Graduate Studies and Research, Alexandria, Egypt, [3]Environmental Studies, Alexandria University, Institute of Graduate Studies and Research, Alexandria, Egypt and [4]Sidi Kerir Petrochemicals Company, Alexandria, Egypt

The Petrochemical Industry is based upon the production of chemicals from petroleum such as natural gas and crud oil. Hydrocarbons are known to be human carcinogens and are associated with the development of chronic health disorders. The aim of the present study was undertaken to investigate the oxidative stress, antioxidant defense response, liver and kidney function parameters and lipids profile and to assess the environmental safety awareness in Egyptian petrochemical workers (300 workers) who are exposed to hydrocarbon. The study was approved by the committee of ethics in research of the Alexandria University and informed consent was required from all participants, according to the guidelines of the local ethics committee. Fifty workers and thirty control subjects were enrolled in the present study. All subjects were matched for age, sex and socio-economic level. Venous blood samples from all the subjects were collected with the anticoagulant, EDTA. Results showed a significant increase in kidney and liver function parameters in addition to lipid proxidation. On the other hand, a significant decrease in enzymatic (SOD, CAT, GST) and non enzymatic (GSH) antioxidants was observed. Also, perturbations in some hematological parameters and lipids profile were detected. In conclusion, a state of oxidative stress in hydrocarbon exposed workers is produced by the depletion of antioxidant capacity that may play a role in the mechanism of its toxicity. Also, environmental safety requirement is good but need more application and update.

PCD277

Heterothermy in free-living vervet monkeys as an index of environmental stress

A. Fuller[1], A. Lubbe[1], R. McFarland[1], D. Mitchell[1], L. Barrett[2,1], P. Henzi[2] and R. Hetem[1]

[1]University of the Witwatersrand, Johannesburg, South Africa and [2]University of Lethbridge, Lethbridge, AB, Canada

Under future climate change scenarios, many species will be faced with natural habitats which progressively fail to meet their niche requirements. For vervet monkeys and other long-lived, slowly reproducing mammals, physiological plasticity is likely to be the first and most robust response to rapidly changing environmental conditions. In order to investigate how physiological plasticity may allow free-living vervet monkeys to respond to environmental change, we implanted miniature data loggers, during surgery (anaesthesia by blowdart with 5 mg/kg ketamine and 0.25 mg/kg midazolam, maintained with 0-2% isoflurane inhaled in oxygen), to measure body temperature and activity continuously in adult animals (3-6 kg) for one year. Data loggers were removed during surgery, with the same anaesthetic protocol, at least one year later, and animals were returned to their natural habitat. Despite black-globe temperatures ranging from below freezing to over 50°C over the year, and a mean 24-h variation in black-globe temperature of 30.0°C, vervet monkeys maintained body temperature around a mean of ~38°C with a 24-h amplitude of the body temperature rhythm of only 2.9 ± 0.1 °C (n=6). The 24-h amplitude of the body temperature rhythm, however, was significantly higher in mid-winter (3.2 ± 0.4°C) than in mid-summer (2.5 ± 0.1°C; paired t-test, t=5.47, P<0.01). In summer, when the primary thermoregulatory challenge was heat dissipation at high environmental temperatures, vervet monkeys had ad libitum access to a natural source of water and long day-lengths that allowed a flexible activity schedule. In winter, short day lengths limited the amount of time available to achieve fundamental activities, with activity also influenced by thermoregulatory requirements at low environmental temperatures and social stress of the coinciding mating season. Heterothermy in winter was associated with low environmental temperatures and low food availability. In free-living mam-

mals, homeothermy appears to be a luxury, evident only in individuals that are well nourished, hydrated and not energetically compromised. Whether the lability of body temperature in vervet monkeys under conditions of environmental stress reflects an inability to maintain homeothermy or a regulated adjustment of the thermoregulatory system to conserve energy remains to be elucidated.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD278

Cheetah do not abandon hunts because they overheat

R.S. Hetem[1], B.A. de Witt[1], A. Fuller[1], L.G. Fick[1], L.C. Meyer[2,1], S.K. Maloney[3,1] and D. Mitchell[1]

[1]Brain Function Research Group, School of Physiology, University of the Witwatersrand, Johannesburg, South Africa, [2]Department of Paraclinical Sciences, University of Pretoria, Pretoria, South Africa and [3]School of Anatomy, Physiology and Human Biology, University of Western Australia, Perth, WA, Australia

Cheetah (*Acinonyx jubatus*) are the fastest mammals, and use "stalk and chase" hunting. Anomalously, they abandon more than half of their chases when prey ought to be in range, and both successful and unsuccessful hunts are followed by periods of inactivity. The entrenched explanation is that cheetah abandon hunts because they overheat. That explanation can be traced to a single study, in which Taylor and Rowntree (1973) ran two hand-reared cheetah on a treadmill, and concluded that cheetah stored metabolic heat to the extent that further exercise soon became impossibly thermally. They predicted that cheetah would not run when body temperature reached 40.5°C. We used biologgers to measure core body temperature (abdominal cavity) and locomotor activity (subcutaneous, hind leg) of four cheetah, living free, and hunting, in a conservancy in Namibia. For implantation, the cheetah were immobilized and anaesthetized with medetomidine (0.023±0.002mg.kg^{-1}, mean±SD) and zoletil (1.5±0.2mg.kg^{-1}) intramuscularly, via capture dart, and intubated; anaesthesia was maintained under spontaneous breathing with 2-4% halothane in oxygen. After recovery, the cheetah were released into the conservancy. We observed both successful (12±3 per cheetah) and unsuccessful (6±2 per cheetah) hunts. We found that the cheetah abandoned many hunts but not because they overheated. Indeed, core body temperature only rarely exceeded 40.5°C, and did not rise significantly during a chase. The abdominal temperature at which unsuccessful hunts were abandoned was 38.3±0.2°C. Abdominal temperature did rise gradually after the chase, for 44±17min after successful hunts. The temperature increase (1.3±0.2°C vs. 0.5±0.1°C, $0.0001<P<0.04$, unpaired t tests on each cheetah) and the area under the temperature increase/time curve (78±19°C.min vs. 9±8°C.min, $0.0004<P<0.04$, unpaired t tests on each cheetah) were significantly higher after successful hunts than after unsuccessful hunts, despite there being no difference in activity between successful and unsuccessful hunts. A similar increase in core body temperature was evident in one cheetah that participated in a feed after a successful hunt by siblings, but was not directly involved in the hunt. We propose that the increased body temperature relates to sympathetic activation, greater following successful than unsuccessful hunts. Why cheetahs abandon a chase when the prey ought to be in range therefore remains unknown.

Effects of high-fat feeding during pregnancy and lactation on the morphofunctional development of the hippocampus in rat offspring

G.L. Gonzalez[1], A.S. Santos[1], A.C. Santana[1], R.P. Gaspar-Reis[1], C.A. Nascimento-Saba[1] and P.C. Barradas[2]

[1]Physiological Sciences, State University of Rio de Janeiro, Rio de Janeiro, Brazil and [2]Pharmacology, University of Rio de Janeiro State, Rio de Janeiro, Rio de Janeiro, Brazil

Change in lifestyle, as increased consumption of dietary fats and reduced physical activity in modern society, are causes of obesity that can lead to diabetes melliuts, hypertension and dementia. Maternal obesity has been documented to play a direct role in the transmission of obesogenic and diabetogenic traits to the next generation and has also been shown to influence the nervous system of offspring. A high-fat diet (HFD) disrupts cognition and contributes to neurodegenerative diseases as well as impairing hippocampal synaptic plasticity, neurogenesis and cognitive abilities. The aim of these study was investigate the effects of maternal high-fat intake in the hippocampal formation of offspring at 10 days of age.
Female adult Wistar rats were feeding with a normal diet (ND, 4% soybean oil, n=6) or a high-fat diet (HFD, 19% soybean oil, n=7) during pregnancy and lactation. Mother and offspring body mass and food intake were monitored. Lipid profile was evaluated. Intraabdominal adipose tissue were collected and weighted. For morphology evaluation, the rats were anesthetized and perfused intracardially with 4% paraformaldehyde in 0.1M PBS (pH 7.4). The brains were transferred to a 30% sucrose solution and then cryoprotected and sectioned serially at 20 μm. The imunohistochemistry evaluation used Ki-67, for cellular proliferation associated with identification of Neu-N (Millipore) - a marker for mature neurons or GFAP (Sigma), a marker of astrocytes. In pregnancy the average body mass of the rats was 234.2 ± 10.91 g. However, at the end of the lactation period the rats of HFD group showed 26% of gain in body mass, without significant difference of food consumption. Offspring of mother fed with HFD showed an increase (16%) in body mass and triglycerides, but intra abdominal adipose tissue mass did not differ. Labeling with Neu-N demonstrates that the granular layer appears thicker in both GD as Ammon's horn (CA1 and CA3). The double labelling (Ki-67 /GFAP) suggests an increase of proliferative cells in the dendate gyrus. The staining with anti-GFAP was more intense and presents more radial profiles (radial glia), suggesting an increased proliferation and/or developmental differentiation of astroglia. Thus, it seems that maternal diet can affect metabolic parameters and slow hippocampal development.

We express our gratitude to Mr Nelcir Rodrigues for animals care. The research was supported by Fundação Carlos Chagas Filho de Amparo à Pesquisa do Estado do Rio de Janeiro (FAPERJ-Brazil), by Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq-Brazil) and Sub-reitoria de Pós-graduação e Pesquisa da Universidade do Estado do Rio de Janeiro (SR2-UERJ).

PCD281

The developmental transition of epicardial, pericardial and omental adipose tissue during early life in the sheep

G.R. Davies[1], M. Birtwistle[1], M. Pope[1], V. Perry[2], H. Sacks[3], H. Budge[1] and M. Symonds[1]

[1]Early Life Nutrition Research Unit, Academic Division of Child Health, School of Clinical Sciences, University of Nottingham, Nottingham, UK, [2]School of Veterinary Medicine and Science, University of Nottingham, Nottingham, UK and [3]Endocrinology and Diabetes Division, VA Greater Los Angeles Health Care System, Los Angeles, CA, USA

Brown adipose tissue is essential in the newborn to protect against hypothermia through thermogenesis and has a crucial role in energy balance in later life in some animal models. Epicardial and pericardial fat depots have both been shown to possess uncoupling protein 1 (UCP1) and function as brown fat [1,2]. The development and modification of these depots in early life in comparison to classical white adipose tissue has not previously been studied. This study focused on the comparison of epicardial, pericardial and omental fat during early postnatal life through gene expression analysis. UCP1 was analysed as a marker of brown or beige fat capable of thermogenesis. Expression of the white fat markers leptin and adiponectin were investigated to elucidate white adipocyte characteristics of each depot. Peroxisome proliferator-activated receptor (PPAR) gamma is involved in white and brown fat differentiation and was assessed as an indicator of mature adipocyte development.
Methods: Four triplet-bearing mothers were entered into the study and a randomly selected triplet was euthanased at 1, 7 or 28 days of age for adipose tissue sampling (n=4 per time point) under Home Office Approval, UK. Pericardial adipose tissue was sampled at 1, 7 and 28 days whereas epicardial and omental adipose tissues were only sampled at 7 and 28 days due to a lack of any observable fat in these depots in 1 day old sheep. RNA was extracted and gene expression analysed by qRT-PCR. Relative mRNA expression was calculated using the GeNorm method corrected to the geometric mean of reference genes IPO8 and RPO, and expressed in arbitrary units [3]. Data are presented as mean ± SEM and analysed using one way ANOVA or unpaired t-Test for comparisons with age.
Results: With increasing age, UCP1 expression decreased and the white fat marker leptin increased in all depots studied (see Figure 1). UCP1 was detectable in epicardial and pericardial adipose tissue and, to a lesser extent in omental fat, at 7, but not 28, days of age. Adiponectin also increased up to 28 days which was most pronounced in the pericardial fat depot. PPAR gamma increased significantly in all depots with age.
Conclusion: Our study suggests a brown to white fat transformation in all adipose tissues during the first month of postnatal life, even in those depots which are undetectable immediately after birth. This may be accompanied by a loss of brown adipose tissue and increased adipocyte differentiation.

Maternal obesity results in lower energy expenditure in adult offspring when exposed to an obesogenic diet in adulthood

X. Maragkoudaki, L. Poston and P.D. Taylor

King's College London, London, UK

Background: Converging lines of evidence suggests that maternal obesity is an independent risk factor for childhood obesity and metabolic syndrome. We have developed a murine model of maternal diet-induced obesity, which gives rise to offspring obesity and metabolic syndrome.
Objective: We investigated whether maternal obesity could alter offspring energy balance and whether offspring exposure to an obesogenic diet in adulthood would exacerbate the effect.
Methods: Female mice were fed standard chow or a highly palatable obesogenic diet, for 6 weeks before mating and throughout pregnancy and lactation. Offspring were weaned onto standard chow. At 3-months of age food intake, energy expenditure (EE) and Respiratory Exchange Ratio (RER) were measured continuously by indirect calorimetry, (Labmaster, TSE). The animals were then challenged for 3 weeks with an obesogenic diet before re-estimation of EE, RER and food intake.
Results: At 3-months of age, offspring of obese mothers (OffOb, n=11) had lower RER over 24hrs ($P<0.05$) compared to offspring of control dams (OffCon, n=10). Following the obesogenic diet challenge OffOb females showed increased calorific intake (OffCon: 17.56±1.72 kcals vs OffOb: 27.65±3.24 kcals, $P<0.01$). OffOb showed reduced average EE compared to OffCon (OffCon: 12.12±0.75 kcal/h/kg, n=11; vs OffOb: 10.76 ±0.31 kcal/h/kg, n=10 $P<0.01$). By 4-months males OffOb showed significantly increased bodyweight (OffCon: 43.93±1.16 g vs 48.1± 1.34 g, $P<0.05$).
Conclusions: Maternal obesity results in lower offspring RER. Maternal obesity showed an apparent interaction with the adult obesogenic diet to increase food intake in females and reduce energy expenditure in both males and females, resulting in increased risk of obesity.

PCD283

Identification and characterisation of human foetal adrenocortical progenitor cells

J. Sampson, D. Wilson and I. O'Kelly

Human Development and Health, Faculty of Medicine, University of Southampton, Southampton, Hampshire, UK

The foetal adrenal gland comprises of two distinct zones; the foetal zone (FZ) and the smaller subcapsular definitive zone (DZ). The FZ produces large amounts of androgens used by the placenta during oestrogen synthesis and expresses cytochrome P450 enzymes, such as CYP21, involved in the synthesis of aldosterone and cortisol. The DZ has been proposed to contain a population of adrenocortical progenitors. These cells are thought to migrate centripetally, perhaps via the distinct columns of cells radiating from the inner layer of the DZ to the outer layers of the FZ, to populate the rest of the gland. This study aims to identify and characterise these cells.
Murine studies have identified Sonic Hedgehog (SHH) pathway in a possible subcapsular non-steroidogenic progenitor population. Activation of this pathway has been implicated in the patterning of other developing endocrine glands however its involvement in the human foetal adrenal gland has yet to be defined. DAX1, dosage-sensitive sex reversal adrenal hypoplasia critical region on chromosome X gene 1, is known to inhibit steroidogenic factor 1 mediated steroidogenesis and murine studies show similar expression profiles to that of SHH. Hence DAX1 expression in the absence of steroidogensis could highlight a progenitor population. We therefore hypothesised that a human adrenal progenitor cell population may be identified using a combination of markers for adrenal DZ and the SHH pathway.
To test this hypothesis a combination of reverse transcription PCR and immunohistochemistry was used to examine the expression of Sonic hedgehog, Smoothened (G protein coupled receptor of the SHH pathway), Gli1 (transcriptional activator of SHH pathway), CD56 (DZ marker), CYP21 and DAX1 mRNA and protein in the human foetal adrenal. Positive transcripts for each of the markers were observed from mRNA extracted from total foetal adrenals (n = ≥1). By immunohistochemistry both SHH and GLI1 showed positive signal at the periphery of the gland, in a similar region to CD56 (n = ≥1). DAX1 expression was also observed to be highest at the periphery of the gland but also localised with CYP21 in the FZ (n = ≥1).
This study has identified a population of GLI1 and DAX1 positive cells which may be representative of an adrenocortical progenitor population. These findings will be advanced by further investigating the involvement of the SHH pathway in the proposed progenitor population. Cyclopamine, an inhibitor of SMO, will be used to assess the importance of the SHH pathway by its effect on the amount of Ki67 and CD56 positive cells in the DZ. Identification and characterisation of the human foetal adrenal progenitors will give a better understanding of gland development.

PCD284

Impact of increased carbohydrate and fat intake during postnatal and juvenile life on gene expression in the sternal fat of sheep

M. Birtwistle[1], P. Khanal[2], A. Kongsted[2], M. Nielsen[2], H. Budge[1] and M.E. Symonds[1]

[1]Early Life Nutrition Research Unit, School of Clinical Sciences, University of Nottingham, Nottingham, UK and [2]Department of Veterinary Clinical and Animal Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

Background and aims:
It has been established that the early life nutritional environment affects current and later adiposity, and therefore adult health outcomes and phenotypes (1). Using sheep as a model, we examined the effects of excess energy intake during early postnatal life on the subsequent growth and development of sternal adipose tissue. Specifically we looked at the expression of adipose tissue-related genes including leptin, adiponectin, FABP4, HOXC9, PPARγ, RIP140 and CIDEA. We hypothesised that excess energy intake would increase the amount of sternal fat, and that genes involved in excess adiposity would respond accordingly.
Materials and methods:
Weight-matched offspring of 13 twin-bearing ewes were separated from their mothers and randomly allocated to one of two different dietary groups from day 3 postpartum until 6 months of age. Each group was balanced by sex. The control group (C, n=13) was fed milk replacer diet for 8 weeks, with green hay added from 14 days of age. The high-carbohydrate high-fat group (HCHF, n=13) was fed a 1:1 mixture of milk replacer and cream together with maize from 14 days of age. At 6 months animals were humanely euthanased and sternal adipose tissue depots dissected. The relative expression of genes of interest was assessed by qPCR. Expression of genes of interest was normalised to the geometric mean expression of two reference genes that had been tested for stability. Gene expression was determined by the comparative C_T method after corrections for qPCR efficiency. Values shown are the mean ± SEM in arbitrary units. A two-tailed t-test or Mann-Whitney U-test, as appropriate, was used to compare gene expression between the two groups.
Results:
At 6 months of age, animals on the HCHF diet were heavier than those on the control diet (C: 36.05 ± 0.79 kg; HCHF: 42.28 ± 2.63 kg; $p<0.05$) and possessed more sternal fat than controls, both in total (C: 36.5 ± 2.5 g; HCHF: 168.3 ± 14.8 g; $p<0.001$) and per kg body weight (C: 1.02 ± 0.07 g; HCHF: 3.96 ± 0.21 g; $p<0.001$). However, expression of mRNA in adiponectin (C: 1.00 ± 0.05; HCHF: 0.60 ± 0.09; $p<0.001$), PPARγ (C: 1.00 ± 0.03; HCHF: 0.52 ± 0.04; $p<0.001$) and CIDEA (C: 1.00 ± 0.14; HCHF: 0.55 ± 0.15; $p<0.01$) was reduced in animals on the HCHF diet compared to controls. There was no difference in the expression of leptin, FABP4, HOXC9 and RIP140 between the two groups.
Conclusions:
Increased energy intake from a high-fat high-carbohydrate diet in early postnatal and juvenile life promotes adiposity, which in the sternal depot results in endocrine adaptations that would be predicted to prevent metabolic and related dysfunction. Future analysis will examine the other major fat depots to assess whether similar responses are found.

Exposure to maternal obesity or to maternal weight loss around the time of conception in the sheep has long term impact on hepatic fatty acid metabolism in the offspring at four months of age

L.M. Nicholas[1], L. Rattanatray[1,2], S.M. MacLaughlin[1], D.O. Kleemann[3], S.K. Walker[3], J.L. Morrison[1], S. Zhang[1] and I.C. McMillen[1]

[1]Sansom Institute for Health Research, School of Pharmacy and Medical Sciences, University of South Australia, Adelaide, SA, Australia, [2]Discipline of Physiology, School of Molecular and Life Sciences, University of Adelaide, Adelaide, SA, Australia and [3]Turretfield Research Centre, South Australian Research and Development Institute, Rosedale, SA, Australia

The obesity epidemic has resulted in an increase in the number of women entering pregnancy overweight or obese range (1). We have previously shown that exposure to maternal obesity in the periconceptional (PC) alone resulted in increased adiposity in female lambs (2). Maternal obesity both before and throughout pregnancy has been shown to result in alterations in hepatic fatty acid (FA) oxidation and lipogenesis, which are characteristic of non-alcoholic fatty liver disease (3-5). This has led to interest in understanding the type of dietary interventions before and during pregnancy, which may lead to optimal outcomes for the mother and offspring (1). Our aim was to determine the impact of exposure to maternal obesity or weight loss around conception in sheep on programming of molecules involved in hepatic FA oxidation and de novo lipogenesis in male and female lambs at 4 months of age.

Donor ewes were allocated to 1 of 4 groups & fed the following diets in the PC period: 100% metabolisable energy requirements (MER) for ≥ 20wks (CC); 100% MER for ≥ 16wks & then 70% MER for 4wks (CR); ~180% MER for ≥ 20wks (HH); ~180% MER for ≥ 16wks & then 70% MER for 4wks (HR). This continued for 1wk post-conception before single embryos were transferred into recipient ewes of normal weight. At 16wks after birth, liver samples were collected to determine gene expression (qRT-PCR) and protein abundance (Western Blotting) of molecules regulating hepatic FA oxidation and synthesis. The effects of PC nutrition and sex were determined using a two-way ANOVA. A Duncan's post hoc test was used to determine significant differences between groups.

HH lambs had decreased gene expression and protein abundance of PPARα and a parallel decrease in PGC1α abundance ($P<0.05$). These lambs also had increased SIRT1 and decreased GCN5 abundance ($P<0.05$). Hepatic AMPKα1, AMPKα2 and SREBP1 was also increased ($P<0.05$) in these lambs. Exposure to maternal weight loss in obese ewes did not abolish all of the effects of maternal obesity on gene expression and protein abundance of these molecules. Furthermore, there was decreased ($P<0.05$) hepatic PGC1α and GCN5 abundance as well as increased ($P<0.05$) AMPKα2 abundance in CR lambs.

We have shown that exposure to maternal obesity in the PC period programs potentially irreversible changes in hepatic lipid metabolism that persist in later life. We have also shown that dietary restriction in obese ewes in unable to abolish all of the effects of maternal obesity. Exposure of both normal weight and obese ewes to moderate dietary restriction resulted in an additional suite of changes within the liver. This highlights that there is vulnerability in offspring after exposure to periconceptional undernutrition to dysregulated hepatic lipid metabolism.

PCD287

Central role for melanocortin system in energy balance and blood pressure regulation in offspring of obese dams

A. Samuelsson, A. Mullier, A. Stepien, K. Patel, J. Pombo, C.W. Coen, L. Poston and P.D. Taylor

Division of Women's Health, Women's Health Academic Center, King's College London and King's Health Partners, UK, King's College London, London, UK

Background: Maternal obesity in rat leads to sympathetic mediated hypertension in the juvenile offspring and hyperphagia and increased adiposity in the adult offspring (1-2). We hypothesise that maternal obesity permanently influences the development of the melanocortin system in the offspring.

Objective: To investigate the role of the melanocortin receptor 3 and 4 (MC3/4R) signaling, using a pharmacological intervention, on the development of juvenile sympathetic mediated hypertension, secondary to maternal obesity.

Methods: Offspring of control (OffCon) and diet-induce obese dams (OffOb; at 23 or 172 days of age) were implanted with telemetry transmitter, inserted into the carotid artery in juvenile rats (DSI PhysioTel PA-C10) and abdominal aorta in adult rats (DSI PhysioTel PA-C40) under general anaesthesia (2% isofluorane). Pre and post-operative analgesia (Buprenorphine 0.1 mg/kg, intramuscular) was maintained for 24h. For drug i.c.v infusion, juvenile rats were anesthetized with ketamine (75 mg/kg, i.p) and domitor (0.5 mg/kg, i.p) and then placed in a stereotaxic frame. Cannula placement was made in the lateral ventricle (coordinates AP-0.9 mm, DV-3.5mm from bregma). MC3/4R antagonist (SHU9119, 1 nmol/h) or saline (Alzet osmotic pump; 0.5 ul/h, i.c.v) was chronically administrated for 7 days and body weight (BW), food intake (FI), mean arterial pressure (MAP) and heart rate (HR) recorded. After the experiments were completed, the rats were sacrificed with overdose of sodium pentobarbital, and their brain removed

and sectioned to confirm accurate placement of the i.c.v cannula. At 6 months of age, MC4R agonist, Melanotan II (MTII, 2 mg/kg, i.p) and saline were injected and BW, FI, MAP and HR were recorded.
Results: Juvenile OffOb rats showed an increased MAP prior to obesity. MC3/4R antagonism (SHU-9119) increased the BW and FI in OffOb relative to OffCon and elicited a greater decline in MAP (OffOb -29±4 mmHg versus OffCon, -12±3 mmHg, P<0.001, n=8). HR was lowered to the same extent in both groups. MTII treatment on the other hand increased HR to a greater extent in the OffOb versus OffCon without any significant difference in MAP response between groups. MTII was also more effective in reducing BW in the OffOb despite not having a differential effect on the FI.
Conclusions: CNS melanocortin system contributes to the elevated MAP in OffOb and may play a key role in the early origin of sympathetic mediated hypertension. Increased signaling by the melanocortin receptor (MC3/4R) is also implicated in altered energy balance in this model.

PCD288

Identification of human adipose tissue native progenitor cell subsets in distinct adipogenic states

D. Esteve[1], N. Boulet[1], A. Zakaroff-Girard[1], S. Ledoux[2], P. Decaunes[1], J. Iacovoni[1], C. Heymes[1], A. Bouloumié[1] and J. Galitzky[1]

[1]I2MC, INSERM U1048, Toulouse Cedex4, France and [2]2-Center Support of Obesity, Hopital Louis Mourier, Colombes, France

Adipogenesis plays an important role in adipose tissue (AT) expansion and in adipocyte turnover. This process involving transcriptional activation/repression netwoks is defined by the shift of undifferentiated and non-committed mesenchymal cells to differentiated metabolically active adipocytes, through different states as comitted progenitors or preadipocytes. Human native progenitor cells CD34+/CD31-, contained in stroma vascular fraction (SVF), display adipogenic potential. However different cellular state markers are lacking. While white and brown AT were well studied in mice, a brite adipocyte was recently evinced in mice and human. More metabolically active than white, brite adipocytes exhibit features at the crossroads of brown and white adipocytes and could be a new target to fight against obesity associated pathologies. We propose to characterize heterogeneity of CD34+/CD31- to identify cell subsets in different states and/or with distinct white or brite fates.Heterogeneity of human CD34+/CD31- cells was studied by flow cytometry (n=54). In vitro experiments on native CD34+/CD31- were done to evaluate modifications on cell subsets ratio during adipogenesis (n=13). Cell sorting approaches were developped to isolate the progenitor subsets. Adipogenic potential of selected cell subsets was assessed in vitro (n=6). Cell subsets states and/or fates in terms of white or brite potentials were assessed by gene expression analyses (n=10). In vivo adipogenic potential of human progenitor subsets was assessed by cellular graft in NMRI mice. 6 weeks after graft, adipocyte formation was checked on implantation site (n=3).We identified 3 progenitor subsets in adult human native AT-SVF. The first one (P1) decreases with obesity. P1 is less represented in human visceral AT (VAT) than in subcutaneous AT (SAT). Futhermore this freshly harvested cell subset displays the highest expression of anti-adipogenic genes as KLF2. Finally P1 has the lowest adipogenic potential in vitro and in vivo. Inversly the second one identified (P2) increases with obesity. P2 is less present in VAT than in SAT. Expression of pro adipogenic genes is higher in P2 compared to P1: PPARγ2 (1.5 fold increase, p<0.05), CHREBP (2 fold increase, p<0.01), and PLIN1 (3 fold increase, p<0.01). P2 displays the better adipogenic potential in vitro and in vivo. P2 has a significant higher expression in brite/brown markers than P1 as CIDEA or TMEM26 (n=9, p<0.05). Mitochondria content, assessed using Mitotracker, is higher in P2 (n=6, p<0.01). The last one (P3) has an intermediate phenotype based on gene expression profile and on adipogenic potential in vitro and in vivo. Our data allow to identify 3 human progenitor subsets in CD34+/CD31- population in different states or with distinct fates. P2 appears as the most committed cell subset and probably contains the white and brite preadipocyte.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD289

Effects of Bone Morphogenetic Proteins (BMPs) on human adipose conversion and adipose tissue (AT) development

N. Boulet, D. Esteve, P. Decaunes, A. Bouloumié and J. Galitzky

I2MC, INSERM U1048, Toulouse, France

Adipogenesis corresponds to the commitment and differentiation of AT progenitor cells into adipocytes. Human AT progenitor cells are CD34+/CD31- and have adipogenic potential under pharmacological PPARγ agonist treatment (1). However in human endogenous signals leading to adipogenic commitment are not clearly known. In mice, BMP2/BMP4 and BMP7 induce the commitment in white and brown adipogenesis respectively (2-3). A third type of adipocytes has been described, brite adipocytes which are white adipocytes with some brown characteristics (4). The present study was undertaken to characterize the effects of these BMPs on human native AT progenitor cells white and brown/brite adipogenesis. Human subcutaneous AT cell populations (adipocytes, immune cells, endothelial cells, and progenitor cells) were isolated by immunoselection/depletion approaches. BMPs gene expressions were determined by RT-qPCR analyses in the different AT cell populations (n=6). BMP receptor gene expressions were performed by RT-qPCR on isolated human AT progenitor cells (n=5). AT progenitor cells were treated (or not, control (ctl)) for 48 hours by BMP2, BMP4 or BMP7 (50ng/ml) then cultured in basal adipogenic medium (without PPARγ agonist) for 9 days (n=7). At day 9, adipogenesis was evaluated by lipid accumulation quantification and RT-qPCR analyses on white and brown/brite adipocyte gene markers were performed (n=6). BMP2 gene expression is higher in immune and endothelial cells compared to adipocytes and progenitor cells (1.5 and 5 fold increase respectively, p<0.05), BMP4 and BMP7 gene expressions are higher in progenitor cells than in others (3 and 50 fold increase respectively, p<0.05). Human AT progenitor cells express BMP receptors ALK2, ALK3, ALK6, BMPR2 and ACVR2. Early BMP2, BMP4 or BMP7 treatment on human AT progenitor cells increases lipid accumulation (3 fold increase

vs ctl, p<0.001) and induces the expression of common adipogenic gene markers such as PPARγ, LEPTIN and PERILIPIN 1 after 9 days (3 fold increase vs ctl, p<0.05). However only BMP7 induces the expression of the common brown/brite adipocyte gene marker UCP1 (3.5 fold increase vs ctl, p<0.05). Classical brown adipocyte genes as PRDM16, CIDEA and PGC1α are not significantly induced by BMP7 treatment. Our study shows that human AT progenitor cells express BMP receptors and that early BMPs treatment induces the commitment and/or differentiation of human AT progenitor cells into adipocyte. BMP2 and BMP4 are white adipogenesis inducers whereas BMP7 induces brown-like/brite adipogenesis. These results suggest that human AT progenitor cells might have brown-like/brite potential and represent a target to fight against obesity-associated pathologies. Finally, BMPs could be produced locally by AT cells and could be endogenous adipogenic signals regulating human white and brite adipogenesis and obesity.

PCD290

The effects of gravidity, digestion, and exhaustive activity on oxygen consumption in the viviparous checkered garter snake

A.G. Jackson[1], N. Ford[2] and J.W. Hicks[1]

[1]Ecology and Evolutionary Biology, University of California, Irvine, Irvine, CA, USA and [2]Biology, University of Texas at Tyler, Tyler, TX, USA

The oxygen transport capacity of the cardiopulmonary system has evolved to meet the demands of simultaneously interacting elevated metabolic states (1). Consequently, scientists have become increasingly interested in the interaction of elevated metabolic states, namely digestion and activity (2). A third, less thoroughly studied physiological state capable of significantly elevating metabolism is gravidity (3). The goals of this study were to measure oxygen consumption (VO2) of gravidity, and study the interactive effects of exhaustive activity and digestion in a viviparous squamate reptile, the Checkered Garter Snake. We examined the metabolic changes during gravidity in this species by measuring oxygen consumption using flow through respirometry.

We hypothesized that 1) gravidity would increase the resting metabolic rate above the resting values of non-gravid females, and 2) that this species would demonstrate an additive response to simultaneous elevated metabolic demands (both metabolic demands will be met with a sufficient supply of oxygen without affecting the performance of either state). Specifically, females would consume more oxygen during digestion, fasting exhaustive activity, and post-prandial exhaustive activity while gravid than during the non-gravid state.

Current results indicate that females of this species increase resting VO2 during gravidity by a factor of 1.6 compared to the non-gravid resting state. Furthermore, compared to non-gravid females, gravid females consume significantly more oxygen during digestion (scope =1.52), but consume significantly less oxygen during fasting exhaustive activity (scope = .830). However, both gravid and non-gravid females demonstrate partial additivity of the digestive and activity responses by consuming more oxygen during post-prandial exhaustive activity (scope =1.30) than either digestion or fasting exhaustive activity alone.

Current results indicate that our hypothesis for increased oxygen consumption during gravidity is supported. On the other hand, our hypothesis for an additive response to simultaneous elevated metabolic states is more complicated. This species does demonstrate an additive response to gravidity and digestion, but not to gravidity and exhaustive activity. Finally, both gravid and non-gravid females experience an additive response to digestion and exhaustive activity. Therefore, we conclude that this species is capable of demonstrating peak VO2 levels only when exhaustive activity is combined with digestion. Future studies might help explain why gravid females demonstrate higher VO2 levels during digestion, but not during exhaustive activity, by examining cardiopulmonary patterns such as ventilation and blood flow distribution patterns.

PCD291

Comparative effects of the long-term black or green tea decoction consumption on lipid digestibility and adipose abdominal tissue mass in rat fed high-fat diet

C. Snoussi[1], K. Dhaouadi[1,2], H. Abaidi[1], S. Fattouch[2] and M.H. Hamdaoui[1]

[1]Research Unit, high School of Health Sciences and Technical, Tunis, Tunisia and [2]Food Biochemistry Laboratory, National institute of applied sciences and technology, tunis, Tunisia

In previous studies, we observed that green or black tea decoction (GTD, BTD) reduced body weight gains and adipose abdominal tissue mass (AATM) in young rats. However, the role of lipids digestibility in this reduction is not yet clear. In the present study, we compared the long-term effect of GTD or BTD consumed ad-libitum on lipid absorption and evaluate its impact on AATM in rats fed high-fat diet (HFD). Thirty-six male Wistar rats were used during an experimental period conducted over 10 weeks. After the adjustment period, the rats were weighed and randomly assigned into 3 groups (n=12 each)with comparable body weights. After, the rats were given the HFD ad libitum with or without tea decoctions as follows: the group 1 received the HFD+ distilled water (CGr), the group 2 received the HFD + GTD (GTGr) and the group 3 received the HFD+ BTD prepared from 50g/L (BTGr). Food intake was recorded throughout the experimental period and quantified by weighing the amount of food spilled and refused. The volume of tea decoction consumed by each rat was measured daily. Fecal matters were individually collected 2 times per

week, lyophilized and stored for total polyphenols, total lipids, triglycerides and caffeine analysis. At the end of the experience, the rats were weighed, and then killed by decapitation. Fasting blood was drawn and the plasma was removed for analysis of total polyphenolic compounds, caffeine, total lipids, some metabolic variables and leptin concentration. In addition, liver, perirenal and epididymal white adipose tissues from abdominal cavity were removed, weighed and stored at -20°C until lipid analysis. Values are means ± S.E.M., compared by ANOVA. After 10 weeks treatment, GTD and BTD reduced body weight gains (CGr: 114.8 ± 5.5 vs. GTGr: 86.8 ± 6.4 and BTGr: 67.8 ± 7.8 g, $p<0.05$) and AATM (CGr: 5.04 ± 0.16 vs. GTGr: 3.13 ± 0.24 and BTGr: 1.97 ± 0.9 g, $p<0.05$). Additionally, they increased plasma polyphenols (CGr: 31 ± 3.3 vs. GTGr: 101.3 ± 6 and BTGr: 76.6 ± 9.4 μg/mL, $p<0.05$) and plasma caffeine (CGr: 0.625 ± 0.13 vs. GTGr: 4.1± 0.5 and BTGr: 6.5 ± 0.6 μg/mL, $p<0.05$). In contrast, GTD and BTD increased lipids (CGr: 213.9 ± 15 vs. GTGr: 301.2 ± 7.6 and BTGr: 351.6 ± 6.5 mg/g, $p<0.05$) and polyphenols (CGr: 112.5 ± 6.2 vs. GTGr: 644 ± 38.9 and BTGr: 643.1 ± 61.9 μg/g, $p<0.05$) excretion in fecal matter. Results showed that the reduction of AATM may be ascribed to the modulation of lipids digestibility by tea-polyphenol and tea-caffeine in the gastro-intestinal lumen and adipose tissue organ which involved different mechanisms and physiological pathway including sympathetic nervous system regulation.

A new mouse model for obesity and steatosis

H. Weng, Y. Naito, K. Endo and N. Iwai

Department of Genomic Medicine, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan

Obesity and obesity-associated fatty liver disease (FLD) are becoming global health problems (Evans et al. 2004). Hepatic triglyceride (TG) accumulation is considered to be a prerequisite for developing FLD. Peroxisomes are single membrane-bound organelles, which have many important functions in lipid metabolism, including fatty acids β-oxidization. Pex11α is one of Pex11 gene factor was shown to promote peroxisome division (Delille et al. 2010, Koch et al. 2010). The pathogenic link between obesity and FLD and peroxisome biogenesis remains unclear. To understand the molecular and physiological functions of the Pex11α gene, we disrupted this gene in mice. Five-week old Pex11α-/- (KO) mice and matched C57BL/6 (WT) mice were fed a high-fat diet (HFD) for 12 weeks. Body weights in KO mice were significantly higher than those in WT mice fed a normal diet or an HFD. The amount of food intake was similar between KO mice and WT mice. Oxygen consumption was significantly lower in KO mice than WT mice. Weights of Epididymal white adipose tissue (e-WAT) of KO mice were significantly greater than WT mice. Large adipocytes were more prevalent in KO mice. Fatty acid synthase and peroxisome proliferator-activated receptor γ mRNA levels were significantly higher in the brown adipose tissues of KO mice than in WT mice by approximately ten- and two-fold. Hepatic TG concentrations in KO mice were significantly higher than those in WT mice fed a normal diet or an HFD. We also characterized the response to 24-hr fasting. Hepatic TG concentrations in fasted Pex11α-/- mice were significantly higher than in fasted WT mice. Very low density lipoprotein production test showed that plasma TG levels increased at higher rates in WT mice than in KO mice after treatment with 500mg/kg of lipoprotein lipase inhibitor tyloxapol. By both catalase (a peroxisome matrix protein) and PMP70 (a peroxisome membrane protein) immunofluorescence staining, the number of peroxisomes was lower in the livers of KO mice than in those of WT mice. Ultrastructural analysis showed that small and regular spherical peroxisomes were more prevalent in KO mice fed normal chow supplemented without or with 0.015% fenofibrate (w/w) for 2 days. We observed a significantly higher ratio of empty peroxisomes containing only PMP70 but not catalase in KO mice. Immunoblotting results also showed a significantly lower ratio of catalase and PMP70 proteins in the peroxisomes of KO mice after fenofibrate treatment. mRNA expression levels of peroxisomal fatty acid oxidation-related genes (ATP-binding cassette, sub-family D, member 2 and acyl-CoA thioesterase 3) were significantly higher in WT mice than in KO mice. Our results provide the first evidence that Pex11α deficiency impairs peroxisome elongation and abundance and peroxisomal fatty acid oxidation, thus contributing to increased lipid accumulation in the liver and increased de novo lipogenesis in adipose tissue.

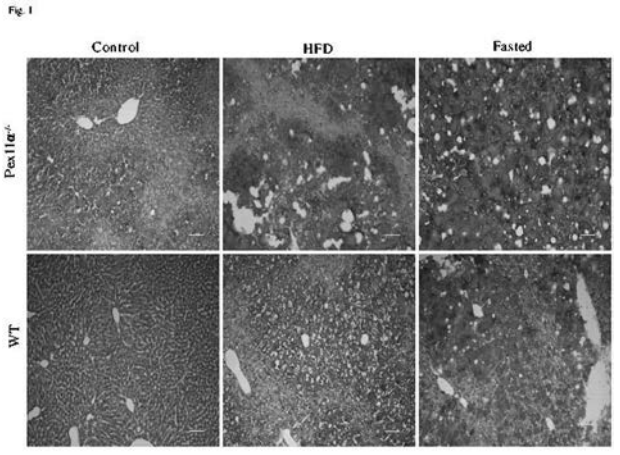

Fig. 1. Pex11α-/- mice develop a fatty liver. WT and Pex11α-/- mice were fed a high fat diet (HFD) for 12 weeks or deprived of food for 24 hr. Oil red O staining of liver sections of mice fed a normal diet (Control), HFD, or fasted for 24 hr. Scale bars = 50 μm.

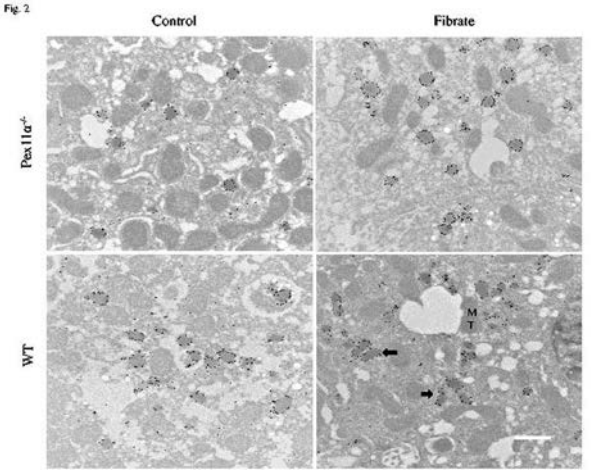

Fig. 2. Electron microscopy indicates that Pex11α deficiency impairs peroxisome elongation and size.Pex11α-/- and WT mice were fed normal chow supplemented without or with 0.015% (w/w) fenofibrate (control and fibrate, respectively) for 2 days.Tubular or elongated peroxisomes are visible (arrows); MT, mitochondria. Scale bar: 1 μm.

PCD293

Hydroxysteroid sulfotransferase SULT2B1b promotes hepatocellular carcinoma cells proliferation in vitro and in vivo

X. Yang, P. Zhou, Y. Ning, X. Zhi, X. Li and L. Yin

Depart of Physiology and Pathophysiology, Fudan University, Shanghai, China

Hydroxysteroid sulfotransferase 2B1b (SULT2B1b) is highly selective for the addition of sulfate groups to 3β-hydroxysteroids. Although previous reports have suggested that SULT2B1b is correlated with cell proliferation of hepatocytes, the relationship between SULT2B1b and the malignant phenotype of hepatocarcinoma cells was not clear. In the present study, we found that SULT2B1b overexpression promoted the growth of the mouse hepatocarcinoma cell line Hepa1-6, while Lentivirus-mediated SULT2B1b interference inhibited growth as assessed by the CCK-8 assay. Likewise, inhibition of SULT2B1b expression induced cell-cycle arrest and apoptosis in Hepa1-6 cells by upregulating the expression of FAS and p-JNK, downregulating the expression of cyclinB1, BCL2 and MYC in vitro and in vivo at both the transcript and protein levels. Knockdown of SULT2B1b expression significantly suppressed tumor growth in nude mouse xenografts. Moreover, proliferation rates and SULT2B1b expression were highly correlated in the human hepatocarcinoma cell lines Huh-7, Hep3B, SMMC-7721 and BEL-7402 cells. Knock-down of SULT2B1b inhibited cell growth and cyclinB1 levels in human hepatocarcinoma cells and suppressed xenograft growth in vivo. In conclusion, SULT2B1b expression promotes proliferation of hepatocellular carcinoma cells in vitro and in vivo, which may contribute to the progression of HCC.

Effects of a crude *Aloe vera* leaf aqueous extract and fenofibrate on diet induced metabolic dysfunction in growing rats

K.H. Erlwanger[1], Z.P. Gasa[1] and S. Makaula[1,2]

[1]School of Physiology, University of the Witwatersrand, 7 York Road, Parktown 2193, Johannesburg, Gauteng, South Africa and [2]Walter Sisulu University, Mthatha, Nelson Mandela Drive, PBag X1, UNITRA 511, South Africa

Globally, the consumption of unhealthy diets and leading sedentary lifestyles contribute significantly to the high prevalence of metabolic syndrome (MetS). Although the complications of MetS can be managed with conventional medicines, there is a growing use of medicinal plants. Previous studies exploring the metabolic effects of *Aloe vera* have been in adult animals in which metabolic dysfunction was induced pharmacologically.

We evaluated the effects of a crude *Aloe vera* leaf extract and fenofibrate on growth, visceral fat, circulating and stored metabolic substrates, and glucose tolerance of growing rats fed a high carbohydrate diet. Fifty nine male Sprague-Dawley rats (21 days old) were randomly allocated to six groups. Group I was fed normal rat chow (NRC). Group II received a high carbohydrate diet (HCD); Group III received NRC and fenofibrate at 100mg.kg^{-1}; Group IV received a HCD and fenofibrate at 100mg.kg^{-1}; Group V received normal rat chow and *Aloe vera* at 300mg.kg^{-1}; Group VI received a HCD and *Aloe vera* at 300mg.kg^{-1}. The *Aloe vera* crude aqueous leaf preparation and fenofibrate were administered in gelatine cubes. After 20 weeks the rats were fasted over night, an oral glucose tolerance test was performed, the rats were then killed with sodium pentobarbital (200mg.kg^{-1} i.p.) and tissue collected for further analysis.

The rats fed the HCD had a significantly higher body mass than the other groups ($p < 0.05$, ANOVA), however the administration of fenofibrate prevented the HCD-induced increase in body mass whilst *Aloe vera* was not effective. Linear growth as measured by the tibial length was not significantly different between the groups ($p > 0.05$, ANOVA). Fasting concentrations of glucose, triglycerides and free fatty acids were not significantly different between the groups and no significant differences ($p > 0.05$, ANOVA) were observed in the circulating concentrations of insulin and the index of insulin resistance (HOMA-IR). The rats in all groups were able to tolerate an oral glucose load. Feeding the rats a HCD resulted in a significantly increased ($p < 0.05$, ANOVA) visceral fat mass. Fenofibrate administration prevented the HCD-induced visceral fat mass gain whilst *Aloe vera* administration had no effect. Although there was no significant difference in the lipid and glycogen content in the liver, fenofibrate administration resulted in a significantly increased liver mass compared to the other groups.

Thus, weaning rats onto a high carbohydrate diet and feeding them the diet for 20 weeks resulted in the development of visceral obesity without altering their glucose tolerance and concentrations of metabolic substrates. Treatment with fenofibrate prevented the high carbohydrate diet-induced visceral adiposity however the *Aloe vera* leaf preparation was ineffective.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Dietary supplementation with coriander (Coriandrum sativum L) seed: Effect on growth performance, circulating metabolic substrates, and lipid profile of the liver and adipose tissue in healthy female Sprague Dawley rats

T.T. Nyakudya[1], S. Makaula[2,3], N. Mkumla[2] and K. Erlwanger[2]

[1]Human Anatomy and Physiology, University of Johannesburg, Johannesburg, South Africa, [2]School of Physiology, University of the Witwatersrand, Johannesburg, South Africa and [3]Physiology, Walter Sisulu University, Unitra, South Africa

The prevalence of diabetes mellitus and metabolic syndrome has reached epidemic levels globally. The rising incidence of diabetes and metabolic syndrome has been attributed to a sedentary lifestyle and the adoption of high energy diets that are deficient in omega-3 fatty acids, and contain excessive amount of omega-6 fatty acids. Coriander seeds, commonly used for culinary purposes, are rich in essential oils and have established hypoglycaemic and hypolipidaemic effects in the obese and diabetics. We investigated the effects of dietary coriander seeds on growth performance, hepatic and visceral adipose tissue lipid storage and circulating metabolic substrates in healthy growing rats. Female Sprague Dawley rats (150-200 g) were fed either standard rat chow (n = 8) or standard rat chow supplemented with crushed coriander seeds (n = 8; 500 mgkg-1 body mass) suspended in gelatine cubes. After five weeks, there were no significant differences in body mass gain, plasma free fatty acids, blood glucose and triglyceride concentrations of the rats from the two dietary groups ($p > 0.05$; t-test). Blood for the determination of circulating metabolites was collected by cardiac puncture under anaesthesia with sodium pentobarbitone. Whilst dietary supplementation with coriander did not affect the lipid content of the liver, however it significantly increased the amount of monounsaturated (MUFA) (22.62 ± 6.48%) and polyunsaturated (PUFA) (54.89 ± 5.10%) fatty acids in the visceral adipose tissue where it also decreased the saturated fatty acid content ($p < 0.05$; t-test). The physiological significance of the effect of coriander on MUFA and PUFA storage in visceral fat, but not in the liver, needs further investigation. The lower ratio omega 6: omega 3 in the visceral adipose tissue may explain some of the health benefits of coriander. These data suggest that dietary coriander supplementation may have beneficial effects on visceral adipose tissue lipid metabolism in healthy subjects.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD297

Attenuation of acetaminophen-induced hepatotoxicity by short day photoperiod in Wistar rats

L.A. Olayaki, E.O. Mbukanma and A.T. Abdulraheem

Physiology, University of Ilorin, Ilorin, Kwara, Nigeria

Short day photoperiod enhances cellular immunity, cortisol production and melatonin secretion, especially in the laboratory animals (Pandi-Perumal et al., 2006; Bilbo et al., 2002). However, field studies of seasonal changes in immunity typically report reduced immune function during the short photoperiod of winter (Sinclair and Lochmiller, 2000). Acetaminophen (Paracetamol, PCM) is widely used as an over-the-counter analgesic and antipyretic drug. Intake of a large dose of PCM may result in severe hepatic necrosis. Therefore, this present study was carried out to investigate the liver protection effect of short photoperiod against acetaminophen-induced hepatotoxicity. Twenty four adult male rats weighing 160±7g were conditioned to different photoperiod regimens for 6 weeks. Group 1, control group, Normal Photoperiod (NP) (12:12, light on from 07:00hr to 19:00hr). Group 2, NP (12:12, light on from 07:00hr to 19:00hr) treated with acetaminophen. Group 3, Short Photoperiod (SP) (8:16, light on from 09:00hr to 17:00hr) treated with acetaminophen. Group 4, Long Photoperiod (LP) (16:8, light on from 05:00hr to 21:00hr) treated with acetaminophen. At the end of the 6th week, rats in groups 2, 3 and 4 were administered oral 2g/kg of PCM solution, while the rats in the control group were administered saline by way of gastric catheter. 24 hours after PCM administration, the rats were sacrificed by cervical dislocation and blood was collected for liver enzymes estimation and liver tissues were collected and homogenised for estimation of lipid peroxidation. The estimated parameters were aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), gamma glutamate transpeptidase (GGTP) and malondialdehyde (MDA) as an index of lipid peroxidation.

Administration of PCM caused a significant ($P<0.001$) elevation of liver enzymes (AST, ALT, ALP and GGTP) level and lipid peroxidation marker, malondialdehyde (MDA) in all the treated groups (groups 1, 2 and 3) when compared to the control (group 1) (See Table 1). However, there was a significant ($P<0.01$) decrease in the serum levels of the liver enzymes concentration and MDA in the group 4 (SP group) compared to the rats in groups 2 and 3. It was concluded that the short day photoperiod has hepatoprotective effect and this could be due to its inhibitory effect on hepatic tissue lipid peroxidation.

Effect of Acetaminophen-Induced Hepatic Toxicity on Serum Liver Enzymes and Liver Tissue Malondialdehyde in Rats

Group	AST (U/L)	ALT (U/L)	GGT (U/L)	ALP (U/L)	MDA (mmol/mg protein)
Group 1	34.5±2.6	72.3±4.3	22.3±4.3	157.6±6.9	172.3±3.3
Group 2	205.7±8.6**	356.7±12.4**	79.1±5.2**	313.9±14.5**	356.7±4.3**

Protective effects of cumin essential oil and a probiotic bacterial strain against cadmium hepatotoxicity in rats

L.S. El Hosseiny[1], F.M. El-Demerdash[2], H.H. Baghdadi[3] and M. El-Shenawy[4]

[1]Environmental Studies, Alexandria University, Institute of Graduate Studies and Research, Alexandria, Egypt, [2]Environmental Studies, Alexandria University, Institute of Graduate Studies and Research, Alexandria, Egypt, [3]Environmental Studies, Alexandria University, Institute of Graduate Studies and Research, Alexandria, Egypt and [4]Environmental Studies, Alexandria University, Institute of Graduate Studies and Research, Alexandria, Egypt

Heavy metals are ranked among the top 10 of the most 275 most hazardous substances in the environment on the current Priority List of Hazardous substances for the Agency for Toxic Substances and Disease Registry (ATSDR). Of all toxic heavy metals, cadmium ranks the highest in terms of damage to human health. Although, there are many studies which have established the toxic effects of cadmium on biological systems, the mechanism of cadmium detoxification and novel detoxifying agents are still under considerable debate and discussion. Accordingly, the present study aimed at investigating the role of a probiotic bacterial strain and cumin essential oil on the hepatotoxic effects induced by cadmium in experimental rats. Seventy male albino rats were used and were handled in accordance with the principles of laboratory animal care as contained in NIH guide for laboratory animal welfare. The rats were assigned into 7 groups of 10 rats each and were orally administered with cadmium chloride (5 mg/Kg BW), cumin essential oil (0.125 mg/Kg BW) and live culture of Lactobacillus bulgaricus (ca 107 cfu) singly or jointly for a period of 30 days. Following the exposure period blood and liver were collected for biochemical and histological analyses. The in vivo exposure of rats to cadmium induced an array of hepatotoxic effects at both the biochemical and histological levels, which ranged from biochemical irregularities in total protein, albumin, globulin and bilirubin levels to structural changes as manifested by elevations in hepatocellular injury biomarkers (aminotransferases, LDH and AlP) and hepatohistological alterations indicative of necrotic and inflammatory lesions. Moreover, an oxidative stress status was evidenced in liver tissue of rats as inferred by escalation in lipid peroxidation and depletion in antioxidant defense parameters including both non-enzymatic and enzymatic antioxidants (GSH content, GST, CAT and SOD). Cumin essential oil and the probiotic bacterial strain alleviated the hepatic dysfunction associating cadmium toxicity as inferred by the restorative effect on hypoproteinemia, hypoglobulinemia, hypoalbuminemia and hyperbilirubinemia. Structurally they restored hepatocellular injury biomarkers to normal or near normal levels and restored their activities both at the tissue and serum levels. Moreover, they preserved the hepatic histological architecture where the hepatic lesions associating cadmium toxicity were alleviated by their single or joint administration. They also combated the oxidative stress status induced by cadmium in liver tissue. Conclusively, both cumin and Lactobacillus exhibited beneficial effects against the physiological threats posed by cadmium and they hold health promoting effects at the biochemical and histological levels.

Antioxidative and hepatoprotective effect of beta carotene on acetaminophen induced liver damage in rats

O.T. Oyelowo[1], A. Morakinyo[2], B. Iranloye[3] and J. Nnaji[4]

[1]Physiology, University of Lagos, Lagos, Nigeria, Lagos, Nigeria, [2]Department of Physiology, University of Lagos, Lagos, Nigeria, [3]Department of Physiology, University of Lagos, Lagos, Nigeria and [4]Department of Physiology, University of Lagos, Lagos, Nigeria

Acetaminophen (APAP) or paracetamol is a widely prescribed analgesic and antipyretic drug either as a single compound or in combination with other medications (Kaplowitz 2004). Excessive use of APAP can damage the liver and if not treated, overdose can lead to liver failure (Larson et al 2005). Beta carotene (BC) is an example of carotenoids and is the major precursor of Vitamin A with immune and antioxidant properties. The role of oxidative stress on hepatic damage caused by acetaminophen (APAP) and the possible protective effects of BC supplement against this damage were investigated. Wistar rats were randomly divided into four groups: control, APAP, BC and APAP+ BC. The control group received distilled water while APAP (750 mg/kg body weight), BC (10 mg/kg/day body weight) were administered to the other groups accordingly. Treatments were administered orally via gavage and lasted for seven consecutive days. Twenty four hours after the last drug administra¬tion, the animals were anaesthetized with diethyl ether and blood was collected from each rat and prepared serum samples were thereafter used for biochemical analy¬sis. The liver from each rat was carefully collected and weighed. They were homogenized with phosphate buffer and used for oxidative analysis. SOD activ¬ity was determined (epinephrine in 0.005 N HCl). CAT (determined by measuring the exponential dis¬appearance of H2O2) and GSH (Ellman's reagent) activities were determined. Lipid peroxidation was also analyzed by the forma¬tion of malondialdehyde (MDA).The serum levels of SGPT, SGOT, and SAP were determined using an automatic enzyme analyzer (Beckman, California, USA). Values are mean ± SEM, compared with ANOVA to show significant differences among groups, Tukey's post hoc test was used to determine specific pairs of groups that were statistically different (GraphPad Software, USA).The serum glutamate oxalate transaminase (SGOT) level of the APAP group was significantly increased compared to the control (272.27 ±18.77 vs 197.75 ± 28.20). An increase was also observed in the serum glutamic pyruvate transaminase (SGPT) (82.80±8.91vs 58.40 ±5.76) as well as the serum alkaline phosphatase (SAP) levels of (177.60±19.53 vs 169.80±13.83; $p<0.01$). These increased levels were ameliorated by the administration of β-carotene. The

SOD, GSH and CAT levels of the APAP groups which were significantly decreased (P<0.001) when compared to the control had a boost in the antioxidant level after the application of BC. SOD level was (APAP vs APAP+ BC; 35±1.50 vs 80± 4.05); GSH (APAP vs APAP+ BC; 40±2.75 vs 70± 5.65); CAT levels (APAP vs APAP+ BC; 300±10.50 vs 460± 12.65). The reverse was the case in the MDA activity (APAP vs APAP+ BC; 15±0.5 vs 10± 0.7). The study showed that BC ameliorates the damaging effect of acetaminophen on liver tissues.

Assessment of coal tar creosote toxicity in rat liver: role of rosemary

E.A. Abbady[1], F.M. El-Demerdash[2] and H.H. Baghdadi[3]

[1]Environmental Studies, Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt, [2]Environmental Studies, Alexandrria University, Institute of Graduate Studies and Research, Alexandria, Egypt and [3]Environmental Studies, Alexandrria University, Institute of Graduate Studies and Research, Alexandria, Egypt

Coal tar is a significant product generated from coal pyrolysis. Coal tar can be utilized as raw materials for various industries such as synthetic fiber, dyestuff, medication, coating and national defense. It is also a type of raw materials from which phenols, naphthalenes and anthracene can be extracted for the production of washing oil, cementitious agents, antiseptic agents, and catalytic hydrogenated to produce gasoline, diesel oil, etc. Therefore, the present study was designed to investigate the possibility of coal tar creosote to induce oxidative stress and biochemical perturbations in rat liver and the role of rosemary in ameliorating its toxic effects. Male Wister Albino rats were randomly divided into four groups of 10 each, group I served as control; group II treated with rosemary (10 ml of extract/kg BW for 21 days), group III received coal tar creosote (200 mg/4ml olive oil/kg BW for 3 days) and group IV treated with both rosemary and coal tar creosote. The local committee approved the design of the experiments, and the protocol conforms to the guidelines of the National Institutes of Health (NIH). The administration of coal tar creosote significantly caused elevation in lipid peroxidation (LPO) and reduction in the activities of superoxide dismutase (SOD), catalase (CAT) and glutathione S-transferase (GST). A significant decrease in reduced glutathione (GSH) content was also observed. Liver aminotransferases (AST and ALT) and alkaline phosphatase (AlP) were significantly decreased while lactate dehydrogenase (LDH) was increased. Rosemary treatment to coal tar creosote treated rat decreased LPO level and normalized SOD, CAT and GST activities, while GSH content was increased. Also, liver AST, ALT, AlP and LDH were maintained near normal level due to rosemary treatment. In conclusion, Rosemary has beneficial effects and could be able to antagonize coal tar creosote toxicity.

The role of the anti-inflammatory cholinergic pathway in the pathogenesis of a rat model of acute colitis

M. Kolgazi[1], U. Uslu[2], M. Yuksel[3], A. Velioglu-Ogunc[3], F. Ercan[4] and I. Alican[1]

[1]Department of Physiology, Marmara University School of Medicine, Istanbul, Turkey, [2]Department of Histology and Embryology, Yeditepe University School of Medicine, Istanbul, Turkey, [3]Marmara University Vocational School of Health Related Professions, Istanbul, Turkey and [4]Department of Histology and Embryology, Marmara University School of Medicine, Istanbul, Turkey

Introduction: Intense local immune response, associated with recruitment and activation of lymphocytes and macrophages, and subsequent release of cytokines and other inflammatory mediators all cause tissue damage and contribute to many of the clinical features of colonic inflammation. The cholinergic anti-inflammatory pathway is a neuro-immune mechanism that regulates innate immune function and controls inflammation. The functional activity of this pathway can be modulated through its neuronal and non-neuronal (α7nACh receptors) cholinergic components. Objective: To explore the role of cholinergic anti-inflammatory pathway in acetic acid-induced acute colitis in rats. Materials and Methods: The colonic inflammation was induced in Sprague-Dawley rats (200-250 g; n=8/group) by intrarectal administration of 0.8 ml of 5% (v/v) acetic acid in 0.9% NaCl. The control rats received same volume of isotonic saline by the same route. The treatment groups were treated with either a natural acetylcholinesterase inhibitor huperzine A (HUP; 0.1 mg/kg) or a cholinergic agonist nicotine (NIC; 1 mg/kg) intraperitoneally. Drugs were given 5 min after induction of colitis and continued for 3 consecutive days. On the fourth day all rats were decapitated. The distal colon was scored and stored for the measurement of malondialdehyde (MDA) and glutathione (GSH) levels, and myeloperoxidase (MPO) activity. The presence of NFκB in colon was also

examined. Formation of reactive oxygen species in colons was monitored by chemiluminescence (CL) method. Trunk blood was collected for the assessment of serum tumor necrosis factor (TNF-α) interleukin (IL)-1β and IL-10 levels. Results: The extent of colonic lesions in colitis group was reduced by HUP and NIC macroscopically ($p<0.05$), the microscopic score was only reduced by HUP treatment ($p<0.05$). Increased NFκB content in colitis group was reduced by HUP and NIC. Increase in colonic lipid peroxidation and lucigenin-enhanced CL in rats with colitis were attenuated by HUP ($p<0.01$). Stimulation of MPO activity in colitis group was attenuated by NIC ($p<0.05$). Increased serum TNF-α and IL-1β levels in colitis group were prevented by HUP ($p<0.001$ and $p<0.05$, respectively). Serum IL-10 level of the colitis and control groups was not significantly different but was increased by both NIC and HUP. Tissue GSH content did not differ among groups. Monitorization of body weigths during the course of study demonstrated a significant reduction in colitis rats which was reversed by NIC ($p<0.05$). Conclusion: Inhibition of AChE or treatment with a cholinergic agonist is beneficial on inflammatory parameters in a rat model of acute colitis. This supports the potential role of anti-inflammatory cholinergic pathway in the treatment of colonic inflammation.

Treating overweight/obesity using alginate enriched bread

D. Houghton[1], M. Wilcox[1], I. Brownlee[2], C. Seal[3] and J. Pearson[1]

[1]Institure for Cellular and Molecular Bioscience, Newcastle University, Newcastle Upon Tyne, Tyne and Wear, UK, [2]Food and Human Nutrition Department, Nanyang Polytechnic, Ang Mo Kio, Singapore and [3]Human Nutrition Research Centre, Newcastle University, Newcastle Upon Tyne, Tyne and Wear, UK

Background and Objectives. Obesity is a rapidly growing medical issue worldwide, and is fast becoming one of the leading causes of mortality. Data from our laboratory have demonstrated that alginates have the ability to inhibit pancreatic lipase activity in-vitro, and may therefore reduce the fat absorbed in the diet [1-3]. This project has developed a bread vehicle designed by Greggs PLC that incorporates alginate and may be used in foods that people are already consuming in a "health by stealth" manner in the battle against obesity. In an acceptability study with 40 participants there were no adverse side effects with either bread, and participants preferred the alginate bread compared to the control bread. The purpose of the present study was to assess the ability of alginate enriched bread to inhibit fat digestion in-vitro and in-vivo. Method. Control bread (CB) and alginate enriched bread (AB) were used in the current study. In-vivo: data presented is preliminary data from a double blind crossover study conducted using ileostomy patients (n=13). Participants consumed a calorific set meal the night before and were then fasted for 12h. Upon arrival participants consumed either 105g CB or AB as toast which included 20g of butter. Blood samples were taken at baseline, immediately post eating and then every 30 minutes for 5 hours, and placed on ice until analysis. Free glycerol and total triglycerides was measured in plasma to assess fat digestion. In-vitro: three fat substrates (Trioctanoate, Trioleate and Tributyrate) were digested in an open model gut system developed within this laboratory, which replicates digestion in the mouth, stomach and small intestines. 500μl of each substrate was added alone or with 5.2g AB or CB (n=9) at 0 minutes. A 1ml sample was then taken at 180 minutes for each sample. Free glycerol was measured to assess fat digestion. A t-test was used to compare CB and AB with normal substrate digestion in the model gut, and to compare total triglycerides in plasma between CB and AB at various time points in ileostomy patients. Data presented as mean ± standard error of the mean (SEM). Results. Preliminary data from ileostomy plasma samples indicated a reduction in the total triglycerides in the plasma ranging from 9-34% from 0-5h compared with the control bread, with a significant difference at 210 minutes ($p>.05$). In the model gut at 180 minutes there was a significant reduction in fat digestion of 47.7% (1.2), 32.5% (2.4) and 51.1% (1.3) for trioctanoate ($p>.05$), tributyrate ($p>.05$) and trioleate ($p>.05$) respectively. Conclusion. This study has the potential to provide evidence that normal foods supplemented with alginate can be used to treat obesity/overweight and could be utilised by the food industry. Further recruitment is required to acquire a larger group of ileostomy patients and to analyse the ileum effluent fluid to determine levels of undigested fat.

Intestinal handling of glucose in rats treated with Kolaviron (A biflavonoid of Garcinia Kola seed)

S.B. Olaleye and O.A. Odukanmi

Physiology, University of Ibadan, Ibadan, Nigeria

Kolaviron (KV) a fraction of Garcinia kola has been found to have hypoglycemic effect on glucose metabolism. The mechanism of its hypoglycemic effect was investigated. KV was isolated according to Iwu et al(1990).The study was executed in three phases. Phase I was conducted to investigate the effect of KV on blood glucose concentration in rats (male, 180-200mg), n=,6) fasted for 18 hours while phase II and IIIwere to investigate the route(s) of glucose utilization in KV treated rats via the artero-venous (A-V) and intestinal glucose absorption where 10-20 cm long segments of the jejunum and ileum were used respectively. The rats (male, 180-200mg) were grouped into four groups of six animals each. Group I represented the control(treated with ?saline) while group II, III and IV were treated with 50mg, 100mg and 200mg of KV per kilogrammme body weight respectively via oral administration using a metal feeding canular. The rats were anaestesized in phases II and III with urethane (0.6ml/ 100mg body weight) given subcutaneously prior to laparotomy. Values bare represented as Mean+/- S.E.M., compared by one way analysis of variance and unpaired Student's 't ' test. Results from phase I showed significant decrease in blood glucose concentration from the various treated groups after 4 hours of administra-

tion, (Control= 69.00+/-2.66 mg/dl, KV 50mg/kg= 64.33+/-2.40mg/dl, KV 100mg/kg= 59.83+/-2.48 mg/dl and KV200mg/kg= 54.00+/-2.82mg/dl) . The A-V study revealed a 13.7%, 36. 99% and 47.94% decrease in blood glucose concentration in the KV50, KV 100 and KV 200 mg /kg groups respectively compared to the control group after 3 hours of administration of KV. The jejunum and ileum glucose absorption significantly increased in all the treated groups compared bro the control animals after 40 minutes of infusion, P<0.05. KV possibly exerts its reported profound hypoglycemic effects through the increased glucose extractions by intestinal cells. More work is required to determine the possible role of insulin and counter- regulatory glucose hormones in mediating the hypoglycemic effect reported.

Blood glucose concentration in rats treated with Kolaviron

Treatment	0 hour	1hour	4hour
Control	70.83+/-2.54	70.67+/-2.25	69.00+/-2.66

Effects of different sweeteners on gastric emptying, incretins release and glucose homeostasis in healthy humans

R.M. Pereira[1], M. Secaf[2] and R.B. de Oliveira[1,2]

[1]Department of Physiology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil and [2]Department of Internal Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

The global rises in the prevalence of obesity, diabetes mellitus and associated diseases, led to an increase of sweeteners consumption around the world. The presence of nutrients in the small intestine plays important roles in appetite regulation, blood glucose (BG) and gastric emptying (GE). These regulatory roles are mediated by peptides called incretins, such as glucagon-like peptide 1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP). The release of these peptides is stimulated mainly by nutrients, whereas the effects of sweeteners, in vivo, on incretins release are not well established. Objective: To determine the effects of addition of sucrose, sorbitol, sucralose or stevia on a standard liquid test meal, on GE, on glucose homeostasis (BG and plasma insulin), as well as on GIP and GLP-1 release in humans. Design: Eleven male healthy volunteers were studied on 4 separate occasions. GE of a caloric test meal (205 kcal), containing technetium (99mTc), were determined by abdominal scintigraphy. Fifteen grams of sucrose, sorbitol, sucralose or stevia were added to the test meal, one each occasion. The GE of test meal was measured by T1/2. Blood glucose, plasma insulin and incretins were determined at t = -10 (fasting), 0, 5, 10, 15, 30, 45, 60, 90 and 120 min after the meal ingestion using a glucometer and specific immunoassay kits. Results: GE of a standard test meal prepared with sucrose was faster than when sorbitol or sucralose were added. The addition of sucrose or sweeteners in the standard meal, did not cause significant difference of BG. The insulin concentrations were significantly raised after the ingestion of sucrose as compared with sorbitol or stevia.The addition of sucrose, sorbitol, sucralose and stevia increased the GLP-1 plasma concentration equally. This increase was different, between sucrose and sucralose, only 120 min after the meal ingestion. Regarding GIP, the meal prepared with sucrose was able to increase its concentration compared with the different sweeteners. Conclusions: Our results showed that the consumption of sweeteners like sorbitol or sucralose, added in a balanced test meal (composed by carbohydrates, protein and lipids), were able to delay the GE. Moreover, the consumption of these substances added in a balanced meal, did not change the incretins release as well as the glucose homeostasis in healthy humans.

PCD305

Metabolic response of growing rats fed fructose from two dietary supplements

A. Ajibola[1,3], J.P. Chamunorwa[2] and K.H. Erlwanger[3]

[1]Vet Physiology & Pharmacology, University of Ilorin, Ilorin, Kwara, Nigeria, [2]Vet Anatomy & Physiology, University of Pretoria, Pretoria, Gauteng, South Africa and [3]School of Physiology, University of the Witwatersrand, Johannesburg, Gauteng, South Africa

Metabolic syndrome (MetS) is the coexistence of obesity, hyperglycaemia, hypertension and dyslipidaemia in an individual (1). The modern human diet contains high fructose level (2), which is culpable in the pathogenesis of MetS in adults (1) and children (3). We investigated the effects of two dietary sources of fructose, natural honey (NH) and cane syrup (GS) on metabolism in growing rat models (Rattus norvegicus) fed from neonatal age. Fifty-nine suckling (7-day old male (18.1±0.78g) and female (17.7±0.63g) rats were divided into five groups, namely NH Low (NHL); NH High (NHH); GS Low (GSL); GS High (GSH); and control (CRF), with replication on gender basis (n=6, except NHH female with 5rats). The rats were fed either NH or GS at low (10ml kg-1 b.wt) or high (20ml kg-1 b.wt) dose daily via stomach tube for 14 days, while the CRF was gavaged with distilled water. On weaning, NH or GS was mixed with rat feed as low (20%) or high, 50% (volume/weight, v/w) supplement, while tap water (20% v/w) was added to the control diet. The rats were euthanized at 13 weeks old to obtain visceral measurements, general health indices and growth parameters. Values are mean ± S.E.M., compared by ANOVA. NHL caused normal body weight gain (498.67±11.51g) as control (475.00±8.92g) in males, but significantly ($p<0.01$) higher than NHH, 407.17±9.75g; GSL, 426.17±9.04g, and GSH, 416.00±6.61g respectively. There was

significant (p<0.05) increase in males' long bone weight and length while there was no difference (p>0.05) in linear growth among the female rats. Dietary cane syrup significantly (p<0.0001) increased the absolute and relative weights of abdominal visceral fat (GSL, 17.70±0.73g, 3.75±0.14%; GSH, 15.48±0.85g, 3.64±0.14%) vs. NHL, 11.11±0.37g, 2.39±0.07%; NHH, 10.21±1.04g, 2.48±0.21%; and CRF, 8.56±0.50g, 1.97±0.13% in males. GS-fed males had significantly (p<0.05) increased liver weight (GSL, 14.23±0.56g; GSH, 12.57±0.30g) vs. NHL, 10.92±0.32g; NHH, 10.24±0.40g; and CRF, 11.16±0.34g. The increased visceral fat and hepatomegaly were neither observed in the NH-fed nor the female rats. The surrogate markers of liver function were normal in the NH males, unlike GS-fed male rats with significantly (p<0.05) increased AST (GSL, 75.5±4.56U/L; GSH, 86.7±8.15U/L; NHL, 58.2±4.19U/L; NHH, 69.9±2.88U/L; CRF, 67.2±2.19U/L) and ALT (GSL, 43.5±9.57U/L; GSH, 32.8±8.68U/L; NHL, 27.5±3.13U/L; NHH, 25.8±2.87U/L; CRF, 28.5±2.46U/L). The rats fed GS diets were predisposed to developing diet-induced MetS. Unlike cane syrup, feeding rats NH from an early age neither caused susceptibility to MetS, nor compromised their health status, despite the similar fructose content of NH and GS. The good metabolic health of the NH-fed rats could be due to micronutrients, antioxidants and phytochemical constituents of NH (4, 5). There are definitely nutritional and health benefits in substituting honey for refined sugars.

Novel insights in the cross-talk of Pparα and Pparγ with the Hedgehog-Signaling Pathway

K. Arnold[1], M. Matz-Soja[1], E. Marbach[1], W. Schmidt-Heck[2], R. Guthke[2] and R. Gebhardt[1]

[1]Faculty of Medicine, Institut of Biochemistry, Leipzig, Germany and [2]Leibniz Institue for Natural Product Research and Infection Biology, Hans-Knöll Institute, Jena, Germany

As the biggest metabolic organ the liver possesses a variety of functions, including carbohydrate and lipid metabolism. The smallest functional unit thereby is displayed by the liver lobules showing a metabolic zonation. Hepatocytes can be roughly divided in periportal (PP) and pericentral (PC) cells. Numerous genes and enzymes are involved in the regulation processes of the metabolism; especially nuclear receptors like Ppars possess a coordinating role for many physiological functions. While Pparα promotes fatty acid oxidation and, thus, is controlling lipid catabolism, Pparγ promotes the storage of lipids. Transcription factors like Ppars also interact with morphogenic pathways. One example is the hedgehog (HH) signaling pathway, which is crucial for embryogenesis and organogenesis. Recent investigations showed that this pathway also plays a critical role in adult organs such as the liver but molecular mechanisms are not well characterized. Our aim was to investigate the interactions between Ppars and Gli-transcriptiption factors (TF).

C57Bl6/N mice (12 week, ♂, 20-25 g) were used to and maintained under controlled conditions (const. 12:12h LD cycle). Mice were anaesthetized with a mixture of atropine (0.1mg/kg), ketamine (100mg/kg) and rompune (5mg/kg). To examine hepatic gene expression, RNA was extracted from whole liver lysates or hepatocytes which were isolated by using collagenase perfusion technique. To receive PP and PC hepatocytes a digitonin-collagenase perfusion was performed. To investigate the functions of Pparα/γ as well as of Gli1/2/3, siRNA-mediated in vitro knockdown (KD) of those genes was performed. Alterations in gene expression of HH signaling components and lipid metabolism target genes were determined by using micro-arrays and qRT-PCR. Values are means ± S.E.M. normalized to β-actin as housekeeping gene, compared by MWUtest.

mRNA expression profiles showed a heterogeneously distribution of Pparα/γ. Pparγ is localized pericentral (PC:1±0.26 vs PP:0.17±0.12,p<0.05; n=3-4), whereas for Pparα no preferential zonated localization could be determined. Transcriptome analyses revealed that a wide variety of genes like genes for biological processes (e.g. ion transports, cell cycle) are effected by Pparγ-KD (n=3). Pparγ-KD also results in downregulation of all 3 Gli-TFs (e.g. Gli1: 0.55±0.13,p<0.05; Gli2:0.42±0.14,p<0.01; Gli3:0.05±0.03,p<0.05; n=7-8). Gli1/2/3-KD showed effects on Ppar-gene expression. Both Ppar heterologous are significantly upregulated in response to Gli3-KD (Pparα: 2.62±0.61, p<0.05; Pparγ: 1.66±0.31, p<0.05; n=4-6).

KD-experiments of Ppars and Gli-TFs and their related mRNA expression profiles indicate a putative mutual interaction between these nuclear receptors and HH signaling forming a negative feedback loop. Future experiments should investigate molecular details of this interaction.

HEDGEHOG AROUND THE CLOCK: Mutual interaction between circadian rhythms of hepatic lipid metabolism and hedgehog morphogen pathway

E. Marbach[1], M. Matz-Soja[1], K. Arnold[1], W. Schmidt-Heck[2], R. Guthke[2] and R. Gebhardt[1]

[1]Institute of Biochemistry, Faculty of Medicine, Leipzig University, Leipzig, Germany and [2]Leibniz Institute for Natural Product Research and Infection Biology – Hans-Knöll-Institute, Jena, Germany

Entrained and reset by external cues, the circadian clock controls physiological processes, including liver metabolism. At the cellular level the clock is characterised by core clock genes, which modulate the fluctuating expression of central metabolic genes as transcription factors. Being an extensive biological process, the clock is linked to the elements of cell cycle control and intracellular signalling pathways. Recent analyses identified the liver clock also to be associated with the hedgehog (HH)-signalling, an evolutionary conserved cascade functioning as crucial modulator of embryogenesis and tissue dif-

ferentiation. Although there is an evidence of its role in adult liver, no exact mechanisms are known.
Our aim was, therefore, to analyse the liver specific interaction of the HH-signalling and the circadian clock, using the transgenic knock-out mice, displaying a hepatocyte specific deletion of Smo (Smo-KO), an essential transducer within the HH-signalling. Mice (male, 10-12 weeks, 19-25g) were maintained under controlled conditions (12:12 h LD-cycle, fed ad libitum) and at different time-points, animals were anesthetised with a mixture of ketamine (100mg/kg), rompune (5 mg/kg) and atropine (0.1 mg/kg). Further, the RNA was extracted either from whole livers or collagenase-perfused isolated hepatocytes. We performed gene microarray analyses, comparing KO- mice and their WT-littermates, considering the different circadian time-points of hepatocyte isolation. The data were classified according to the GO clusters and evaluated using the ANOVA statistical analyses. Generally, due to hepatic Smo deletion the results show strong alterations in the circadian expression levels of genes involved in metabolic and transport processes (e.g. Smo-WT:179 vs. Smo-KO:234 genes are up-regulated, n=3/genotype). However, these alterations seem not to provide a significant effect on the global scale (P=0.175). In contrast, especially the circadian rhythm of the lipid metabolism is significantly affected by inactive HH-pathway (e.g. Smo-WT:39 vs. Smo-KO:30 genes are up-regulated, whereby only 17 genes are common for both genotypes, P=0.001).
Verified by qRT-PCR analyses, some core clock genes exhibit strong alterations in their expression due to Smo-KO (e.g. level of Per3 is elevated at 09:00 to a factor 2.7±0.5, P=0.007; Per1 - to a factor 1.7± 0.2, P=0.5; n=6-10; values are means ±S.E.M.). A putative transcription factor binding site prediction, generated using Fantom4 database, allows us to conclude that in adult liver the HH signalling seems to be closely related to the circadian clock and, thus, might be involved in the regulation of the rhythmicity of lipid metabolic processes. However, the precise function of HH-signalling within the clock regulatory circuit still has to be evaluated, requiring further investigations.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD309

Impairment of cerebrovascular reactivity is proportional to degree of insulin resistance in patients with type 2 diabetes

A. Jaryal[1], K. Prakash[1], D.S. Chandran[1], R. Khadgawat[2] and K. Deepak[1]

[1]Physiology, All India Institute of Medical Sciences, New Delhi, India and [2]Endocrinology, All India Institute of Medical Sciences, New Delhi, India

Increased risk of cerebrovascular diseases in type 2 diabetes mellitus is associated with impaired cerebrovascular reactivity (CVR) as well as the degree of insulin resistance. Recent studies in healthy human subjects have shown that CVR measured in response to hypercapneic stimulus is associated with significant rise in arterial blood pressure (ABP) and hence must be corrected for associated changes in ABP (Claasen et al, 2007). The aim of the study was to investigate the relationship between CVR and insulin resistance in the patients of type 2 diabetes mellitus after correcting for the associated ABP changes during CVR assessment. The middle cerebral artery blood flow velocity (MCAV) was measured by transcranial ultrasound technique. The non-invasive beat-to-beat blood pressure was measured from finger using technique of Penaz. The CVR was assessed by measuring the changes in MCAV and cerebrovascular conductance (CVC, calculated as MCAV / mean ABP) after breathing of 6% CO2 for 2 minutes in 34 uncomplicated type 2 diabetic patients and after breath holding for 30 second. Insulin resistance was assessed by Homeostatic model assessment of insulin resistance (HOMA-IR). The HOMA-IR of the subjects was 3.88 ± 1.84 (mean ± S.D). On breathing 6% CO2, the mean ABP increased from baseline 87.68 ± 10.52 to 101.0 ± 14.32 mmHg ($p<0.0001$), the MCAV increased from baseline 45.76±10.02 to 66.94±18.11 cm/sec ($p<0.0001$) and CVC increased from baseline 0.527 ± 0.125 to 0.669 ± 0.182 cm/s/mmHg ($p<0.0001$). On breath holding, the ABP, MCAV and CVC increased significantly as compared to baseline (101.2 ± 19.06, $p<0.0001$; 61.13 ± 16.59, $p<0.0001$ and 0.621 ± 0.186, $p<0.0001$ respectively). During 6% CO2, both MCAV and CVC were significantly correlated with HOMA-IR ($r = -0.340$, $p = 0.0491$ and $r = -0.3749$, $p = 0.0289$, respectively). However, during breath holding MCAV did not significantly correlate with HOMA-IR ($r = -0.3406$, $p = 0.0799$) while the CVC was significantly correlated ($r = -0.3746$, $p= 0.0291$). In conclusion, hypercapneic stimulus given to assess the cerebrovascular reactivity causes substantial increase in the blood pressure. The increase in blood pressure can affect the MCAV during the tests and therefore it is better to measure CVC rather than MCAV to correct for blood pressure rise during these tests. The degree of impairment of CVR is associated with severity of Insulin resistance in uncomplicated type 2 diabetes mellitus.

Rice bran proteins inhibit effects of angiotensin and oxidative stress in murine macrophage cells

V. Kukongviriyapan[1], K. Boonloh[1], P. Pannangpetch[1], B. Kongyingyoes[1], U. Kukongviriyapan[2] and S. Thawornchinsombut[3]

[1]Department of Pharmacology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand, [2]Department of Physiology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand and [3]Department of Food Technology, Faculty of Technology, Khon Kaen University, Khon Kaen, Thailand

Rice bran contains a number of compounds which have shown to present beneficial effects on cardiovascular system. The renin-angiotensin system is suggested to play roles in insulin resistance and cardiovascular diseases. Rice bran products have been reported to ameliorate type 2 diabetes. The protein fraction from rice bran is a rich source of valuable nutrition, however, there is only few reports on its effects on angiotensin system. Rice protein hydrolysates (RBP) were prepared from defatted Hom-Mali rice cultivated in the North-East region of Thailand with controlled enzymatic hydrolysis. Murine macrophage RAW 264.7 cells were cultured in DMEM media supplemented with 10% fetal bovine serum. Exposure of RAW 264.7 cells to angiotensin-I (ANG-I) and ANG-II resulted in stimulation of superoxide formation, as detected by lucigenin-enhanced chemiluminescent assay. RBP (20-400ug/mL) concentration-dependently suppressed the oxidant formation. The suppression effect may be in part due to the inhibition of angiotensin converting enzyme (ACE) activity, as shown by an

in vitro assay using rabbit ACE and specific substrate. Thus, RBP possesses ACE inhibiting activity and Since ANG may participate in inflammatory processes in diabetes and metabolic syndrome, nitric oxide formation was measured as a marker of induction of iNOS. Rice bran protein hydrolysates (100-800 ug/mL) showed to suppress ANG-I and ANG-II-induced nitric oxide generation. This study suggests that rice bran protein hydrolysates could suppress angiotensin-mediated oxidative stress and may provide beneficial effect as food supplement in diseases with oxidative stress conditions.

Non-genomic effect of 17 β estradiol in the endothelial domination role via nitric oxide in the aorta of guinea pig: study in HUVECs culture and bioassay

R. Ratnawati[1], M.A. Widodo[2] and N. Permatasari[2]

[1]Physiology, Brawijaya University, Malang, Jawa Timur, Indonesia and [2]Pharmacology, Brawijaya University, Malang, Jawa Timur, Indonesia

Background: There were some non-linier doses, low usefulness and disadvantages resulted from epidemiological studies using Estrogen Replacement therapy as prevention or active treatment in coronary Vascular Diseases. In vitro studies also showed that the increase of the dose of Estrogen used it was not increase the diameter of the vessels. Therefore the aim of this study was to elucidate the effect of 17 β Estradiol induce NO (nitric oxide) in endothelial dysfunction of HUVEC (human umbilical vein endothelial cell) culture, and also its effect in the denuded and intact aorta of guinea pig.
Method : This study used experimental design to observe the effect of 17 β Estradiol in vasodilatation aorta ring of female guinea pigs and the concentration of NO released from normal and dysfunction endothelial of HUVECs culture. Endothelial dysfunction was done by exposed high glucose (33mM) to HUVECs culture. The study used non genomic (8 minutes) and genomic (30, 60, 120 and 240 minutes) effect of 17 β Estradiol (10-8M). To observe the vasodilatation and the concentration of NO, bioassay technique was used.
Results: The results showed that there was an increase of NO release from HUVEC culture exposed to high glucose when incubated by 17 β Estradiol (10-8M), but this increase of NO never reached the normal value. In the intact aorta was approved that 17 β Estradiol (10-8M) was more higher the ability of relaxation compare to the denuded aorta.
Conclusion: it is concluded that non genomic effect of 17 β Estradiol (10-8M) shows the domination of endothelial role to increase the activation of NO regard to the vasodilatation effect.

This study was funded partly by Hibah Pasca (Ministry of the National Higher Education of Indonesia).

Layer-specific dilation of cortical arteries during stimulation of the nucleus basalis of Meynert in mice

H. Hotta[1], K. Masamoto[2,3], S. Uchida[1], Y. Sekiguchi[4], H. Takuwa[2], H. Kawaguchi[2], K. Shigemoto[5], R. Sudo[4], K. Tanishita[4], H. Ito[2] and I. Kanno[2]

[1]Department of Autonomic Neuroscience, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, [2]Molecular Imaging Center, National Institute of Radiological Sciences, Chiba, Japan, [3]Center for Frontier Science and Engineering, University of Electro-Communications, Tokyo, Japan, [4]School of Integrated Design Engineering, Keio University, Yokohama, Japan and [5]Department of Geriatric Medicine, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan

The majority of cholinergic fibers in the cerebral cortex originate in basal forebrain nuclei. Fiber terminals from basal forebrain cholinergic areas have intimate contact not only with cortical neurons, but also with cortical parenchymal blood vessels, such as penetrating arteries and microvessels (1). Stimulation of basal forebrain cholinergic nuclei such as nucleus basalis of Meynert (NBM) produces an increase in cortical parenchymal blood flow, by activating muscarinic and nicotinic cholinergic receptors (2,3). An increase in cortical blood flow during NBM stimulation is uncoupled from cortical glucose metabolism, indicating that cholinergic projection from NBM is important for vascular control in the cerebral cortex (2). However, measurements of vascular responses are limited (4). Therefore, we examined whether cortical parenchymal arteries dilate during NBM stimulation using two-photon microscopy. Imaging of cortical vasculature was performed in adult male mice (22 - 38 g, n=7) anesthetized with urethane (1.1 g/kg, i.p.) and artificially ventilated (3). The diameter of single penetrating arteries at different depths (~750 μm, layers I-V) of the frontal cortex was measured (5) and examined changes in the diameter during focal electrical stimulation of the NBM (0.5 ms at 30-50 μA and 50 Hz) (3) and hypercapnia (3% CO_2 inhalation). Values are means ± S.E.M., compared by ANOVA. At the resting condition, the diameters of 8 penetrating arteries measured ranged 10 - 28 μm over the cortical depths. The artery showed only a marginal increase in diameter at the cortical surface following stimulation of the NBM in accordance with the previous report (2). In contrast, the artery at a depth of 50 μm from the surface showed an obvious increase in diameter during stimulation of the NBM: the diameter of 15.6 ± 1.6 μm before stimulation increased to 17.6 ± 1.7 μm during NBM stimulation. A significant increase ($p<0.05$) in arterial diameter by 9 - 13% was observed throughout the different layers of the cortex, except at upper part of layer V, where the diameter of penetrating arteries increased only slightly during NBM stimulation. Hypercapnia caused obvious dilation of the penetrating arteries in all cortical layers, including the surface arteries. The diameters began to increase within 1 sec after the onset of NBM stimulation in the upper cortical layer, and later in lower layers. Our results indicate that activation of the NBM dilates cortical penetrating arteries in a layer specific manner in magnitude and latency, presumably related to the density of cholinergic nerve terminals from the NBM.

PCD313

Vasorelaxant mechanism of 3, 5, 7, 3', 4'-pentamethoxyflavone on isolated thoracic aorta of female rats

C. Jansakul

Physiology, Prince of Songkla University, Hat-Yai, Songkhla, Thailand

One major flavone isolated from the rhizomes of Kaempferia parviflora, is 3, 5, 7, 3', 4'-pentamethoxyflavone (PMF). Extracts from this rhizome have been used in Thai traditional medicine for many purposes including improvement of blood circulation. However there has been no scientific evidence to support this therapeutic claim. The present study aimed to establish if PMF had any effect on blood vessels and if it did what was its mode of action. Studies were performed in vitro on isolated rat thoracic aorta obtained from female rats (220-260g) after being killed by decapitation with a guillotine, and placed in oxygenated Krebs Heinseleit solution at 37oC (PSU-Ethic No. 22/52). Cumulative concentration-response (C-R) curves were recorded by a Grass Polygraph. Data are expressed as a mean ± S.E.M. (6 rats/group/each experiments) with significant differences ($p \leq 0.05$) between tests and control identified using the Student's paired t-test. PMF (0.5-50 μM) caused a concentration dependent dilatation of thoracic aortic rings preconstricted with 3 μM phenylephrine. NG-nitro-L-arginine (LNA, 300 μM), a nitric oxide synthase inhibitor, or removal of the endothelium caused a significant parallel shift of the PMF induced C-R curve to the right. In the endothelium-intact thoracic aortic ring, ODQ (soluble guanylate cyclase inhibitor, 10 μM) significantly caused a rightward shift of the PMF C-R curve. Glybenclamide (10 μM) potentiated the PMF C-R curve on the thoracic aorta that was endothelium independent. Tetraethylammonium (1 mM) had no effect on the PMF C-R curves. In normal Krebs solution with LNA and nifedipine, or in Ca2+-free Krebs solution with LNA, PMF produced a further inhibition of the Phe C-R curve on the thoracic aortic ring. With thoracic aortic rings treated with LNA and thapsigargin, PMF suppressed the C-R curve produced by Phe and a further suppression was found when nifedipine (3 μM) was also added. No further suppression was achieved with a sequential addition of SKF-96365 (100 μM). However, when Y-27632 (Rho-kinase inhibitor, 30 μM) was also added into the above incubation medium cocktail, a complete suppression of the Phe C-R curve on the thoracic aortic ring was obtained. These results indicated that PMF produced an endothelium independent dilatation of the thoracic aortic ring. The mechanism responsible for this effect would be that PMF inhibited intracellular Ca2+ mobilization, stimulated the soluble guanylate cyclase and also the release of the nitric oxide from the vascular endothelium. It is unlikely that PMF caused an opening of the Ca2+- or ATP sensitive K+ channels, neither as an L-type Ca2+ channel or store-operative Ca2+ channel blockers. These results partly support the claims that extracts from rhizomes of the K. parviflora would improve blood circulation in men.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD314

Mineral imbalance and loss of contractile phenotype induce vascular smooth muscle cell calcification by promoting exosome secretion

A.N. Kapustin[1], I. Drozdov[1], D. Soong[1], M. Furmanik[1], D. Alvarez-Hernandez[1], P. Sanchis[1], R. Molls[1], R. Shroff[1], X. Yin[1], J. Skepper[2], M. Mayr[1] and C.M. Shanahan[1]

[1]Cardiology, King's College London, London, UK and [2]Anatomy, Cambridge University, Cambridge, UK

Vascular calcification is a tightly-regulated pathological process that is triggered by multiple factors ranging from extracellular mineral imbalance to pro-inflammatory cytokines and orchestrated by the osteogenic phenotypic transition of vascular smooth muscle cells (VSMCs). VSMCs secrete matrix vesicles (MVs), loaded with the calcification inhibitor fetuin-A, into the extracellular matrix and these serve as a nidus for calcification. Here we studied the mechanisms of MV secretion by VSMCs.

Fetuin-A is internalized by VSMCs and delivered to late endosomes/multivesicular bodies and secreted in MVs via the exosomal pathway. Biochemical analysis showed that MVs originate from multivesicular bodies and are enriched with exosomal markers including CD9, CD63 and Tsg101. Proteomic analysis showed that VSMC exosomes partially share proteomic composition with exosomes secreted by other cells and are enriched with proteins involved in the regulation of cell adhesion and migration. Furthermore, fetuin-A secretion and VSMC MV secretion were blocked by GW4869, an inhibitor of sphingomyelin phosphodiesterase 3 (SMPD3) which regulates exosome biogenesis.

Treatment of VSMCs in the presence of elevated extracellular calcium resulted in a significant increase in exosome secretion and this was associated with the upregulation of SMPD3 expression. Inhibition of SMPD3 prevented VSMC calcification indicating that exosome secretion is required for the initiation of VSMC calcification. Next we examined how the phenotypic transition influences exosome secretion and VSMC calcification. Heparin and TGF-β treatment markedly reduced VSMC proliferation and induced expression of VSMC contractile markers, calponin and α-smooth muscle actin. In contrast, treatment with the pro-inflammatory cytokine TNF-α induced VSMC proliferation accompanied by a reduction in contractile phenotype markers. Comparing exosome secretion revealed a significant increase in exosome secretion in the presence of TNF-α and reduced exosome production by the heparin or TGF-β treated VSMCs.

Finally, in agreement with our in vitro data, EM analysis of longitudinal sections of VSMCs in human vessel rings ex vivo revealed MVB-like structures in VSMCs. Immunohistochemical staining of normal and atherosclerotic human aortic and carotid artery samples showed no presence of exosomal marker CD63 in the normal vessel wall. However, extensive CD63 staining was observed in the atherosclerotic vasculature particularly in association with calcified VSMCs.

In conclusion, we found that fetuin-A is recycled via exosomal pathway and VSMC exosome secretion is regulated by SMPD3. Modulation of exosome secretion by mineral imbalance and phenotypic transition as well as loading with fetuin-A are novel regulatory pathways for VSMC calcification.

Prevention of macrophage-induced adhesion molecules production and endothelial permeability in SEVC endothelial cells by Sporopollenin

M. Shih[1], S. Liou[1], L. Chen[1], S. Chen[1], S. Luo[1], I. Chen[2] and L. Chen[3]

[1]Pharmacy, Chia-Nan University of Pharmacy & Science, Tainan, Taiwan, [2]Pharamcy, Taipei city Hospital, Taipei, Taiwan and [3]Health, Taipei City Government, Food and Drug Division, Taipei, Taiwan

The inflammatory response in large vessels involves the up-regulation of key vascular adhesion molecules, such as inter-cellular adhesion molecule (ICAM)-1 and vascular cell adhesion molecule (VCAM)-1, by pro-inflammatory cytokines in the development of atherosclerosis. Chlorella has been shown to possess strong anti-inflammatory effect and to suppress high fat diet-induced atherosclerosis. The aim of this study is to investigate the possible preventing role of Sporopollenin derived from Chlorella against pro-inflammatory cytokine-induced expression of vascular adhesion molecules and endothelial permeability. Endothelial SVEC cells were treated with conditioned media (normal culture media contains 50% of LPS-activated macrophage culture media, in which contained IL-6, TNF-α and MCP-1, with and without Sporopollenin (0.5 and 1 mg/mL). Indomethacin (0.25 mM) was used as a positive control. Productions and mRNA expression of ICAM-1 and VCAM-1 and endothelial permeability were monitored. ICAM-1 and VCAM-1 production and gene expression were all induced by the conditioned media. In the concentration ranges that were devoid of cytotoxicty, the inductions of ICAM-1 and VCAM-1 production and mRNA expression by conditioned media were significantly suppressed by Sporopollenin. Indomethacin was only effectively in preventing the conditioned culture media-induced VCAM-1 production. Cell permeability was also increased in the presence of conditioned culture media. The increased permeability was also inhibited by Sporopollenin but not by indomethacin. These data indicate that Sporopollenin can be a potential material in preventing chronic inflammatory-related vascular diseases.

PCD316

Semaphorin 4D recruits pericytes and regulates vascular permeability through endothelial production of PDGF-B and ANGPTL4

H. Zhou and J.R. Basile

Oncology and Diagnostic Sciences, University of Maryland Dental School, Baltimore, MD, USA

Semaphorin 4D (SEMA4D) acts through its receptor Plexin-B1 to regulate axon growth cone guidance, lymphocyte activation, and bone density (Hota & Buck, 2012). It is also overexpressed by some malignancies and plays a role in tumor-induced angiogenesis, similar to vascular endothelial growth factor (VEGF) (Basile et al, 2006). We previously noted that inhibition of VEGF and SEMA4D both restricted tumor vascularity and size, but vessels forming under conditions of VEGF blockade retained association with pericytes while those arising under SEMA4D deficiency did not (Zhou et al, 2012). These findings suggested a novel approach to anti-angiogenic therapy for certain solid tumors, as tumor vessels with pericyte sheaths often exhibit resistance to anti-VEGF therapeutic intervention (Erber et al, 2004). Here we utilize ELISA-based arrays to demonstrate an approximately 2.5-fold increase in production of platelet-derived growth factor-B (PDGF-B), which attracts pericytes to endothelial cells, and angiopoietin-like 4 (ANGPTL4), a protein upregulated in some tumors that induces vascular permeability and metastasis, in human umbilical vein endothelial cells (HUVECs) incubated with SEMA4D but not VEGF (Fig. 1). Confirmation of these results by immunoblot and RT-PCR using the Rho-signaling inhibitor C3 demonstrates that this effect occurs in a Plexin-B1/ RhoA-dependent manner. Upregulation of PDGF-B from HUVECs by soluble SEMA4D leads to differentiation of C3H/10T1/2 mesenchymal stem cells into pericytes (as determined by increased RGS5 expression in an immunoblot), as well as their proliferation, migration, and co-association with HUVEC, while ANGPTL-4 enhanced permeability of a HUVEC monolayer in vivo. Pericyte effects are unlikely to be caused by SEMA4D directly, as an immunoblot analysis of the pericyte cell line hPC-PL does not demonstrate expression of Plexin-B1. We also show that malignancies may use this mechanism to regulate tumor-induced angiogenesis. SEMA4D shed from the head and neck squamous cell carcinoma line HN12 elicits similar responses, not through autocrine or paracrine production of PDGF-B and ANGPTL4 but instead by causing robust upregulation of these proteins in HUVEC, which immunofluorescence analysis shows affects association of endothelial cells with pericytes in the stroma of tumors derived from HN12 grafted subcutaneously into the flanks of athymic Foxn1nu (nude) mice. Taken together, these data show that SEMA4D-mediated induction of PDGF-B and ANGPTL4 from HUVECs influences vessel stability and permeability, possibly in developing malignancies, and suggest that targeting SEMA4D along with VEGF represents a novel anti-angiogenic therapeutic strategy for the treatment of solid tumors.

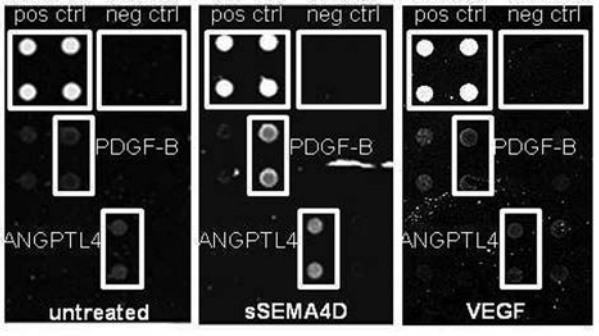

Fig. 1: An angiogenesis array reveals upregulation of PDGF-B and ANGPTL4 in HUVECs treated with

purified soluble SEMA4D, a response not observed for VEGF.

Exposure to low level of arsenic and lead in drinking water alter cardiovascular parameters and reduces vasomotion in rat aorta

J. Palacios[1], J. Vega[2] and F. Cifuentes[2]

[1]Departamento de Ciencias Químicas y Farmacéuticas, Facultad de Ciencias de la Salud, Universidad Arturo Prat, Iquique, Chile and [2]Experimental Physiology Laboratory (EPhyL), Instituto de Antofagasta, Universidad de Antofagasta, Antofagasta, Chile

The purpose of this study was to compare vascular and cardiovascular response in rats exposed to low levels of heavy metals in drinking water. Treated group was Sprague-Dawley rats exposed to drinking water from Antofagasta city, with total arsenic of 30 ppb and lead of 53 ppb for 4 months, control group was exposed to purified water by reverse osmosis. All groups drank tap water from the time of weaning. In each vascular reactivity experiment, we studied 4 to 8 adjacent aortic rings from the same animal, using the method for isometric tension measurements (Palacios et al., 2006). Animals were sacrificed by cervical dislocation. Treated group presented arsenic and lead in the hair of rats. QT interval corrected for heart rate is a sensitive biomarker for heavy metals toxicity. QT interval increased significantly in treated group compared to the control group. Treated group showed a significantly increase in systolic blood pressure, heart rate, cardiac output, and decreased the peripheral resistance, compared to the control group. Rhythmical contractions known as vasomotion occur in small resistance and larger vessels, as the aorta. This phenomenon is commonly described under pathological conditions than in physiological conditions. We hypothesize that vasomotion may contribute, in part, to regulate blood flow (Funk et al., 1983). The incubation of aortic rings with 10-7 M acetylcholine following 10-6 M phenylephrine reduced rhythmical contractions in treated group (13±3 mg maximum amplitude; $P<0.001$) compared to control group (41±6 mg maximum amplitude). However, the incubation of aortic rings with 10-8 M sodium nitroprusside (a nitric oxide donor; SNP) following 10-6 M phenylephrine increased rhythmical contractions in treated group (55±11 mg maximum amplitude; $P<0.05$) compared to control group (25±3 mg maximum amplitude). No significant differences in the relaxation properties of ACh were observed in aortic rings from treated and control groups; in both groups, the vascular relaxation was completed. Whereas, the relaxation response to SNP in treated group (121±6% of relaxation PE-induced contraction; SNP 10-7M; $P<0.05$) increased versus control group (99±6% of relaxation PE-induced contraction). In conclusion, these data suggest that exposure to low levels of arsenic and lead in drinking water could reduce rhythmical contractions in blood vessels and alter the cardiovascular parameters.

PCD319

Tight junction in hyaloid vessels could be induced by interaction between pericytes and endothelial cells

J. Kim[1], D. Jo[1], C. Cho[2] and J. Kim[1]

[1]Ophthalmology, Seoul National University Hospital, Seoul, Republic of Korea and [2]Pharmacology, Seoul National University, Seoul, Republic of Korea

The hyaloid vessel is a transient vascular network that nourishes the lens and the primary vitreous in the early developmental periods. In hyaloid vessels of developing C57BL6/J mouse eye devoid of the support of astrocytes, we demonstrate that tight junction proteins, zonula occludens-1 and occludin, are regularly expressed at the junction of endothelial cells. To figure out the factor influencing the formation of tight junctions in hyaloid vessels, we further progress to investigate the interactions between endothelial cells and pericytes, two representative constituent cells in hyaloid vessels. Interestingly, endothelial cells interact with pericytes in the early postnatal periods and the interaction between two cell types provokes the upregulation of TGF-β1. Further in vitro experiments demonstrate that TGF-β1 induces the activation of Smad2 and Smad3 and the formation of tight junction proteins. Taken together, in hyaloid vessels, pericytes seem to regulate the formation of tight junctions by the interaction with endothelial cells even without the support of astrocytes. Additionally, we suggest that the hyaloid vessel be a valuable system that can be utilized for the investigation of roles of cell-cell interaction in the formation of tight junctions in developing vasculatures.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD320

Blood-retinal barrier breakdown of diabetic retinopathy could be attenuated by blockade of protein kinase C ζ signaling pathway

J. Kim, H. Jun and J. Kim

Ophthalmology, Seoul National University Hospital, Seoul, Republic of Korea

Vision loss in diabetic retinopathy is due to macular edema characterized by increased vascular permeability, which involves phosphorylation associated with activation of protein kinase C (PKC) isoforms. In this study, we demonstrated blockade of PKC ζ could prevent blood-retinal barrier breakdown in diabetic retinopathy. Using streptozotocin-induced diabetic mice and vascular endothelial growth factor (VEGF)-treated human retinal microvascular endothelial cells (HRMECs), effect of PKC ζ inhibition on vascular permeability and tight junction protein expression was investigated through western blotting, RT-PCR, fluorescein angiography and immunohistochemistry. Increased vascular permeability of diabetic retina is accompanied by a decrease of zonula occludens (ZO)-1 and ZO-2 expression. In diabetic retina and VEGF-treated human retinal microvascular endothelial cells, vascular leakage and loss of ZO-1 and ZO-2 on retinal vessels were effectively restored or prevented with treatment of PKC ζ inhibitor, transfection of siRNA for PKC ζ. PKC ζ activation is involved in vascular permeability in response to diabetes, and inhibition of PKC ζ effectively restores loss of tight junction proteins in retinal vessels. Therefore, we suggest that inhibition of PKC ζ could be an alternative treatment to blood-retinal barrier breakdown in diabetic retinopathy

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD321

Inhibitory effect of the antidepressant paroxetine on human *ether-a-go-go*-related gene (hERG) K^+ current

H. Hong, S. Jo and M. Park

Department of Physiology, School of Medicine, Kangwon National University, Chuncheon, Gangwon-do, Republic of Korea

Paroxetine is a selective serotonin reuptake inhibitor (SSRI) for psychiatric disorders that can induce QT prolongation, which may lead to torsades de pointes. We studied the effects of paroxetine on human *ether-a-go-go*-related gene (hERG) channels expressed in Xenopus oocytes and on action potential in guinea pig ventricular myocytes. The hERG encodes the pore-forming subunits of the rapidly-activating delayed rectifier K^+ channel (I_{Kr}) in the heart. Mutations in hERG reduce I_{Kr} and cause type 2 long QT syndrome (LQT2), a disorder that predisposes individuals to life-threatening arrhythmias. Paroxetine induced concentration-dependent decreases in the current amplitude at the end of the voltage steps and hERG tail currents. The inhibition was concentration-dependent and time-dependent, but voltage-independent during each voltage pulse. The S6 domain mutation Y652A did not affect the drug-induced hERG current block. In guinea-pig ventricular myocytes held at 36°C, treatment with 0.4 μM paroxetine for 5 min decreased the action potential duration at 90% of repolarization (APD_{90}) by 4.3%. Our results suggest that paroxetine is a blocker of the hERG channels, providing a molecular mechanism for the arrhythmogenic side effects during the clinical administration of paroxetine.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD322

Direct inhibition of hERG K^+ channel by classic histamine H_1 receptor antagonist hydroxyzine

B. Lee, S. Jo and M. Park

Department of Physiology, School of Medicine, Kangwon National University, Chuncheon, Gangwon-do, Republic of Korea

Hydroxyzine is a potent first-generation histamine H_1 receptor antagonist that can increase action potential duration and induce QT prolongation in several animal models. Since block of cardiac human *ether-a-go-go*-related gene *(hERG)* channels is one of leading causes of acquired long QT syndrome, we investigated the acute effects of hydroxyzine on hERG channels to determine the electrophysiological basis for its proarrhythmic potential. We examined the effects of hydroxyzine on the hERG channels expressed in *Xenopus* oocytes using two-microelectrode voltage-clamp techniques. Hydroxyzine induced a concentration-dependent decrease of the current amplitude at the end of the voltage steps and hERG tail currents. The IC_{50} of hydroxyzine-dependent hERG block in *Xenopus* oocytes increased progressively relative to the degree of depolarization. Hydroxyzine affected the channels in the activated and inactivated states but not in the closed states. The S6 domain mutation Y652A attenuated the hERG current block. The IC_{50} value of hydroxyzine-dependent hERG block increased from 5.9 μM to 35.1 μM by the mutation from tyrosine to alanine at 652 amino acid of the channel. These results suggest that the H_1 antihistamine, hydroxyzine is a blocker of the hERG channels, providing a molecular mechanism for the drug-induced arrhythmogenic side effects.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD323

Prelamin A accelerates vascular calcification via activation of the DNA damage response and senescence associated secretory phenotype in vascular smooth muscle cells

Y. Liu[1], I. Drozdov[1,2], R. Shroff[3], L.E. Beltran[1] and C.M. Shanahan[1]

[1]Cardiovascular Division, King's College London, London, UK, [2]Centre for Bioinformatics, King's College London, London, UK and [3]Nephrology Unit, Great Ormond Street Hospital and UCL Institute of Child Health, London, UK

Vascular calcification is prevalent in the ageing population yet little is known of the mechanisms driving age-associated vascular smooth muscle cell (VSMC) phenotypic change. Recent evidence has implicated nuclear lamina dysfunction, especially the accumulation of premature forms of lamin A, in promot-

ing premature cellular ageing, as typified in the premature ageing disorder Hutchison-Gilford Progeria Syndrome.[1, 2] Our previous data showed that Prelamin A, the unprocessed form of the nuclear lamina protein lamin A, accumulates in aged and atherosclerotic arteries and, acts as a specific hallmark of VSMC ageing, within the general population.[3] In the current study we investigated whether prelamin A accumulation plays a role in driving VSMC osteogenic differentiation.
We found that prelamin A accumulated in cacifying VSMCs both in vitro and in vivo and that overexpression of prelamin A in vitro promoted VSMC osteogenic differentiation and mineralization. During VSMC ageing in vitro prelamin A accumulation occurred concomitantly with increased p16 expression and osteogenic differentiation and was associated with increased levels of DNA damage. Microarray analysis showed that DNA damage repair pathways were significantly impaired in VSMCs expressing prelamin A and chemical inhibition or siRNA depletion of the DNA damage response (DDR) kinases ATM/ATR effectively blocked VSMC osteogenic differentiation and mineralization. In co-culture experiments, prelamin A expressing VSMCs induced alkaline phosphatase (ALP) activity in mesenchymal progenitor cells and this was abrogated by inhibition of ATM signalling suggesting DNA damage induces the secretion of pro-osteogenic factors by VSMCs. Cytokine array analysis identified a number of ATM-dependent senescence associated secretory phenotype (SASP) factors/cytokines released by prelamin A positive VSMCs including the calcification regulators BMP2, OPG and IL6, and these data were validated by quantitative PCR and ELISA.
This study demonstrates that prelamin A promotes premature VSMC calcification and ageing, in part, by inducing persistent DNA damage signalling which acts upstream of VSMC osteogenic differentiation and the SASP. Agents that target the DDR and/or prelamin A toxicity may be potential therapies for the treatment of vascular calcification.

Blockade of the renin-angiotensin system improves cerebral microcirculatory perfusion in diabetic hypertensive rats

V. Estato[1], N. Obadia[1], F. Freitas[1], M. Lessa[1], P. Reis[2], H. Castro-Faria-Neto[2], J. Carvalho-Tavares[3] and E. Tibiriçá[1]

[1]Laboratory of Cardiovascular Investigation, Oswaldo Cruz Foundation-FIOCRUZ, Rio de Janeiro, RJ, Brazil, [2]Laboratory of Immunopharmacology, Oswaldo Cruz Foundation-FIOCRUZ, Rio de Janeiro, RJ, Brazil and [3]Núcleo de Neurociências, Departamento de Fisiologia e Biofísica, UFMG, Belo Horizonte, MG, Brazil

Motivation: Hypertension often precedes the diagnosis of type 2 diabetes. It occurs twice as frequently in diabetic patients than in non-diabetic individuals, and aggravates the complications of diabetes. The high susceptibility of individuals with hypertension and diabetes to stroke depends on the sensitivity of the cerebral vasculature to increased blood pressure. It also depends on the occurrence of brain disorders such as capillary rarefaction and astrogliosis of the cerebral cortex caused by associated chronic diseases. Methods: We examined the functional and structural microcirculatory alterations in the brain, skeletal muscle and myocardium of non-diabetic spontaneously hypertensive rats (SHR) and diabetic SHR (D-SHR), as well as the effects of long-term treatment with the angiotensin AT1-receptor antagonist olmesartan (D-SHR OLM) and the angiotensin-converting enzyme inhibitor enalapril (D-SHR ENA). Diabetes was induced by a combination of a high-fat diet with a single low dose of streptozotocin (35 mg/kg, ip). D-SHR were orally administered with olmesartan (5 mg/kg/day), enalapril (10 mg/kg/day) or vehicle for 28 days, and compared with vehicle-treated non-diabetic SHR (SHR VEH) or normotensive non-diabetic Wistar–Kyoto rats (WKY VEH). The cerebral and skeletal muscle functional capillary density of pentobarbital-anesthetized rats was assessed using intravital fluorescence videomicroscopy. All experimental procedures were conducted in accordance with the Care and Use of Laboratory Animals and were approved by the FIOCRUZ Animal Welfare Committee (# LW-10/12). Chronic treatment with OLM or ENA significantly lowered blood pressure and reversed brain functional capillary rarefaction (D-SHR OLM 187 ± 10 or D-SHR ENA 220 ± 38 capillaries/mm2 vs. D-SHR VEH 94 ± 9 capillaries/mm2; $p<0.05$). Brain oxidative stress was reduced to non-diabetic control levels in animals treated with OLM or ENA. OLM or ENA treatments were able to significantly reduce the number of rolling leukocytes in (D-SHR OLM 5.9 ± 0.1 cells/min; $p<0.05$ or D-SHR ENA 4.1 ± 0.7 cells/min; $p<0.05$), when compared with the control D-SHR VEH group (10.6 ± 1.8 cells/min). Histochemical analysis showed that both OLM and ENA increased the capillary-to-fiber ratio in skeletal muscle (D-SHR OLM 2.1 ± 0.1 or D-SHR ENA 2.1 ± 0.1 vs. D-SHR VEH 1.5 ± 0.1; $p<0.001$) and in the left ventricle (D-SHR OLM 0.23 ± 0.01 or D-SHR ENA 0.30 ± 0.02 Vv[cap]/Vv[fib] ratio vs. D-SHR VEH 0.09 ± 0.01 Vv[cap]/Vv[fib] ratio; $p<0.001$). OLM or ENA also prevented collagen deposition and the increase in cardiomyocyte diameter in the left ventricle. Our results suggest that the association between hypertension and diabetes results in microvascular alterations in the brain, skeletal muscle and myocardium that can be prevented by chronic blockade of the renin-angiotensin system. PCD325

Vascular reactivity and membrane potential in survivor and non-survivor rats with peritonitis-induced septic shock

S. Chen[1], C. Shih[3], C. Tsao[2] and C. Wu[3]

[1]Nursing, Kang-Ning Junior College of Medical Care and Management, Taipei, Taiwan, [2]Anaesthesiology, Taipei Veterans General Hospital, Taipei, Taiwan and [3]Pharmacology, National Defence Medical Centre, Taipei, Taiwan

Vascular hyporeactivity and hyperpolarization are important causes of circulatory failure in septic shock. However, there is no data regarding the differences of vascular reactivity and resting membrane potential in survivors and non-survivors of sepsis. Thus, the aim of this study was to examine and compare the changes of vascular reactivity and resting membrane potential in survivor and non-survivor rats after cecal ligation and puncture (CLP)-induced sepsis. Wistar rats were anaesthetised by sodium pentobarbital (30 mg/kg, i.p.), and then, subjected to CLP or sham operation after the carotid artery and vein were cannulated. The changes of hemodynamics, biochemical variables, aortic isometric tension, smooth muscle membrane potential, and aortic superoxide levels were monitored during the experimental period. The CLP surgery caused circulatory failure, multiple organ dysfunction syndrome (MODS), vascular hyporeactivity to norepinephrine (NE), and vascular hyperpolarization. Compared with survivors, non-survivor rats showed a more severe organ dysfunction and a less increase in aortic superoxide levels at 9 h. In addition, non-survivor rats manifested less decreases in vascular reactivity to NE and resting membrane potential in the aortas when compared with those in the survivors. These results demonstrate significant differences of vascular reactivity and resting membrane potential in survivor and non-survivor rats after CLP-induced sepsis. However, vascular hyporeactivity and hyperpolarization only partially contributed to the early death of septic animals, while this early death was most likely due to organ dysfunction (i.e. MODS) in this CLP-induced sepsis model.

PCD326

Molecular profile of fibrosis and elastogenesis in the vein wall of human leg varicose veins. An immunohistochemical and morphometrical study

J. Regadera[1], J.P. Velasco-Martin[1], M. Rubio[2], G. España-Caparros[2], P. Prachaney[3], P. Rodriguez-Rodriguez[4], L.M. Reparaz[5] and S.M. Arribas[4]

[1]Departament of Anatomy, Histology and Neuroscience, University Automa Madrid, Madrid, Madrid, Spain, [2]Vascular Surgery Unit, Moncloa Universitary Hospital, Madrid, Madrid, Spain, [3]Anatomy Department, Khon Kaen University, Khon Kaen, Thailand, [4]Physiology Department, University Automa Madrid, Madrid, Spain and [5]Angiology and Vascular Surgery Department, University Hospital Gregorio Marañon, Madrid, Spain

Pathological changes of chronic venous insufficiency is a common disease that appears in 20% of the world population. It is characterized by intimal and medial fibrosis of venous wall. Our aim was to link the correlation between Doppler sonography data and the degree of intimal and medial lesions in varicose saphenous veins at different locations.

Saphenous veins from ten patients were evaluated by Doppler sonography and inmunohistochemestry. Collagen I, III and IV, smooth muscular actin, laminin and vimentin were studied from normal to pathological vein lesions. Collagen fibers distribution and extracellular matrix were also studied by Red Sirius Stain. Elastogenesis was studied by confocal microscopy and orcein stain. The evaluation of each molecule was explored using almost two slides per case. Quantification of these molecules and structures were made by Image J software.

In initial lesions of varicose vein, intimal layer double their size compared to normal wall vein. Present a progressive increase of collagen I, III and IV, is also associated to an increase of extracellular matrix and myofibroblast (vimentin+ and SMA+) proliferation. At severe intimal varicose lesions, lumen of vein decreased, and Doppler sonography blood flow was lower. In this field we observed thickness in intimal wall, corresponding to significatilly increase of SMA+ cells and collagen I, III and IV deposition.

The morphometric data showed that SMA+ area at intimal layer is correlated negatively to intimal thickness. In addition, quantification of elastic fibers at intimal varicose veins is significantly high compared to normal vein. Correlation between elastics fibers area and intimal high were negative. In the intima, a deposition of elastic fibers, which were shorter and disorganized was observed. The vascular medial layer shows atrophy of smooth muscular cells and presence of fibrous tissue. The intimal and medial fibrotic changes were not related to mast cell or immunocompetent cells proliferation.

These data suggest a progressive transformation from normal to pathological varicose vein. In the eco Doppler sonography area reflux of varicose veins, we found a well established intimal and medial lesions characterized by deposition of collagen I, III and IV and extracellular matrix. These lesions are an irreversible fibrotic process in patients with leg chronic venous insufficiency.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD327

Large-scale analysis and characterisation of the cardiac microvascular endothelial proteome

H. Strijdom[1], A. Genis[1], S. Van Rensburg[1] and S. Smit[2]

[1]Division of Medical Physiology, University of Stellenbosch, Tygerberg, Western Cape, South Africa and [2]Proteomics Unit, Central Analytical Facility, University of Stellenbosch, Tygerberg, Western Cape, South Africa

Vascular endothelial cells show considerable diversity, particularly when located within a specific organ such as the heart [1]. Myocardial capillaries, lined by cardiac microvascular endothelial cells (CMECs), are critical in the development of end-organ damage [2], and show adaptations in view of their close association with cardiomyocytes, whose function they tightly regulate [3]. Little is known about the total protein expression patterns in CMECs. The aim of the study was to perform a comprehensive large-scale proteomic analysis of adult rat CMECs under normoxic, baseline and hypoxic conditions in order to gain more information on their functional properties. Methods: Adult rat (Rattus norvegicus) CMECs were purchased and passaged until generation 4-7. CMECs were incubated under normoxia (21% O_2), or hypoxia (<1% O_2) for 24h. Samples were then subjected to SDS-PAGE/in-gel trypsinisation or filter-aided sample preparation (FASP) before separation of peptides by nano-LC chromatography and analysis by a LTQ Orbitrap Velos mass spectrometer. Proteins were identified with 4 different protein database search engines. Finally, protein lists were analysed for functional and pathway annotations.Results: A total of 1388 proteins were identified. The majority of proteins were expressed in the cytosol (28.3% of the proteome; $p=1.1 \times 10^{-63}$), followed by mitochondrial (22.4%; $p=1.1 \times 10^{-27}$), cytoskeletal (15.4%; $p=3.5 \times 10^{-15}$), and vesicular (11.5%; $p=2.3 \times 10^{-14}$) proteins. The top 5 biological processes represented in the CMEC proteome were: protein localisation (9.8%; $p=1.5 \times 10^{-10}$), oxidation reduction (9.6%; $p=2.7 \times 10^{-11}$), protein transport (8.8%; $p=4.9 \times 10^{-11}$), translation (8.4%; $p=2.4 \times 10^{-14}$), and vesicle-mediated transport (7.7%;$p=2.1 \times 10^{-11}$). The hypoxia protocol induced demonstrable injury (1.5-fold and 2.2-fold increase in necrosis and apoptosis respectively; $p<0.05$). 267 new proteins were expressed, whereas 32 proteins were lost in hypoxia. Five out of the 10 upregulated proteins in hypoxia were glycolytic enzymes. The cytosolic protein fraction increased to 47% of the hypoxic CMEC proteome, whereas mitochondrial proteins decreased to 16%. There was a significant presence of ribonucleoproteins (26.3%; $p= 7.8 \times 10^{-23}$), and translation (24.5%) and glycolysis (6%) were more prominent vs normoxia.Apoptotic and hypoxia response proteins were overexpressed in hypoxia (9% and 4.8% respectively).Conclusions: This is the first comprehensive characterisation of the CMEC proteome under normoxic and hypoxic conditions. Normoxic CMECs demonstrated significant mitochondrial protein expression, which decreased after hypoxia. Conversely, glycolytic proteins increased in hypoxia suggesting a metabolic switch in the cells. Vesicular and protein transport proteins were prominently expressed in the CMECs, indicative of the capillary-derived origin of the cells.

Cilostazol inhibits leukocyte-endothelial cell interaction in murine microvessels after transient bilateral common carotid artery occlusion

T. Fukuoka, T. Hayashi, H. Maruyama, H. Sano, M. Hirayama and N. Tanahashi

Saitama Medical University International Medical Center, Hidaka, Japan

Leukocyte behavior in the cerebral microvasculature following vessel occlusion has not been fully elucidated. The purpose of this study was to investigate the effects of cilostazol on leukocyte behavior (rolling and adhesion) in murine cerebral microvessels following transient bilateral carotid artery occlusion using intravital fluorescence microscopy. Three groups of mice were assigned: sham group(n=8), ischemia reperfusion(I/R) group(n=6), I/R+cilostazol (CZ) group (ischemia reperfusion after cilostazol administered orally 30 mg/kg) (n=8). Ischemia was induced of 15 min of bilateral common carotid artery (CCA) occlusion using microvascular clips. Leukocyte labeled with 0.05%acridine orange were intravenously administered and their behavior was investigated at 3 and 6 h, through a parietal lesion window made just after the ischemic period. The number of rolling or adhering leukocyte was expressed per square millimeter per 30 seconds. Numbers of rolling and adhesion leukocyte at 3 or 6 h after reperfusion in I/R group were significantly increased compared to sham group and numbers of rolling and adhesion leukocyte in the CZ group were significantly inhibited at 3 or 6 h after reperfusion compared to the I/R group in pial veins ($P<0.05$) and in pial arteries ($P<0.05$). Cilostazol inhibited leukocyte-endothelial interactions following cerebral ischemia and reperfusion.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD329

Low Akt activity, decreased VEGFR-2 expression and bcl-2 suppression are associated with regressing vascular tumors in mice

P. Mabeta[1] and M.S. Pepper[2]

[1]Anatomy and Physiology, University of Pretoria, Pretoria, South Africa and [2]Immunology, University of Pretoria, Pretoria, South Africa

Angiogenesis, the process of new blood vessel formation, is a central mechanism underlying the development of hemangiomas.1,2 Hemangiomas are benign neoplasms of the vasculature frequently encountered in children. 1,2 Growth factors which mediate angiogenesis such as vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (bFGF) have been implicated in the pathogenesis of hemangiomas.3 Recently we reported on the antiangiogenic effects of bleomycin in vitro in cultured human hemangioma biopsies.4 In the present study we investigated the antiangiogenic effects of bleomycin (0.6–1.2 mg/kg) in vivo in a hemangioma mouse model using C57BL6 female mice. Tumors were induced by

injecting mice on the flanks with endothelioma cells. Tumor growth was monitored every second day up to 15 days post treatment. Mice were anaesthetised using 3% Isoflurane. Tissue samples were stained with hematoxylin and eosin for light microscopy, and processed for immunohistochemistry and immunofluorescent microscopy evaluation. Blood samples were collected by cardiac puncture for the measurement of VEGF using ELISA. Analysis of tumor volumes revealed a significant reduction in tumor growth in mice treated with Bleomycin when compared with those treated with buffered saline (n = 5 per group; $p<0.05$). Low levels of the angiogenic factor VEGF were measured in samples of mice treated with bleomycin. Histological evaluation revealed a reduced microvessel density (MVD) in tumors from bleomycin-treated mice compared to those treated with saline. No tumor growth was observed in baseline mice (the group that was not injected with endothelioma cells). Tumor growth inhibition was associated with the suppression of Flk-1, bcl-2 and Akt activity. Our observations reveal a possible mechanism for the inhibitory effects of bleomycin on hemangiomagenesis, and raise the possibility that the suppression of bcl-2 in particular may provide a therapeutic target for the treatment of vascular tumors of infancy.

PCD330

cAMP signalling in endothelial cells: Differential effects on angiogenesis via PKA and Epac signalling

M. Aslam[2,1], S. Rohrbach[1], R. Schulz[1], C. Hamm[2] and D. Guenduez[2]

[1]Institute of Physiology, Justus Liebig University, Giessen, Germany and [2]Cardiology and Angiology, Justus Liebig University, Giessen, UK

Background: cAMP signalling regulates several endothelial functions such as endothelial barrier integrity, nitric oxide (NO) production, and proliferation and migration in response to growth factors. cAMP mediates these effects via activation of its two well known effector proteins i.e. PKA and Epac (exchange protein directly activated by cAMP). The signalling pathways activated by PKA and Epac might be overlapping, non-overlapping, or even antagonistic. The aim of the present study was to analyse the differential signalling response of PKA and Epac on endothelial barrier, cell migration and differentiation.
Methods: The study was carried out on cultured human umbilical vein endothelial cells (HUVEC). cAMP analogues, 8-CPT-cAMP, 6-Bnz-cAMP and Forskolin (FSK) were used to activate Epac, PKA or adenylyl cyclase, respectively. Endothelial cell proliferation, migration, and sprouting were quantified by crystal violet staining, wound healing assay, and tube formation and spheroid sprouting assay, respectively. Endothelial barrier function was analysed by measuring the flux of trypan blue-labeled albumin.
Results: Specific activation of either PKA or Epac induced barrier protective response in HUVEC monolayers which was additive when both PKA and Epac were activated together. Activation of both Epac and PKA caused Akt phosphorylation at S473 which was antagonised by inhibitors of alpha and beta but not by gamma and delta isoforms of PI3K. Both Epac and PKA induced ERK phosphorylation accompanied by increased cell proliferation and migration which was abrogated by inhibition of MAPK pathway. Activation of PKA induced endothelial cell sprouting and tube formation and enhanced VEGF-mediated effect. Contrarily, activation of Epac antagonised VEGF-mediated sprouting and tube formation. Moreover, Epac activator-treated endothelial cells tend to establish monolayer on matrigels rather than forming network like structures.
Conclusion: The data of present study shows that endothelial cell functions are differentially regulated by PKA and Epac signalling. Both PKA and Epac activation stabilize endothelial barrier function, however, both have opposite effects on angiogenesis. PKA activation promotes angiogenesis while Epac activation antagonises angiogenesis.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD331

The AMP-activated protein kinase (AMPK) decreases endothelial angiotensin converting enzyme (ACE) expression by phosphorylation of p53 and post-transscriptional upregulation of microRNA (miR)-143/145

K. Kohlstedt[1], C. Trouvain[1], T. Boettger[2], B. Fisslthaler[1], L. Shi[1] and I. Fleming[1]

[1]Goethe-University, Institute for Vascular Signalling, Frankfurt am Main, Germany and [2]Dept. Cardiac Development and Remodelling, Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany

High ACE levels are a risk factor for cardiovascular disease, but little is known about the molecular mechanisms regulating ACE expression in endothelial cells. Here, we determined the role of the AMPK and the miR-143/145-cluster, since they regulate ACE expression in other cell types and are activated/upregulated in response to shear stress.
Shear stress time-dependently decreased ACE expression in human endothelial cells, an effect sensitive to silencing (siRNA) of the catalytic AMPK α2 (but not the α1) subunit. The AMPK activators, AICAR and metformin also decreased ACE expression in cultured endothelial cells and endothelial cells from AMPKα2-/- (but not AMPKα1-/-) mice expressed significantly higher ACE levels. Consequently, AMPKα2-/- mice were more sensitive to the hypotensive effect of the ACE-inhibitor ramipril and demonstrated an impaired bradykinin-induced hindlimb vasodilatation. The latter response was restored by ramiprilat and was also evident in endothelial cell specific AMPKα2 knockout mice. In miR-143/145-deficient LacZ reporter gene mice, ACE was identified as target of the miR-143/145 cluster in vascular smooth muscle cells. We confirmed the suppressive effect of miR-143/145 on ACE-expression in isolated endothelial cells from these mice as well as in human endothelial cells by overexpressing miR-143/145. AMPKα2 deletion (in vitro and in vivo) decreased miR-143/145 levels and overexpression of pre-miR-143/145 decreased endothelial ACE expression. Because shear

stress increased levels of premature and mature miR-143/145, without affecting the primary transcript or miR-143/145 promoter activity, it seems that AMPKα2 regulates miR expression via a post-transcriptional rather than transcriptional mechanism. Since p53 is an AMPK target, regulates miRs at the transcriptional and post-transcriptional levels and shear-stress elicited the AMPKα2-mediated phophorylation of p53 (Ser15), we focused on validating AMPK-p53 effect on miR expression. Suppression of p53 (siRNA) decreased miR-143/145 levels, increased endothelial ACE expression and prevented its shear stress-induced downregulation. Streptozotocin-induced diabetes increased the phosphorylation of the AMPK substrates, p53 and acetyl-coenzyme A carboxylase, at the same time as increasing miR-143/145 and decreasing ACE levels.
In conclusion, the activation of AMPKα2 suppresses endothelial ACE expression via p53 activation and post-transcriptional upregulation of miR-143/145. Since dysregulation of AMPK as well as p53 plays a major role in the development of several diseases (e.g. diabetes, cancer), their effect on the regulation of miR-143/145 and thus ACE levels might explain the development of disease-associated cardiovascular disorders.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Tetrahydrocurcumin ameliorates vascular dysfunction and aortic remodeling in nitric oxide-deficient rats

U. Kukongviriyapan[1], O. Boonla[1], S. Nakmareong[2], P. Pakdeechote[1], V. Kukongviriyapan[3], P. Pannangpetch[3], P. Surawattanawan[4] and S.E. Greenwald[5]

[1]Department of Physiology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand, [2]Faculty of Associated Medical Sciences, Khon Kaen University, Khon Kaen, Thailand, [3]Department of Pharmacology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand, [4]Research and Development Institute, Government Pharmaceutical Organization, Bangkok, Thailand and [5]Barts & The London School of Medicine & Dentistry, Queen Mary University of London, London, UK

Nitric oxide (NO) depletion induces hypertension, oxidative stress and arterial stiffness. Previous study has shown that tetrahydrocurcumin (THU), a major antioxidant and anti-inflammatory agent, improved aortic stiffening of rats with NO-deficiency, however, the associated mechanism remains unclear. The objective of this study was to determine whether THU could attenuate vascular dysfunction and aortic remodeling in NO-deficient rats. The procedures and experimental protocols were reviewed and approved by the Institutional Animal Ethics Committee of Khon Kaen University, Thailand. Male Sprague-Dawley rats weighing 200-220 g were divided into normotensive and hypertensive groups (n=6-8/group). Hypertension was induced by administering Nω-nitro-L-arginine methyl ester (L-NAME) at a dose of 50 mg/kg/day in their drinking water for 5 weeks. After 3 weeks, hypertension had been established and was sustained in all animals. During the last two weeks, L-NAME hypertensive rats were randomly divided into three treatment groups. Group 1 was intragastrically administered with polyethylene glycol (PG), a vehicle. Group 2 and 3 were intragastrically administered with THC for 2 weeks at doses of 50 and 100 mg/kg/day, respectively. The normotensive controls were received tap water ad libitum and intragastrically administered with PG. At the end of treatment, animals were anesthetized with pentobarbital sodium (60 mg/kg body weight, i.p.), arterial blood pressure and vascular response to acetylcholine (3, 10 and 30 nmol/kg, i.v.) were determined. Thereafter, rats were sacrificed by overdose of an anesthetic drug. The thoracic aortas were excised and used for quantitative morphometric analysis of structural changes and immunohistochemistry staining of MMP-2. Values are means ± S.E.M., compared by one way ANOVA. L-NAME significantly increased blood pressure, blunted vascular response and induced aortic remodeling. THU 50 and 100 mg/kg/day significantly decreased mean arterial pressure (174 ± 2 and 165 ± 2 mmHg, respectively vs. 189 ± 2 mmHg in L-NAME control rats; $P < 0.01$), and prevented the reduction in endothelium-dependent vasodilatation. THU reduced the increases in media thickness, cross-sectional area, smooth muscle cells proliferation and collagen accumulation in the aortic wall. Increased MMP-2 expression was found in the aortas of L-NAME, and THU at test doses significantly reduced it ($P < 0.05$). Our results suggest that MMP-2 plays a role in L-NAME hypertension and its structural and functional vascular changes, which were attenuated by THU.

This study was supported by grants from the Faculty of Medicine, Khon Kaen University, the Thailand Research Fund (Grant No. DBG5380045) and the British Council PMI2 Grant (#RC53).

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD333

Nitric Oxide-cGMP signalling induces β-Catenin nuclear translocation and transcriptional activity

C. Warboys[1], N. Chen[1,2], Q. Zhang[1], Y. Shaifta[3], J. Ward[3] and A. Ferro[1]

[1]Cardiovascular Division, King's College London, London, UK, [2]Institute of Vascular Medicine, Peking University Third Hospital, Beijing, China and [3]Division of Allergy, Asthma and Lung Biology, King's College London, London, UK

Nitric oxide (NO) plays a key regulatory role in cardiovascular physiology due to its vasodilatory, anti-thrombotic and anti-atherogenic properties. In endothelial cells NO is synthesised by endothelial NO synthase (eNOS), which is known to associate with a number of other proteins. Our aim was to identify novel protein associations with eNOS in human umbilical vein endothelial cells (HUVEC) and to clarify the physiological role of such associations. Analysis of eNOS immunoprecipitated from lysates of HUVEC by mass spectrometry revealed a previously unrecognised association with β-catenin. This was confirmed by western blot analyses of eNOS and β-catenin immunoprecipitates, since each protein was detected in immunoprecipitates of the other (n=3). Nuclear translocation of β-catenin following eNOS activation was assessed by western blot of nuclear lysates. eNOS stimulation with adenosine, salbutamol, histamine or thrombin increased nuclear translocation of β-catenin compared to untreated controls (n=4), as did spermine NONOate or 8-bromo-cGMP (n=5). Transcriptional activity of β-catenin, a co-activator of T cell factor (TCF) / lymphoid enhancing factor (LEF) transcription factors, was assessed using a luciferase reporter assay in HUVEC transfected with TCF/LEF reporter plasmids. Spermine NONOate, 8-bromo-cGMP or sildenafil increased TCF/LEF-mediated luciferase activity relative to controls ($p<0.05$, $P<0.01$, $P<0.05$ respectively, n=6). The role of β-catenin in NO-cGMP

signalling was examined in mouse pulmonary endothelial cells (MPECs) using an *in vitro* angiogenesis assay. Stimulation of NO-cGMP signalling in wild-type (WT) MPECs using vascular endothelial growth factor (VEGF), spermine NONOate, 8-bromo-cGMP or sildenafil significantly increased tube length compared to untreated controls (respective means ± SEM 13922 ± 549, 15030 ± 605, 14445 ± 549, 14589 ± 796 *vs.* 11608 ± 971, P<0.05); these responses were not seen with MPECs lacking the β-catenin gene (β-cat$^{-/-}$) (10748 ± 473, 10424 ± 1105, 9326 ± 821, 10162 ± 1015 *vs.* 9908 ± 918). Both types of MPECs exhibited normal angiogenic responses to basic fibroblast growth factor which acts independently of NO-cGMP signalling (WT 9240 ± 518 *vs.* 7715 ± 101, P<0.05; β-cat$^{-/-}$ 10006 ± 250 *vs.* 8528 ± 83, P<0.01; n=4). Spermine NONOate, 8-bromo-cGMP or sildenafil also increased VEGF expression (which is known to be NO-dependent) relative to control in WT but not β-cat$^{-/-}$ MPECs, as determined by western blot of cell lysates (n=4). In summary, activation of the NO-cGMP pathway induces nuclear translocation of β-catenin and increased transcriptional activity, which may be facilitated by close approximation of β-catenin with eNOS in the resting state. Additionally, β-catenin plays a key role in NO-mediated angiogenesis and may be an important contributor to NO-mediated gene transcription and endothelial cell function.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD334

Cytochrome P450-epoxygenase metabolites play role in vasodilation of middle cerebral arteries in response to reduced pO2 in healthy and diabetic rats that underwent hyperbaric oxygenation

S. Unfirer[1], J.R. Falck[2] and I. Drenjancevic[1]

[1]Department of Physiology and Immunology, Faculty of Medicine Osijek, University of J.J. Strossmayer Osijek, Osijek, Croatia and [2]Department of Biochemistry, University of Texas Southwestern Medical Center, Dallas, TX, USA

Introduction: Vasodilation in response to hypoxia is mainly mediated by cyclooxygenase (COX) activation and production of prostacyclin (PGI2) (1). However, there are evidences that cytochrome P450-epoxygenase metabolites contribute to vasodilation in healthy vessels (2).
Materials and Methods: Hyperbaric oxygenation (HBO2) was performed in a chamber with 100% O2 (2 bar) 2 hours/day for 4 consecutive days. Male Sprague-Dawley rats (N= 5) were divided in 4 groups; control, diabetic (DM) (DM induced by streptozocin 60mg/kg i.p.), HBO2 treated DM rats (DM+HBO2) and HBO2-control rats. On the 5th day, prior to decapitation, rats were anesthetized with ketamin-chlorid (75 mg/kg) and midazolam (0.5 mg/kg). Isolated middle cerebral arteries (MCA) were mounted on glass pipettes of DMT 110P pressure myograph system for internal diameter measurements in normoxia (21% O2 in superfusate and perfusate), and reduced pO2 (0%) conditions. To assess the role of CYP450-epoxygenases' vasodilating metabolites (EETs), the CYP450 inhibitor –MS-PPOH (10-5M) was used. To assess the role of COX metabolites, indomethacin (INDO) (10-5M) was used. The data were analyzed with One-way ANOVA and presented as mean±SEM (microns); p<0.05 was considered statistically significant. The Ethical Committee of Faculty of Medicine University of Osijek approved the study.
Results: MCA of control rats exhibit significant vasodilation (23±3) compared to DM rats which failed to dilate in response to reduced pO2 (0±3). INDO or MS-PPOH did not affect this lack of response in DM rats. Vasodilation was restored in DM+HBO2 rats (14±2). In the presence of MS-PPOH, vasodilation to reduced pO2 was diminished in control group (11±1) and more inhibited in control + HBOT group (4±1), while vasodilation was eliminated in DM+HBO2 group (-6±2) and in DM group (-6±2). INDO eliminated dilation to reduced pO2 in control (-5±4) and DM (-2±6) groups but only partly reduced it in both HBO2 groups.
Conclusion: Partially preserved vasodilation in the presence of INDO in HBO2 groups, and eliminated vasodilation in response to reduced pO2 in the presence of MS-PPOH in both HBO2 groups suggest that HBO2 affects CYP450-epoxigenase in MCAs of healthy and DM rats and shifts vasodilatory mechanisms in response to reduced pO2 towards EETs mediated pathways.

Endothelial T-type channels (Cav3.1) are co-localized with eNOS and promote NO-formation and vasodilatation during depolarization in mesenteric resistance arteries

P.B. Hansen[1], P. Svenningsen[1], A.D. Thuesen[1], K. Andersen[1], H.S. Shin[2], B.L. Jensen[1] and O. Skott[1]

[1]Cardiovascular and Renal Research, University of Southern Denmark, Odense, Denmark and [2]Center for Neural Science, Korea Institute of Science and Technology, Seoul, Republic of Korea

Voltage-gated calcium channels are involved in the excitation-contraction mechanism of resistance vessels. However, T-type channels are also involved in relaxation of mesenteric, coronary and renal blood vessels. We investigated the mechanisms involved in the T-type channel-dependent dilatation. The secondary dilatation after potassium-induced contraction of isolated perfused mesenteric arteries was reduced significantly in Cav3.1-/- compared to Wt mice and use of eNOS -/- mice led to a significantly attenuated dilatation. Western blotting showed no difference in phosphorylated eNOS-pS1117 levels between wild type and Cav3.1-/- mice. Immunoprecipitation of Cav3.1 pulled down eNOS, and immunoprecipitation of eNOS pulled down Cav3.1 showing co-localization of Cav3.1 and eNOS. Confocal laser-scanning microscopy of mesenteric arteries labeled with antibodies against eNOS and Cav3.1 confirmed the co-localization of eNOS and Cav3.1 in endothelial cells, and showed that Cav3.1was also expressed in vascular smooth muscle cells. The basal cGMP levels in isolated aortae were not different between genotypes. We conclude that endothelial calcium-influx through Cav3.1 T-type calcium channels that are co-localized with eNOS, stimulates eNOS and NO production which, in turn, affects NO-dependent dilatation after depolarization in mesenteric resistance arteries. This

mechanism could be important for maintaining the systemic impact of NO on total peripheral resistance.

Properties and roles of tunneling nanotubes in vascular endothelial cells

L. McKeown[1,2] and D.J. Beech[1,2]

[1]School of Biomedical Sciences, University of Leeds, Leeds, UK and [2]Multidisciplinary Cardiovascular Research Centre, University of Leeds, Leeds, UK

Cell to cell communication plays a role in many physiological processes. A newly discovered route of communication is via Tunneling Nanotubes (TNTs) which are tubular projections that connect cells over long distances (1). TNTs have been shown to facilitate the rescue of stressed cells by allowing the transfer of cellular constituents such as organelles and Ca2+ signals (2). Using high resolution microscopy we have identified multiple types of F-actin containing intercellular connections in human umbilical vein endothelial cells. These can be classified into groups according to their diameter. Fine TNTs are less than 700nm wide. We find that the structures can permit the propagation of mechanically induced Ca2+ signals between cells over long distances (160 μm). In addition there are TNT-like structures that are similar to intercellular bridges observed in epithelial cells and which contain obvious actin bundles and have greater diameters. Staurosporine-induced TNTs were observed in situ in endothelial cells lining the murine aorta. It is concluded that TNTs exist between endothelial cells in intact blood vessels and that they can transfer Ca2+ signals from endothelial cell to endothelial cell over long distances. It is hypothesized that TNTs play important roles in endothelial repair

Hyperglycaemia downregulates TRPV4 channels in retinal endothelial cells

K. Monaghan, J.E. McNaughten, D. Kyle, C. Kelly, M.K. McGahon, R. Hamilton, N. Scholfield, G. McGeown and T.M. Curtis

Centre for Vision and Vascular Science, Queen's University Belfast, Belfast, UK

Presently, the molecular mechanisms underlying endothelial dysfunction in diabetes are not fully understood. TRPV4 channels have been shown to play an essential role in endothelial-dependent vasodilatation in various vascular beds. In the present study, we have characterised the molecular and functional expression of TRPV4 channels in bovine retinal endothelial cells (BRECs) following culture in both normal (5mM) and high glucose (25mM) conditions (72 h incubations). (Data are presented as mean±SEM). In cells cultured in normal glucose, the TRPV4 agonist, 4α-PDD (1μM) induced a rise in $[Ca^{2+}]i$ (fura-2 microfluorimetry) (0.2±0.03 R340/380, n=8) which could be blocked by the non-selective TRPV4 antagonist, ruthenium red (10μM) (0.06±0.01 R340/380, n=6) and siRNA-mediated knockdown of TRPV4 channel expression (0.01±0.002 R340/380, n=5). The 4α-PDD response was abolished in the absence of extracellular Ca^{2+} (0.001±0.00001 R340/380, n=6) and greatly reduced following Ca^{2+} store depletion using the SERCA pump inhibitor, CPA (20μM) (0.04±0.01 R340/380, n=6). This suggests that activation of TRPV4 channels in BRECs triggers both influx of extracellular Ca^{2+} and Ca^{2+} store release. We subsequently examined the effects of high glucose on TRPV4 mRNA expression in BRECs. TRPV4 transcripts as well as protein levels were appreciably lower in cells treated with high glucose. Following pre-incubation of BRECs with CPA, the Ca^{2+} influx component of the 4α-PDD response was attenuated in cells grown under high glucose conditions (0.02±0.005 R340/380, n=8). Experiments were also performed to examine TRPV4-mediated membrane currents using the whole-cell patch clamp technique. The TRPV4 specific agonist GSK1016790A (1μM) increased membrane current amplitude at -80mV (-5.14±3.17 to -12.55±5.09 pA/pF, n=6) and this was reversed by the TRPV4 antagonist HC-067047 (1μM) (-5.53±2.80 pA/pF, n=6). The effects of GSK1016790A were abolished after culturing cells in high glucose (-0.78±0.34 pA/pF before and -1.14±0.39 pA/pF after GSK1016790A; -0.99±0.34 pA/pF after HC-067047, n=8). Osmotic control experiments were undertaken using mannitol or L-glucose (20mM + 5mM D-glucose). The gene and protein expression and functional responses of TRPV4 channels were identical to those observed under normal glucose condition. These results show that the expression and function of TRPV4 channels is downregulated in retinal endothelial cells under hyperglycaemic conditions. Changes in TRPV4 expression may contribute to endothelial cell dysfunction during diabetes, an issue that warrants further investigation.

PCD342

Elevated expression levels of microRNA-143/145 drive aberrant smooth muscle cell phenotype and function in Type 2 diabetes – evidence of metabolic memory

K. Riches[1,4], N.A. Turner[1,4], D.J. O'Regan[2,4], I.C. Wood[3] and K.E. Porter[1,4]

[1]Division of Cardiovascular and Diabetes Research, University of Leeds, Leeds, UK, [2]The Yorkshire Heart Centre, Leeds General Infirmary, Leeds, UK, [3]Faculty of Biological Sciences, University of Leeds, Leeds, UK and [4]Multidisciplinary Cardiovascular Research Centre (MCRC), University of Leeds, Leeds, UK

Individuals with Type 2 diabetes mellitus (T2DM) are at increased risk of premature atherosclerosis and coronary heart disease, and suffer poorer outcomes following surgical intervention. Smooth muscle cells (SMC) within the vessel wall play key roles in adaptation to physiological and pathological stimuli through inherent plasticity that permits phenotypic switching between quiescent, contractile and active, synthetic states. MicroRNAs (miRs) are short, non-coding RNAs that negatively regulate gene expression in a variety of pathologies and whilst roles for miRs have been associated with development of

T2DM, their influence on macrovascular complications and specifically at the level of vessel wall SMC is unknown.
SMC were cultured from saphenous vein explants of non-diabetic (ND) patients and those with established T2DM. Cell morphology was analysed using phase contrast microscopy and ImageJ software. Cytoskeletal structure (F-actin) was examined using rhodamine phalloidin fluorescence microscopy and cell proliferation was determined by direct cell counting. Expression of miRs was quantified by TaqMan real-time RT-PCR assays. Over-expression and knock-down of miRs was achieved by transfection of premiRs and antimiRs respectively.
SMC from T2DM individuals were significantly larger than ND SMC (9181 ± 926 μm2 vs. 5621 ± 431 μm2, n=15, p<0.001) with a disorganised cytoskeleton and impaired proliferation (33% reduction, n=6, p<0.01). TaqMan assays revealed a specific 1.6-fold up-regulation of miR-143 and miR-145 in SMC from multiple T2DM patients relative to ND SMC (n=10, p<0.05). Over-expression of miR-143/145 in ND cells induced an increase in spread cell area (7641 ± 863 μm2 vs 5634 ± 319 μm2 in controls, n=4, p<0.001), truncated F-actin fibres and reduced proliferation rate (35% reduction, n=6, p<0.05), similar to that observed in native T2DM SMC. Conversely, antimiR-143/145 transfection in T2DM cells reversed the phenotype towards that of native ND SMC.
In summary, SMC from T2DM patients exhibit a distinct phenotype that exhibits features of both contractile and synthetic cells. Importantly, these characteristics are maintained throughout culture and passaging, suggestive of metabolic memory. Our data support the hypothesis that aberrant expression of miR-143/145 in vascular SMC confers a persistent "T2DM phenotype". The perceived detrimental effects of miR-143/145 may impact on the functional ability of SMC to remodel the vessel wall and contribute to vascular complications in patients with T2DM. Thus, miR-143/145 may be attractive targets for therapeutic intervention.

PCD343

Investigating a role for CGRP in the ageing cardiovascular system

R. King, S.J. Smillie and S. Brain

Cardiovascular Division, King's College London, London, UK

The sensory neuropeptide calcitonin gene-related peptide (CGRP) is a potent microvascular vasodilator (Brain et al. 1985). CGRP receptors are comprised of the seven transmembrane GPCR, the calcitonin-like receptor (CLR), a receptor activity-modifying protein 1 (RAMP1) molecule and an intracellular protein, known as the receptor component protein (RCP). Previous work in our laboratory has shown that genetic deletion of aCGRP in mice leads to increased susceptibility to elevated blood pressure and associated vascular remodeling in an Ang II model of hypertension. We now investigate the role of CGRP within the cardiovascular system of the ageing mouse.
Male and female aCGRP wild type (WT) and knockout (KO) mice were used, aged 15 months, and juveniles aged 3 months. Blood pressure measurements were taken via tail cuff (Kent Scientific) for one week following a one-week training protocol. Heart rate was determined by pulse oximetry (Kent Scientific). Mice were killed via induction of anaesthesia and subsequent cervical dislocation. We characterised potential gross organ pathology by measuring body weights and organ weights, including heart and kidney. Aortae were processed into paraffin blocks for histology (Masson's trichrome). Aortic mRNA expression of CGRP receptor constituents were analysed by RTqPCR. Raw data were normalized to reference genes and data were expressed as copies per microliter of sample. All data are expressed as mean ± SEM and data were interrogated by two-tailed unpaired t-test or one-way ANOVA, where appropriate. A level of $p < 0.05$ was deemed to be statistically significant.
Both WT and KO animals aged 15 months did not appear to display any gross organ pathology and did not differ with respect to cardiac or renal hypertrophy as determined by weight. Furthermore, we found no differences in baseline blood pressure in aged aCGRP WT and KO mice (mean arterial pressure 105.1 ± 4.1 and 104.9 ± 3.0 mm Hg, respectively, n=6). We also have shown a trend towards an increased mRNA expression of RAMP1 in KO mice (25.71 ± 21.59 vs 270.4 ± 183.9 copies/ul) and a significant increase in CLR mRNA in KO aortic tissue (1,775 ± 1,163 vs 6,732 ± 1,977 copies/ul, two tailed unpaired t-test, $P < 0.05$, n=4) was also observed. RCP expression appeared to be unchanged between groups (3,564 ± 1,404 vs 16,024 ± 10,188 copies/ul).
In conclusion, we provide new evidence showing that genetic deletion of aCGRP appears to have little effect on gross organ pathology as animals age to 15 months. Furthermore, we have shown that CGRP appears to have little role to play in the regulation of blood pressure both at baseline in juvenile animals and as age progresses. This minimal effect of CGRP deletion on haemodynamics occurs in spite of an apparent increase in CGRP receptor constituent gene expression.

Endocannabinoid-mediated CB1 receptor activation attenuates the vasoconstrictor effect of angiotensin II and other Ca2+-mobilizing GPCR agonists in skeletal muscle resistance vasculature

M. Szekeres[1], G.L. Nádasy[2], G. Turu[1], E. Soltész-Katona[1], E. Szabó[3], Z.E. Tóth[4], Z. Takáts[3] and L. Hunyady[1,5]

[1]Department of Physiology, Semmelweis University, Budapest, Hungary, [2]Institute of Human Physiology and Clinical Experimental Research, Semmelweis University, Budapest, Hungary, [3]1st Department of Pediatrics, Semmelweis University, Budapest, Hungary, [4]Neuromorphological and Neuroendocrine Research Laboratory, Hungarian Academy of Sciences, Budapest, Hungary and [5]Laboratory of Molecular Physiology, Hungarian Academy of Sciences, Budapest, Hungary

Calcium-mobilizing G protein-coupled receptor (GPCR) agonists, such as angiotensin II (AngII), endothelin and vasopressin induce vasoconstriction. Activation of AT1 angiotensin- and other Gq/11 protein-coupled receptors leads to diacylglycerol (DAG) formation, which can be converted to 2-arachidonoylglycerol (2-AG), an important endocannabinoid by the effect of DAG lipase (1,2). Cannabinoids via CB1 cannabinoid receptors (CB1R) have peripheral hypotensive and vasodilator

actions. We tested the hypothesis that 2-AG release can modulate the vasoconstrictor action of AngII and other calcium-mobilizing hormones in rodent vascular tissue.
Male Wistar rats (300-350g), C57BL6 and CB1R knockout mice (21-25g, 3) were anaesthetised with pentobarbital (50mg kg-1 ip.). Rat skeletal muscle (gracilis) arterioles and mouse saphenous arteries were isolated, pressurized and subjected to microangiometry. Also, rats (200-250g) were anaesthetised and aorta was removed for vascular smooth muscle cell (VSMC) isolation. Vascular expression of CB1R was demonstrated with immunohistochemistry. In accordance with the functional relevance of these receptors WIN55212, a CB1R agonist caused vasodilation, which was absent in CB1R knockout mice. In gracilis arterioles dose-dependent vasoconstrictions for AngII, norepinephrine (NE), endothelin, vasopressin and prostaglandin (PG)F2α were obtained. Inhibition of CB1Rs with neutral antagonist O2050 in gracilis arterioles augmented the vasoconstriction induced by AngII, NE, endothelin and vasopressin (from 29.1±5.8% to 47.5±3.2% and from 38.8±7.6% to 76.3±4.8%, effects of 10nM AngII and 1μM NE, respectively, $p<0.05$) but did not influence the contractile effect of PGF2α (45.6±9.9% and 36.9±9.8% at 1μM, n.s.). Inhibition of CB1Rs enhanced AngII-induced vasoconstrictor action in saphenous arteries of wild type, but not of CB1R knockout mice. Inhibition of DAG lipase by tetrahydrolipstatin (THL) also augmented the vasoconstrictor effect of AngII, suggesting the role of 2-AG in CB1R activation. In VSMCs AngII-stimulated 2-AG formation was inhibited by THL but potentiated by JZL184, an inhibitor of monoacylglycerol lipase, an enzyme catalyzing degradation of 2-AG. Inhibition of CB1R also increased the sustained phase of AngII-induced calcium signal and this effect was found to be independent of nitric oxide synthase activity and of endothelial function.
These data demonstrate that vasoconstrictor effects of calcium mobilizing GPCR agonists are physiologically attenuated by agonist-induced endocannabinoid release and consequent CB1R activation. It is proposed that this effect may serve as a beneficial control mechanism by moderating the microvascular tone in high contractile states.

TRPA1 mediates the cold-induced hemodynamic changes observed in the arthritic knee following exposure to low temperature

E.S. Fernandes[1,3], C. Sand[1], R. Salamon[1], J.V. Bodkin[1], A.A. Aubdool[1,2] and S.D. Brain[1,2]

[1]Vascular Biology Group - Cardiovascular Division, King's College London, London, UK, [2]Centre for Integrative Biomedicine - Cardiovascular Division, King's College London, London, UK and [3]Programa de de Pós-Graduação em Biologia Parasitária, Universidade Ceuma, Sao Luis, Brazil

Rheumatoid arthritis is a common disease, characterised by persistent synovitis, systemic inflammation and severe pain. A relationship between environmental cold exposure and increased pain in arthritic joints has been suggested (Smedslund and Hagen, 2011), although the underlying mechanisms are unknown. Changes in joint vascularization and the development of pain have been previously hypothesized to be linked in arthritis, with evidence of a correlation provided in osteoarthritis (Walsh et al., 2010; Ashraf et al., 2011). We have been studying the role of Transient Receptor Potential (TRP) channels in arthritis. We recently found by using a mono-arthritis model induced by a single injection of Complete Freund's Adjuvant (CFA; 10 ug/joint; 10 ul) in to the knee joint; that the TRP Ankyrin 1 (TRPA1), a suggested cold sensor, mediates CFA-induced secondary mechanical hyperalgesia (Fernandes et al., 2011). We have now investigated the contribution of TRPA1 activation for blood flow changes in the arthritic knee joint of mice exposed for 1h to environmental cold (10oC). We used male CD1 and TRPA1 wild-type (WT) and knockout (KO) mice (10-12 weeks of age). Blood flow was recorded by using full-field laser perfusion imager (FLPI) following cold exposure, 2 weeks after arthritis induction, in anaesthetised mice (mixture of ketamine (75 mg/kg) + medetomidine (1 mg/kg)). Briefly, after anaesthesia, the patellar ligament was carefully dissected off the knee joint to expose the synovial membrane. Changes in blood flow were then recorded for 30 min. Data obtained from the arthritic knee joint (ipsilateral knee; CFA-treated) was compared to the contralateral knee joint (saline-treated; 10 ul/joint). Naive joints were used as controls. Whilst cold exposure caused vasoconstriction in naive mice, a significant vasodilatation was observed in arthritic animals, with both saline- and CFA-treated joints exhibiting increased blood flow (1.5- and 2-fold increase, respectively). This response was not observed in mice treated systemically with the selective TRPA1 antagonist HC-030031 (100 mg/kg; 1h before blood flow recording; n=7). Similarly, vasodilatation was not present in the arthritic knee joints of TRPA1 KO mice (n=9) when compared to their WT controls (n=9). We suggest TRPA1 mediates hemodynamic changes in arthritic joints exposure to lower temperatures. This could be a potential and additional mechanism by which TRPA1 channels modulate arthritis progression and pain sensitivity.

PCD346

MicroRNA-26a regulates Ca^{2+} signalling via the IP_3 pathway in retinal endothelial cells

A. O'Connor, J. Guduric-Fuchs, D.A. Simpson and T.M. Curtis

Centre for Vision and Vascular Science, Queen's University Belfast, Belfast, UK

Primary bovine retinal microvascular endothelial cells (RMECs) are widely used for angiogenesis-based studies. Ca^{2+} signalling is a fundamental part of many cellular functions including the responses of RMECs to angiogenic stimuli and this relies upon appropriate regulation of gene expression. MicroRNAs (miRNA) are endogenous, non-coding RNAs which regulate mRNA expression at the post-transcriptional level. The ability of miRNAs to target multiple genes suggests that they can potentially modulate the expression of several genes in a specific pathway. We therefore investigated the possibility that miRNAs can regulate Ca^{2+} responses in RMECs by targeting genes of the IP_3- Ca^{2+} signalling pathway. Both mRNA and miRNA expression in RMECs was quantified by high throughput, next generation sequencing (NGS) on an Illumina Genome Analyzer. Predicted target genes of the miRNAs expressed in RMECs were downloaded from the miRNA prediction algorithm TargetScan (1) and were compared with those genes in the Ca^{2+} signalling pathway which were shown to be expressed in RMECs. MiRNA-26a (miR-26a) was selected for further analysis as it was found to be within the top 20 most highly expressed miRNAs in RMECs and it was predicted to target key genes of the IP_3- Ca^{2+} signalling pathway found to be expressed in these cells (IP_3 receptor type 1 (ITPR1) and phospholipase C beta 1 (PLCB1). Overexpression (oe) of miR-26a from a plasmid vector, pSM30 (2) or knockdown (kd) with an LNA inhibitor, followed by RT-PCR, Western blotting (WB) and luciferase assays confirmed ITPR1 as a target at the protein level (3.5 fold decrease upon miR-26a oe *vs.* scrambled oe control and a 2 fold increase in miR-26a kd *vs.* scrambled kd control for WB, n=5, $p<0.05$, Student's paired t-test). Uridine triphosphate (UTP) was found to induce a transient increase in RMEC $[Ca^{2+}]_i$ that was dependent on IP_3-Ca^{2+} signalling, as determined by the use of known IP_3 receptor inhibitors, xestospongin C (3) or 2-aminoethoxydiphenyl borate (2APB) (4) and fura-2 Ca^{2+} microfluorimetry. Overexpression of miR-26a decreased the elevation in $[Ca^{2+}]_i$ observed in response to UTP and knockdown of miR-26a increased the response (0.49±0.02 change in fura-2 340/380 nm ratio in scrambled oe control decreased to 0.13±0.02 upon miR-26a oe, and increased from 0.44±0.02 in scrambled kd control to 0.69±0.04 upon miR-26a kd. Mean data ± SEM, n=12, $p<0.001$, one-way ANOVA). Taken together, our results suggest that miR-26a, can modulate the Ca^{2+} responses of RMECs by targeting the IP_3-Ca^{2+} signalling pathway. Further studies are now warranted to determine the functional significance of miR-26a in both retinal microvascular endothelial cell physiology and pathophysiology.

The new NO-donor does not induce *in vitro* tolerance in rat aorta

T. Banin, L. Pernomian, R.S. da Silva and L.M. Bendhack

Physics and Chemistry, FCFRP/ USP, Ribeirão Preto, SP, Brazil

The nitrite anion (NO2-) can be the major source of intravascular and tissue storage of nitric oxide (NO), important modulator of vascular tone and blood pressure. The NO donor RUBPY synthesized by our group, releases NO inside the vascular smooth muscle cell in a tissue dependent manner. Long-term treatment with organic nitrates like nitroglycerin, leads to the development of tolerance characterized by the rapid loss of vasodilator effects. Tolerance is a multifactorial process. It may be due to endothelial dysfunction that involves increased production of vascular reactive oxygen species (ROS), decreased activity of soluble guanylyl-cyclase and increased phosphodiesterase expression and activity. This study aimed to investigate the *in vitro* tolerance to the pre-exposure of intact endothelium aorta (e+) or denuded aorta (e-) with RuBPY (EC100:10 μM). It was also evaluate if the compound releases NO in the endothelial cells in the incubation time studied. The aortic rings were isolated and used for the functional studies. Aortic rings (e+/e-) were contracted with phenylephrine, and after reaching a stable and maintained contraction, RuBPY (3 nM-5 μM) was added to the organ bath. Experiments were conducted after pre-exposure to RuBPY (tolerance) or in the absence of RuBPY (control). The maximum effect (ME) and potency (pD2) of RuBPY in inducing relaxation were evaluated. Endothelial cells were incubated with the fluorescent dye DAF-2/DA (10 μM) to quantifying the cytosolic NO and DHE (2.5 μM) to quantifying ROS. The intensity of fluorescence was detected in the absence or after exposure to RuBPY at different times (5-60min). This study was approved by the Ethical Animal Committee of the University of São Paulo (2012.1.134.53.12). The compound RuBPY induced concentration-dependent relaxation in e+ aortas (pD2:7.81±0.18; ME:101.6± 1.4%, n=7) and e- (pD2:7.54±0.13; ME:103.4±0.4%, n=6). The incubation with 10 μM RuBPY for 5 min followed by 20 min of washout did not affect the ME induced by the compound in e+ aorta (pD2:7.99±0.18; ME:98.5 ±1.6%, n=5) or in e- aortas (pD2:7.89±0.18, ME:100.0 ±0.4%, n=6). Pre-exposure for 10 min with RuBPY in e+ aortas did not alter the relaxation to RuBPY compared to respective control. However, in e- aortas the relaxing effect of RuBPY was potentiated (pD2:7.37±0.12, ME:101.5±1.0%, n=5, $P<0.05$). Pre-exposure for 30 min with RuBPY did not change the relaxation to RuBPY in e- aortas as compared to the control. RuBPY did not release NO and ROS in the endothelial cells up to 60 min incubation. Taking together, our results demonstrate that the new NO donor RuBPY does not induce tolerance in rat aorta, which is

probably due to the lack effect of RuBPY on the endothelial cells.

PCD348

The new nitric oxide donor (RuBPY) induces tolerance only after 60 minutes exposure and it does not induce cross-tolerance with acetylcholine

M. Paulo, M.D. Grando, J.A. Vercesi, R.S. da Silva and L.M. Bendhack

Physics and Chemistry, University of São Paulo, Ribeirão Preto, SP, Brazil

Nitric oxide (NO) donors like nitroglycerin (GTN) are widely used as pharmacological tool to understand the physiological effect of NO, and in the treatment of cardiovascular diseases. The major therapeutic limitation of GTN is the tolerance that is characterized by rapid loss of its effects in long-term administration, or cross-tolerance to other vasodilator, which cause(s) is still not clear. It is endothelium-dependent and the uncoupling endothelial NO-synthase (eNOS) could contribute to the tolerance. The major clinical benefit of organic nitrates, including the GTN has been attributed to their potent venodilator effect. This study aimed to verify if the new NO donor synthesized in our laboratory (RuBPY) induces in vitro tolerance and cross-tolerance to acetylcholine and sodium nitroprusside (SNP) in rat cava vein. We compared the effects of RuBPY with GTN in relation to the maximum effect (ME) and potency (pD2). In vitro tolerance was induced by incubation for 10, 30 or 60 min with RuBPY (2 μM or 10 μM) or GTN (4 μM or 0.1mM). In vitro cross-tolerance to acetylcholine and SNP was induced by the veins pre-incubation with RuBPY (2 μM) or GTN (4 μM) for 60 min. The eNOS phosphorylated in the activation site (Ser1177) and in the inactivation site (Thr495) was accessed by Western Blotting. The cytosolic concentration of NO ([NO]c) was measured by flow cytometry and confocal microscopy. Our results demonstrated that RuBPY induced greater relaxation (ME: 92.8 ± 4.4%; n=7, P<0.05) than GTN (ME: 75.3 ± 3.7%, n=6). Both NO donors increased [NO]c in vascular smooth muscle cells. Previous exposure for 10 min with RuBPY (2 μM or 10 μM) or GTN (4 μM or 0.1mM) did not induce tolerance. However, 30 min pre-exposure did not change the relaxation to RuBPY, but it reduced the relaxation to GTN (with 4 μM, ME: 45.4 ± 2.2%, n= 6, P<0.05, and 0.1 mM, ME: 39.2 ± 1.4%, n= 6, P<0.05). Pre-exposure for 60 min with RuBPY reduced the relaxation in the concentrations of 2 μM (ME: 48.0 ± 2.3%, n= 7, P<0.05) and to 10 μM (ME: 30.1±1.2%, n= 7, P<0.05). Pre-exposure to RuBPY or GTN did not reduce the relaxation to SNP. Cross-tolerance to acetylcholine was induced only with GTN. The ME stimulated with acetylcholine was reduced from100.3 ± 5.3% to 75.1 ± 4.2% (n=7, P<0.05). Whereas RuBPY and GTN had phosphorylated eNOS in Thr495, only GTN phosphorylated eNOS-Ser1177. In conclusion, our data demonstrate that RuBPy induces tolerance in both concentrations, only after 60 min exposure. It does not induce cross-tolerance to acetylcholine and SNP. It does not interfere with the activation site of eNOs.

PCD349

Effects of acute and long-term incubation with high D-glucose on mechanisms that induces nitric oxide and reactive oxygen species in human fetal endothelium

C. Valenzuela[1], P. Ávila[1], S. Rojas[1], R. Villalobos[1], C. Palma[1], V. Gallardo[1], L. Sobrevia[2] and M. González[1]

[1]Fisiologia, Universidad de Concepcion, Concepcion, Chile and [2]Obstetrics and Gynaecology, Medical Research Centre (CIM), Pontificia Universidad Catolica, Santiago, Chile

There is evidence that the endothelial dysfunction would be caused by an increase of reactive oxygen species (ROS) and reactive nitrogen species (RNS) induced by high extracellular concentrations of D-glucose (González et al., 2011). In human fetal endothelium, the synthesis of ROS is mediated by NADPH oxidase (Villalobos et al., 2012); meanwhile the synthesis of nitric oxide (NO) is mediated by the L-arginine uptake dependent of human cationic amino acid transporter 1 (hCAT-1)(Shin et al., 2011). Our aim is describe the mechanisms underlie the effects of high extracellular D-glucose on synthesis of NO and ROS in human umbilical vein endothelial cells (HUVEC). Biological samples were obtained from normal pregnancies (ethics committee approval and informed patient consent were obtained). HUVEC were isolated by collagenase digestion (37 celcius degree) and cultured in medium 199 (M199) supplemented with 20% newborn and fetal calf sera. HUVEC were incubated (0-30 min or 1-24 h) with M199 containing 5 mM (control) or 25 mM of D-glucose (high D-glucose) en absence or presence of apocynin (100 μM, NADPH oxidase inhibitor), N-ethylmaleimide (NEM, 200 μM, CAT inhibitor), L-NAME (200 μM, eNOS inhibitor) or insulin (1 nM, 8 h). After incubations, were determined L-arginine uptake (100 μM L-arginine, 2 μCi/mL L-[3H]arginine), NO and ROS synthesis using diaminofluorescein (DAF-2DA) and dichlorofluorescein (DCF), respectively, and hCAT-1 and NADPH oxidase expression by real time PCR and western blot. High D-glucose increased (ANOVA unpaired Student's t test, P<0.05, n=5-10) the L-arginine uptake after 10 (3±0.7-fold) and 30 (3±0.6-fold) min of incubation. These effects were blocked by pre-incubation with NEM and L-NAME. The acute incubation with high D-glucose not alter the ROS levels, but increased (P<0.05, n=3) the NO levels 2.1±04-fold and 2.8±0.6-fold after 10 and 30 min, respectively. Long term incubation with high D-glucose (24 h) increased (P<0.05, n=5-10) the L-arginine uptake (3±0.5-fold), ROS (1.8±0.1-fold) and NO (1.5±0.1-fold) levels. These effects of high D-glucose are related with increased (P<0.05, n=5-10) of mRNA (6±1-fold) and protein (2.7±0.2-fold) for hCAT-1 and mRNA for subunits of NADPH (1.5-fold). Insulin blocked the effects of high D-glucose on ROS, NO levels and hCAT-1 expression. In conclusion, the acute effect of high D-glucose is related with increases of L-arginine/NO pathway, without changes in ROS levels. Long term incubation with high D-glucose maintains the activation of this pathway but there is a concomitant activation of NADPH oxidase/ROS pathway. The endothelial dysfunction induced by high D-glucose could be prevented by insulin.

PCD350

Withdrawal of early age acute statin treatment alters RhoA pathway gene expression long term in rat mesenteric arteries

P.H. Keskivali[1], N.P. Curzen[1,2], G.F. Clough[1] and C. Torrens[1]

[1]Human Development and Health, Faculty of Medicine, University of Southampton, Southampton, Hampshire, UK and [2]Wessex Cardiothoracic Unit, Faculty of Medince, University of Southmapton, Saouthampton, Hampshire, UK

Maternal protein restriction (PR) in rats induces vascular dysfunction and though this can be ameliorated by chronic statin treatment, statin treatment and withdrawal in adolescent rats leads to a sustained increase in mesenteric artery constriction. In adult rats increase in constriction after statin withdrawal has been shown to be transient and RhoA pathway has been implicated as the mechanism. RhoA promotes constriction by activating Rho kinases (ROCK) which inhibit myosin light chain phosphatase. Statins inhibit RhoA activity but increase RhoA mRNA levels which remain elevated briefly after statin withdrawal contributing to increased RhoA activity. In this study the mRNA levels of RhoA pathway genes were investigated in the control and PR rat offspring mesenteric arteries where withdrawal of early age statin treatment lead to sustained increase in constriction.

Male and female Wistar rat offspring of dams fed 18 % protein (control) or 9 % protein restricted (PR) diet during pregnancy were given atorvastatin (10mg/kg) in drinking water from 3-5 weeks. This gave four experimental groups; control, no statin (CS: n=6 males, n=5 females), control, statin (CS: n=6 both), PR diet, no statin (PR: n=5 males, n=4 females) and PR diet, statin (PRS: n=5 both). At 16 weeks the animals were euthanised with CO2 inhalation and cervical dislocation. Segments of mesenteric arteries were frozen in liquid nitrogen. RNA extraction was carried out in Trizol and RNA was reverse transcribed into cDNA. Real time PCR was carried out with FAM/TAMRA primers and probes and gene expression was normalised against β-actin which was chosen as a stable housekeeping gene after geNorm analysis. mRNA levels of RhoA, ROCK 1 and ROCK 2 were investigated. The differences were assessed with two-way ANOVA. Results are presented as mean±SEM. Significance was accepted at $p<0.05$.

No significant differences were seen in mRNA levels of RhoA in the males ($p>0.05$) but in the females statin treatment increased RhoA mRNA expression irrespective of maternal diet (RhoA/b-actin: C 0.63±0.06; CS 0.86±0.10; PR 0.53±0.05; PRS 0.70±0.07; $p<0.05$ for statin effect; $p>0.05$ for maternal diet effect and interaction). Statin treatment increased ROCK 1 mRNA levels in the male offspring irrespective of maternal diet (ROCK1/β-actin: C 0.55±0.06; CS 0.93±0.11; PR 0.70±0.14; PRS 0.90±0.17; $p<0.05$ for statin effect; $p>0.05$ for maternal diet effect and interaction) but no significant differences were seen in the females ($p>0.05$). No significant differences were seen in the ROCK 2 mRNA levels in either males or females ($p>0.05$).

These data indicate that sustained upregulation of gene expression of RhoA pathway genes in the mesenteric arteries could contribute to the long term increase in constriction observed after withdrawal of early age statin treatment in C and PR offspring.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD351

Giα-coupled β2-adrenoceptor signaling mediates oxidative stress and the endothelial dysfunction induced by isoproterenol

A.C. Davel[1], P.C. Brum[2] and L.V. Rossoni[3]

[1]Structural and Functional Biology, State University of Campinas, Campinas, Campinas, Brazil, [2]School of Physical Education and Sport, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil and [3]Physiology and Biophysics, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil

Background and aim: We have demonstrated that overactivation of β-adrenoceptors induces oxidative stress and increases vasoconstrictor responses in rat aorta. This study focusing to investigate the β-adrenoceptor subtype as well the signaling pathway involved in these vascular effects.
Methods and results: Male, 3-mo-old mice lacking β1- or β2-adrenoceptors subtypes (β1KO, β2KO, N=12-16) and wild-type (WT, N=14) were daily treated with isoproterenol (ISO, 15 mg/kg/day, s.c.) or vehicle for 7 days. ISO treatment significantly ($p<0.05$, One-Way ANOVA) enhanced the vasoconstrictor response to phenylephrine (PHE) in aorta from WT and β1KO mice as compared to vehicle (34 and 35% of increase in Emax to PHE, respectively), but not in β2KO. Nitric oxide synthase inhibitor L-NAME (100 μM) increased Emax to PHE in aorta from all groups evaluated. This effect was lesser pronounced in aorta from ISO-treated WT and β1KO mice than vehicle-treated groups, but was similar between ISO-treated and non-treated β2KO mice. Incubation with superoxide dismutase (SOD, 150 U/mL) normalized increased Emax to PHE observed in aortic rings from ISO-treated WT and β1KO mice, but did not significantly change this response in ISO-treated β2KO mice. Immunoblotting experiments revealed increased expression of Giα protein (+50%) and of phosphorylated[Thr202/Tyr204]-ERK1/2 (+90%) in aorta from ISO-treated WT compared to vehicle WT. In addition, incubation with Gi inhibitor pertussis toxin (PTx, 4 μM) normalized the enhanced Emax to PHE observed in aortic rings from ISO-treated WT mice. ISO treatment enhanced fluorescence to hydroethidine (+100%) in aortas from WT, indicating oxidative stress that was significantly reduced by SOD and PTx. These effects of ISO were abolished in β2KO mice.
Conclusions: Giα protein coupled to β2-adrenoceptor plays a pivotal role in the oxidative stress and endothelial dysfunction induced by persistent β-adrenergic activation.

PCD352

Valve defects in *Foxc2*$^{+/-}$ mice predispose lymphatic vessels to pump failure

M.J. Davis[1], A. Sabine[2], T.V. Petrova[2], N. Miura[3] and J.P. Scallan[1]

[1]Department of Medical Pharmacology and Physiology, University of Missouri, Columbia, MO, USA, [2]Division of Experimental Oncology, University of Lausanne, Lausanne, Switzerland and [3]Hamamatsu University Medical School, Hamamatsu, Japan

Lymphedema distichiasis (LD) is a form of primary lymphedema associated with mutations in the *forkhead* transcription factor gene FOXC2. Homozygous loss of *Foxc2* in the mouse is associated with agenesis of secondary lymphatic valves as well as other cardiovascular and skeletal defects that contribute to lethality between E12.5 and P1. *Foxc2*$^{+/-}$ mice are characterized by distichiasis, reduced lymphatic drainage and lymph backflow, similar to patients with LD.

We previously demonstrated a novel type of lymphatic pump dysfunction, termed valve lock, which can be experimentally induced if healthy single lymphangions or chains of lymphangions are subjected to pressure conditions that mimic those associated with the development of edema in peripheral extremities. Valve lock is due in part to a normal property of intraluminal lymphatic valves in which valve closure becomes more difficult as the vessel becomes distended (i.e. the adverse pressure gradient required for closure rises 20 fold). As we also recently reported, tests of isolated valves from *Foxc2*$^{+/-}$ mice indicate that about 50% of the valves have elevated back-leak and appear to be abnormally stiff. Here we tested whether lymphatic vessels from *Foxc2*$^{+/-}$ mice exhibit pumping deficits as a result of these valve abnormalities.

Segments of collecting lymphatic vessels, each containing two valves, were isolated from the popliteal region of anesthetized adult C57Bl/6 (WT) or *Foxc2*$^{+/-}$ mice (Nembutal, 60 mg/kg, i.p.), cannulated at each end with a micropipette. Intraluminal pressure (P_L) was measured between the valves with a servo-null micropipette, while tracking vessel diameter and monitoring the leaflet position of the output valve using video methods. A servo controller held input pressure (P_{in}) at 1 cmH_2O while output pressure (P_{out}) was slowly elevated rampwise. The pumping limit (P_{limit}) was defined as the output pressure at which the output valve first failed to open. About half of the WT vessels simply failed to eject at high P_{out} (P_{limit} ~12 cmH_2O); in the other half, valve lock occurred before this point (P_{lock}). On average *Foxc2*$^{+/-}$ vessels exhibited lower values for P_{limit} compared to WT vessels (8.0±0.8 vs 13.9±0.2 cmH_2O, respectively) and lower values for P_{lock} (10.5±0.7 vs 15.9±0.1 cmH_2O, respectively) and a higher susceptibility to valve lock (68% vs 25%).

These new methods for studying mouse lymphatic vessels under defined conditions reveal that the abnormal valves in *Foxc2*$^{+/-}$ vessels render the collecting lymphatics more susceptible to pump failure. The same susceptibility may be characteristic of lymphatic vessels in human patients with LD and contribute to the peripheral edema from which those patients suffer.

PCD353

Vascular endothelial growth factor-C induces angiogenesis and lymphangiogenesis in the rat mesentery culture model

R.S. Sweat and W.L. Murfee

Biomedical Engineering, Tulane University, New Orleans, LA, USA

Lymphatic and blood microvascular systems are critical for tissue function and remodeling. New insights into the coordination of both systems can be gained by better investigating the relationships between lymphangiogenesis and angiogenesis in controlled environments. Recently, our laboratory has established that in the rat mesentery culture model lymphatic and blood microvascular networks remain intact and viable (Stapor et al., 2013). The objective of this study was to determine whether the rat mesentery culture model can be used to identify temporal relationships between lymphangiogenesis and angiogenesis induced by vascular endothelial growth factor-C (VEGF-C). Adult male Wistar rats (n=4) were anaesthetized by i.m. injection of ketamine (80 mg/kg) and xylazine (8 mg/kg) and then euthanized. Mesenteric tissue windows were aseptically harvested and cultured for 3 days or 5 days in either serum-free minimum essential media (MEM) or MEM supplemented with VEGF-C (100 ng/ml) (n=10-12 tissues per group). Tissues were immunolabeled for PECAM and LYVE-1 to identify blood and lymphatic endothelial cells, respectively. Tissues selected randomly from those containing vascular networks were quantified for angiogenesis and lymphangiogenesis (n=4-6 tissues per group). Values are means ± S.E.M. and were statistically compared using Student's *t*-tests. VEGF-C treatment resulted in a significant increase in the density of blood vessel sprouting compared to MEM controls by day 3 (22.2±1.8 vs. 13.8±1.6 sprouts/mm^2, $p<0.01$). By day 5, lymphatic sprouting was significantly increased along the hierarchy of intact lymphatic networks compared to MEM controls (7.2±0.6 vs. 4.0±0.4 sprouts/mm^2, $p<0.01$). These results are consistent with *in vivo* findings that lymphangiogenesis lags angiogenesis after chronic stimulation (Sweat et al., 2012; Baluk et al., 2005) and the results establish the rat mesentery culture model as a tool to investigate the interrelationships between lymphangiogenesis and angiogenesis *ex vivo* in a multisystem environment.

PCD354

Characterisation of cannabinoid-induced vasorelaxation in human mesenteric arteries

C.P. Stanley and S.E. O'Sullivan

University of nottingham, Derby, UK

In animal arteries cannabinoids induce vasorelaxation through mechanisms that are influenced by both the cannabinoid ligand, the artery used and species studied. In human arteries the potential vascular effects of cannabinoids have not been fully investigated. The aim of the present study was to investigate the effects of a range of cannabinoids in human mesen-

teric arteries. With ethical approval and written informed consent, human mesenteric arteries were taken from patients receiving colorectal surgery. Arteries were dissected from mesenteric tissue, mounted on a Mulvany-Halpern myograph and bathed in oxygenated physiological saline solution (PSS) at 37°C under a set tension of 90% of 100 mmHg. Arteries were contracted and concentration response curves were carried out to anandamide (AEA), 2-arachidonyl-glycerol (2-AG), Δ-9 tetrahydrocannabinol (THC), cannabidiol (CBD), CP55,940 and HU-308. In some experiments, cannabinoid mechanisms of action were probed pharmacologically. Cannabinoid maximum responses (Rmax) were derived using mean percentage vasorelaxation data that was fitted to sigmoidal slopes using GraphPad Prism software. Comparisons between Rmax values were made using 1-way ANOVA with Bonferroni post-hoc test. Comparisons between concentration response curves in the presence or absence of pharmacological inhibitors were made using 2-way ANOVA, $P<0.05$ was taken as significant. With the exception of HU-308, all cannabinoids caused significant vasorelaxation of human mesenteric arteries (Rmax: AEA≈30%, 2-AG≈40%, THC≈25%, CBD≈40%, CP55,940≈55%, n=12). CP55,940 was the most efficacious cannabinoid tested with a higher Rmax than AEA ($P<0.001$), 2-AG ($P<0.01$), THC ($P<0.001$) and CBD ($P<0.001$). 2-AG was the most efficacious endocannabinoid tested causing greater vasorelaxation than AEA ($P<0.05$). CBD was the most efficacious phytocannabinoid tested causing greater vasorelaxation than THC ($P<0.05$). 2-AG-induced vasorelaxation was inhibited by COX inhibition ($P<0.001$, n=8), prostanoid receptor antagonism (EP4 $P<0.01$, n=6 & IP $P<0.001$, n=9), in arteries that were contracted using high K+ PSS ($P<0.001$, n=8) and arteries that were bathed in Ca2+-free PSS ($P<0.01$, n=7). Experiments probing the action of CBD revealed that vasorelaxation was dependent on CB1 ($P<0.001$ n=8) and TRPV1 ($P<0.001$, n=7) receptor activation, nitric oxide production ($P<0.001$, n=6), the endothelium ($P<0.001$, n=8) and ion channel modulation ($P<0.001$, n=5). AEA-induced vasorelaxation was inhibited by CB1 receptor antagonism ($P<0.001$, n=7), endothelium removal ($P<0.01$, n=6), nitric oxide inhibition ($P<0.001$, n=6) and inhibition of a novel, as yet uncharacterised, endothelium bound cannabinoid receptor ($P<0.001$, n=6). This study shows that cannabinoids cause vasorelaxation in human mesenteric arteries and therefore suggests that the endocannabinoid system may modulate vascular tone humans.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD355

Microparticles in diabetes-associated microvascular dysfunction

P. He, C.J. Stork, D. Yuan and S. Xu

Physiology and Pharmacology, West Virginia University, School of Medicine, Morgantown, WV, USA

Microparticles (MPs) are small vesicles released from cell membrane following cell activation and apoptosis. Elevated levels of circulating MPs have been reported in many cardiovascular diseases and have been proposed as clinical markers for cardiovascular risk. Released MPs carry a range of antigens depending on the type and activation state of their parental cells. Therefore, it has been suggested that MPs may play important roles in the processes of inflammation and the progression of many cardiovascular diseases. Diabetes is commonly associated with microvascular dysfunction. Our recent study found that microvessels of streptozotocin-induced diabetic rats had increased basal permeability and markedly enhanced permeability responses to inflammatory mediators. We also found that diabetic rats had a significantly increased number of circulating MPs. We hypothesized that the elevated circulating MPs in diabetic rats serve as vectors to actively disseminate inflammation to the vascular system. We used flow cytometry to quantify the numbers of MPs and their cell origins. MPs in diabetic plasma was 5.7 ± 0.9 times of that in normal rat, with 80% of these increased MPs exhibiting exposed phosphatidylserine (PS) on their surface (n=9 per group). The functional roles of MPs were examined by perfusing a matched number of MPs isolated from normal and diabetic rat plasma into individually perfused rat mesenteric venules. Each vessel was perfused with isolated MPs for 30 min followed by 10 min of resumed blood flow. When the same vessel was recannulated with BSA-Ringer perfusate, a large number of adherent leukocytes were found in the diabetic MP-perfused vessels. The adhered leukocytes were 17 ± 2.9 and 5.7 ± 0.5 per 100 μm of vessel length in vessels perfused with diabetic and normal MPs, respectively. An increase in hydraulic conductivity (7.1 ± 1.2-fold) occurred when chemoattractant fMLP (10 μM) was applied to vessels with adherent diabetic MPs. Confocal imaging showed that diabetic MPs, not normal MPs, directly adhered on microvessel walls through single vessel perfusion. Blocking PS on the surface of MPs through precoating of Annexin V prevented the adhesion of diabetic MPs to microvessel walls and also abolished MP-mediated leukocyte adhesion. Flow cytometry analysis showed that diabetic MPs had a 6.4 ± 1.1-fold higher PS exposure per MP compared to those in normal plasma MPs. These results suggest that the increased number of MPs, as well as the larger PS surface area of each diabetic MP play an essential role in their interaction with endothelium and subsequent leukocyte adhesion. These results support our hypothesis that increased MPs in diabetic rats are more than simply biomarkers of the disease, but are direct mediators of leukocyte adhesion and actively disseminate inflammation to remote regions of the vasculature.

PCD357

FAM3A promotes proliferation and migration of vascular smooth muscle cells via activation of Akt and ERK1/2 pathways through P2Y receptor

S. Jia, Z. Chen, Y. Guan and J. Yang

Department of Physiology and Pathophysiology, Key Laboratory of Cardiovascular Science of the Ministry of Education, Peking University Health Science Center, Beijing, China

Objective - To date, the biological function of FAM3A, a member of FAM3 gene family, remains unknown. This study aimed to determine the role of FAM3A in proliferation and migration of vascular smooth muscle cells (VSMCs).
Methods and Results – Immunohistochemical staining revealed that FAM3A protein is expressed in tunica media of rodent and human arteries. FAM3A expression is reduced in tunica media of mouse femoral artery and rat carotid artery injuried by a guidewire or balloon, and in cultured rat VSMCs stimulated by

FBS or PDGF-BB with increased expression of prostaglandin E receptor 2 (EP2). Adenoviral-mediated overexpression of FAM3A promotes proliferation and migration of VSMCs independent of FBS stimulation. FAM3A activates Akt via a PI3K-dependent manner, whereas it induces ERK1/2 activation independent of PI3K in VSMCs. FAM3A protein is located in mitochondrion of VSMCs, where it promotes ATP produce and secretion. Activation or overexpression of EP2 represses FAM3A expression with inhibited ATP produce and secretion in VSMCs. FAM3A-induced activation of Akt and ERK1/2 pathways, proliferation and migration of VSMCs is blocked by suramin, a broad-spectrum P2 receptor inhibitor, but not by PPADS, a specific P2X receptor inhibitor. Moreover, inhibition of phospholypase C (PLC) and inositol 1,4,5-triphosphate receptor (IP3R) also blocks FAM3A-induced activation of Akt and ERK1/2 pathways, and proliferation of VSMCs.
Conclusion – FAM3A promotes proliferation and migration of VSMCs via P2Y receptor-mediated activation of Akt and ERK1/2 pathways. Repression of FAM3A expression by EP2 activation might be a protective mechanism against excessive neointima formation in injuried vessles.

PCD358

Inhibition of phospholipase c and protein kinase c activity from human umbilical veins endothelial cells by aqueous extract of *Bixa orellana* leaves

Y. Yong[1], Z. Ahmad[1], J. Tan[2] and D. Israf Ali[1]

[1]Biomedical Science, Universiti Putra Malaysia, UPM Serdang, Malaysia and [2]Advance Medical and Dental Institute, Universiti Sains Malaysia, Kepala Patas, Malaysia

Phospholipase C (PLC) and protein kinase C (PKC) are known for their vital role in regulating endothelial permeability. PKC induces endothelial permeability through disassembly of adherences junctions and increased actin polymerization, whereas PLC activation triggers production of downstream signaling molecules, such as intracellular calcium, nitric oxide and cyclic guanosine monophosphate (cGMP). Previous studies showed that *Bixa orellana* leaves extract attenuated acute inflammation that caused by snake venom [1] and bradykinin [2]. Therefore, the aim of this study was to investigate the effect of aqueous extract of *B. orellana* leaves (AEBO) on PLC and PKC activities in bradykinin-induced endothelial hyperpermeability. Bradykinin-induced hyperpermeability in human umbilical veins endothelial (HUVEC) was successfully suppressed by AEBO at 0.1 – 0.4 mg/ml after 12 h pre-treatment. AEBO at 0.4 mg/ml exerted maximum inhibition with a rate of 86.7%, 70.5% and 57.5%, at 5, 15 and 30 min, respectively. Inositol phosphate production, which represent PLC activity was significantly suppressed by AEBO at 0.2 mg/ml (to 51.9 ± 0.2 nM) and 0.4 mg/ml (to 89.4 ± 1.4 nM), but notat 0.1 mg/ml, compared to untreated control. Similar inhibitory effect on PKC activity was also observed in AEBO-treated group at 0.4 mg/ml, with a maximum rate of inhibition of 44.5%. However, there was no alteration on PKC activity detected in AEBO-treated group at 0.1 mg/ml. In conclusion, AEBO possesses anti-endothelial hyperpermeability effect against bradykinin through suppression of PLC and PKC activities.

Functional restoration of tissue perfusion by strategic recruitment of proangiogenic leukocytes to the ischemic hindlimb

E. Vågesjö[1], G. Christoffersson[1], O. Korsgren[2], M. Essand[2] and M. Phillipson[1]

[1]Medical Cell Biology, Uppsala, Sweden and [2]Immunology, Genetics and Pathology, Uppsala, Sweden

OBJECTIVE:
The importance of leukocyte subsets in angiogenesis is emerging. The aim of this project is to investigate if vascular repair during muscle ischemia can be promoted by strategic recruitment of specific leukocytes to the afflicted site as well as induce local leukocyte polarization towards a proangiogenic phenotype.
METHODS AND RESULTS:
Plasmids encoding the chemokines CCL2 and CXCL12 were constructed together with a GFP and luciferase reporter system and injected intramuscularly in wild type or CX3CR1-GFP mice. Muscle ischemia was induced immediate before plasmid delivery by excision of the femoral artery, where after restoration of functional blood flow was assessed by vascular responsiveness to heat challenge at day 1, 2, 3 and 7 post-insult in anesthetized mice using Laser Doppler flowmetry. The role of macrophages was studied by clodronate liposome-depletion two days prior to induction of ischemia. Leukocyte subsets in the injured muscle, perfused vessels and total vascular densities were quantified using confocal microscopy of ischemic tissues at 3 and 7 days post-insult.
Plasmid gene expression correlated to luminescent signal and was demonstrated to peak at day 3, but could be detected in the muscle for a period extending 4 weeks. Blood flow response to heat challenge was improved in ischemic limbs over expressing CXCL12 at 2, 3 and 7 days post induction of ischemia, and higher density of perfused capillaries was detected at days 3 and 7. Further, increased number of macrophages (F4/80+) and polarization towards the proangiogenic M2 phenotype (F4/80+/MRC1+) were observed in the ischemic muscles expressing CXCL12, while functional blood flow was not improved by CXCL12 over expression in mice depleted of macrophages. Over expression of CCL2 did not increase vascular repair as demonstrated by vascular density and blood flow recordings, and the M2 macrophage population was not amplified at the site of ischemia.
CONCLUSIONS:
Treatment of ischemic hind limbs with plasmid encoded CXCL12 partially restores a functional blood perfusion in response to heat by increasing total capillary density and perfusion, which is completely dependent on the expansion and polarization of the macrophage population into the M2 phenotype.

Vascular smooth muscle cell-derived exosomes isolated from human blood are enriched with fetuin-A, and may be involved in the mechanisms of vascular calcification

S.S. Kalra, A. Kapustin, A. Abbas, A. Smith, M. Waltham and C.M. Shanahan

Cardiovascular Division, King's College London, London, LONDON, UK

Vascular calcification (VC) is a highly regulated process with many similarities to developmental osteogenesis. Key features include release of vascular smooth muscle cell (VSMC) derived exosomes and dysregulated expression of physiological inhibitors of calcification such as fetuin-A (1). In vitro, fetuin-A is internalised by VSMCs and loaded into these exosomes which is thought to be a physiological mechanism to inhibit calcification. However this process becomes overwhelmed by calcification-inducing stress resulting in the loss of fetuin-A from the exosomes, thereby rendering them mineralisation competent to form the nidus for calcification (2).
In dialysis-dependent patients with chronic renal disease, lower levels of serum fetuin-A are associated with VC (3) and fetuin-A co-localises with calcified arteries (2) suggesting that a similar inhibitory mechanism exists as seen in vitro. However it is unknown if an exosome-fetuin mechanism exists in the general, non-renal failure, population.
Determine if fetuin-A enriched VSMC exosomes are found in the human circulation and if they reflect calcification stress.
Exosomes isolated from human whole blood by differential centrifugation were enriched with the exosomal marker CD63 and contained the VSMC-specific marker α-smooth muscle actin, as detected by Western Blot.
Using Western blot, fetuin-A was also detected in VSMC exosomes isolated from patients with and without clinically confirmed VC, with an observation of lower levels of fetuin-A in subjects with VC.
In a cohort (n=16) of patients with VC, we investigated the relationship between exosomal fetuin-A (as determined by ELISA), exosomal calcium (as determined by a cresolphthalein assay) and clinically quantified VC (computed tomography derived calcium score). Linear regression analysis showed a negative correlation between the exosomal fetuin-A:calcium ratio and calcium score [r^2 = -0.65; p<0.05] (see figure 1).
VSMC-derived exosomes are present in the human circulation and contain the calcification inhibitor fetuin-A. A negative correlation exists between VSMC exosomal fetuin-A and clinical calcification, confirming previous in vitro observations that fetuin-A enriched VSMC exosomes may inhibit VC and could serve as a clinical marker of VC in the general population.

Effect of Nigella sativa (Blackseed) oil on inflammation and nitric oxide productionin wistar rats

A. Amin and V.B. Owoyele

Physiology, University of Ilorin, Ilorin, Kwara, Nigeria

Nigella sativa (NS) is an herbal plant commonly cultivated in many Asian countries but the products are exported to different parts of the world including Nigeria. The medicinal effects of the plant have been the subject of many scientific researches. The oil derived from its seed had been shown to possess anti-inflammatory (Mutabagani et al., 1997), and antipyretic (Ashour et al., 2006) activities among others. In this study, the effect of NS oil on inflammation and the nitric oxide (NO) system was investigated. Chronic inflammation was induced using formaldehyde as described by Owoyele et al., 2010. In this model, wistar rats (120-150g) were divided into four groups of five animals each as follows: Grp A, B, C, and D, they were administered normal saline, indomethacin (5mg/Kg), NS oil (1ml/Kg), and NS oil (2ml/Kg) orally respectively. Two models of acute inflammation, carrageenan and histamine-induced paw oedema were employed using methods described by Winter et al., 1962 and Perianayagam et al., 2006 respectively. The animals were divided into five groups of five animals each as follows: Grp A, B, C, D, and E, they were administered normal saline, indomethacin (5mg/Kg), L-NAME (100mg/Kg), NS oil (1ml/Kg), and NS oil (2ml/Kg) orally respectively. To check for the involvement of nitric oxide, the experiment was repeated (employing the acute inflammatory models) with L-arginine administered intraperitonially to all groups 1hr after inflammation induction. Change in paw circumference (oedema) after inducing inflammation was measured daily for the 10-day duration of the chronic inflammatory model and hourly for the 6-hour duration of the acute inflammatory models. Arthritis in the chronic inflammatory model was significantly reduced (P< 0.05) from 3.40 ± 0.37 to 0.80 ± 0.01mm, and 5.40 ± 0.78 to 1.00 ± 0.02mm in the groups that received indomethacin, and NS oil (2ml/Kg) respectively. In the carrageenan model, oedema reduced significantly (P< 0.05) from 1.60 ± 0.24 to 2.80 ± 0.20mm, and 1.80 ± 0.37 to 2.60 ± 0.24mm in the groups that received L-NAME, and NS (2ml/Kg) respectively. In the histamine model, oedema reduced significantly (P< 0.05) from 1.40 ± 0.22 to 3.00 ± 0.43mm, and 3.00 ± 0.19 to 4.80 ± 0.36mm in the groups that received L-NAME, and NS (2ml/Kg) respectively. Oedema further reduced significantly (P< 0.05) upon administration of L-arginine in groups that received normal saline and NS oil. The result showed that NS oil and nitric oxide worked in synergy, producing an additive effect on the anti-inflammatory activity of NS oil. It is hereby concluded the anti-inflammatory effect of NS oil may be enhanced by nitric oxide synthase

Blocking selectin reduced late intimal hyperplasia in vein graft in mice

C. Tseng, Y. Chang, M. Kronqvist, M. Lengquist, U. Hedin and E.E. Eriksson

Karolinska institutet, Stockholm, Sweden

Background - Venous grafts (VG) are the most used conduit in re-building arterial circulation in clinic. However, VGs degenerate easily after being implanted in the arterial circulation system. Intimal hyperplasia (IH) is the major cause of VG failure. The role of selectin-dependent leukocyte recruitment in development of IH in VG is still unclear.
Methods - VGs were studied at different time points postoperatively (Time 0, 7, 28, 63 days). VG implantation was performed by cuff fashion of the thoracic vena cava from donor mice to left carotid artery in recipients. The development of IH after VG implantation was studies by histology. Intravital microscopy was used to study interactions between leukocytes and endothelium in the native vessels and in transferred graft. VG in P- and E-selectin deficiency mice (PE-/- mice) and P-selectin deficiency mice (P-/- mice) display the effect of selectin in intimal hyperplasia. For the role of selectin-dependent leukocyte recruitment in VG, wild type mice (WT mice) transferred with VG were injected by mixture of rat anti-mouse P-selectin (100 μg, clone RB40.34) and rat anti-mouse E-selectin functional (100 μg, clone 9A9) blocking antibody through experimental time. Early single bolus of rat anti-mouse P-selectin antibody (200 μg, clone RB40.34), or early single bolus of rat anti-mouse PSGL-1 antibody (200 μg, clone 4RA10) in WT mice with VG was used to clarify the effect of P-selectin in early period after venous grafting. Immunohistochemistry showed the infiltration of leukocyte in IH of VG.
Results- Intravital microscope showed less rolling and adhesive numbers of leukocytes along venous graft endothelium in PE-/- mice during entire experimental period whereas PE-/- mice had much higher circulating leukocytes. IH developed well in VG by 28 days in WT mice. In PE-/- mice and P-/- mice, VG developed less IH compared to WT mice up to 63 days post-transfer. Moreover, P-/E-section mixture antibody injection induced reduction of IH and the number of leukocyte infiltration in WT mice VG at 28 days after transferred. Early single bolus of P-selectin antibody injection led to similar IH reduction and decreased number of leukocyte infiltration in VG IH by 28 days. At the same time, early single bolus of PSGL-1 antibody showed less IH reduction and number decreasing in leukocyte infiltration at 28 days.
Conclusions – P-/E-Selectin-dependent leukocyte recruitment is an important factor in development of intimal hyperplasia of venous graft. Functional blocking of P-and E-selectin can decrease the recruitment of leukocyte and subsequent leukocyte infiltration in IH of VG. Early single P-selectin functional blocking inhibited leukocyte recruitment and led to late IH reduction. P-selectin antagonist or combined P-/E-selectin antagonist could be a potential choice to prevent IH after VG transferred.

PCD363

Selective Estrogen Receptor Modulators benefits endothelial function by enhancing the nitric oxide via and reducing oxidative stress in ovariectomized rats

A.Z. Lamas, I. Caliman, P. Dalpiaz, P. Oliveira, A. Melo Júnior, S. Figueiredo, M. Moysés and N. Bissoli

Department of Physiological Sciences, Federal, University of Espírito Santo, Vitória, Brazil

Estrogen deficiency associated endothelial dysfunction contributes for the increased cardiovascular incidence in post-menopausal women. Because of the many complications presented by estrogen therapy, alternative therapies have emerged. The SERMs are a class of synthetic compounds that act as antagonists or agonists of the estrogen receptors. Tamoxifen (TAM) is the most widely used anti-estrogen for the management of breast cancer. Raloxifene (RAL) is used for the treatment and prevention of post-menopausal osteoporosis. This study evaluated the influence of RAL, TAM and 17-β estradiol (E) treatment on mesenteric bed (MB) vascular reactivity in rats with E deficiency. The investigation was conducted in accordance with the biomedical research guidelines for the care and use of laboratory animals, and it were approved by Ethics Committee (n°012/2008). All the surgical experiments were carried out under anesthesia (Ketamine70mg/kg+xylazine10mg/kg,i.p). Female rats were studied (n=6/group): control (SHAM); ovariectomized (OVX), OVX treated with E (0.5μg/Kg/day), RAL (2mg/Kg/day) or TAM (1mg/Kg/day), 21 days after bilateral ovariectomy. On day 35, the MB was isolated, perfused and constricted with noradrenaline. Dose response curves of ACh were obtained in absence or presence of L-NAME (NOS inhibitor) or aminoguanidine (AG iNOS inhibitor). Inducible NOS (iNOS), endothelial NOS (eNOS) and NADP(H) oxidase protein expression by western blot were analyzed. The data are reported as means±SEM, compared by ANOVA. The vasodilatation obtained in the OVX was lower compared to the SHAM Emax81±3 vs 60±3 %relaxation P<0.05. In the presence of L-NAME EmaxSHAM 31±3; OVX 21±2; E 34±9; RAL 16±2; TAM 19±4 %relaxation, decreased in all groups. In the presence of AG EmaxSHAM 76±3 vs OVX 36±3 %relaxation P<0.05; the concentration-response curve for Ach was reduced further in the OVX group and the other groups did not change when compared with non-blocking EmaxE 79±4; RAL 80±8; TAM 63±3. The levels of iNOS and NADP(H) oxidase (NOX2) protein expression in MB were elevated in OVX iNOS: SHAM 0.84±0.05; OVX 0.99±0.04 P<0.05 and NOX2: SHAM 0.76±0.10; OVX 1.12±0.13 P<0.05, while levels of eNOS were reduced in OVX when compared to SHAM eNOS: SHAM 1.07±0.10; OVX 0.71±0.10 P<0.01. All treatments were able to restore the protein expression values to those similar to control group iNOS: E 0.81±0.05; RAL 0.65±0.07; TAM 0.69±0.06; eNOS E 1.13±0.08; RAL 0.91±0.02; TAM 0.99±0.08 and NOX2 E 0.80±0.07; RAL 0.58±0.04; TAM 0.68±0.02. The treatments were able to normalize the impaired vasorelaxation of estrogen-deficient rats, indicating that despite the estrogen and SERMs present structural differences in treatment efficacy was similar to reduce a possible inflammatory and improve vascular reactivity in rats with endothelial dysfunction.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD366

Decreased K^+ current in arterial myocytes of angiotensin II-induced hypertensive rats and its recovery by exercise training

E. Seo, H. Kim, C. Jin, Y. Zhang and S. Kim

Department of Physiology, Seoul National University College of medicine, Seoul, Republic of Korea

A moderate increase in extracellular K^+ induces relaxation of small arteries via augmenting inwardly rectifying K^+ current. The K^+-vasodilation is one of the mechanisms for the regional control of blood flow in response to neuronal and skeletal muscle activity. Previously we reported that exercise training (ExT) upregulates Kir current in smooth muscle cells of cerebral and skeletal arteries (CA and DFA). Here we investigated whether Kir current and K^+-vasodilation are affected in these arteries of hypertensive rats with or without ExT. To establish hypertension, rats were implanted with osmopumps delivering either Ang II (125 ng/kg/min) or saline. At 4 weeks, smooth muscle cells of CA (CASMCs) and DFA (FASMCs) were isolated and then we voltage clamped to evaluate the Ba^{2+}-sensitive Kir current and voltage-dependent K^+ current. The current density of both Kir and Kv (pA/pF) decreased in Ang II-treated hypertensive rats (AII-R). We trained rats with treadmill running for the latter two weeks (3rd and 4th weeks of Ang II application). ExT recovered Kir and Kv currents in CASMCs and FASMCs. At the same time depolarizing inward conductance (nonselective cation current) was also increased by ExT in CASMCs while not in FASMCs. This background inward current was partly inhibited by amiloride, an inhibitor for ENaC and ASIC channel. Also GTPγS, non-hydrolysable GTP analogue, induced a slowly inward current in AII-R CASMCs. And this GTPγS-activated current was further increased by ExT. The K^+-vasodilation was monitored by using video-analysis of pressurized artery. Consistent with the changes in Kir current, vasodilation by adding 2 mM KCl was weakened in both DFA and CA from AII-R. The K^+-vasodilation of DFA but not of CA was recovered in AII-R with ExT. A bath application of Ang II did not induce constriction of CAs, suggesting that the changes in K^+ channels are not directly induced by Ang II but by indirect effects of hypertension. The decreased K^+ conductance might reflect an adaptive change of resistance arteries to prevent over-perfusion of vital organs such as brain. The recovery of Kir and Kv currents by ExT might be one of the mechanisms for the beneficial effects of regular exercise on hypertension.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Macrophage heterogeneity in developing vulnerable atherosclerotic plaques modulated by shear stress

A.N. Seneviratne[1,2], J.E. Cole[1], M.E. Goddard[1], R. Krams[2] and C. Monaco[1]

[1]Kennedy Institute of Rheumatology, University of Oxford, London, UK and [2]Department of Bioengineering, Imperial College London, London, UK

Purpose: Atherosclerosis is a multi-factorial disease occurring in vascular sites subjected to complex flow; such as arterial bifurcations experiencing Oscillatory shear stress (OSS) and curvatures where Low shear stress (LSS) occurs. The behaviour and phenotype of macrophages, the most abundant innate immune cell in atherosclerosis, is crucial in determining the outcome of atherosclerotic plaque formation. Macrophage behaviour is conditioned by their polarisation towards a pro-inflammatory phenotype (called M1) or a regulatory one (broadly named M2). The aim of this study is to establish the activation and polarisation status of macrophages in different plaque phenotypes and shear stress conditions.
Methods: We utilised a murine model which imposes LSS to develop vulnerable plaques, and OSS to induce a stable plaque phenotype. A perivascular shear stress modifying cast was tied around a carotid artery mimicking LSS and OSS in ApoE-/- mice fed a high fat diet (HFD) from 17 weeks of age. We examined the cellular protein expression of the pan-macrophage marker CD68 and polarisation markers iNOS (M1), CD206 (M2) and HO-1 (Mox subset) in the aortic root and cast-treated carotid artery by Immunohistochemistry and Confocal Immunolocalisation at early (12 weeks), intermediate (28 weeks), and late stages of atherosclerosis (53 weeks).
Results: In the aortic roots, the majority of CD68+ cells stained positively for HO-1, reaching a maximum at 28 weeks (36.3±1.2% of lesion area; $p<0.001$ vs. 12 and 53 weeks). Immunopositivity for iNOS and CD206 were confined to a small proportion of macrophages in aortic roots (max 5.6±2.3% and 4.2±1.1% of lesional area at 20 weeks respectively). In stark contrast, the majority of macrophages in the LSS-induced carotid artery lesions express iNOS (23.6±5.1% vs. 5.4±2.7% lesion area; $p=0.006$). The expression of CD206 and HO-1 instead was not different between LSS and OSS.
Conclusions: The majority of macrophages in early and intermediate lesions of the aortic root express HO-1 (Mox phenotype). M1 or M2 polarised macrophages are present in smaller numbers at early and intermediate stages of disease but not in late disease. In atherosclerotic lesions of the carotid artery, M1 macrophages are significantly more prevalent in the low shear stress-modulated plaque. These differences suggest low shear stress promotes polarisation towards the M1 macrophage phenotype.

Endothelin-1-mediated vasoconstriction: is there therapeutic potential for intracellular sarcoplasmic reticulum calcium blockade?

Y.Y. Chan[1,3], B.J. Reddi[1,4], J.F. Beltrame[2,3], G.Y. Rychkov[1] and D.P. Wilson[1,3]

[1]School of Medical Sciences, Department of Physiology, University of Adelaide, Adelaide, SA, Australia, [2]School of Medicine, University of Adelaide, Adelaide, SA, Australia, [3]Vascular Diseases and Therapeutics Research Group, Basil Hetzel Institute, The Queen Elizabeth Hospital, Adelaide, SA, Australia and [4]Intensive Care Unit, Royal Adelaide Hospital, Adelaide, SA, Australia

Introduction: Levels of the potent vasoconstrictor, endothelin-1 (ET-1), are elevated in several pathological states, including atherosclerosis (Ivey et al., 2008), vasospasm (Clark and Pyne-Geithman, 2005), pulmonary hypertension (Barman, 2007) and coronary slow flow phenomenon. Vasoconstriction is mediated by the activation of voltage-gated calcium channels (VGCC) and intracellular sarcoplasmic reticulum (SR) calcium release, which elevates intracellular cytosolic calcium concentration. Inhibition of myosin phosphatase by protein kinase C/CPI-17 or the RhoA/Rho kinase-dependent pathways enhances calcium sensitisation, further augmenting vasoconstriction. However, recent evidence has also implicated the involvement of non-selective cation channels (NSCC) in the activation of VGCC (Wang et al., 2008).
Aims: This study aims to (1) document the role of SR calcium and calcium sensitisation in ET-1-mediated vasoconstriction, (2) identify the extent to which L-type calcium channel blockade attenuates extracellular calcium entry and vasoconstriction, and (3) identify whether NSCC are important in mediating activation of L-type calcium channels in ET-1-mediated vasoconstriction.
Methods and results: Male Sprague-Dawley rats, weighing 350g were killed by carbon dioxide inhalation. Primary smooth muscle cells from rat mesenteric arteries coupled with patch clamping analysis demonstrated that ET-1 (100nM) increased the amplitude of L-type calcium current (n=9). Using functional wire myography, pharmacological blockade of VGCC using nifedipine (10μM) significantly attenuated the ET-1-mediated vasoconstriction ($p<0.05$; n=9). Depletion of SR calcium using cyclopiazonic acid (10μM) and the IP3 receptor and NSCC blocker, 2-APB (100μM), also reduced ET-1-dependent vasoconstriction ($p<0.05$; n=9). Ionic substitution of Na+ with NMDG+ did not alter the magnitude or rate of ET-1 developed tension, suggesting that Na+ entry through NSCC was not important in ET-1-dependent contraction ($p>0.05$; n=4-5). Using an EGTA/ calcium-free solution to deplete both extra and intracellular calcium stores revealed the involvement of calcium sensitisation pathways ($p<0.05$; n=8) and was consistent with biochemical analysis, documenting an increase in the Thr855 phosphorylation state of myosin phosphatase ($p<0.05$; n=8). All data were expressed as means ± SEM and analysed using Students paired or unpaired t-test, as appropriate. Comparisons between treatment groups were analysed using one-way analysis of variance (ANOVA) followed by Bonferroni correction.
Conclusion: These data highlighted the therapeutic potential of SR calcium blockade but not NSCC blockade in mediating ET-1-dependent contraction.

Endothelial endoglin expression and phatobiology mechanism regulation of angiogenesis in wound healing and skin angiomas

J.P. Velasco-Martin[1], L. Recio[2], J. Regadera[1], M.L. Ojeda[2], F. Leyva[3] and L.M. Botella[2]

[1]Departament of Anatomy, Histology and Neuroscience, Madrid, Spain, [2]Centro de Investigaciones Biológicas, CSIC, Madrid, Spain and [3]Service of Plastic Surgery, Hospital Clínico, Madrid, Spain

Human endothelial cells of both vascular and not vascular soft tissues tumors were all identified by using vimentin and factor VIII antibodies. However, these molecules did not allow to know the functional state of cell activity. Nowadays, experimental and human research angiogenesis can show a heterogeneous functional response of endothelial cells explored by endoglin and SMAD regulation, KLF 6, VEGF and VEGFR.
These molecules had not been quantified in cutaneous soft tissue tumours. In this report the immunochemistry and molecular expression of these endothelial epitopes in hemangiomas, dermatofibromas and lymphangiomas is evaluated, as well as in the angiogenic process found in pyogenic granuloma and granulation tissues of wound healing.
5 patients per group diagnosis of hemangioma, dermatofibromas, lymphagiomas, pyogenic granuloma and 10 patients with burned skin ulceration were examinted. The immunochemistry and molecular expression of endoglin, SMAD 1/5, SMAD 2/3, SMAD 4, KLF 6, VEGF, VEGF-R2, VEGF-R3 as well as vimentin and VIIIFG were evaluated. The evaluation of each molecule was explored using almost two slides per case.
Endothelial cells in hemangiomas express VIIIFG and vimentin and no differences were found regardless of the different types of hemangiomas. The endoglin expression of hemangiomas was observed only at endothelial proliferative cells and it seems to be higher at unicellular angiotubes. Intense endoglin expression was also seen in the lumen from proliferative new vessels that showed intense endoglin expression. However, no endoglin expression was found in endothelial cells of cavernous dilation in malformative hemangiomatosis. In hemangiomas, the endothelial cell expressed SMAD 2/3 and SMAD 4, but not SMAD 1/5.
Positive expression of Kruppel-like factor 6 was observed in all types of hemangiomas; but expression in proliferative endothelial cells was higher than in normal endothelial cells. Endothelial VEGF-R2 and VEGF-R3 inmunodetection was similar in hemangioma and normal vessels. Nevertheless, PCPH was found in higher concentrations in normal endothelial cells and quiescent hemangiomas, and their expression decrease in proliferative hemangiomas.
In conclusion, endothelial cells in angiogenic process and vascular tumours were morphology similar, but these cells express different endothelial molecules related to distinct functional endothelial activity. Tumoral angiogenic were very heterogeneous. In hemangiomas, endoglin regulation by SMAD 2/3 and SMAD 4 indicated activation of ALK 5 that signalled pathway in these tumors.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Differences in the signalling mechanisms underlying UTP-evoked vasoconstriction of pulmonary and systemic-like arteries

N.H. Syed[1,2], A. Tengah[1,3], S. Abdul Talip[1,3], S. Bujang[1,3] and C. Kennedy[1]

[1]SIPBS, University of Strathclyde, Glasgow, Scotland, UK, [2]University College of Pharmacy, University of the Punjab, Lahore, Punjab, Pakistan and [3]PAPRSB Institute of Health Sciences, Universiti Brunei Darussalam, Gadong, Brunei Darussalam

P2Y receptors are GPCRs that are activated by the endogenous nucleotide UTP. In the vascular system, endothelial P2Y receptors mediate vasodilation, whilst P2Y receptors located on arterial smooth muscle cells mediate vasoconstriction (Chootip et al., 2002). Previously we showed that Ca2+ influx via Cav1.2 ion channels contributes to the UTP-evoked contraction of rat intrapulmonary arteries (rIPA) (Mitchell et al., 2012). The aim was to characterise and compare the contribution of Ca2+ release and influx, rho kinase and protein kinase C (PKC) in rIPA, a low pressure, low resistance vessel and rat tail artery (rTA), a resistance-like, systemic artery.
5 mm rings of rIPA and rTA were dissected from male Sprague-Dawley rats (200-250g). The endothelium was removed and rings were mounted under isometric conditions in 1ml baths at 37°C and resting tension of 0.5-0.75g. Tension was recorded by Grass FT03 transducers connected to a Powerlab/4e system (AD Instruments). Contractions were elicited by adding UTP (300μM-rIPA; 1mM-rTA) to the bath. Data were analysed using Student's t tests.Values of $P<0.05$ were considered to be statistically significant.
UTP evoked slowly developing contractions in both tissues, which peaked within 2-3 min. Thapsigargin (1μM) depressed significantly contractions by 30-40% (rIPA-$P<0.001$, n=8; rTA-$P<0.05$, n=4), but ryanodine was ineffective (n=5). The rho kinase inhibitor, Y27632 (10μM) significantly reduced the peak amplitude of contractions by about 20% in rIPA ($P<0.01$, n=5) and by more than 80% in rTA ($P<0.01$, n=4) and the inhibition was significantly greater in rTA ($P<0.001$). The PKC inhibitor, GF109203X (10μM) also significantly reduced the peak amplitude in rIPA by over 20% ($P<0.01$, n=7) and by around 40% in rTA ($P<0.001$, n=5). Inhibition was again significantly greater in rTA ($P<0.05$). In rIPA, adding Y27632 (10μM), GF109203X (10μM), thapsigargin (1μM) and nifedipine (1μM) together abolished the UTP response (n=4). In rTA nifedipine (1μM) significantly reduced the amplitude of UTP responses by about 60% ($P<0.01$, n=6). Furthermore, contractions were abolished by Y27632 (10μM) plus thapsigargin (1μM, n=5), GF109203X (10μM, n=4) or nifedipine (1μM, n=4). Adding thapsigargin (1μM), GF109203X (10μM) and nifedipine (1μM) together abolished UTP-evoked contractions (n=4).
These results indicate that Ca2+ release from the sarcoplasmic reticulum and Ca2+ influx through Cav1.2 channels, con-

tribute to UTP-evoked vasoconstriction of rIPA and rTA. Rho kinase and protein kinase C are also involved, but more so in rTA. Thus relative importance of signalling components differs in pulmonary compared with systemic arteries.

Synthetic or contractile, that is the question: comparing in vitro methods to modulate VSMC phenotype

J.J. Patel[1,2], M.M. Fowler[1] and R.C. Siow[2]

[1]Unilever Discover, Sharnbrook, UK and [2]Cardiovascular Division, King's College London, London, UK

Vascular smooth muscle cells (VSMCs) have the innate ability to modulate cellular phenotype in response to environmental factors such as vessel damage or disease. This phenotypic plasticity ranges between a contractile phenotype, the most common form found in vessels, to a synthetic phenotype which are unable to contract though play a vital role in vessel remodelling. Variations in VSMC phenotype are evident with changes in cell morphology, expression of SMC markers, proliferation and migratory characteristics. *In vitro* culture methods utilising calf serum and enzymatic digestion are known factors which can shift contractile VSMCs to a more synthetic phenotype. If assessing cellular contraction, changes in phenotype *in vitro* may lead to findings which may have little or no *in vivo* relevance. Numerous *in vitro* culture techniques have been suggested to maintain VSMCs in a contractile phenotype; however, no comparative study has been conducted using human aortic smooth muscle cells. In this study, VSMC gene marker expression was utilised to compare culture methods which may induce a contractile phenotype. Aortic smooth muscle cells (Lonza, Slough, UK) were cultured between passages 7 and 11 in basal medium (DMEM supplemented with 10% FCS), and compared to cells grown in DMEM with 5% FCS or Lonza medium (EBM+SmGM-2 BulletKit). In addition, cells were cultured in basal medium on plates coated with either fibrillar or monomeric collagen, or treated with heparin. Expression of mRNA for smoothelin, a contractile phenotype marker, was up-regulated at all passages in cells cultured on monomeric collagen, compared to basal medium. Expression of mRNAs for other contractile markers: caldesmon, heavy chain 11 smooth muscle and actin alpha 2 smooth muscle, was also favourable in monomeric collagen coated cultures. Cells cultured on fibrillar collagen also followed a similar pattern of mRNA expression to monomeric, though to a lesser extent. VSMCs grown in Lonza medium and DMEM supplemented with 5% FCS exhibited mRNA marker expression suggestive of a more synthetic phenotype, compared to basal medium. Further to this, VSMCs treated with heparin showed favourable mRNA expression of contractile markers, which in cases was better than that observed with monomeric collagen; however, given that heparin can effect cellular contraction, this may not be as viable a method to induce a contractile phenotype. Taken together, these findings suggest that culturing VSMCs in Lonza medium may promote the more proliferative synthetic phenotype and may serve to build up cell populations. These cells could subsequently be transferred onto cultureware coated with monomeric collagen which would induce a contractile phenotype and thus be appropriate for *in vitro* studies of cellular contraction.

Does oxidative stress has effect on microvascular reactivity in young healthy individuals?

A. Cosic, A. Cavka, L. Rasic and I. Drenjancevic

Department of Physiology and Immunology, Faculty of Medicine Osijek, University of J.J. Strossmayer Osijek, Osijek, Croatia

Objective: Changes in skin microcirculatory blood flow assessed by laser Doppler flowmetry (LDF) represent well systemic microvascular function (1-3). Oxidative stress appears to be the common underlying cellular mechanism for the development of endothelial dysfunction with subsequent changes in microvascular reactivity in various vascular diseases (4,5). The aim of this study was to evaluate the effect of oxidative stress on skin microcirculatory blood flow in young healthy individuals.
Materials and Methods: 40 healthy female medical students (age 20-23 yrs), volunteered to participate in this study. The study protocol and procedures conformed to the standards set by the latest revision of the Declaration of Helsinki and were approved by the Ethical Committee of the Faculty of Medicine, University of Osijek. Skin microcirculatory blood flow was assessed by LDF (MoorVMS-LDF, Axminster, UK). Changes in blood flow were measured during baseline and reactive hyperaemia following release of a 1 minute occlusion of blood flow Lipid peroxidation was measured by TBARS method (Thiobarbituric Acid Reactive Substances) and antioxidant activity by FRAP (Ferric Reducing Antioxidant Power) method in venous blood samples taken before the occlusion. Correlation analysis was calculated using Pearson's correlation coefficient at 95% confidence of interval (SigmaPlot v11.2, Systat Software, Chicago, USA).
Results: There was statistically significant negative correlation between reactive hyperaemia in skin microcirculation and lipid peroxidation (R and TBARS, Pearson r = -0.3309, R2=0.1095, P=0.037). There was no correlation between reactive hyperaemia and plasma antioxidant activity (FRAP) (R and FRAP, Pearson r=0.1404, R2=0.01973, P=0.3874).
Conclusion: The results of this study clearly suggest that the level of common oxidative stress has significant effect on microvascular reactivity in the population of young healthy individuals, and that increased oxidative stress may affect normal vascular function. This study shows that the maintaining of oxidative balance has an important role in preservation of vascular health.

PCD373

Cutaneous microvascular regulatory response to ischaemia and association with mean oxygen saturation

D.D. Adingupu, C. Thorn, F. Casanova, S. Elyas, P.E. Gates, A.C. Shore and W.D. Strain

Diabetes and Vascular Medicine, Institute of Biomedical and Clinical Science Peninsula College of Medicine and Dentistry, Exeter, UK

Introduction: We have previously described three distinct cutaneous microvascular responses to an ischaemic stimulus using laser Doppler fluximetry (Strain et al., 2005). These are associated with a gradation of cardiovascular risk. 1) "normal response" with a controlled graded rise to peak at ~10-15 seconds, 2) "non-dominant early peak (NDEP)," with an abnormal early peak within 2 seconds of lower amplitude than the subsequent "normal" graded rise to peak, 3) "dominant early peak (DEP)" within 2 seconds of cuff release with maximum amplitude, which declines rapidly and is then followed by a lesser "normal" peak. Exact mechanism involved in abnormal peak responses are unclear, however we believe it represents a proxy for systemic microvascular (MV) regulatory disturbance.

Aims: To explore associations between microvascular regulatory responses and cutaneous blood oxygenation (SO2, %).

Methods: Post occlusive reactive hyperaemia of the microcirculation was assessed on the foot of participants with cardiovascular disease (CVD), diabetes (DM), both (DM+CVD) or neither (controls) using laser Doppler fluximetry and Oxygen to See, which measures blood oxygen saturation in the first 1mm of skin. All participants underwent basic demographic & biochemical screening.

Results: 232 participants were studied, 76 controls, 106 with CVD, 34 with DM and 16 with DM+CVD. . Results were stratified by peak response groups. In keeping with previous reports, there was an increase in CVD, diabetes and CVD risk factors across peak response groups (Table 1). Area under the curve (AUC) of oxygen saturation was incrementally lower in those with impaired autoregulation. After adjustment for CVD, diabetes, blood pressure, heart rate and BMI, this remained strongly negatively associated with abnormal peak responses, geometric mean (95% CI) normal 1459(1364-1554) vs. NDEP 1212(1132-1292) (p=0.001) vs. DEP 1142(1040-1245) (p<0.001).

Conclusion: These data suggest that the previously described abnormal peak responses have significant consequences in the delivery of oxygen as they are independently associated with reduced mean oxygen saturation post ischaemia.

PCD374

Contradictory role of apelin in vascular calcification

X. Teng[1,2], Y. Qi[3], Z. Lu[3], Y. Zhou[3], Y. Cai[3] and C. Tang[3]

[1]Department of Physiology, Hebei Medical University, Shijiazhuan, Hebei, China, [2]Hebei Key Laboratory of Laboratory Animal Science, Hebei Medical University, Shijiazhuang, Hebei, China and [3]Laboratory of Cardiovascular Bioactive Molecule, Peking University, Beijing, China

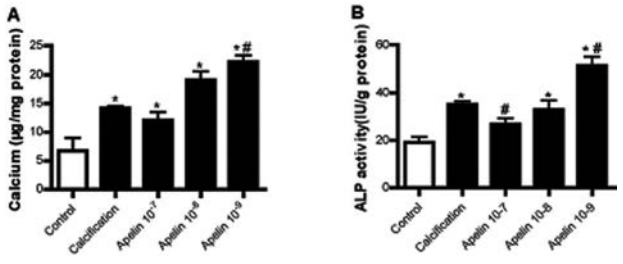
Background: Apelin is a cardiovascular peptide with multiple functions regulating homeostasis of the circulatory system and is the endogenous ligand of angiotensin receptor AT1 (APJ). The role of apelin/APJ system in vascular calcification (VC) was investigated here.

Methods: Male Sprague–Dawley (SD) rats (200±10 g) were used. A rat aorta VC model was induced by vitamin D3 plus nicotine (VDN) in vivo, and cultured vascular smooth muscle cell (VSMC) calcification of rat thoracic aortic arteries was induced in vitro by beta-glycerophosphate [1, 2]. Rats anesthetized with urethane (1 g/kg, intraperitoneally) were killed. In aortic tissure or VSMCs, von Kossa staining, calcium content and alkaline phosphatase (ALP) activity was detected [1, 2]. Immunohistochemical assessment was used to detect alpha-actin. RT-PCR was used to detect mRNA expression of apelin and APJ, and Western blot was used to detect protein expression of apelin and alpha-actin.

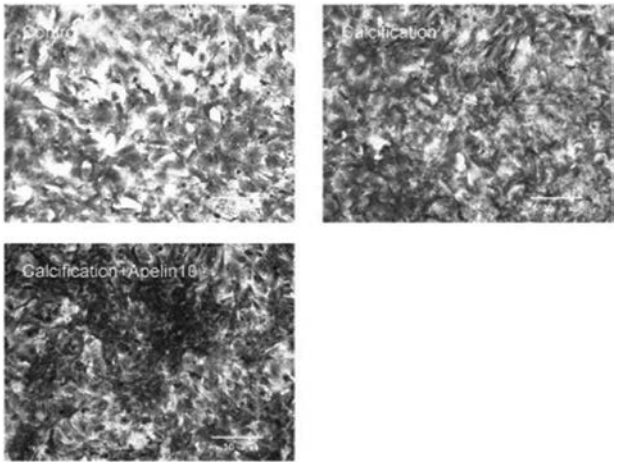
Results: Von Kossa staining revealed dispersed calcified nodules among the elastic fibres in calcified aortas but not in control aortas (n=6). As compared with controls, media from arteries with calcification showed significantly decreased level of alpha-actin on Western blot analysis (-18.4%, P<0.05, n=3, repeated three times). The mRNA relative level of apelin in the aorta of rats with vascular calcification was increased by 91.6% (P<0.05, n=3, reperated three times). However, the APJ mRNA expression have not significantly difference between two groups. To further investigate the effects of apelin, calcified VSMCs induced by beta-glycerophosphate were used. Compared with control group, protein expression of alpha-actin

was significantly down-regulated in calcification group (P < 0.05, n=3, repeated three times). Calcium content and ALP activity increased by 109.6% and 83.7%, resprectively in calcification VSMCs (all P<0.05, n=6). Von Kossa staining showed dispersed calcified nodules in calcification group but not in control group (n=6). 10-9 mol/L apelin could further promote calcium content, ALP activity and calcified nodules than calcification alone (all P<0.05, n=6). However, 10-7 mol/L apelin ameliorated the calcified-induced augmentation of ALP activity (P< 0.05, n=6).

Conclusions: These results suggest that apelin-APJ system might function as a regulator of VC, and could be new therapeutic targets for VC in patients.



The role of different concentration Apelin on calcification VSMCs. A, calcium content; B, ALP activity. Values are expressed as mean±SD. * P < 0.05 vs control group. #P < 0.05 vs calcification group.



Von Kossa staining for VSMCs showed a strong positive staining of black / brown areas among VSMC (original magnification 200×). A, control group; B, calcification group; C, calcification + apelin 10-9 mol/L group.

PCD375

Influence of hyperbaric oxygenation on gene expression in diabetic and healthy female Sprague-Dawley rats

S. Novak[1], D. Manojlovic[2], Z. Mihaljević[1] and I. Drenjancevic[1]

[1]Department of Physiology and Immunology, Medical Faculty Osijek, J.J. Strosmayer University Osijek, Osijek, Croatia and [2]Department of Surgery, General Hospital Vukovar, Vukovar, Croatia

INTRODUCTION: Our previous study demonstrated increased expression of mRNA CYP4A1 in aortas of healthy male Sprague-Dawley (SD) rats treated with hyperbaric oxygenation (HBO2) (1,2). The aim of this study was to determine the influence of HBO2 on expression of CYP4A1, CYP4A3 and thromboxane-2 synthase (TXA2) (producing vasoconstrictor 20-HETE and TXA2, respectively) and CYP2J3 and CYP4A3 genes (producing vasodilator EETs) in aorta of healthy and diabetic female SD rats.

METHODS: Female SD rats - control group, diabetic (DM) group; and control-HBO2 rats and DM-HBO2 rats that underwent HBO2 (120 minutes in duration, at 2.0 atm for 4 consecutive days, 5th day sacrified) (12 weeks-old at the time of experiment, 6 weeks DM duration) were included in the study (N=9/per group). Diabetes mellitus was induced by 1 injection of 60mg/kg i.p. streptozocin in 6 weeks old rats. Prior to decapitation, rats were anesthetized with ketamin-klorid (75 mg/kg) and midazolam (2.5 mg/kg). Aortas were collected for mRNA expression analysis by RT-PCR. Data are normalized with expression of HPRT housekeeping gene. The data are presented as mean±SEM and analyzed with t-test; p<0.05 was considered statistically significant. The Ethical Committee of Faculty of Medicine University of Osijek approved the study.

RESULTS: There is significant up-regulation of CYP2J3 gene in DM-HBO2 rats compared to all groups, and significantly higher expression of CYP2J3 in control-HBO2 compared to control group. Control group has significantly higher expression of CYP2J3 and CYP4A3 genes compared to DM group. Additionally, expression of CYP4A3 is significantly higher in control-HBO2 compared to DM-HBO2 rats. Control-HBO2 rats had significantly higher expression of TXA2 mRNA compared to DM-HBO2.

CONCLUSION: Present results demonstrated that there is a down-regulation of CYP genes in diabetic rats aortas. HBO2 led to up-regulation of CYP genes in both, control and diabetic rats, and in TXA2 expression in healthy-HBO2 rats. This finding is important in light of the role of eicosanoids produced by these enzymes in mediating various vascular responses to vasodilator stimuli, which are changed in diabetes (3).

PCD376

Transient receptor potential vanilloid 1 in the vascular system, at baseline and in inflammation

C. Sand[1], A. Grant[2] and M. Nandi[1,3]

[1]Cardiovascular Division, King's College London, London, UK, [2]Wolfson Centre for Age-Related Diseases, King's College London, London, UK and [3]Institute of Pharmaceutical Sciences, King's College London, London, UK

Vascular inflammation greatly increases the risk of cardiovascular dysfunction, and in the setting of sepsis is an important determinant of clinical outcome. Transient receptor potential vanilloid 1 (TRPV1) is expressed in sensory neurons that contain vasoactive neuropeptides, as well as in the vasculature itself, and has been implicated in both haemodynamic regulation and inflammation (Clark *et al*, 2007; Wang *et al* 2008). We hypothesise that TRPV1 may function as a vascular regulator under inflammatory conditions, and aimed to investigate its vascular function at baseline and in inflammation. To characterise vascular TRPV1 expression, we isolated mouse aortae and cultured endothelial cells from 3 species (human, cow and mouse). Using RT-PCR we found TRPV1 mRNA expression in mouse aorta, and in all endothelial cell lines. We also investigated TRPV1 activity in isolated bovine endothelial cells by calcium fluoromtery using the selective agonist capsaicin. We found no response to 1 μM capsaicin, however, 13.75% of cells responded to 10 μM capsaicin, and the number responding to 100 μM capsaicin was significantly increased to 55.23% ($P<0.001$, compared with 1 μM capsaicin, $P<0.05$, compared with 10μM capsaicin, 1-way ANOVA with Bonferroni post-hoc test). In order to assess TRPV1 vasoactivity in resistance beds *in situ*, we developed a novel method of measuring murine mesenteric blood flow by laser speckle flowmetry. Mice were anaesthetised under 2 % isoflurane, and the small intestine was externalised through a midline incision to expose the mesenteric vasculature. Baseline mesenteric blood flow was recorded for 5 min before spray-application of 10 μM capsaicin followed by a further 5 min recording. Data are represented as mean area under the curve (flux units.time) ± SEM for baseline compared with capsaicin response. In naïve mice, capsaicin caused a significant decrease in mesenteric flow (817915 ± 34335 to 641242 ± 57640, p=0.0152, unpaired 2-tailed T-test, n=6). Conversely, in mice treated with LPS (12.5 mg/kg, 6 h or 24 h), capsaicin caused a subtle increase in blood flow at both time points (650563 ± 67794 to 711032 ± 70034 and 493428 ± 38088 to 526678 ± 25895, respectively, ns, n=3). We have demonstrated evidence of non-neuronal TRPV1 expression in vascular tissues. We hypothesise that the capsaicin-induced vasoconstriction in murine mesenteric vessels is due to TRPV1 expression in the vascular smooth muscle, and that LPS-induced endotoxaemia causes an upregulation of neuronal and/or endothelial TRPV1, generating a vasodilatory drive sufficient to overcome constriction. This may represent a protective mechanism against the lethal hypoperfusion that occurs in septic shock, though further experiments are required to confirm initial results and to understand the mechanisms involved.

Effects of dietary zinc and selenium on vascular responses to acetylcholine and reduced pO2 in aortic rings of male Sprague-Dawley rats

A. Cavka[1], I. Grizelj[1], A. Cosic[1], S. Novak[1], Z. Loncaric[2], B. Popovic[2] and I. Drenjancevic[1]

[1]Department of Physiology and Immunology, Faculty of Medicine Osijek, University of J.J. Strossmayer Osijek, Osijek, Croatia and [2]Desk of Plant Nutrition and Fertilization, Faculty of Agriculture Osijek, University of J.J. Strossmayer Osijek, Osijek, Croatia

Objective: Increased oxidative stress is known to decrease the bioavailability of NO, affect cyclooxygenases (COX) activity and lead to impairment of vascular function (1,2). Trace elements both zinc (Zn) and selenium (Se) are important components of antioxidative enzymes. Lack of Zn and Se in daily diet may be involved in the initiation of endothelial dysfunction (3-5). However, at the present there are no functional vascular studies to address this issue. The objective of this work was to determine if changes in dietary content of Zn and Se affect vascular responses in rat aortic rings.

Materials and Methods: Fifteen male Sprague Dawley rats were fed with 3 types of custom made rat chow (Faculty of Agriculture University of Osijek, Croatia) from weaning for 10 weeks: a) high Zn(70.81 mg/kg)-low Se(0.043 mg/kg) group (N=5); b) high Se (0.363 mg/kg)-low Zn(30.16 mg/kg) group (N=5) and c) low Zn(28.56 mg/kg)-low Se(0.030 mg/kg) group (N=5). Thoracic aortic rings were used to test dose responses to Ach (10-9-10-5 M) and response to reduced pO2 (bath gas mixture containing N2 95%, CO2 5%) after precontraction with noradrenaline (NA) for 5 minutes, in the absence/presence of the NOS inhibitor L-NAME or COX-1,2 inhibitor indomethacin (INDO) in the tissue bath. Viability of rings at the end of the hypoxic relaxation protocol was tested with their ability to contract in 95% O2-5% CO2 bath solution. To test differences among groups One-way ANOVA or t-test was used when appropriate. Statistical significance was set at $P<0.05$ (SigmaPlot v11.2).

Results: ACh induced relaxation (AchIR) was significantly reduced in low Zn-low Se group compared to both high Zn-low Se and high Se-low Zn groups ($P<0.001$ for 10-7-10-4 M Ach concentration). L-NAME blocked AChIR in all three groups of rats ($P<0.001$ for 10-7-10-4 M Ach concentration), while INDO significantly reduced AChIR only in high Se-low Zn group ($P<0.01$ for 10-7-10-4 M Ach concentration). Hypoxia induced relaxation (HIR) was significant in all study groups. However, HIR was significantly reduced in high Se-low Zn group and low Zn-low Se group compared to high Zn-low Se group ($P<0.01$). L-NAME and INDO significantly blocked HIR in high Zn-low Se and low Zn-low Se groups and INDO reduced HIR more than L-NAME. In high Se-low Zn group HIR was blocked only after INDO administration.

Conclusion: These data suggest: 1) Zn and Se deficiency affected vascular response to ACh and reduced pO2 in rat aortic rings; 2) Zn deficiency may affect vascular NO system more than Se deficiency; 3) adequate Se levels seem to have influence of the COX-dependant pathways; and 4) it seems that for

ACh dependent relaxation both microelements are equally important, while for HIR, adequate Zn level is more important.

Deficiency in endothelial cell tetrahydrobipterin reveals hydrogen peroxide mediated changes in vascular function and blood pressure in vivo

S. Chuaiphichai, E. McNeill, J.K. Bendall, G. Douglas, M.J. Crabtree, A.B. Hale, N.J. Alp and K.M. Channon

Department of Cardiovascular Medicine, University of Oxford, Oxford, UK

Nitric oxide (NO), produced by endothelial NO synthase (NOS) is a key regulator of vascular tone and blood pressure. Tetrahydrobiopterin (BH4) is an essential cofactor for endothelial NOS. When BH4 levels become limiting, eNOS produces superoxide anion rather than NO and in turn further reduces NO bioavailability, resulting in endothelial dysfunction. Endothelial cell BH4 has been hypothesized to be critical in maintaining vascular function, but to date in vivo models of BH4 deficiency have achieved only partial global depletion of BH4 synthesis. We have investigated the specific role of endothelial cell BH4 using a novel line of conditional knockout mice.
Mice homozygous for a floxed GCH1 ($GCH1^{fl/fl}$) allele (encoding for GTPCH I protein an essential enzyme in BH4 biosynthesis) were crossed with Tie2-cre transgenic mice to produce $GCH1^{fl/fl}$/Tie2-cre line, where the GCH1 gene is knocked out in endothelial cells. We have shown that the GCH1 gene is completely excised in isolated endothelial cells, with an accompanying lack of BH4 production in aortas from $GCH1^{fl/fl}$/Tie2-cre mice. To assess the effects of endothelial cell BH4 deficiency on eNOS uncoupling, superoxide production in the aorta was measured using dihydroethidium fluorescence. Endothelial-derived superoxide production was significantly 4-fold greater in $GCH1^{fl/fl}$/Tie2-cre mice compared to wild-type littermates, and was abolished by the NOS inhibitor L-NAME. Vasomotor studies demonstrated that $GCH1^{fl/fl}$/Tie2-cre aortas had enhanced vasoconstriction to phenylephrine (Emax, 97.8±7.3 vs 118.4±5.6; P<0.05) that normalised in the presence of L-NAME. Endothelium-dependent vasodilatations in response to the receptor-mediated eNOS agonist, acetylcholine were impaired in isolated aortic rings (- log ECH_{50}, 7.53±0.05 vs 7.30±0.05; P<0.01) and vasodilatations were abolished in the presence of L-NAME in both genotypes. The NOS-derived vasodilator in $GCH1^{fl/fl}$/Tie2-cre aortas was identified as H_2O_2 using the scavenger PEG-catalase, which inhibited vasodilatation only in $GCH1^{fl/fl}$/Tie2-cre aortas. *Ex vivo* supplementation of aortic rings with BH4 analogue sepiapterin restored normal endothelial function and abolished eNOS-derived H_2O_2 production in $GCH1^{fl/fl}$/Tie2-cre aortas.
Non-invasive blood pressure measurement using tail-cuff plethysmography demonstrated higher systolic blood pressure in $GCH1^{fl/fl}$/Tie2-cre mice than wild-type littermates (96.4±0.8 in WT vs 103.4±1.3 in $GCH1^{fl/fl}$/Tie2-cre) that normalised when L-NAME was given in drinking water (114.3±1.1 in WT vs 113.4±1.8 in $GCH1^{fl/fl}$/Tie2-cre). These findings demonstrate that endothelial cell BH4 plays a pivotal role in maintaining normal vascular function and determining the formation of the alternative eNOS-derived vasodilators, NO vs H_2O_2.

PCD379

Simvastatin and lovastatin reverse functional microvascular rarefaction in the brain and skeletal muscle of spontaneously hypertensive rats

F. Freitas, V. Estato, M. Lessa and E. Tibiriçá

Physiology and Pharmacodynamic, Oswaldo Cruz Foudation, Rio de Janeiro, Rio de Janeiro, Brazil

Motivation: Microvascular rarefaction is an aggravating factor of hypertensive end-organ damage. However, the microcirculatory effects of statins in hypertension remains unknown. Thus, this study was designed to investigate the acute effects of simvastatin and lovastatin on cerebral and muscular microcirculation in Spontaneously Hypertensive Rats (SHR). Methods: Male normotensive Wistar rats (WKY) and SHR were divided into 4 groups of 6 animals each: WKY and SHR-CTL treated with 0.9% saline solution, and SHR+SIM and SHR+LOVA treated with simvastatin (SIM) and lovastatin (LOVA) 30 mg/kg/day during 3 days orally by gavage. Systolic Blood Pressure (SBP) was measured by a computerized tail-cuff plethysmography system. We investigated brain and skeletal muscle (SM; gracilis muscle) Functional Capillary Density (FCD) of pentobarbital-anesthetized rats (75 mg/kg) using intravital fluorescence videomicroscopy. Values are means ± S.E.M., compared by Two-tailed unpaired t test. All surgical procedures and protocols were approved in accordance with the internationally accepted principles for the Care and Use of Laboratory Animals (license # L-48/12). Results: SIM administration reduced SBP in SHR (SHR-CTL 203±3 vs. SHR+SIM 172±6 mmHg; p< 0.001; in contrast LOVA treatment was not able to reduce SBP (SHR+LOVA 192±3 mmHg). SHR showed a significantly lower FCD in the gracilis muscle compared to WKY (SHR-CTL 210±17 vs. WKY 338±16 capillaries/mm^2 ; p<0.01). SIM (SHR+SIM 447±20 capillaries/mm^2) and LOVA (SHR+LOVA 418±22 capillaries/mm^2) treatment reverted functional capillary rarefaction in the SM of SHR (SHR-CTL 210±17 capillaries/mm^2; p<0.001). Cerebral FCD was reduced in SHR compared with WKY (SHR-CTL 337±61 vs. WKY 421±35 capillaries/mm^2, p<0.05). The administration of SIM (SHR+SIM 530±31 capillaries/ mm^2) and LOVA (SHR+LOVA 471±37 capillaries/mm^2) during 3 days was capable to increase cerebral

FCD in SHR (SHR-CTL 337±61 capillaries/mm^2; p< 0.05). Leukocyte rolling was significantly greater in SHR when compared with WKY (SHR-CTL 6.2±0.7 vs. WKY 2.7±0.5 cells/min; p<0.05), and 3 day treatment with SIM (SHR+SIM 2.8±0.6 cells/min; p< 0.01) and LOVA (SHR+LOVA 1.8±0.5 cells/min; p< 0.001) reduced leukocyte rolling when compared with SHR (SHR-CTL 6.2±0.7 cells/min). Conclusions: Acute treatment with simvastatin and lovastatin significantly reduced brain post-capillary venules leukocyte rolling and reversed microvascular rarefaction in SHR. In addition to cholesterol-lowering effects, pleiotropic effects of statins could turn out to be a new therapeutic approach for improving microcirculatory function in hypertensive patients. However, it is necessary to further investigate the mechanisms and pathways which may additionally play important roles in statin-mediated cardiovascular protection in hypertension.

Dynamics of neutrophil-endothelial interactions governs dissemination of local inflammation

J.V. Bodkin[1], M. Beyrau[1], A. Woodfin[1], B. Colom[1], N. McCloskey[1], M. Bianchi[2] and S. Nourshargh[1]

[1]Queen Mary University of London, London, UK and [2]San Raffaele University and Scientific Institute, Milan, Italy

Neutrophil transmigration through venular walls is an important physiological reaction to inflammatory insults. This response normally occurs in vivo in a luminal-to-abluminal direction, however neutrophil reverse transendothelial migration (rTEM) has been observed in an in vitro flow model[1]. Furthermore, we recently reported on the occurrence of directionally disrupted modes of neutrophil TEM in an in vivo mouse model of ischemia-reperfusion (I-R) injury[2]; namely "hesitant" TEM (characterised by oscillatory movements within the endothelial cell junction followed by complete transmigration) and reverse TEM (migration in an abluminal-to-luminal direction resulting in return of the neutrophil to the circulation). Of importance, the latter was causally linked with the appearance of a phenotypically distinct and pathogenic subset of neutrophils found within the lung vasculature[2]. The present study further characterises the profile and prevalence of these rare and disrupted TEM phenomena in response to a range of inflammatory agents.

Neutrophil TEM was induced in the cremaster muscle microcirculation of LysM-EGFP$^{+/-}$ mice through local application of multiple inflammatory stimuli. Dynamics of neutrophil TEM was subsequently measured under ketamine/xylazine anaesthesia by 4D confocal intravital microscopy as previously detailed [2]. Neutrophils in the blood, pulmonary vasculature and lung tissue were quantified and phenotypically analysed by flow cytometry.

TEM induced by LPS and leukotriene B_4 involved a high frequency of rTEM (~10-25% of all TEM events quantified), whereas TNF and HMGB1 caused low levels of rTEM (~0-2%), but were associated with significant levels of 'hesitant' TEM (~11-21%). In contrast, a relatively low percentage of disrupted TEM events was observed in KC and IL1-β-stimulated tissues. In all the models investigated, the frequency of rTEM was associated with the occurrence of lung inflammation alongside a sub-set of ICAM-1^{+ve} neutrophils in the pulmonary vasculature. Our findings demonstrate that inflammatory stimuli can cause distinct neutrophil TEM dynamics, which specifically contribute to the pathogenic outcome of these reactions at sites distant from the inflammatory insult.

Signalling responses in cardiac endothelial cells, following treatment with high concentrations of TNF-α, with or without co-treatment with Oleanolic Acid

A. Genis, C. Westcott, M. Mudau and H. Strijdom

Biomedical Sciences, University of Stellenbosch, Cape Town, Western Cape, South Africa

Introduction: TNF-α is a pro-inflammatory cytokine and harmful circulating stimulus (1). Endothelial cells are targets of harmful TNF-α (1) and high concentrations of TNF-α can set off signalling events that can lead to endothelial injury. Oleanolic Acid (OA) is a triterpenoid found in food and plants (2) and has previously been shown to have antioxidant properties (3). Combination treatment with TNF-α and OA has not been investigated before.

Aims: Investigating the effects of TNF-α (20ng/ml, 24h), OA (40μM, 24h) or OA pre-treatment+TNF-α on the eNOS-NO biosynthesis pathway, oxidative stress and cell viability in vitro.

Methods: CMECs (*Rattus norvegicus*) were incubated with: TNF-α and/or OA-containing medium. At the end of incubation, samples were prepared for flow cytometric (FC) and western blot analyses (WB). Intracellular levels of nitric oxide (NO) and reactive oxygen species (ROS) were determined by FC analyses of DAF-2/DA and DHR-123 fluorescence. eNOS, iNOS, PKB, caveolin-1, HSP90, nitrotyrosine, p22-phox, cleaved caspase-3, cleaved PARP and Iκβα were determined by WB measurements.

Results: TNF-α resulted in decreased NO levels (77.32±0.87 *vs*. 100; p<0.05). TNF-α and TNF-α+OA resulted in reduced phospho/total ratio eNOS (0.79±0.05; 0.79±0.04 *vs*. 1; p<0.05). A reduction in caveolin-1, HSP90 and phospho/total ratio PKB was also seen in TNF-α and TNF+OA (p<0.05). Despite reduced ROS levels observed with TNF-α, p22-phox expression increased in all three groups (1.93±0.05; 1.38±0.09; 2.06±0.04 *vs*. 1; p<0.05). Reduced DHR-123-sensitive ROS corresponded with reduced nitrotyrosine in TNF-α and OA groups (p<0.05). Caspase-3 increased in TNF-α (1.12±0.02 *vs*. 1; p<0.05), whereas OA resulted in reduced caspase-3 (0.94±0.01 *vs*. 1; p<0.05). No changes were observed in cleaved PARP. Reduced Iκβα expression was observed in all treatments (p<0.05).

Discussion: The TNF-α-induced decrease in NO seemed to be associated with a decrease in phospho/total eNOS ratios, accompanied by reduced PKB ratio, HSP90 and caveolin-1. The TNF-α-induced decrease in ROS levels, contradicted the increase observed in p22-phox expression. The reduced DHR-123-sen-

sitive ROS levels corresponded with a reduction in nitrotyrosine. TNF-α seemed to be pro-apoptotic, whereas OA was anti-apoptotic. The increase in p22-phox (TNF-α, OA and TNF+OA) did not translate in increased ROS generation. In conclusion, TNF-α induced an overall adaptive response with early signs of increased NADPH-oxidase activity and apoptosis. OA seemed to be protective, though it was not able to reverse the effects seen with TNF-α.

PCD383

Regulation of lymphatic endothelial cell migration by platelets

S.A. Langan, L. Navarro-Núñez, S.P. Watson and G.B. Nash

Centre for Cardiovascular Sciences, University of Birmingham, Birmingham, UK

Introduction: Podoplanin, a transmembrane receptor expressed on lymphatic endothelial cells (LEC), is the only known endogenous ligand for the platelet receptor CLEC-2[1]. Both of these proteins are thought to be involved in lymphatic development as mice deficient in either CLEC-2 or podoplanin develop a blood-lymphatic mixing phenotype. Work by others has also shown that podoplanin knockdown reduces LEC migration in response to vascular endothelial growth factor C (VEGF-C)[2]. Therefore, we aimed to assess whether the interaction between podoplanin and CLEC-2 on platelets regulates LEC migration, and to begin to uncover the signalling mechanism underlying this.
Methods: Transfilter assays were used to assess human LEC and human microvascular endothelial cell (HMEC)-1 migration. VEGF-C solution or normal culture medium was placed in the lower chamber of the well before endothelial cells were seeded onto the filter. After an hour, washed human platelets, antibodies or a Rho inhibitor (CT04; Cytoskeleton Inc., CO) were added to the filter. Percentage transmigration was assessed after 12 or 24 hours. A paired t-test was used to determine significance of single treatments. To compare several conditions, an ANOVA was performed, followed by post hoc Dunnett test.
Results: Platelets inhibited VEGF-C mediated increase in LEC migration in a count-dependent manner, but had no effect in the absence of VEGF-C ($P<0.05$; N=4). Similarly, platelets were able to inhibit VEGF-C mediated increase in migration of HMEC-1 cells ($P<0.05$; N=3), which are described as a microvascular endothelial cell line, but are known to express podoplanin and vascular endothelial growth factor receptor 3 (VEGFR3)[3]. Crosslinking podoplanin with an anti-human podoplanin antibody and an appropriate secondary also inhibited VEGF-C mediated LEC migration ($P<0.01$; N=3). Rho inhibitor CT04 inhibited migration but combining the inhibitor with crosslinking did not have an additive effect.
Conclusions: Platelets have a strong inhibitory effect on LEC migration in response to VEGF-C, which may be due to the interaction of CLEC-2 and podoplanin. Platelets also inhibited VEGF-C mediated migration of HMEC-1, further supporting the hypothesis that this is due to the interaction of CLEC-2 and podoplanin. Antibody-mediated crosslinking also inhibited VEGF-C mediated LEC migration, suggesting that CLEC-2 may be clustering podoplanin. Combining crosslinking with the Rho inhibitor CT04 did not have an extra inhibitory effect, suggesting that the effects of crosslinking podoplanin may involve Rho signalling.

Targeted deletion of the extracellular calcium-sensing receptor (CaSR) from vascular smooth muscle cells reveals roles for the receptor in blood pressure regulation and protection against vascular calcification

M. Schepelmann[1], T. Davies[1], P. Yarova[1,2], S. Brennan[1], J. Graca[3], W. Chang[4], D. Bikle[4], P. Edwards[1], M. Krssak[5], D. Ward[6], A. Canfield[6], D. Edwards[7], S. Price[3], P. Kemp[1] and D. Riccardi[1]

[1]School of Biosciences, Cardiff University, Cardiff, UK, [2]Kings College, London, UK, [3]Astra Zeneca, Macclesfield, UK, [4]Department of Medicine, University of California, San Francisco, CA, USA, [5]Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, [6]Faculty of Medical and Human Sciences, University of Manchester, Manchester, UK and [7]School of Medicine, Cardiff University, Cardiff, UK

Background: The extracellular Calcium Sensing Receptor (CaSR) is expressed in the vasculature where its roles are still poorly understood. In this study, we investigate the physiopathological roles of the CaSR in the vasculature in a mouse model of vascular smooth muscle cell (VSMC) specific targeted CaSR deletion (SM22α-Cre x LoxP-CaSR) by performing *in vitro*, *ex vivo* and *in vivo* studies.
Results: Wild type (WT) and knock-out (KO) mice were identical in size, lifespan, and reproductive capability. ***In vitro*:** In the presence of calcifying concentrations of inorganic phosphate (Pi; 3 mM) and Ca^{2+} (1.8 mM), cultured VSMC from KO mouse aortae showed a significant increase in calcification compared to WT control (24.60±2.84 vs. 0.99±0.90, arbitrary units, $p<0.001$, N=6-8, Alizarin Red densitometry), while the allosteric CaSR agonist R-568 reduced Pi/Ca^{2+}-dependent calcification in WT, but not KO VSMC. ***Ex vivo*:** Wire myography on aortic rings of WT and KO mice demonstrated that aortae from KO mice had significantly narrower luminal diameters compared to those from WT control (950.2±25.6 vs. 1024.7±36.0 μm, $p<0.01$, N=5-8). Contractile force of KO aortae in response to KCl and phenylephrine (PE) was significantly impaired compared to that of WT control (3.57±0.79 vs. 5.76±1.36 mN $p<0.01$, N=5-8, 3 μM PE). ***In vivo*:** Blood pressure of 3-6 month old KO mice was significantly reduced compared to WT (106±6 vs. 134±7 mm Hg diastolic, $p<0.01$ and 157±4 vs. 180±5 mm Hg systolic, $p<0.05$; N=10-11, tail-cuff).

Cardiac MRI performed under anaesthesia showed significant heart remodelling of 14 month old KO mice compared to WT control in the form of increased left ventricular ejection fractions (74.3±1.9 vs. 59.0±2.5 %, p<0.01, N=3) and reduced diastolic and end-systolic volumes. Accordingly, heart wet-weight of 18 month old, but not 3 month old, KO mice was higher than that of age-matched WT control, suggesting that the observed heart remodelling progresses with age. (All data mean±SEM, two-tail t-test)
Conclusions: Under pathological conditions of elevated Ca^{2+} and Pi concentrations, loss of CaSR increased *in vitro* VSMC calcification while CaSR activation with a calcimimetic reduced VSMC calcification. The reduction in contractile force in aortae from KO is consistent with the observed decrease in blood pressure compared to WT control. The reduction of aortic luminal diameter and heart remodelling indicate a compensatory response to the hypotensive phenotype. Together, these data suggest that the vascular CaSR plays an important role in physiology, by influencing blood pressure regulation, and in pathology, by preventing vascular calcification.

PCD385

Characterization of endothelial progenitor cell migration in vivo

J. Pircher, K. Pogoda and U. Pohl

Walter-Brendel-Centre of Experimental Medicine, Munich, Germany

Introduction: Endothelial progenitor cells (EPCs) are not only involved in physiological neovascularization but also play an important role in wound healing, tissue regeneration and remodeling (e.g. in myocardial ischemia), and tumor angiogenesis. To exert some of these functions migration of the cells within the tissue is required. However, the kinetics of migration as well as the underlying mechanisms in vivo are still poorly understood. Therefore we aimed to develop a model to investigate migration of EPCs in vivo.
Methods and Results: EPC migration in vivo was investigated in the dorsal skinfold chamber model in C57Bl/6 mice. Cultivated murine embryonic EPC (Hatzopoulos et al. 1998) were stimulated with SDF1-α (100ng/mL) to induce a migratory phenotype and labeled with Carboxyfluorescin (CFDA-SE 10μM) for 30 minutes before being detached from the culture plate using accutase. Immediately after preparation of the dorsal skinfold chamber model 10μL of the cell suspension (about 10^6 cells/mL) were injected into the dermal tissue in close apposition to a medium sized skin arteriole (diameter about 50μm) using a 30g needle. Application of the cells did not result in tissue edema or overt inflammation over an observation period of 3-4 days. According to expansion of the tissue volume covered by EPCs most cells remained intact and showed migratory activity as revealed by conventional intravital fluorescence microscopy as well as two-photon microscopy. While most cells migrated individually others formed larger aggregates within the tissue. Regular observations of migrating cells were possible by two-photon microscopy over several days.
Conclusions: We established a model which allows us to characterize behavior and migration of EPCs in the perivascular tissue of the skin for several days. By using two-photon microscopy we were able to follow small changes and movements of single cells in the deeper layers of the tissue in a three-dimensional manner. Our model constitutes a potentially useful tool to investigate mechanisms involved in homing and migration of endothelial progenitor cells in response to different migratory stimuli.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD386

Targeting vulnerable *loci* in the endothelium

J. Amado-Azevedo, J. van Bezu, E.T. Valent, V. van Hinsbergh and G.P. van Nieuw Amerongen

Physiology (ICar-VU), VU University Medical Center, Amsterdam, NH, Netherlands

Despite being an extremely thin single-cell layer, the endothelium performs exceedingly well in preventing blood fluids from leaking into the surrounding tissues. However, under specific pathological conditions this cell layer can be affected, compromising the barrier's integrity. Vascular leakage is a hallmark of many cardiovascular diseases and albeit its medical importance no specialized therapies are available to prevent it or reduce it (1). Rho (Ras homology) GTPases are known as key regulators of different aspects of cell behavior, such as cell shape, migration, tension, division and contraction. The activity of Rho proteins is regulated by conformational changes induced by binding of guanine nucleotides, being GTP-bound Rho the active form and GDP-bound Rho the inactive (2). The regulators of this activation-inactivation cycle are: *ca* 70 GAPs (GTPase Activating Proteins) responsible for the inactivation process and approximately 80 GEFs (Guanine nucleotide Exchange Factors) controlling the activation. Interestingly, studies have shown that they can exert both positive and negative effects on the endothelial barrier's integrity (3). Knowledge about both the precise mechanism of this regulation and the individual contribution of these specific regulatory proteins remains fragmentary.
In order to identify suitable targets for intervention with the underlying RhoA-mediated signaling, we propose to study all known regulators of RhoGTPase activity. RNA interference screens will be carried out with small interfering RNA (siRNA) libraries targeting RhoGAPs, RhoGEFs and effectors, using human umbilical vein endothelial cells (HUVECs). With this approach we will be able to: test the effect of depletion on cellular morphology and endothelial barrier integrity using Electric Cell-Substrate Impedance Sensing (ECIS) technology and permeability assays; and also test the effect of depletion on RhoGTPase activity using an automated microscope (Cellomics Array Scan), as well as Rho G-LISAs. Positive candidates will be further studied using in-depth FRET-based biosensors in order to determine their role in regulation of RhoGTPase activity.
The outcome of this project will provide detailed information on cellular RhoGTPase activity measured in space and time, as well as valuable insight regarding both the regulatory mechanism of these important proteins and the vulnerable *loci* in the endothelium. This mechanistic understanding will unveil unanticipated pathways suitable for therapeutic intervention, through which specific molecular targets for stabilization of the endothelial barrier will be identified, limiting episodes of vascular leakage.

PCD387

Endothelial-dependent relaxation in the murine thoracic aorta is transiently increased after high fat feeding

C.J. Cobb, R.E. Walker, K.A. Farrell, D. Eisner, C.E. Austin and C.M. Holt

Institute of Cardiovascular Sciences, University of Manchester, Manchester, Greater Manchester, UK

Hypercholesterolaemia is an associated risk factor for cardiovascular disorders, including atherosclerosis and hypertension, and is thought to contribute to endothelial dysfunction. The role of cholesterol in the modulation of vascular endothelial and smooth muscle signalling has previously been demonstrated via its removal from membranes using agents such as methyl-β-cyclodextrin. However, to date there has been limited investigation into the effects of increased serum cholesterol concentration on vascular function. In this study, wire myography was employed on sections of thoracic aorta taken from the apolipoprotein-E knock-out mouse model ($ApoE^{-/-}$) of hypercholesterolaemia. The tissue was equilibrated at 5mN of resting tension for 1hr before endothelial-dependent relaxation was assessed by exposure to 10μM acetylcholine, after pre-constriction with 10μM phenylephrine. Data are expressed as means ± S.E.M., compared by one-way ANOVA, unless stated. $ApoE^{-/-}$ mice fed a normal chow diet (8 weeks), showed no change in endothelial dysfunction when compared to age and strain matched controls (42.5±10.5 vs. 45.1±4.4% relaxation, respectively). However, feeding with a high fat diet (HFD; 8 weeks) caused a significant increase in thoracic aorta endothelial-dependent relaxation in both $ApoE^{-/-}$ (69.4±3.0 vs. 45.1±4.45% relaxation; $p<0.05$, n=7,8) and control mice (75.3±4.5 vs. 45.1±4.4% relaxation; $p<0.01$, n= 7,8) compared to the chow fed controls. This augmented response was not maintained after further high fat feeding to 16 weeks (51.6±12.1 vs. 45.1±4.4% relaxation; n=4,8). The transient increase in endothelial–dependent relaxation in high fat fed control mice was preserved after incubation with a nitric oxide synthase inhibitor (LNNA (N-nitro-L-arginine) 50μM; 24.7±6.0 vs. 50.4±8.0% relaxation; chow vs HFD, post-treatment; $p<0.05$, unpaired t-test, n = 4) but was reduced after incubation with a cyclooxygenase inhibitor (indomethacin 10μM; 60.2±4.3 vs. 71.8±3.8% relaxation; chow vs HFD, post-treatment; n=4). These data suggest that high fat feeding results in a transient increase in endothelial-dependent relaxation that is mediated by cyclooxygenase signalling. It is widely known that cyclooxygenase activity is modulated by inflammation; therefore, it is possible that the response observed may represent a compensatory vascular reaction to inflammation induced by high fat feeding.

This studentship was funded by the British Heart Foundation.

Chronic hypoxia-enforced inhibition of vascularization; Involvement of HIF1α and HIF2α

T. Nauta[1,3], E. Weijer[1], S. Gibbs[2], R. Scheper[3], V. van Hinsberg[1] and P. Koolwijk[1]

[1]Physiology, VU University Medical Centre, Amsterdam, Netherlands, [2]Dermatology, VU Medical Centre, Amsterdam, Netherlands and [3]ASkin BV, Amsterdam, Netherlands

Motivation
Many patients with chronic open wounds need skin tissue transplantation. Transplantation with donor skin often results in rejection of the donor skin and nowadays transplantation with a tissue engineered scaffold is performed. Successful tissue transplantation and engineering requires adequate vascularization. Even though it is generally accepted that short term hypoxia stimulates angiogenesis, in chronically ischemic/hypoxic tissues and tissue-engineered scaffolds, endothelial cells have reduced angiogenic capacities. Despite the progress in knowledge on inhibiting angiogenesis, little is known about the stimulation. Exposure of endothelial cells to high concentrations of angiogenic growth factors induces chaotic and unstable vascular structures that are not adequately perfused. Therefore, it is important to understand how the induction of angiogenesis during hypoxia can be controlled. Many of the processes induced by hypoxia are mediated by the Hypoxia Inducible Factors, a family of transcription factors that directly induce the expression of many genes. Mainly HIF1α and HIF2α are involved in the regulation of genes under hypoxic conditions. Therefore, this study aims to investigate the putative role of HIF1α and HIF2α in chronic hypoxia-enforced inhibition of vascularization in vitro.
Methods
Human microvascular endothelial cells (hMVECs) were cultured at 20% oxygen or 1% oxygen for 14 days, without reoxygenation, and transfected with short interfering RNA (si-control, si-HIF1α or si-HIF-2α). The hMVECs were seeded on top of 3D fibrin matrices, and stimulated with the combination of VEGF and TNFα for 6 days to induce tube formation.
Results
hMVECs cultured at 20% oxygen formed tube-like structures in vitro, whereas those cells that were preconditioned at low (1%) oxygen did not form these structures. Surprisingly, cells transfected with si-HIF2α were able to form tube-like structures at 1% oxygen while the cells transfected with si-HIF1α or si-control did not (n=3).
Conclusion
Clearly, the formation of tube-like structures was inhibited under chronic hypoxia. However, transfection of chronic hypoxic cells with si-HIF2α restored the sprouting of endothelial cells. This indicates that counter intuitively HIF2α can impair tube formation in vitro. It is, therefore, important to further unravel its actions by using genome-wide RNA-sequence analysis and determine which transcription factor(s) and pathways downstream of HIF2α are involved.

PCD389

Investigating the role of perivascular adipose tissue on vasoconstriction in mouse mesenteric arteries

P. Thakore[1], A.A. Aubdool[2], S.D. Brain[2] and I. McFadzean[1]

[1]Institute of Pharmaceutical Sciences, King's College London, London, UK and [2]BHF Centre of Cardiovascular Excellence and Centre of Integrative Biomedicine, King's College London, London, UK

Soltis and Cassis (1991) initially discovered that perivascular adipose tissue (PVAT) is able to regulate vascular tone. Since then a number of groups confirmed this finding, but most studies have been carried out in large conduit arteries. The aim of this study was to determine the influence of PVAT on vasoconstrictor responses in small resistance arteries. Male CD1 mice (3 months; 35-45g) were culled by cervical dislocation. First-order mesenteric arteries (either with or without associated PVAT) were mounted onto a wire myograph (Danish Myo Technology) and bathed in a modified Kreb's-Henseleit solution, gassed with 95% air/5% CO_2, warmed to 37ºC and set to a resting tension of 13.3kPa. Vasoconstrictor responses were expressed as a percentage of the increase in tension produce by 80mM KCl. Log-concentration *vs.* response curves were fitted with a 4 parameter logistic function to obtain E_{Max} (maximum response) and pEC_{50}. Results are shown as mean ± SEM and analysed by Student's unpaired *t-test*.

In the first series of experiments the effects of PVAT on responses to contractile agents was investigated. The presence of PVAT produced a significant reduction in the maximum response to phenylephrine (+PVAT E_{Max}=21.4±3.2% *vs.* -PVAT E_{Max}=47.8±4.8%, p<0.01; n=4) with a concomitant decrease in pEC_{50} (+PVAT pEC_{50}=5.1±0.1 *vs.* -PVAT pEC_{50}=5.8±0.1, p<0.05). The presence of PVAT also produced a right-ward shift in the concentration response curve to U46619 (100pM-1μM; +PVAT pEC_{50}=7.0±0.2 *vs.* -PVAT pEC_{50}=8.1±0.2, p<0.01; n=4) however this was not accompanied by a decrease in Emax (+PVAT E_{Max}=104.2±13.3% *vs.* -PVAT E_{Max}=100.8±9.2%). The presence of PVAT had no significant effect on contractile responses to KCl (n=4).

We next investigated whether PVAT releases a diffusible factor to inhibit vasoconstrictor responses. Vessels denuded of PVAT were set up in the myograph as described. The effect of a 30 minute co-incubation with PVAT collected from first order mesenteric arteries on contractile responses was then tested. The maximum response to phenylephrine was significantly reduced in the presence of PVAT (PVAT E_{Max}=19.5±2.2% *vs.* time control E_{Max}=61.8±9.5%, p<0.01; n=5). However the responses to U46619 (n=5) and KCl (n=4) were comparable in both groups.

These results suggest that PVAT releases a factor that attenuates phenylephrine-induced vasoconstrictor responses in mouse mesenteric arteries. The lack of effect of PVAT on contractions produced by raised extracellular potassium may suggest the involvement of K^+ channels in the inhibition produced by the adipose tissue.

Microcirculation disorders and inflammatory markers in patients with coronary artery decease and chronic heart failure

A. Shchendrygina, E. Privalova and Y. Belenkov

I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Abnormalities of microcirculation occur in multiple tissue beds in patients with cardiovascular diseases (CVDs) and lead to end-organ damage. It is known that high levels of inflammatory markers in CVDs patients were found. The purpose of our study was to estimate whether micro vascular disorders correlates with level of inflammatory markers. In patients with coronary artery disease CAD (n=37; male: 23; mean age: 62,7±6) and chronic heart failure (CHF) (n=33; male: 20; mean age: 58,2±7,5) New York Heart Association (NYHA) class II -III and 34 healthy controls (male: 17; mean age: 57,3± 7,9) digital photoplethysmography and nail fold videocapillaroscopy at resting baseline, during venous occlusion were performed. We evaluated structural changes of microcirculation in small resistance arteries (reflection index, RI) and diameters of arterial (Da) and venous (Dv) part of capillary loop. Endothelial function (occlusion index, IO) of arterioles and capillary function (percent capillary recruitment, pCR) (Cheng C et al. (2008). Ther Adv Cardiovasc Dis. 2(2), 79–88) were estimated. Inflammatory markers such as C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and fibrinogen were determined. Values are median and IQI, compared by Mann-Whitney U-test. Correlation was estimated by Spearman's Rank Correlation Coefficient (rs). In patients with CAD and CHF structural and functional of microcirculation in arterioles were found. IO in CAD and CHF patients was significantly different from controls (IO CAD: 1,6 (1,4;1,9) vs. CHF: 1,5 (1,3;1,7) vs. control: 1,8 (1,5;2,7); p<0.05). Structural changes in arterioles level (RI) were above norm (< 30%), in all groups but there was no different RI between groups (RI CAD 37,2 (22,3;47,5) vs. CHF 32,2 (25,3;47,2) vs. Control: 33,5 (29,5;47), p= 0.3). Functional disorders of capillary (pCR) in patients with CAD and CHF were found. pCR was significantly lower in CVDs groups than in controls, while there was no differences between CAD and CHF groups (pCR CAD: 90 (82;93) vs. CHF: 88 (75;95) vs. control: 93 (88;96), p<0.05). Da was significantly lower in CAD patients than controls (Da CAD: 5.2 (4.9;5.5) vs. control 7.1 (7.0;9.5), p<0.05). Dv was higher in CHF patients (Dv CHF: 13.7 (10.5;17) vs. control 2.1 (10.8;14.6), p<0.05), while there was no differences between CAD and control. Correlation between Da and CRP (rs = 0,34; p<0.05), Da and fibrinogen (rs = -0,28; p<0.05) were found. Dv correlated with ESR (rs = -0,23; p<0.05). This data show that abnormalities of microcirculation in capillary level correlate with levels of inflammatory markers in patients with coronary artery decease and chronic heart failure. It might be that micro vascular disorders are also occurs via mechanisms of inflammation.

Responses of aortic and cardiac microvascular endothelial cells to TNF-α: Does endothelial heterogeneity matter?

M. Mudau, A. Genis, C. Westcott and H. Strijdom

Biomedical Sciences, Stellenbosch University, Tygerberg, Western Cape, South Africa

Background: Endothelial heterogeneity represents the structural and functional ability of the endothelium to cater for the diverse needs of the underlying tissues in the vascular tree [1]. TNF-α is an inflammatory cytokine which has been associated with endothelial dysfunction (ED) and hence cardiovascular disease [2].**Objectives**: To compare the *in vitro* TNF-α induced responses of two cell lines from distinct vascular sites, viz. cardiac microvascular endothelial cells (CMECs) and aortic endothelial cells (AECs).**Methods**: Adult rat (Rattus Norvegicus) CMECs and AECs were treated with 0.5, 5 and 20ng/ml TNF-α (24 and 48H). Nitric oxide (NO) and reactive oxygen species (ROS) were measured by DAF-2/DA and DHR fluorescence respectively. Cell viability was quantified by PI/Annexin-V fluorescence. The following proteins were measured by Western blotting: eNOS, PkB/Akt, heat shock protein 90 (HSP90), caveolin-1, nitrotyrosine and IkBα in cells treated with 5 and 20 ng/ml TNF-α (24h). All data are expressed as % of control (control:100%).**Results**: After 24H, AECs treated with 5ng/ml TNF-α showed significantly lower NO-production vs. control (AECs: 54±7.7% vs. Control, p<0.05). At 48h, all TNF-α concentrations significantly reduced NO-production in AECs and CMECs vs. controls; however, there were no differences in AECs vs. CMECs. TNF-α decreased DHR sensitive ROS in both cell lines vs. control, with a significantly greater reduction in CMECs vs. AECs. There were no differences in cell viability in either cell line after 24h. At 48h, CMECs showed higher % apoptosis vs. AECS, and 20ng/ml TNF-α significantly increased necrosis in CMECs (8.30±1.3%) vs. AECs (1.0±0.3%), p<0.05. At 20ng/ml TNF-α, phospho/total eNOS ratios were significantly lower in CMECs (68±5%) vs. AECs (94±10%); p <0.05. Although total PKB/Akt expression was significantly lower in CMECs vs. AECS (5ng/ml and 20ng/ml TNF-α), a significant reduction in phospho/total PKB/Akt ratio was only observed at 20ng/ml TNF-α (AECs: 94±4% vs. CMECs: 55±4%, p<0.05). HSP90 was decreased in both cell lines after TNF-α treatment vs. controls; with no differences observed in CMECs vs. AECs. IkBα expression was reduced in CMECs (5ng/ml: 70±2%; 20ng/ml: 50±10% vs. controls; p<0.05) and vs. AECs (5ng/ml:100±0.2%; 20ng/ml:75±10%; p<0.05). Caveolin -1 and nitrotyrosine levels remained unchanged.**Conclusion**: The PKB/Akt-eNOS pathway is a principal source of NO production in ECs [2]. TNF-α resulted in a downregulation of this pathway in AECs and CMECs, which was more pronounced in CMECs. The TNF-α-induced attenuation of the PKB/Akt-eNOS pathway suggested an early dysfunctional response in our cells. The reduced expression of IkBα (more pronounced in CMECs) is a reflection of NFkB-activation, a major pro-inflammatory pathway[3]. Overall, CMECs appeared to be more susceptible to the harmful effects of TNF-α than AECs.

PCD392

Exchange protein activated by cAMP (Epac) inhibits human vascular smooth muscle cell migration

J.S. McKean[1], D. Shewan[1], G. Gibson[2] and G.F. Nixon[1]

[1]School of Medical Sciences, University of Aberdeen, Aberdeen, UK and [2]Department of Cardiothoracic Surgery, Aberdeen Royal Infirmary, Aberdeen, UK

Following vein grafting, endothelial damage initiates vascular smooth muscle cell (VSMC) migration to the intima leading to neointimal hyperplasia. Inhibition of VSMC migration is therefore a therapeutic target in vascular disease. Cyclic adenosine monophosphate (cAMP) inhibits VSMC migration and activation of this pathway could be used to prevent neointimal hyperplasia. Prostacyclin analogues, such as beraprost and iloprost, bind to prostanoid receptors and induce cAMP production. This project aims to characterise the effects of prostacyclin analogues in VSMC migration and determine the cAMP downstream molecules involved, specifically examining the role of protein kinase A (PKA) and exchange protein activated by cAMP (Epac). Saphenous veins were obtained from patients undergoing coronary artery bypass. VSMCs were primary cultured and migration measured using a chemotaxis chamber. Cells were seeded onto membranes with 8 μm pores and platelet-derived growth factor-BB (PDGF) (10 ng/ml) was added to the lower well of the chemotaxis chamber. Chemotactic cell migration after 4 hours at 37°C was significantly increased with PDGF in comparison to the migration towards the vehicle (PDGF - 402 ± 31 migrated cells, vehicle - 148 ± 14, n=14 each group, mean ± S.E.M, p<0.05, ANOVA). Cell migration stimulated by PDGF was significantly inhibited in the presence of iloprost (100 nM) (174 ± 13 migrated cells, n=4) or beraprost (100 nM) (130 ±11, n=4) in comparison to PDGF alone (324 ± 26, n=4, p<0.05). To examine potential mechanisms of beraprost/iloprost inhibition of PDGF-induced migration, selective agonists for direct activation of PKA (N^6-Phenyl-cAMP, 5μM) and Epac (8-CPT-2'-O-Me-cAMP, 2μM) were added to the bottom well of the chemotaxis chamber. Both the Epac agonist and PKA agonist significantly reversed migration towards PDGF in comparison to PDGF alone (PDGF - 438 ± 53 cells migrated; PDGF + Epac agonist - 275 ± 22; PDGF + PKA agonist - 313 ± 35, n=8 each group, p<0.05). As Epac and PKA agonists inhibit migration and could both be activated by prostacyclin analogues, the effects of a PKA inhibitor KT-5720 (2 μM) was examined. KT-5720 did not significantly change the inhibition of PDGF-induced migration previously observed with beraprost (PDGF + beraprost - 123 ± 23 cells migrated; PDGF + beraprost + KT-5720 - 160 ± 42, n=3 each group, not significant). This potentially indicates that prostacyclin analogues may inhibit VSMC migration via activation of Epac. To examine Epac localisation in VSMCs, labelling of cells with the Epac1 antibody was investigated. Epac1 was localised to the perinuclear region of cells and at the leading edge of migrating cells. In conclusion prostacyclin analogues inhibit VSMC migration, and activation of Epac may be sufficient for this inhibitory pathway. This may provide a new therapeutic target to prevent neointimal hyperplasia.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD394

Concordant low frequency oscillations in tissue blood flux and oxygenation in human skin

K. Kuliga[1], A.J. Chipperfield[2], R. Gush[3] and G.F. Clough[1]

[1]Faculty of Medicine, University of Southampton, Southampton, Hampshire, UK, [2]Faculty of Engineering, University of Southampton, Southampton, Hampshire, UK and [3]Moor Instruments Ltd, Axminster, UK

Adequate skin microvascular blood flow and oxygenation are fundamental for tissue health. Detection of impairments in peripheral perfusion may allow for early diagnosis of microvascular dysfunction. Laser Doppler flowmetry (LDF) and white light spectroscopy are non-invasive techniques for measuring microcirculatory blood flux (BF) and tissue oxygenation (SO2). We have used frequency domain power spectral analysis (PSD) to investigate the relationship between the rhythmic low frequency variations in skin BF and SO2 associated with endothelial (0.0095-0.02Hz), neurogenic (0.02-0.06Hz), myogenic (0.06-0.15Hz), respiratory (0.15-0.4Hz) and cardiogenic (0.4-1.6Hz) activity in the skin of 19 healthy individuals (31±10y; mean±SD; 8 males) before and during maximal vasodilatation induced by local warming of the skin to 43oC for 20 min. BF (arbitrary perfusion units, PU) and SO2 (%) were recorded simultaneously at the same skin site using a combined OXY+flow+temperature probe (moorCP1T-1000, Moor Instruments, Axminster UK) and data analysed using a Fourier transform and magnitude squared coherence. The relationship between BF and SO2 was described by a one-phase association ($SO2=-22.8+104.2x(1-e^{-0.097xFlux})$) with an SO2 plateau of 81% for BF values >150 PU. At room temperature PSD of the respiratory and cardiac frequency bands in the SO2 signal was significantly lower than that in the BF signal. Low frequency BF and SO2 activities oscillated coherently (mean±SD, endothelial, 0.64±0.12; neurogenic, 0.60±0.18; myogenic, 0.32±0.14). However, the relative PSD contribution of the three low frequency bands to the BF and SO2 activities differed significantly ($P<0.0004$, paired t test) with the neurogenic component the most prominent in both BF and SO2 signals. The increase in microvascular BF and tissue SO2 during local skin warming was associated with an increase in the total spectral power of the BF signal and reduction in the total spectral power SO2 signal. The relative contribution in both BF and SO2 signals of myogenic activity was augmented and neurogenic activity reduced in vasodilated skin compared with skin at room temperature. These data demonstrate an association between a simultaneous measure of microvascular blood flux and tissue oxygenation. They suggest that there are multiple continuously varying and coherently coupled oscillations in local control mechanisms that contribute to the homeostatic regulation of skin blood flow and tissue oxygenation.

Scavenger receptors mediate uptake of modified low-density lipoprotein by circulating blood monocyte subsets: consequences for atherosclerosis

W. Jackson[1], R. Khamis[2], D. Haskard[1,2] and K. Woollard[1]

[1]Medicine, Imperial College London, London, UK and [2]NHLI, Imperial College London, London, UK

A major risk factor for cardiovascular disease (CVD) is elevated LDL-cholesterol, which can undergo oxidative modification (mLDL) (1). Experimental models show that mLDL in atherosclerotic prone vascular beds leads to increased monocyte derived macrophage foam cell formation and atherosclerosis (2). However, an increasing appreciation of blood monocyte functional heterogeneity has complicated this model and the subset specific functions of blood monocytes in atherosclerosis is unknown (3). In humans, three circulating monocyte subsets can be identified based on CD14 and CD16 expression and 2 subsets in mice based on Gr1 expression. $CD14^{high}CD16^{low}$ ($Gr1^{high}$) monocytes are well-characterized inflammatory monocytes that respond to bacterial cues, while $CD14^{low}CD16^{high}$ ($Gr1^{low}$) monocytes can crawl on the vascular endothelium in the steady state, although their role in homeostatic conditions is largely unresolved (4). $CD14^{high}CD16^{high}$ are poorly described in mice, but are shown to have increased frequency in human inflammatory disease (5). We aimed to characterise the blood monocyte subset response to mLDL by addressing the quantitation and mechanisms of uptake, subsequent functionality and how intravascular crawling monocytes may regulate mLDL endothelial deposition.

We have demonstrated differential intracellular uptake kinetics of mLDL in vitro by human monocyte subsets via quantitative imaging and flow cytometry. $CD14^{high}CD16^{high}$ monocytes showed greatest uptake after 2 hours, via the scavenger receptor CD36 (fig1). In-vivo experiments in mice showed similar uptake in monocyte subsets, peaking at 4 hours post mLDL infusion ($Gr1^{high}$: 4hrs 6.9 +/- 2.8, 24hrs 5.7 +/- 3.9; $Gr1^{low}$: 4hrs 10.3 +/- 4.4, 24hrs 4.3 +/- 2.8. Percentage cells mLDL positive, mean+/-S.E.M, n=3). Currently, we are developing whole body imaging modalities and high-resolution intravital microscopy in mice to attempt to understand the fate and function of 'LDL-loaded' blood monocytes. Preliminary data suggests LDL loaded monocytes localise to discrete tissues and that crawling $Gr1^{low}$ ($CD14^{low}$) monocytes can scavenge LDL at the endothelial interface. Further work will determine whether they transmigrate into the arterial wall, undergo differentiation or apoptosis, localise to draining lymph nodes and/or efflux lipid to anti-inflammatory HDL. In summary, these complementary approaches add to existing knowledge on the role of mLDL and blood monocytes in atherosclerosis.

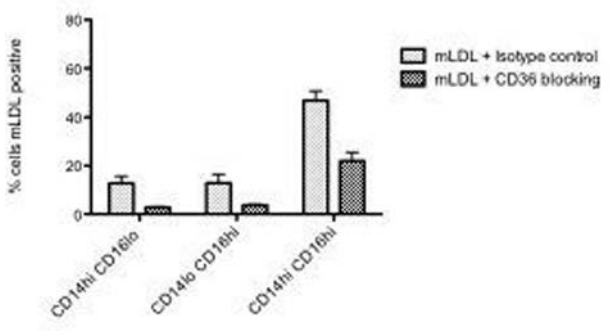

Figure 1: CD14 ^{high}CD16 ^{high} monocytes show preferential mLDL uptake via CD36. Human blood monocytes incubated for 30 minutes with a CD36 blocking antibody or isotype control (ctrl), followed by a 2-hour incubation with DiO labelled mLDL. mLDL uptake was analysed in monocyte subsets via flow cytometry. (n=3, in triplicate. Error= mean +/- SEM). P=<0.0001, Two-way ANOVA, Ctrl v CD36 Block.

Investigating the effects of L-phenylalanine on the endogenous tetrahydrobiopterin regulatory system in spontaneously hypertensive rats

L. Heikal[1], A. Starr[2], D. Hussein[2], J. Prieto-Lloret[3], P. Aaronson[3], L. Dailey[1] and M. Nandi[2]

[1]Pharmacy, Kings College London, London, UK, [2]Pharmacology and therapeutics group, Kings College London, London, UK and [3]Asthma and lung biology, Kings College London, London, UK

Strategies to pharmacologically modulate pathways that stimulate endogenous nitric oxide (NO) bioavailability have generated considerable interest for the treatment of cardiovascular disease. Tetrahydrobiopterin (BH4) is an essential cofactor for the synthesis of nitric oxide (NO). Clinical studies have shown that intravenous administration of BH4 improves vascular function in cardiovascular disease patients, however oral BH4 appears to lack efficacy, possibly due to oxidative inactivation during absorption. BH4 is synthesised from GTP with GTP-cyclohydrolase 1 (GCH1) catalysing the first and rate limiting step of the reaction. The amino acid L-phenylalanine (L-Phe) can activate GCH-1 when it is complexed to an allosteric regulatory protein (GFRP); indeed oral administration of L-Phe increases plasma biopterin (a marker of BH4 levels) in humans. The aim of this study was to investigate the effects of exogenous L-Phe administration on BH4 levels and vascular function in wild type mice and spontaneously hypertensive rats (SHR). Wild type mice were administered with an oral L-Phe challenge (100 mg/Kg) and BH4 and NO levels measured in multiple tissues. Concentrations of nitrite, BH4 and catecholamines in tissue/plasma and superoxide levels in aorta, were measured in male SHRs and wild type normotensive rats (WKY). The effect of L-Phe on endothelium dependent vascular relaxation to acetylcholine was assessed functionally using aortic and mesenteric vessels from SHR and WKY. All tissues were collected after animals were exsanguinated under terminal anaesthesia (2% isofluorane).Oral L-Phe challenge caused a significant and temporal rise in BH4 tissue levels in wild type mice, an effect that was pronounced in aorta (n=8). Consistent with their hypertensive pathology, BH4 and nitrite levels were lower whilst catecholamines and superoxide levels were elevated in SHR compared to WKY (n=18). SHR demonstrated endothelial dysfunction compared to WKY basally in aortic and mesenteric tissues [EC50 aorta (μM): SHR0.21±0.004 vs WKY0.08±0.0005; n=12] [EC50 mesenteric (μM): SHR0.03±0.0001 vs WKY0.01±0.003; n=6]. Incubation with 500 μM L-Phe significantly improved ACh induced vasorelaxation in SHR whilst having no effect in WKY (EC50 shifted to 0.038±0.0007 μM and 0.014±0.002 μM in SHR aorta and mesenteric respectively; n=6). The L-Phe effect was found to be endothelium-dependent.

L-Phe was used as a tool to investigate the potential to activate GCH1 and enhance vascular function. Consistent with our hypothesis, oral L-Phe enhanced aortic BH4 in wild type mice and improved vascular relaxations in SHR ex vivo. Small molecules that mimic this allosteric activation of GCH1 represent a potential novel therapy for the treatment of endothelial dysfunction, circumventing the problems with administering BH4 orally.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Comparative morphological, temporal and pharmacological profiles of two 96-well *in vitro* kinetic angiogenesis co-culture assays

C. Szybut[1], D. McEwan[2], K. Patel[1], K. Allard[2], B. O'Clair[2], E. Endsley[2], T. Dale[1], V. Groppi[2] and D. Trezise[1]

[1]Essen BioScience, Welwyn Garden City, Hertfordshire, UK and [2]Essen BioScience, Ann Arbor, MI, USA

Angiogenesis, the sprouting of new blood vessels from pre-existing ones, is a key mechanism for solid tumour growth and survival as well as damaged tissue revascularisation. In vitro models of angiogenesis play an important role in elucidating relevant signalling pathways and identifying novel therapeutic strategies. Here we compare two co-culture assays in which fully kinetic measures of vascular tube formation are enabled using live content imaging.

Co-cultures of (1) GFP-labelled human umbilical vein endothelial cells (HUVEC) and normal human dermal fibroblasts (NHDF)[1] or (2) GFP-labelled endothelial colony forming cells (ECFC) and adipocyte derived stem cells (ADSC)[2,3] were created on 96-well assay plates. Vascular tube formation was quantified (tube length, branch points) from fluorescent images (every 6-12h) using an IncuCyte live content imaging system. Exogenous growth factors evoked time and concentration-dependent increases in both assays (e.g. VEGF; HUVEC EC_{50} 28pM, ECFC EC_{50} 54pM). In the HUVEC assay vascular structures were highly branched and formed complex tubular networks. In contrast the ECFC model exhibited more regular cord-like structures; peak cord formation occurred within the first 48h and then stabilised, whereas HUVEC tube structures continued to develop over 2 weeks. From end point antibody staining the tube and cord structures were labelled by vascular markers (CD31, VEGF-R2, n=3). In the ECFC, but not HUVEC model, stromal cells surrounding the vascular structures

stained positive for pericyte markers (αSMA and PDGFR-β, n=3).
Effects of small molecule pathway inhibitors (e.g. wortmannin, suramin, CCT108159) yielded comparable inhibitory effects across the two models albeit with different temporal profiles. Striking differences in the sensitivity of developing and established tube/cord networks to the anti-VEGF antibody bevacizumab were observed. Neo-angiogenesis was substantially inhibited by bevacizumab (e.g. maximal inhibition at 6.4μg ml^{-1}: HUVEC, 99 ± 0.4%; ECFC, 85 ± 3%) whereas established tube/cord networks were resistant to disruption (HUVEC, 60 ± 3%; ECFC, 30 ± 1%). The γ-secretase inhibitor L-685458 (1-4μM) markedly increased late stage branching in the HUVEC model.
Together these data findings further validate these kinetic co-culture models for translational angiogenesis research. The presence of pericyte-like cells in the ECFC/ADSC model may be relevant to the observed resistance of established cords to bevacizumab given that previous studies indicate a role for pericytes in vascular stabilisation. This resistance of established vascular structures to bevacizumab may represent a useful translational paradigm for addressing tumour resistance of anti-VEGF therapies.

The adhesion of platelets to monocyte subsets in stirred whole blood in response to different platelet agonists

C.L. Box, C. Yates, M. Chimen, M. Harrison, G. Nash, S. Watson and E. Rainger

Clinical and Experimental Medicine, University of Birmningham, Birmingham, UK

Introduction: Using in vitro and in vivo models of vascular inflammation which resemble aspects of the chronic inflammatory environment in the atherosclerotic artery wall, we have recently described a paradigm where platelets recruited to intact endothelial cell monolayers formed adhesive bridges between the vessel wall and flowing leukocytes. Interestingly, monocytes, the major inflammatory leukocyte population recruited during atherogenesis, were preferentially recruited from flowing blood. In these models, platelet adhesion to endothelial cells preceded interaction with monocytes. However, the formation of platelet-monocyte aggregates in the circulating blood is well documented, as is the propensity for such heterotypic aggregation to increase in patients with cardiovascular and chronic inflammatory disease. It is unknown whether heterotypic aggregation increases the efficiency of monocyte recruitment during vascular inflammation, a phenomenon we will investigate in the near future. The aim of the current study was to determine how efficiently platelet-monocyte aggregates could form in whole blood, in particular monitoring heterotypic aggregation on monocyte subsets in response to different platelet agonists.
Methods: Whole blood was treated with the platelet agonists adenosine diphosphate (ADP; 30μM), thrombin receptor activating peptide (TRAP; 100μM), thromboxane mimetic, U46619 (10μM), rhodocytin, (100nM) or collagen related peptide (CRP-XL; 1μg/ml). Blood was placed on a rolling mixer at 37°C and aliquots were periodically taken for analysis. Heterotypic aggregation was assessed by flow cytometry using antibodies against monocyte markers (CD14 and CD16) and against platelet GPIb (CD42b). Statistical significance was determined by ANOVA and Bonfferoni.
Results: After treatment with any of the agonists there was a significant increase in heterotypic aggregate formation compared to untreated control for both $CD14^+CD16^-$ and $CD14^+CD16^+$ monocyte subsets, the incidence of aggregate formation did not vary between the subsets. Interestingly, there were significant differences between the rate and efficiency of heterotypic aggregate formation with different agonists, with CRP-XL being the weakest agonist (≈30% of $CD14^+CD16^-$ monocytes positive for GPIb) and TRAP the most potent (≈65% of $CD14^+CD16^-$ monocytes positive for GPIb) after 30 minutes of stirring.
Conclusions: Platelet-monocyte aggregates form in whole blood in response to a range of platelet agonists, although the efficiency of aggregation varies in an agonist dependent manner. Both monocyte subsets form heterotypic aggregates with equal efficiency. These data imply that the route of platelet activation may be an important arbiter of the efficiency of platelet-monocyte interaction in whole blood and could influence down stream functional outcomes such as monocyte recruitment.

Evaluation of the mechanisms involved in the reduced vascular contraction in aortas of diabetic female rats: role of iNOS and insulin

S.M. Sartoretto[1], R.A. Dos Santos[1], G.S. Ceravolo[1], R.C. Tostes[2], M.C. Carvalho[1], Z.B. Fortes[1] and E.H. Akamine[1]

[1]Institute of Biomedical Science, University of São Paulo, São Paulo, São Paulo, Brazil and [2]Faculty of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

Objective: Although hypertension can be a complication of diabetes mellitus, hypotension and reduced pressor response to vasoconstrictor agents have been observed, especially in type 1 diabetes. The mechanisms by which this reduction occurs remain unclear, but increased expression of iNOS seems to be involved at least in male rats. We previously observed reduced contractile response induced by noradrenaline (NE) in aortas of diabetic female (DF) rats, but the mechanisms were not investigated. It has been observed that estrogen receptor (ER)β activation induces expression of iNOS in vascular smooth muscle of diabetic male rats, but nothing is known in female. The objective of this study was to investigate whether the reduction of vasoconstrictor response in aortas of DF rats is due to increased expression of iNOS/ERβ and the effects of insulin. Methods and Results: Diabetes was induced in female Wistar rats (180-200g) by an injection of alloxan (40 mg/kg) and after 3 and 15 days, treatment with iNOS inhibitor L-NIL (3 mg/kg/day/30 days) and insulin (NPH, 6IU/day/15 days) began, respectively. At the end of the treatment period, we analyzed the iNOS mRNA expression, the ER-α and ER-β protein expression by immunohistochemistry, and concentration-response curves were performed in endothelium-denuded aor-

tic rings to NE and potassium chloride (KCl). The results are expressed as means ± S.E.M., compared by ANOVA followed by Bartlett's test for homogeneity of variances and Tukey-Kramer multiple comparisons test. We observed that the expression of iNOS mRNA is increased in diabetic endothelium-denuded aortas (80%) in comparison to control aortas. Treatment with insulin did not correct it. The maximum contraction to NE (Control (n=6): 3.21±0.23 g; DF (n=7): 2.19±0.16 g; $p < 0.05$) and KCl (Control (n=8): 2.70±0.13 g; DF (n=9): 2.15±0.08 g; $p < 0.05$) was reduced in diabetic endothelium-denuded aortic rings. After treatment with L-NIL and insulin only the reduced maximum contraction to NE (L-NIL (n=6): 3.03±0.23 g; insulin (n=6): 3.12±0.16 g) was corrected. We found that ER-α immunostaining was similar among the groups. On the other hand, the ER-β immunostaining was increased in aorta of DF rats. Treatment with insulin, but not with L-NIL, corrected the increased ER-β immunostaining. Conclusion: Our data suggest that the increased iNOS and/or ER-β expression are involved in the reduced NE-induced contraction in DF rats, by interfering with the adrenergic receptor pathway, and not by reducing the ability of the smooth muscle to contract. The effects of the insulin treatment are selective on the adrenergic receptor pathway and may be dependent on ER-β, but not on iNOS, reduction.

PCD401

Vitronectin stabilizes neutrophil-endothelial cell interactions in the inflamed microvasculature

G. Zuchtriegel[1,2], K. Lauber[3], F. Krombach[2] and C. Reichel[1,2]

[1]Department of Otorhinolaryngology, Head and Neck Surgery, Ludwig-Maximilians-Universität München, Munich, Germany, Munich, Germany, [2]Walter Brendel Centre of Experimental Medicine, Ludwig-Maximilians-Universität München, Munich, Germany, Munich, Germany and [3]Department of Radiation Oncology, Ludwig-Maximilians-Universität München, Munich, Germany, Munich, Germany

Background: Leukocyte recruitment from the microvasculature to the site of inflammation represents a key event in the pathogenesis of inflammatory diseases. Vitronectin is a glycoprotein present in serum and extracellular matrix. Through interaction with integrins and components of the fibrinolytic system vitronectin has been implicated in cell adhesion and migration. The role of this glycoprotein in the extravasation process of leukocytes, however, remains unclear.
Methods: Using in vivo microscopy on the cremaster muscle of anesthetized (ketamine, 75 mg/kg b.w. i.p., and xylazine, 25 mg/kg b.w. i.p.) wild-type and vitronectin-deficient mice, intravascular rolling and adherence as well as transmigration of leukocytes were analyzed in postcapillary venules upon intrascrotal stimulation with the C-X-C motif chemokine CXCL1/KC or lipopolysaccharide (LPS). Phenotyping of transmigrated leukocytes was performed by immunostaining of paraffin-embedded tissue sections. For statistical analysis, the ANOVA on ranks test followed by the Student-Newman-Keuls test was used.
Results: Intrascrotal stimulation with CXCL1 or LPS induced a significant elevation in numbers of intravascularly firmly adherent (cells remaining stationary on the endothelium for > 30 s) and transmigrated leukocytes (> 90 % Ly-6G-positive neutrophils) as compared to PBS-treated controls. In vitronectin-deficient animals, this elevation was significantly diminished, while the number of leukocytes only temporarily adhering to microvascular endothelial cells (cells remaining stationary on the endothelium for < 30 s) was significantly increased. The average time leukocytes arrest on endothelial cells before detachment was less than 5 s in vitronectin-deficient animals. No significant differences were observed in numbers of intravascularly rolling leukocytes and in leukocyte rolling velocities among experimental groups.
Conclusions: Vitronectin is critically involved in the extravasation process of neutrophils by stabilizing the adherence of these phagocytes to inflamed microvascular endothelial cells.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD402

TMEM16A: Do we have suitable pharmacological tools?

R. Brookfield, A. Gurney and P. Tammaro

Faculty of Life Sciences, The University of Manchester, Manchester, UK

Calcium-activated chloride channels (CaCC) are expressed in almost every cell type and are implicated in a plethora of physiological functions, spanning from smooth muscle contraction to the control of cardiac and neuronal excitability. TMEM16A was recently found to encode the major component of CaCCs. The exact role of this protein in the tissues where CaCCs have been detected remains, however, largely unexplored: this issue is currently the subject of intense investigation by the scientific community. Potent and selective channel blockers would prove invaluable as pharmacological tools for TMEM16A research. Our work explored the ability of available chloride channel blockers to inhibit cloned human TMEM16A channels. Blockers studied were niflumic acid, 4,4' diisothio-cyanatostilbene-2,2'-disulfonic acid (DIDS), tannic acid, penta-O-galloyl-β-D-glucose (PGG), epigallocatechin gallate (EGCG), flufenamic acid, mefenamic acid, meclofenamic acid, glibenclamide and $T16A_{inh}$-A01, a compound recently identified via high-throughput screening against TMEM16A. Human TMEM16A (splice variant, *abcd*) was permanently expressed in HEK-293 cells. Heterologous channel expression was verified using immunocytochemistry and whole cell patch-clamp recordings. The extent of inhibition that each compound produced on hTMEM16A mediated currents was measured in the presence of equimolar trans-membrane Cl^- and ~103 nM intracellular free Ca^{2+}. The selectivity of blockers was also explored by screening activity against 7 human cardiac ion channels (Cav1.2, Nav1.5, Kv7.1, Kv4.3, hERG, Cav3.2, Kv1.5) using IonWorks high-throughput patch clamp technique. None of the compounds tested presented complete selectivity for TMEM16A channels. Tannic acid was the least selective compound. It irreversibly inhibited TMEM16A with IC_{50}=5±2μM (n=5), but also blocked 6 of the cardiac ion channels tested with IC_{50}<100 μM. The most selective was DIDS, which reversibly inhibited TMEM16A with IC_{50}=14±3μM (n=11). Although it inhibited Nav1.5 with similar potency, it did not block the other cardiac channels. $T16A_{inh}$-A01 blocked up to 60% of hTMEM16A current with an IC_{50} of 0.26 ± 0.09 μM (n=7). It also inhibited Nav1.5 and Kv7.1, but at concentrations 2 orders of magnitude higher (IC_{50}=74 and 88 μM, respec-

tively). This difference in potency suggests $T16A_{inh}$-A01 may be a selective blocker of TMEM16A if used at sub-μM concentrations. In general though, the currently available chloride channel blockers lack selectivity and are therefore not ideal pharmacological tools for TMEM16A research. This work highlights the need for the identification and development of more potent and selective hTMEM16A blockers.

Redox-dependent angiogenesis by nucleoside derivatives of deoxyribose-1-phosphate

D. Vara[1], C. Wheeler-Jones[2], H. Mellor[3] and G. Pula[1]

[1]Pharmacy & Pharmacology, University of Bath, Bath, UK, [2]Comparative Biomedical Sciences, The Royal Veterinary College, London, UK and [3]School of Biochemistry, University of Bristol, Bristol, UK

Reactive oxygen species (ROS) are associated with multiple cellular functions such as cell proliferation, differentiation and apoptosis. Signal transduction by ROS, 'redox signaling' in angiogenesis is an important and emerging topic in cardiovascular sciences. ROS mediate vascular endothelial cell (EC) proliferation and migration, but the molecular mechanism underlying this phenomenon remains largely unclear. Recently we investigated the pro-angiogenic effect of deoxyribose-1-phosphate (dRP) released by stimulated platelets, which was shown to induce an increase in EC motility in vitro and a strong angiogenic response in vivo. In this study, we investigated the role of ROS generation in the angiogenic response mediated by dRP. ROS generation was investigated in human umbilical vein endothelial cells (HUVECs) by live cell confocal imaging, which showed that the addition of exogenous dRP decisively increased ROS generation. Similarly, the dRP derivatives deoxyribose-5-phospate (dR5P), glyceraldehyde-3-phosphate (G3P), and ribose-1-phosphate (R1P) also induced ROS accumulation in HUVECs, whereas deoxyribose (dR) did not. As expected, the redox stress marker heme oxygenase-1 (HO-1) was shown to be upregulated by dRP and its derivatives. The expression of critical pro-angiogenic molecules such as vascular endothelial growth factor (VEGF), interleukin 8 (IL-8), and stromal cell-derived factor 1α (SDF-1α) in HUVECs treated with dRP was tested by immunoblot. Interestingly, integrin β3 was shown to be upregulated by HUVEC treatment with dRP and its phorphorylated derivatives (i.e. except dR), as demonstrated by immunoblot experiments in the presence of the ROS scavenger N-acetyl-cysteine (NAC) and the antioxidant apocynin. In parallel, only the phosphorylated derivatives of dRP appeared to increase HUVEC cell motility in scratch-healing assay. The causative link between integrin β3 upregulation and increased HUVEC motility was proved using integrin-specific inhibitory antbodies. In summary, this study demonstrates a link between dRP-dependent increase in endothelial ROS generation, the upregulation of integrin β3 and the increase in endothelial cell motility and angiogenic activity. The paracrine regulation of endothelial cell motility by platelet-derived dRP is likely to play an important role in the stimulation of postnatal angiogenesis and tissue repair.

PCD404

Hyperoxic-induced contraction in porcine pulmonary veins

A. Arnold[1], C. Hannon[1], C. Dospinescu[2], H. Widmer[1], I. Rowe[1] and S.F. Cruickshank[1]

[1]Pharmacy and Life Sciences, The Robert Gordon University, Aberdeen, UK and [2]Department of Cardiology, Aberdeen Royal Infirmary, NHS Grampian, Aberdeen, UK

Hypoxia induces a transient contractile response of the porcine pulmonary vein (PV)(1). In 3rd-4th order intrapulmonary veins, this contraction is followed by a relaxation to below baseline while subsequent exposure to hyperoxia produces a second contractile response (unpublished observations). The underlying cellular effectors of this contraction in response to high oxygen conditions remain unclear, though hyperoxia has been shown to result in medial thickening and lumen occlusion of rat PVs(2).

Porcine lungs were obtained from a local abattoir. Size-matched 3rd order superior and 4th order inferior pulmonary veins (mean external diameter 3.3± 0.4 mm, n=3-4) were dissected free and mounted in a four channel myobath. Resting tone was 1.5g. KREB's-based bath solutions were gassed with 95% O_2/5% CO_2 (hyperoxia) or 95% N_2/5% CO_2 (hypoxia). Hypoxic and hyperoxic contractions were induced in the absence of pharmacological pre-tone. PVs samples were snap frozen in liquid N_2 and K^+ channel expression identified using end point RT-PCR. Data are expressed as a % of KCl-induced contraction and presented as mean values ± S.E.M. Statistical significance was determined at $P< 0.05$ using a Students unpaired *t*-test.

Under control conditions, hyperoxia did not induce a contractile response in either superior or inferior PV rings. Hypoxia induced a transient, monophasic contractile response in 89% of PV rings. There was no significant difference in the hypoxia-induced venoconstriction between superior and inferior PVs (37±12 (n=4) and 35±15%KCl (n=3), respectively; $P>0.05$). and 76% of the veins then relaxed to below baseline tension. All PV rings tested contracted when gassing was reverted from hypoxia to hyperoxia. There was no significant difference in the maximal contractile response between superior and inferior PVs (37±16%KCl for superior (n=4) and 24±7%KCl for inferior PVs (n=3);$P>0.05$). The large conductance Ca^{2+}-activated K^+ channel (BK_{Ca}) blocker Penitrem A(1) (500nM) inhibited hypoxia-induced relaxation and pre-incubation with 2 μM ryanodine (known to inhibit SR Ca^{2+} release(3)) prevented both the hypoxia-induced relaxation and hyperoxic-induced contraction. RT-PCR and product sequencing identified a truncated BK_{Ca} Zero and STREX splice variant in PVs (n=3)(1).

Hyperoxic-induced contraction and hypoxia-induced relaxation in 3rd-4th order PVs require an intact ryanodine-sensitive Ca^{2+} source. The underlying mechanisms and regulatory pathways require clarification but may involve the activation of BK_{Ca} channels.

PCD405

Induction of classically activated macrophages results in the loss of anti-contractile effect of perivascular adipose tissue

L.J. Murfitt, S.B. Withers, C.E. Bussey and A.M. Heagerty

University of Manchester, Institute of Cardiovascular Sciences, Manchester, UK

Introduction: Perivascular adipose tissue (PVAT) is now regarded as a metabolically active organ that exerts an anti-contractile effect which is lost in obesity. Here, PVAT undergoes conformational change: there is adipocyte hypertrophy and an increase in the infiltration and activation of macrophages, leading to inflammation. Lean individuals have alternatively activated macrophages (AAMs) but this polarisation shifts to classically activated macrophages (CAMs) with increasing adiposity. These CAMs produce pro-inflammatory cytokines that stimulate inflammation, abrogating the anti-contractile response of PVAT. Previously, we have shown the presence of macrophages in mediating the loss of anti-contractile effect following the induction of experimental hypoxia. (Withers *et al*. 2011). Therefore, the aim of this study was to determine whether the induction of CAMs by LPS and IFN-γ abrogated the anti-contractile effect of PVAT *in vitro*.
Method: Small segments of mesenteric arteries ±PVAT (diameter 250-300 μm) from male Sprague-Dawley rats (350 g) underwent pharmacological assessment using wire myography. All procedures were performed in accordance with Scientific Procedures Act (1986). Induction of inflammation and CAMs activation was carried out by overnight incubation in Dulbecco's Modified Eagle Medium (DMEM) containing 1 μg/ml LPS and 0.1 μg/ml IFN-γ. Cumulative noradrenaline (1 x 10^{-9} to 3 x 10^{-5} M) dose response curves were calculated as a percentage of KCl (60 mM) contraction and expressed as mean±SEM. Data were analysed by two-way ANOVA and Bonferroni post hoc test. P values <0.05 were deemed significant.
Results: PVAT exerted an anti-contractile effect compared to no PVAT which is consistent with previous work (PVAT vs. no PVAT: P<0.001, n=7). After induction of inflammation and CAMs activation, PVAT had a significant loss of anti-contractile effect compared to PVAT controls (PVAT control vs. PVAT + LPS/IFN-γ: p=0.0168, n=7). No significant difference was seen in no PVAT vessels treated with LPS and IFN-γ compared to no PVAT controls (no PVAT control vs. no PVAT + LPS/IFN-γ: p=0.7053, n=7).
Conclusions: This study indicates a major role of CAMs in the loss of PVAT function as seen in inflammation and obesity. Research is ongoing to ascertain the presence of CAMs and inflammation in LPS and IFN-γ treated ±PVAT mesenteric vessels.

Withers, S. B., Agabiti-Rosei, C., Livingstone, D. M., Little, M. C., Aslam, R., Malik, R. A. & Heagerty, A. M. (2011). Macrophage activation is responsible for loss of anticontractile function in inflamed perivascular fat. Arterioscler Thromb Vasc Biol, 31(4), 908-13.

PCD406

β-adrenergic signalling contributes to the anticontractile action of perivascular adipose tissue through nitric oxide release

C.E. Bussey, S.B. Withers, G. Edwards and A.M. Heagerty

Cardiovascular Medicine, University of Manchester, Manchester, UK

Introduction: Perivascular adipose tissue (PVAT) exerts an anti-contractile effect. Studies using various vasoconstrictors suggest that this may be dependent on adrenergic stimulation and the subsequent release of nitric oxide. This has not previously been investigated in PVAT but β3-adrenoceptors are known to be the predominant subtype mediating lipolysis in rodent adipocytes.
Design and methods: The effects of PVAT on the contractility of isolated Wistar rat mesenteric arteries were investigated using wire myography. All procedures were performed in accordance with Scientific Procedures Act (1986). Concentration-response curves to noradrenaline ($1x10^{-5}$ - $3x10^{-9}$ mol.l^{-1}) or phenylephrine ($1x10^{-5}$ - $3x10^{-9}$mol.l^{-1}) were generated in the presence and absence of the β3-adrenergic agonist, CL-316,243 (10 μmol.l^{-1}). In addition, a Griess reagent kit was used to determine NO production from adipose tissue surrounding the mesenteric artery in response to adrenergic agonist stimulation +/- the nitric oxide synthase inhibitor, L-NMMA (100 μmol.l^{-1}).
Results and summary: The vasoconstrictor response to noradrenaline was reduced in the presence of PVAT through an endothelium-dependent mechanism involving activation of vascular smooth muscle K+ channels (endo: PVAT vs no PVAT P<0.01, n = 12, no endo: PVAT vs no PVAT P=0.54, n=12). A reduced anticontractile effect was observed in response to phenylephrine (P=0.45, n =12), which acts mainly via α-adrenergic receptors, suggesting that the anticontractile effect of PVAT is dependent on β-adrenergic stimulation. Moreover, in vessels with intact PVAT but lacking endothelium, the presence of CL-316,243 caused a reduction in the vasoconstrictor effect of phenylephrine (P<0.05, n=6) whereas the vasoconstrictor response to noradrenaline was unaltered reaffirming the role of β-adrenergic stimulation in the anticontractile effect of PVAT.
Adrenergic stimulation of adipose tissue (devoid of vessels) with noradrenaline and CL-316,243, but not phenylephrine, was associated with a significant increase in nitric oxide production (P<0.05, n=5), which was inhibited by the presence of L-NMMA. The similarity in response to noradrenaline and CL-316,243 suggests that β3-adrenoceptors are the main β-adrenergic subtype mediating this response.
Overall, this study indicates a role for β-adrenergic stimulation and subsequent nitric oxide production in the anticontractile action of PVAT.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD407

Investigating tetrahydrobiopterin biosynthesis

D. Hussein, A. Starr, L. Heilkal and M. Nandi

King's College London, London, UK

Background: Tetrahydrobiopterin (BH4) is an essential cofactor for aromatic amino acid-hydroxylases and all isoforms of nitric oxide-synthase. In the cardiovascular system nitric oxide (NO) acts as a potent vasodilator and maintains endothelial function. Administration of BH4 can improve endothelial function in numerous cardiovascular pathologies, an effect that likely results from increased NO bioavailability and local antioxidant effects. GTP cyclohydrolase 1 (GCH1) is the rate-limiting enzyme for BH4 biosynthesis. GCH1 activity has been shown to be modified by both levels of phenylalanine and BH4 through allosteric regulation when bound to GCH1feedback regulatory protein (GFRP). Studies have shown that phenylalanine(L-phe) binds to and activates the GCH1-GFRP complex, whilst BH4 binding to the complex inhibits GCH1 activity. Our studies aim to investigate the significance of this protein-protein interaction on BH4 bioavailability.

Methods: Human proteins GCH1 (both the full length and truncated forms) and GFRP, were recombinantly expressed, and the binding affinities were determined using surface plasmon resonance (SPR). In addition the activity of purified recombinant enzymes has been measured by two methods; using both a kinetic micro-plate assay and high performance liquid chromatography (HPLC). In order to investigate the regulation of BH4 levels in vivo via the GCH1-GFRP axis we conducted an oral challenge of L-phe (100mg/kg) in mice (n=8) and measured levels of L-phe and biopterin (a marker of BH4) in both tissue and plasma.

Results: Soluble human truncated and full length GCH1 and GFRP have been successfully expressed (with the truncated form of GCH1 lacking the first 42 animo acids of the N-terminus). Initial SPR experiments determined a Kd of approximately 20-40nM for GCH1-GFRP. The activity of both truncated and full length GCH1 was measured by two methods and we found truncated GCH1 to be more active than full length GCH1. Oral L-phe challenge in mice (n=8) was shown to significantly increase biopterin production in both plasma and tissue $p<0.001$ ANOVA (vs. saline control).

Conclusion: The aim of this project is to investigate the protein-protein interaction between GCH1 and GFRP. Targeting BH4 bioavailability can provide a means to restore endothelial dysfunction in a range of cardiovascular disorders. Our studies suggest a regulatory role for the first 42 amino acids which may influence the interaction of GCH1 with GFRP. L-Phe oral challenge was shown to cause a rise in circulating and vascular biopterin in mice indicating the potential of pharmacological agents that can mimic the feed-forward allosteric changes to regulate BH4 levels. Further studies are required to understand the different factors that may affect the nature of the GCH1-GFRP interaction and how it may influence BH4 bioavailability.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD408

Endothelial cell-mediated lipid handling in human adipose tissue

F. Volat, P. Decaunes, A. Zakaroff-Girard, J. Galitzky and A. Bouloumié

INSERM U1048 - Institut des maladies métaboliques et cardiovasculaires, Toulouse, France

Human adipose tissue (AT) is well recognized as a key player in energy homeostasis due to its storage function of circulating non-esterified free fatty acids (NEFA) as triglycerides in adipocytes. A defective extraction of plasma NEFA by adipose tissue might lead to post-prandial hyperlipidemia and thus increase the risk to develop insulin resistance. Human AT-endothelial cells (ECs) are the first cell type that modulates lipid passage from the blood compartment to the adipose tissue. However, mechanisms underlying lipid handling in human adipose tissue remain to be fully characterized in AT-ECs.

Using a fluorescent-activated cell sorter (FACS) approach, uptake of fluorescent labelled fatty acid by stroma-vascular cells from human subcutaneous AT was studied. AT-ECs (CD34+/CD31+ cells) are able to incorporate several saturated FA such as palmitic (C16:0) and lauric (C12:0) acids. FA-uptake kinetics of AT-ECs depend on the length of fatty acid chain and differ from that of progenitors cells (CD34+/CD31- cells).

Trans-endothelial transport of NEFA in human adipose tissue may occur by diffusion or may be mediated by plasma-membrane and cytoplasm proteins. Real-time PCR and FACS analyses performed on AT-ECs isolated from freshly harvested stroma-vascular fraction revealed that these cells express several fatty acid transport proteins (FATPs) and fatty acid binding proteins (FABPs) and the fatty acid translocase FAT/CD36. AT-ECs also express the transcription factor PPARγ known as the major regulator of adipocyte lipid storage and we observed that maintaining AT-ECs in culture with an adipogenic media supplemented by PPARγ agonist leads to lipid droplet formation. This effect of PPARγ agonists was only observed on endothelial cells isolated from the adipose tissue.

In agreement with lipid droplet formation, immunohistochemical approaches revealed a marked accumulation of the lipid droplet-associated protein ADRP/Adipophilin in endothelial cells of subcutaneous AT from obese patients (BMI>30) (n=8) compared to lean patient (BMI<25) (n=7).

In addition, compared to AT-ECs of non obese patients (n=4-6), AT-EC of obese patients (n=4-9) exhibited a lower expression of proteins involved in the endothelial barrier function including VE-cadherin (adherens junction), JAM2 and Claudin 5 (thight junction) and CD31.

Our results showed that endothelial cells of human adipose tissue exhibit specific properties regarding lipid handling and suggest that, during obesity, a local dysfunction of adipose tissue endothelial cells occurs. This dysfunction might be a primary event involved in the genesis of obesity-associated pathologies.

PCD409

Divergent vascular effects of hydrogen-peroxide in isolated systemic and coronary arterioles

V. Csató[1], A. Tóth[1], . Koller[2], I. Édes[1] and Z. Papp[1]

[1]Cardiology, University of Debrecen Medical and Health Science Center, Debrecen, Hungary and [2]Pathophysiology and Gerontology, University of Pécs, Pécs, Hungary

Hydrogen-peroxide (H_2O_2) has been reported to either relax or constrict blood vessels depending on species and vessel type.

Arteriolar responses (internal diameter (i.d.) and changes in $[Ca^{2+}]_i$ by Fura-2 fluorescence ratio ($F_{340/380}$)) were determined in isolated, cannulated and pressurized (80 mmHg) arterioles obtained from rat skeletal muscle (i.d.: 168±6 μm, n=50), from rat coronaries (i.d.: 120±9 μm, n=6), or from human coronaries (i.d.: 138±29 μm, n=5). Wistar rats (male, 250-350 g, n=50) were anaesthetized with an I.P. injection of pentobarbital-natrium (150 mg/kg). Human arterioles were dissected from right atrial appendages of patients (n=5) who underwent cardiac surgery. Data are shown as average diameter ± S.E.M., compared by Student's t-test or ANOVA. Arteriolar constrictions were expressed as changes in i.d. as a percentage of the baseline diameter, dilations were represented as changes in i.d. as percentage of maximal dilation.

H_2O_2 evoked biphasic responses in skeletal muscle arterioles: constriction at lower (10 μM-100 μM, 34±3% at 100 μM, $p<0.001$) and dilation at higher concentrations (1 mM-10 mM, 80±11% at 10 mM, $p<0.001$). In contrast, H_2O_2 (10 mM) caused only vasodilation in rat (96±3%, $p<0.001$) and human (94±14%, $p=0.01$) coronary arterioles. The H_2O_2 evoked constriction in skeletal muscle arterioles was not accompanied by significant changes in $F_{340/380}$ in a range of H_2O_2 concentrations between 1 μM and 100 μM, but higher concentrations of H_2O_2 elicited significant decreases in $[Ca^{2+}]_i$ (decrease in $F_{340/380}$ from 1.13±0.03 to 1.01±0.01 at 1 mM H_2O_2, $p<0.05$). In skeletal muscle arterioles 100 μM H_2O_2 induced constrictions were inhibited in the absence of endothelium (0±8% constriction, $p=0.03$). Moreover, in the presence of antagonists of: thromboxane A2 (1 μM SQ-29548), cyclooxygenase (10 μM indomethacin), or protein tyrosine phosphatase (5 μM α-Bromo-4-methoxyacetophenone) the 100 μM H_2O_2-induced constrictions were converted to dilations (44±11%; 50±17%, or 22±17%, respectively, $p<0.005$). Furthermore, antagonists of phospholypase A (100 μM 7,7-Dimethyl-(5Z,8Z)-eicosadienoic acid), protein kinase C (10 μM chelerytrine), phospholypase C (1 μM U-73122), or src kinase (1 μM Src inhibitor-1) decreased the 100 μM H_2O_2-induced constriction (9±2%, 9±4%, 4±2%, 8±3%, respectively, $p<0.005$).

Our data suggest that in skeletal muscle arterioles H_2O_2 increases the Ca^{2+} sensitivity of the contractile apparatus of arteriolar smooth muscle and activate the endothelial src kinase, phospholypase C, protein kinase C, phospholypase A, cyclooxygenase pathway leading to the synthesis of thromboxane A2 an hence generate constriction. In contrast, in coronary arterioles this pathway is not functional, suggesting differences in H_2O_2 mediated physiological responses in particular endothelium-derived hyperpolarizing factor like effects in these vessels.

Spironolactone but not losartan prevents enhanced contractility and oxidative stress mediated by nitric oxide synthase uncoupling in aortas from isoproterenol-treated rats

J.A. Victorio[1], L.V. Rossoni[2] and A.P. Davel[1]

[1]Structural and Functional Biology, UNICAMP, Campinas, São Paulo, Brazil and [2]Physiology and Biophysics, USP, São Paulo, São Paulo, Brazil

Overactivation of β-adrenoceptors induced by isoproterenol (ISO) treatment causes cardiac remodeling and vascular dysfunction. It is known that angiotensin II via AT1 receptor and aldosterone via mineralocorticoid receptor (MR) partially mediates the cardiac injury induced by ISO, including: myocardial hypertrophy and fibrosis, oxidative stress and inflammation. In the present study we tested the hypothesis that signaling pathways activated by AT1 and/or MR receptors are involved in the impairment of nitric oxide (NO) bioavailability induced by ISO treatment. Male Wistar rats were treated with ISO (0.3 mg/kg/day, s.c.) or vehicle (CT) and co-treated or not with the AT1 antagonist losartan (LOS, 40 mg/kg/day, p.o.) or MR antagonist spironolactone (SPI, 200 mg/kg/day, p.o.) for one week. In isolated aortic rings with endothelium (n=6-8 in each group), maximal response (Rmax) evoked by phenylephrine (Phe, 1ηM- 10μM) was enhanced in ISO-treated rats (CT= 6.8 ± 0.4 vs. ISO= 8.8 ± 0.5 mN/mm; $p<0.05$; n=6-8). LOS co-treatment did not modify this contractile hyperresponsiveness (ISO/LOS= 8.3 ± 0.2 mN/mm; n=6; $p<0.05$ vs. ISO), while SPI abolished this effect (ISO/SPI= 6.3 ± 0.3 mN/mm; n=8; $p<0.05$ vs. ISO). The NO synthase (NOS) inhibitor L-NAME (100 μM) enhanced the Rmax to Phe in aortas from all groups, abolishing differences among then. The superoxide dismutase (SOD, 150 U/mL) reduced Rmax to Phe only in ISO and ISO/LOS groups. This result suggests an enhanced participation of superoxide anion on aortic contractile response of ISO-treated rats that is normalized by SPI but not altered by LOS. Fluorescences to hydroethidine (DHE, 2 μM) and to diaminofluorescein-2 (DAF-2, 8 μM) were used to quantify reactive oxygen species and NO, respectively (n=5-6 in each group). Elevated DHE (+44%) and reduced DAF-2 (-60%) fluorescence was observed in aortas from ISO-treated rats; SPI co-treatment, but not LOS, normalized it. Incubation with L-NAME significantly reduced the fluorescence to DHE (-33%) in aortic slices of ISO group. Protein expression was evaluated in aortic homogenates (n=6-8 in each group) and no significant changes in SOD-1, -2 and -3 protein expression among groups were observed. On the other hand, eNOS protein expression was significantly enhanced by ISO treatment (+56%) whilst phosphorylation of eNOS at Ser1177 (normalized by total eNOS content) was reduced (-43%). Neither LOS nor SPI modified this ISO effect. In conclusion, data suggest that ISO treatment could enhance vascular contractility due to high superoxide anion production via uncoupled eNOS and reduced NO availability. These vascular effects seem to be mediated by MR but not by AT1 receptor.

Inhibitory influence of physiological levels of arterial shear stress on local proteolysis and podosome formation of endothelial cells

T. Fey, U. Pohl and A. Dendorfer

Walter-Brendel-Centre for Experimental Medicine, Ludwig Maximilians University, Munich, Germany

Vascular remodelling can often be observed as consequence of chronic changes in blood flow. Whereas arteriogenesis is thought to be induced by elevated flow, a decrease in flow may result in plaque formation or atherosclerosis. Both processes are tightly controlled by proteases and their individual inhibitors. Podosomes are actin-rich cell protrusions which are locally associated with enhanced proteolysis of the extracellular matrix. To delineate the role of podosomes for endothelial matrix degradation, we studied the gelatinolytic activity and cellular arrangement of podosomes in endothelial cells exposed to shear stress.

Human umbilical vein endothelial cells (HUVEC, passage 2 to 3) were grown on fluorescent gelatin (Oregon green-conjugated) whose structure was imaged by confocal microscopy. The cells constitutively formed podosomes that were identified via costaining of cortactin and F-actin. Gelatinolytic activity of HUVECs was quantified according to gelatin fluorescence and to the density of circular gelatin defects. Shear stress was produced by unidirectional perfusion of a parallel plate flow chamber (Ibidi).

Cells grown under static conditions expressed podosomes either in even distribution or in circular arrangements (rosettes) that were associated with corresponding structures of gelatin degradation. Rosette density and gelatin degradation were highly increased after 2 hours of protein kinase C (PKC) stimulation by PMA (phorbol-12-myristate-13-acetate, 50 ng/ml) (reduction of gelatin fluorescence to 68% of control). Inhibition of matrix metalloproteinase (MMP) activity by GM6001 (15 μM) virtually abolished the occurrence of gelatin defects in untreated and PMA-treated endothelial cells. Exposure to shear stress for 48 hours altered the density of ring-shaped gelatin defects of 5 - 30 μm in diameter. Under very low shear stress (< 1 dyn/cm^2) the amount of rosette imprints was significantly increased compared to physiological flow (10 - 20 dyn/cm^2) and medium flow conditions (2 - 4 dyn/cm^2) (high flow 45 ± 10, medium flow 43 ± 28 vs. low flow 83 ± 7 per mm^2, n = 3, means ± S.D., ANOVA). HUVECS demonstrated typical alignment under high shear stress, but no signs of altered cell density or damage.

Thus gelatinolytic activity of endothelial cells is locally upregulated at podosome rosettes under low flow conditions, as compared to physiological arterial shear stress. This effect is presumably produced by an increased number in podosome rosettes recruiting higher MMP activities. Since matrix degradation promotes cell migration and impairs vessel stability, shear stress is critically important to stabilize the structure of the vascular wall under physiological conditions through mechanisms that locally regulate proteolytic activities.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD413

C-type natriuretic peptide reduces phenylephrine-induced vasoconstriction in intact endothelium aorta isolated from rats submitted by septic shock

L. Pernomian[1] and L. Bendhack[2]

[1]Pharmacology, Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, SP, Brazil and [2]Physics and Chemistry, Faculty of Pharmaceutical Sciences of Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, SP, Brazil

Septic shock is systemic inflammatory condition secondary to an infectious process leading to systemic hypotension and reduced vasoconstriction to several agonists with great production of nitric oxide (NO). Plasma concentration of C-type natriuretic peptide (CNP) is increased in animal models and patients in sepsis. The present study aimed to evaluate the contractile response induced by phenylephrine (PE) and the effect of CNP on this response in the isolated aorta from rats submitted to sepsis by ligation and puncture model (CLP). All the experimental protocols used in this study are approved by the Ethics Committee of the University of São Paulo (#144/2011). Male rats (35 days old) were anaesthetized with tribromoethanol (250 mg/Kg, ip). They were submitted to catheterization of femoral artery and vein 24h before the surgery to sepsis induced by CLP (16G needle) or sham-surgery (control rats, CO). The mean arterial pressure (MAP) of the rats was measured 4h after the surgery following PE administration (10-10 a 10-8 mol/Kg or saline, iv). The aortic rings were isolated from CO and CLP rats, for in vitro experiments of vascular reactivity. It was performed cumulative concentration-effect curves to PE (10-10 a 10-5 mol/L) with (E+) or without (E-) endothelium, in the absence or in the presence of CNP (10-8 mol/L). The aortic endothelial cells were used for flow cytometry studies. The cytosolic concentration of NO ([NO]c) was measured by using DAF-2/DA (10-5 mol/L). It was evaluated the maximum effect (Emax) and potency (pD2) of the PE. The MAP was higher in CO rats (74.3±0.3 mmHg, n=13) than in CLP rats (49.5±0.8 mmHg, n=15, P<0.05) 4h after the surgery, and the heart rate was enhanced in both groups as compared to the basal levels. Intravenous administration of PE increased the MAP and reduced the heart rate in both groups. PE induced contractile response in aortic rings from CO and CLP. It was reduced in CLP E+ group (Emax: 733±63,2g/g; pD2: 6,89±0,06, n=5, P<0.05) compared to CLP E- (Emax: 1468,3±181,7g/g; pD2: 7,51±0,31, n=8, P<0.05) and CO E+(Emax: 1231,4±106,4g/g; pD2: 7,32±0,10, n=11, P<0.05). CNP presented a negatively modulation in this PE response, only in E+ (CO Emax: 723,6±154,6g/g; pD2: 6,92±0,09; CLP Emax: 284,39±9,3g/g; pD2: 6,32±0,09, n=4, P<0.05). In the endothelial cells, the increase of [NO]c was higher in CLP (2706,3±325,8U, n= 4, P<0.05) than in CO rat aortic endothelial cells (1794,8±38,5U, n=4). Taken together, the results indicate that the vasoconstriction to PE is decreased in septic rat aorta, which should be due the enhanced production of NO in the endothelial cells. PE-induced contractile response is negatively modulated by CNP in intact-endothelium CO and CLP rat aortas.

Cannabidiol ameliorates the increased permeability of the blood-brain barrier following oxygen-glucose deprivation, an in vitro study

W.H. Hind, T.J. England and S.E. O'Sullivan

Vascular Medicine, The University of Nottingham, Derby, UK

During stroke, blood-brain barrier (BBB) permeability increases and cannabidiol (CBD) has shown protection in animal stroke models. The aim of this study was to establish if CBD modulates BBB permeability following oxygen-glucose deprivation (OGD).

To model the BBB co-cultures of human brain microvascular endothelial cells (HBMECs) and human astrocytes were grown on inserts. BBB permeability was measured by transepithelial electrical resistance (TEER) using STX2 electrodes and an EVOM2 meter. Inserts were subjected to 4h OGD by incubation in GasPak pouches with glucose-free RPMI medium. Reperfusion was established by returning cells to normoxia and their normal medium; TEER was measured at various time-points over 28h. CBD, receptor antagonists, or vehicle were added pre or post-OGD. The effect of giving 10μM CBD 2 or 4h into reperfusion was also investigated. Lactate dehydrogenase (LDH) was measured using a kit and VCAM-1 was measured by ELISA. Levels of cytokines/chemokine's known to be altered in stroke were measured by Multiplex. HBMEC-monocultures were also grown on 6 well-plates, and IL-6 and VCAM-1 were measured by ELISA, both in the presence and absence of OGD. Statistics: Student's t-test or one-way ANOVA with Dunnett's. Exposing the BBB to 4h OGD increased its permeability ($P<0.001$). Pre-treatment with 10μM CBD attenuated this increase ($P<0.05$), and 100nM, 1 or 10μM CBD decreased barrier permeability during reperfusion ($P<0.001$-0.05, n=8-11). CBD given post-OGD decreased barrier permeability during reperfusion ($P<0.01$-0.05, n=8-16). Receptor antagonists for CB1, CB2, PPARα, adenosine-A2A, 5-HT1A and TRPV1 did not affect CBD responses (n=6-10). However, the effect of CBD was inhibited by PPARγ antagonism ($P<0.001$-0.05, n=6). Administration of the PPARγ agonist Pioglitazone post-OGD also decreased barrier resistance during reperfusion ($P<0.01$-0.05, n=6). CBD given 2h into reperfusion decreased permeability ($P<0.05$, n=8-11), but CBD given 4h into reperfusion did not (n=6-9). LDH was raised following 4h OGD and 28h reperfusion ($P<0.05$), this was inhibited by CBD ($P<0.05$) in a non-PPARγ manner (n=6-9). Detectable levels of IL-10, IL-6, MIP-1α, MIP-1β and VEGF did not differ with CBD treatment. However, VCAM-1 at the end of reperfusion was attenuated by CBD ($P<0.05$, n=6), which was insensitive to PPARγ-antagonism. VCAM-1 in medium from HBMEC-monoculture was also attenuated by CBD both in the presence ($P<0.05$, n=3) or absence ($P<0.01$, n=3) of OGD. IL-6 from HBMEC-monoculture medium was increased by OGD exposure ($P<0.001$, n=6), and this increase was even greater in CBD-treated cells ($P<0.001$, n=6). Furthermore, CBD increased IL-6 in a concentration-dependent manner in HBMEC-monocultures that had not been exposed to OGD ($P<0.05$, n=3).

In conclusion, CBD given pre- or post-OGD decreases barrier permeability.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCD416

The effects of endocannabinoids on permeability in a cell culture model of the blood-brain barrier

W.H. Hind, T.J. England and S.E. O'Sullivan

Vascular Medicine, The University of Nottingham, Derby, UK

The blood-brain barrier (BBB) is a selective barrier. Other groups have demonstrated the ability of various cannabinoids to attenuate damage caused to the BBB in a range of pathologies. The role that AEA, and other endocannabinoids (eCBs), play in regulating BBB permeability has yet to be investigated using human cells, therefore, the aim of the present study is to establish whether they modulate BBB permeability. To model the BBB, co-cultures of human brain microvascular endothelial cells and human astrocytes were grown to confluence on Transwell collagen-coated inserts. BBB permeability was measured by transepithelial electrical resistance (TEER) using STX2 electrodes and an EVOM2 resistance meter. Resistance readings were taken at various intervals over 96h and compared to their baseline value. AEA (100 nM, 1 or 10μM) or other eCBs (10μM), and/or antagonist were added to the endothelial cells at 0 and again at 48h when the medium was replaced. In a separate series of experiments, inserts were subjected to 4h oxygen-glucose deprivation (OGD, to model ischaemia) by incubating them in GasPak EZ Anaerobe pouches with glucose-free RPMI medium. Reperfusion was established by returning the cells to normoxia and their specialised medium, and TEER was measured at various time-points over 28h. eCBs were added either pre- or post-OGD. Statistical analysis was conducted using one-way ANOVA with Dunnett's post hoc test. Administration of AEA at 10μM only resulted in a significant, acute decrease in BBB permeability (i.e. an increase in barrier tightness) compared to baseline at 2, 50 and 52h (i.e. immediately after AEA administration; n=9; $P<0.001$-0.05). Receptor involvement was probed, and AM251 (CB1, 100nM), GW6471 (PPARα, 100nM) and GW9662 (PPARγ, 100nM) had not effect. However, the AEA-induced decrease in permeability was significantly inhibited by AM630 (CB2, 1μM) ($P<0.001$-0.05) and capsazepine (TRPV1, 1μM) ($P<0.001$-0.05). The decrease in permeability was also inhibited by URB597 (FAAH inhibitor, 1μM) ($P<0.01$-0.05) (n=6-8 for all antagonist studies). Of the other eCBs investigated, 2-AG, PEA and virodhamine did not alter permeability. However, NADA increased BBB permeability ($P<0.001$-0.01), whilst OEA decreased BBB permeability ($P<0.05$-0.001) (n=6-8). 4h OGD increased BBB permeability ($P<0.001$), but administration of AEA following OGD did not decrease permeability (n=7-12). However, AEA (100nM, 10 or 30μM) given pre-OGD promoted a more rapid decrease in permeability during reperfusion ($P<0.001$-0.05; n=5-7), as did OEA ($P<0.001$-0.05), PEA ($P<0.05$) and virodhamine ($P<0.01$-0.05) (n=5-6). 2-AG did not alter BBB permeability following OGD. In conclusion, this study demonstrates that eCBs do play a role in regulating BBB permeability in vitro using human cells.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Impairment of aortic structure and function in a mouse model of neurofibromatosis type 1

K. Jett[1,3], J. Cui[2,3], H. Chohan[2,3], D. Arman[2,3], A. Tehrani[2,3], J. Friedman[1,3], C. Van Breemen[2,3] and M. Esfandiarei[2,3]

[1]Medical Genetics, University of British Columbia, Vancouver, BC, Canada, [2]Pharmacology and Therapeutics, University of British Columbia, Vancouver, BC, Canada and [3]Child and Family Research Institute, Vancouver, BC, Canada

Neurofibromatosis 1 (NF1) is an autosomal dominant disorder with complete penetrance and an estimated prevalence of 1 in 3000. Clinical manifestations are extremely variable. The disease is characterized by multiple café-au-lait spots (skin pigmentation), iris harmartomas, and multiple benign and malignant nerve sheath tumors (neurofibromas) in the central and peripheral nervous systems (Jett and Friedman 2010). NF1 vasculopathy is a serious and well documented but poorly understood feature of NF1. NF1 vasculopathy may result in hypertension, cerebrovascular disease, ischemia, aneurysm, hemorrhage or death in young adults (Rasmussen et al 2001). The response to standard therapeutic interventions is often disappointing (Friedman et al 2002), so further understanding of the underlying mechanisms for vascular complications in NF1 is essential. Endothelial and vascular smooth muscle functions are altered in Nf1+/- mice in vitro (Li et al 2001, Li et al 2006, Munchhof et al 2006), however, it is unknown how these alterations affect function of the vessel.

We have compared vascular function of the thoracic aorta in Nf1+/- mice with age-matched control littermates (n=16) using a small vessel myograph (A/S Danish Myotechnology, Aarthus N, Denmark). Isometric force measurements revealed increased contraction in response to depolarization (maximal response of3.3 ± 0.32 in Nf1+/- aorta versus 2.0 ± 0.22 in controls; p= 0.005), but diminished contraction in response to phenylephrine in Nf1+/- thoracic aorta at 6 months of age (pEC50 = 5.36 ± 0.18 in Nf1+/- aorta versus 7.02 ± 0.09 in controls; maximal response, Emax = 67.28 ± 3.4 in Nf1+/- aorta versus 86.34 ± 5.7; p= 0.008). Stress-strain curves indicated that arterial stiffness was increased at 6 months of age in Nf1+/- vessels. Elastin staining revealed disorganization of elastic fibers in Nf1+/- vessels.

In conclusion, the pathogenesis of NF1 vasculopathy in the thoracic aorta increases stiffness and impairs vasomotor function.

PCD418

The role of microRNA-30c-2* as an anti-angiogenic mediator

S. Shantikumar[1], A. Caporali[1], M. Meloni[1], M. Marchetti[1], L. Howard[1], F. Martelli[2] and C. Emanueli[1]

[1]Bristol Heart Institute, Bristol, UK and [2]Department of Vascular Pathology, IDI-IRCSS, Rome, Italy

Purpose: MicroRNAs (miRs) are small noncoding RNAs which negatively regulate the expression of targeted mRNA transcripts. Some miRs are already known to modulate angiogenesis. The p75 neurotrophin receptor (p75NTR) is upregulated in endothelial cells (ECs) of diabetic models and contributes to impaired post-ischaemic reparative angiogenesis in diabetes. To elucidate the miR signature of p75NTR in ECs, human umbilical vein ECs (HUVECs) infected with Ad.p75NTR demonstrated the upregulation of miR-30c-2* on an array. We aim to characterize the impact of miR-30c-2* on EC function.

Methods: Array results were confirmed by q-PCR using validated miR primers and SnU6 as an internal reference. To mimic advanced diabetes, where hyperglycaemia is accompanied by tissue starvation, HUVECs were cultured in high D-glucose (HG, 25 mM) and low growth factors (LGF). For modulating miR expression, HUVECs were transfected with pre-miR precursor, anti-miR inhibitor or negative control. Transfected cells were prompted in proliferation (BrdU incorporation) and in vitro angiogenesis on Matrigel assays. Predicted miR target genes were searched using the databases Microcosm and TargetScan. Finally, relative miR-expression was quantified in limb muscles of type 2 diabetic db/db mice and non-diabetic controls. Statistical analyses are performed using either an unpaired t-test (two groups) or ANOVA (more than two groups).

Results: Relative expression of miR-30c-2* was upregulated (three-fold) in p75NTR–transduced HUVECs ($p<0.01$ vs. null-HUVECs) and five-fold in HG/LGF compared to culture in normal conditions ($p<0.01$). Overexpression of miR-30c-2* in HUVECs impaired both proliferation and angiogenesis (40% decrease in proliferation and 25% decrease in tube length of Matrigel network, $p<0.01$ for both). In addition, miR-30c-2* was upregulated three-fold in the adductor muscles of db/db diabetic mice ($p<0.05$ vs. non-diabetic controls). A bioinformatics analysis identified the cell cycle regulator minichromosome maintenance complex component 7 (MCM7) as a putative miR-30c-2* target, In line, MCM-7 mRNA levels were decreased in p75NTR–HUVECs (by 57% vs. Null-HUVECs, $p<0.05$) and in HUVECs cultured in HG/LGF. Overexpression of miR-30c-2* also reduced MCM7 mRNA (by 64%, $p<0.01$).

Conclusion: Our data suggest that the p75NTR-induced miRNA miR-30c-2* may act as an anti-angiogenic mediator in the context of diabetes by inhibiting the cell cycle regulator MCM7. miR-30c-2* may prove to be a novel therapeutic target for diabetes-induced impairment of post-ischaemic reparative neovascularisation.

Non-L-type calcium channels play a role in regulating contractile responses in human mammary arteries

A.D. Thuesen[1], L. Rasmussen[1], A. Toft[2], N. Marcussen[3], S. Walther[2], B.L. Jensen[1], L.M. Rasmussen[4] and P.B. Hansen[1]

[1]Cardiovascular and Renal research Unit, Institute of Molecular Medicine, Odense, Denmark, [2]Urology, Odense University Hospital, Odense, Denmark, [3]Pathology, Odense University Hospital, Odense, Denmark and [4]Clinical biochemistry, Odense University Hospital, Odense, Denmark

Calcium channel blockers are widely used for treatment of hypertension, and L-type voltage-gated calcium channels are regarded as the subtype involved in the excitation-contraction mechanism in resistance vessels. However, both L- and P/Q-type calcium channels are of functional importance for the depolarization-induced contraction in human renal blood vessels. It was hypothesized that non-L-type channels are of general importance for vascular function in human blood vessels. In human internal mammary arteries from bypass surgery patients, PCR analysis showed expression of L-type (Cav 1.2) and T-type (Cav 3.1 and Cav 3.2) voltage-gated calcium channels and variable expression of P/Q-type (Cav 2.1) channels between patients. Immunohistochemical labeling of human mammary arteries vessels revealed signal for Cav 2.1 in both endothelium and smooth muscle cells. The T-type blocker mibefradil (10-7 M) significantly attenuated the depolarization-induced contraction (60 mM potassium) by 21±6,7% in human mammary arteries using a myograph set-up. The P/Q type antagonist, ω-agatoxin IVA (10-9 M and 10-8 M) inhibited the potassium-induced contraction with large variations between patients. In human intrarenal arteries, mibefradil had a tendency to inhibit the contraction induced by 60 mM potassium. In summary, human mammary arteries express functionally significant L-type and T-type channels with variable presence and significance of P/Q-type channels. We conclude that non-L-type channels are involved in excitation-contraction coupling in human arteries and could be involved in regulation of blood pressure.

Background/Objectives
A considerable number of patients with symptoms of chest pain during exercise have no functional relevant stenosis in their coronary arteries. In these patients the angina may relate to coronary microvascular dysfunction as a consequence of glycocalyx loss; since the latter has been associated with an impaired ability of adenosine to increase microvascular blood volume, we hypothesize that non-invasive measurements of myocardial microvascular blood volume recruitment with MRI could diagnose patients with coronary glycocalyx loss. As a first step, we measured in the current study coronary microvascular blood volume using first-pass dynamic contrast-enhanced MRI to assess myocardial microvascular blood volume in healthy control rats under baseline conditions and during adenosine infusion.
Methods
Rats (male, 300-450g, n=5) were anaesthetised with isoflurane (induction chamber 4,5% isoflurane and 1% oxygen, during experiment 2% isoflurane and 0,4% oxygen). MRI was performed on a 7.0 Tesla Bruker Biospec animal scanner. A bolus of 150 μl Gadovist (Gd-DTPA) was injected in the femoral vein, while scanning continued. The method was optimized to capture the first pass of the contrast agent through the heart. Measurements were performed at baseline and during intravenous adenosine infusion (3 mg/ml; 1,5 ml/h). In the first-pass perfusion images, regions of interest (ROI) were placed in the left ventricular (LV) lumen and in the myocardium of the LV wall. Signal intensity-time curves were calculated for all ROIs and were corrected for baseline. The following semi-quantitative parameters of myocardial perfusion and volume were derived from these curves: total area under the curve (AUC), peak intensity and the upslope to the peak.
Results
Values are percentages of changes after adenosine infusion compared to baseline ± S.E.M., compared by t-test. A significant increase of 47% ± 14 in total AUC was seen in rats after intravenous adenosine infusion compared to baseline ($P<0.05$). Peak intensity increased significantly with 49% ± 36 in rat hearts during adenosine infusion compared to baseline conditions. Also a significant increase (63% ± 64) was seen for the upslope of the first-pass peak during adenosine infusion compared to baseline conditions.
Conclusion
Adenosine-induced increases in myocardial microvascular blood volume in the rat heart are reflected by increases in first-pass MRI-derived contrast intensity. Our next step is to study the effect of glycocalyx damage on myocardial microvascular blood volume recruitment in rats using pharmacological and dietary degradation of the glycocalyx.

Zebrafish caudal fin regeneration – a novel quantitative angiogenic assay in vivo

D. Brönnimann

University of Bern, Bern, Switzerland

Background: Teleost fish, including zebrafish, are able to regenerate heart, retina, spinal cord, and fins after a lesion. The tie2-eGFP zebrafish is a suitable model to study the whole vascular tree down to the capillary level. Therefore, we introduced a novel assay to quantify angiogenesis after partial amputation of the zebrafish caudal fin.
Methods: At first, the zebrafish caudal fin was partially amputated. Complete regeneration of the vasculature and the fin itself occurred within five weeks at 30°C. Remarkably, initial

size and shape of the fin as well as the vascular parameters and patterns were completely restored. Most importantly, the concept of a reference situation was therefore introduced. Alterations in the neo-angiogenesis induced by external manipulations (pharmaceutical compounds, growth factors, flow disturbance etc.) can be precisely observed and quantified using stereomicroscopic imaging. Because blood vessels run straight and planar at the site of interest, the zebrafish caudal fin is introduced as a 2D-model. Three main quantitative parameters were introduced in this angiogenic assay. First, the total area (TA) represents the area of the fin that regenerated after partial amputation. Second, the vascular projection area (VPA) represents the regenerated vascular area visualized by a stereomicroscope. Third, the contour length (CL) represents the length of the blood vessel wall visualized by a stereomicroscope. During the first seven days of regeneration, extensive angiogenic growth was observed. Therefore, we introduced the short angiogenic assay. It allows evaluation of pro- and anti-angiogenic compounds within a week using unbiased stereological methods. In addition, this novel angiogenic assay includes a multitude of investigations in parallel. By the use of confocal imaging and transmission electron microscopy, morphology is linked to observed alterations in vivo. Hemodynamic conditions and their role in the process of neo-angiogenesis are evaluated. Moreover, the interplay between the two most important modes of angiogenesis (sprouting and intussusceptive angiogenesis) is evaluated.
Conclusions: The zebrafish caudal fin regeneration assay is a promising and highly reproducible model for time-efficient quantitative evaluation of angiogenesis. It is useful to assess neo-angiogenic mechanisms and the effects of different pro- and anti-angiogenic treatments. The model has potential implications on future treatment strategies of angiogenesis related diseases such as carcinogenesis, retinopathy, macular degeneration, and wound healing, among others.

Uric acid prevents middle cerebral artery structural and mechanical alterations induced by focal cerebral ischemia in rats

Y. Onetti, F. Jiménez, B. Pérez and E. Vila

Oxidative stress, a major contributor to brain damage in ischemic stroke, is involved in alterations of cerebrovascular properties after an episode of ischemia/reperfusion. (Jiménez-Altayó F et al., 2009). Uric acid (UA) is an endogenous antioxidant that protects the rat brain in a model of thromboembolic (Romanos E et al., 2007) and transient focal (Yu et al., 1998) ischemic injury. Nevertheless, little is known about the mechanisms whereby UA exerts its beneficial effects. We hypothesized that UA could influence the changes on vessel properties due to ischemia/reperfusion. Male Sprague-Dawley rats (270-320g) were subjected to right middle cerebral artery (MCA) intraluminal occlusion (90 min) followed by 24 h reperfusion. Sham-operated animals underwent the same surgical procedure but the MCA was occluded for less than 1 min. Rats were anaesthetized with isoflurane (3-2.5 %) in a mixture of O2 and N2O (30:70) and divided into 4 groups: sham-operated vehicle (n=7), ischemic vehicle (IV, n=18), sham-operated UA (n=4) and ischemic UA (IUA, n=9). UA (16 mg/kg in 3 ml Locke's buffer, i.v.) or vehicle (3 ml Locke's buffer, i.v.) was infused during 20 min at 30 min reperfusion. Mean arterial pressure, rectal temperature and cortical cerebral blood flow was permanently monitored. Afterwards (24 h), rats were killed under isoflurane (4%) and the ipsilateral MCA was removed and set up in a pressure myograph under physiological conditions. Values are means ± S.E.M., compared by two-way ANOVA or Student's t-Test. Mean arterial blood pressure (IV: 94.7±1.6 mmHg, n=18; IUA: 91.3±1.0 mmHg, n=9) and rectal temperature (IV: 37.3±0.119 °C, n=18; IUA: 37.0±0.197 °C, n=9) was similar in all groups. UA reduced infarct volume (IV: 129.6±23.5 mm^3, n=18; IUA: 48.9±16.6 mm^3, n=9, $p<0.01$), neurological score (IV: 3.4±0.4, n=18; IUA: 2.0±0.3, n=9, $p<0.05$) and brain oedema (IV: 7.7±1.1, n=16; IUA: 2.9±1.4, n=7, $p<0.05$). Ischemia/reperfusion increased MCA wall thickness ($p<0.01$), cross-sectional area ($p<0.05$) and wall/lumen ratio ($p<0.05$) while decreased wall stress ($p<0.05$) and stiffness (β value SV: 7.8±0.1, n=5; β value IV: 6.8±0.2, n=17, $p<0.001$). UA prevented all MCA changes induced by ischemia/reperfusion. These results show that a single dose of UA administered early after the onset of reperfusion prevents MCA structural and mechanical alterations induced by ischemia/reperfusion. We suggest that UA might exert beneficial actions on ischemic damage through prevention of cerebrovascular remodelling. These results reinforce the involvement of the vascular response in brain damage.

Diltiazem prevents aortic aneurysm formation via inhibition of Interleukin-6-induced AP-1 promoter activity in macrophages

A. Mieth[1], M. Revermann[1], A. Weigert[2], B. Brüne[2] and R.P. Brandes[1]

[1]Institut für Kardiovaskuläre Physiologie, Goethe-Universität Frankfurt am Main, Frankfurt am Main, Germany and [2]Institut für Pathobiochemie, Goethe-Universität Frankfurt am Main, Frankfurt am Main, Germany

Abdominal aortic aneurysm is an important manifestation of arteriosclerosis with increasing incidence in the western world. Progressive inflammatory processes involving infiltration and differentiation of monocytes into the vessel wall, proliferation and migration of smooth muscle cells and eventually the degradation of the internal elastic lamina are causal for aneurysm formation. Since calcium channel blockers exert multiple beneficial effects in the vascular system we investigated the effect of the benzothiazepine-type calcium channel blocker diltiazem (DIL) on aneurysm formation.
Angiotensin II infusion (ATII, 4 weeks, 1.44 mg/kg bw/d) induced massive aneurysm formation in ApoE-deficient mice that was blocked by co-treatment with DIL (100 mg/kg bw/day). Additional treatment with phenylephrine (PHE, 18 mg/kg bw/d) to counteract the blood pressure-lowering effect

of DIL had no influence on its beneficial effect. Moreover DIL prevented the ATII-induced mRNA expression of pro-inflammatory cytokines in the aortic arch after 6 days of ATII treatment due to a reduction in the amount of locally infiltrating macrophages which was accompanied by attenuated systemic CCL12 serum level.
Ex vivo, DIL (10 μM) did not reduce the ATII-induced (100 nM) expression of promigratory chemokine CCL2 and proinflammatory cytokine IL-6 of vascular segments in organ culture or vascular smooth muscle cells. Moreover, DIL (30 μM) did not affect the recruitement of Ly6C+-monocyte into subcutaneously implanted matrigel plugs filled with CCL2 (600 ng/ml) in ApoE-deficient mice. In contrast, in peritoneal macrophages and RAW264.7 cells, DIL prevented the IL-6-induced (10 ng/ml) mRNA expression of IL-1β and CCL12. As underlying mechanism, DIL abrogated the IL-6 induced activation of AP-1 promoter without affecting NF-kB activity as well as phosphorylation and nuclear translocation of MAPK1 and Stat3 or intracellular calcium.
These observations indicate that DIL prevents aneurysm formation by a mechanism independent of its blood pressure and intracellular calcium lowering effects.
