In bipolar cells we made three striking observations. 1) Calcium-triggered fusion events happen mainly at the rim of synaptic ribbons – highly specialized release sites – and are correlated in time with an increase in the clathrin signal. 2) Individual clathrin events occur significantly further away from ribbons. 3) Two different kinds of clathrin events could be recorded. The first was a sudden decrease in the clathrin signal, signifying movement of clathrin-coated structures away from the plasma membrane. The second signal was an immediate recruitment of clathrin to the membrane colocalized with sites of vesicle fusion.

Findings obtained by fluorescence correlation spectroscopy in both bipolar cell terminals and hippocampal neurons showed that the synaptic vesicle marker synaptophysin was associated with clathrin on the same relatively slowly diffusing structures. Only about 25% of the total clathrin was diffusing freely in the cytosol. These results were also verified by fluorescence recovery after photobleaching.

Taken together our results from ribbon and hippocampal synapses indicate that clathrin is associated with synaptic vesicles even before a fusion event. This may provide a mechanism for priming vesicles of the readily releasable pool for the fast mode of endocytosis, making them readily retrievable.

PCA156

A novel technique that combines single cell electroporation with extracellular recordings *in vitro* and *in vivo*

B.R. Dempsey, L. Bou Farah, A.J. Turner and S. McMullan

Australian School of Advanced Medicine, Macquarie University, Sydney, NSW, Australia

Single cell electroporation (SCE) is an electrophysiological technique that uses trains of voltage pulses to disrupt the cell membrane and simultaneously drive macromolecules such as fluorescent dyes or DNA into a target cell. SCE has emerged as an important step in developing 'connectomic' technology that can resolve the architecture of neuronal networks in single cell resolution [1]. However, two key limitations restrict the applicability of SCE. Firstly, SCE requires direct visualisation of target neurons, limiting its use *in vivo* to regions of the brain that can be resolved optically. Secondly, SCE is incompatible with standard electrophysiological recording techniques, meaning that data from electroporated cells cannot be interpreted in light of their functional properties. In the current study we validate a novel technique that combines single cell electroporation with extracellular recording, permitting functional identification of neurons prior to electroporation with fluorescent dextrans or plasmids encoding a variety of genes.

Methods: *In vitro* experiments were conducted on acute or cultured brain slices obtained from neonatal (P5-10) rat pups. Rats were deeply anaesthetised with isoflurane and killed by decapitation. *In vivo* experiments were conducted on urethane anaesthetised (acute experiments: dextran) or isoflurane anaesthetised (recovery experiments: plasmid) adult rats (300 – 500 g). Borosilicate pipettes filled with either fluorescent dextran or plasmid solutions were used to obtain extracellular recordings from single neurons. Once physical contact between pipette and cell was established the recording amplifier was programmed to deliver a train of current pulses through the pipette, using pipette resistance to calculate the current required to generate the desired voltage (7.5 V: dextran, -12 V: plasmid).

Results: Dextran labelling was achieved in >95% of cells (N>40) recorded *in vitro*, provided the pipette was within 6 μm of the target cell. *In vivo* successful electroporation was obtained in 48/105 spontaneously active brainstem neurons recorded up to 9 mm deep . Preliminary experiments using plasmid DNA in the recording solution indicate that the same principle is compatible with single cell gene delivery: fluorescent proteins are transcribed within 18 hours of electroporation in cultured neurons and *in vivo*, although further refinements are required to improve the reliability of this approach.

Conclusion: We have developed a technique that combines SCE with extracellular recording, negating the need for optical guidance and permitting functional identification of target neurons prior to electroporation. This technique will permit the application of novel genetic techniques to physiologically characterised neurons.

PCA157

Neuregulin-2 regulates synaptogenesis in hippocampal newborn granule cells

K. Lee[1], H. Lee[1], C. Yang[1], C. Park[2], W. Ho[1] and S. Lee[1]

[1]Physiology, Seoul Nat'l Univ. College of Medicine, Seoul, Republic of Korea and [2]Hanyang Biomedical Research Institute, Hanyang University, Seoul, Republic of Korea

Neuregulin-2 (NRG2) has been identified as a member of the family of growth factor that contains an EGF-like domain with its domain structure similar to NRG1. NRG1 and NRG2 are expressed in distinct cell populations in the brain. Unlike the expression of NRG-1 which is sporadic but widespread over

the brain, NRG2 is expressed in a few restricted regions in the brain including the hippocampal dentate granule cell (GC) layer. NRG2 has been implicated in proliferation of neural stem cells in the subventricular zone, but it is little understood whether NRG2 plays a role in synaptogenesis, which is essential for newborn neurons to be integrated into a preexisting neural circuit. Using retrovirus encoding GFP and RNAi against NRG2, we studied the role of NRG2 in development of GFP-labeled newborn GCs in rat organotypic hippocampal culture. To study the role of NRG2 in synpatogenesis, we infected the organotypic cultured hippocampal slice with retrovirus encoding NRG2-targeting miRNA cloned downstream of tetracycline-response element (TetOn-miNRG-2). Newborn GCs infected with such retrovirus displayed significantly lower expression of NRG2 after treatment with doxycycline (dox) than non-treated newborn GCs as a control. To assess the synaptic development in newborn GCs, we recorded GABAergic or glutamatergic postsynaptic current (GPSC or EPSC) induced by stimulation of the perforant pathway. Under the control conditions, the amplitude of GPSC started to increase from 7th day post-infection (7dpi) and reached a plateau level at 10dpi. Treatment of doxycycline from 4dpi abolished such a steep increase in the GPSC amplitude. Accordingly, immunohistochemistry using anti-VGAT revealed that the number of GABAergic presynaptic terminals on the soma of newborn GCs was lower in the dox-treated hippocampal slice than the control slice. In contrast, dox-treatment from 7dpi or 10dpi displayed no significant effect on GPSC, suggesting NRG2 plays essential role in GABAergic synapse formation at 4~7dpi but not in its maintenance after 7dpi. The amplitude of AMPA and NMDA receptor-mediated excitatory postsynaptic currents (AMPA-EPSC and NMDA-EPSC, respectively) started to steeply increase from 13dpi. We studied the role of NRG2 in glutamatergic synapse formation by treating the culture with dox from 7dpi, which had a limited effect on GPSC. The amplitudes of AMPA- and NMDA-EPSCs were significantly lower in dox-treated newborn GCs compared with control GCs. Furthermore, the ratio of AMPA- to NMDA-EPSC was reduced by dox-treatment from 7dpi, implying that NRG2 contributes to the maturation of excitatory synapses. These results indicate that the NRG2 expression in newborn GCs is essential for both GABAergic and glutamatergic synaptogenesis.

PCA158

The Cu/Zn superoxide dismutase inhibitor diethyldithiocarbamate inhibits axonal transport in cultured mouse dorsal root ganglion neurons

R. Isonaka[1], T. Kusakabe[2], T. Katakura[1], T. Takenaka[1] and T. Kawakami[1]

[1]Physiology, Kitasato University School of Medicine, Sagamihara, Japan and [2]Sport and Medical Science, Kokushikan University, Tama, Japan

Axonal transport is a fundamental neuronal cell function, which supplies neuron materials and conveys information. Thus, any increase or decrease in axonal transport expresses the state of neurons, and impairment of axonal transport is a cause of neuronal degeneration. Excessive reactive oxygen species (ROS) have been implicated in damage to neurons, therefore oxidative stress is known to be a major cause of neurodegenerative diseases. Cu/Zn superoxide dismutase (SOD1) is an enzyme, which protects cells against ROS. In this study, we investigated the effects of the SOD1 inhibitor diethyldithiocarbamate (DDC) on axonal transport in cultured dorsal root ganglion neurons.

Adult male C57BL/6 mice (n=5) were euthanized by intraperitoneal injection of pentobarbital sodium (60 mg/kg of body weight), and dorsal root ganglia were removed. Cells were enzymatically and mechanically isolated and cultured for 48 h in Ham's F-12 medium containing 10% fetal bovine serum at 37°C under humidified condition in 5% CO2. Movement of organelles in neurites was observed in real-time by using video-enhanced microscopy, and the number of organelles transported in anterograde and retrograde directions was counted manually before and during the addition of DDC (the number of experiments=48).

DDC significantly reduced the number of transported organelles in a time-dependent manner, compared with PSS. The percentage of transported organelles after 40-min treatment with DDC was 50% of the baseline (before application with DDC, in the control PSS medium) at 100 nM, 43% at 1 μM, 25% at 10 μM, 9% at 100 μM. We further examined whether the anti-oxidant α-tocopherol can prevent DDC-induced inhibition of axonal transport. The inhibitory effects of DDC on axonal transport was partially blocked by pretreatment with α-tocopherol, the value after 40-min treatment with DDC at 100 nM-100 μM was significantly higher than administration of DDC alone.

These results suggested that endogenous oxidative stress increased with DDC treatment and that it inhibited axonal transport. The DDC-induced inhibition of axonal transport was blocked by α-tocopherol. Based on these things, α-tocopherol might be of help in rescuing impairment of axonal transport in response to oxidative stress.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA159

Enhanced inhibitory synaptic transmission underlies the input-specific suppression of long-term depression by serotonin in the rat visual cortex

H. Jang[1,2], Y. Jo[1] and D. Rhie[1,2]

[1]Department of Physiology, Catholic University of Korea, Seoul, Republic of Korea and [2]Catholic Neuroscience Institute, Catholic University of Korea, Seoul, Republic of Korea

Serotonin [5-hydroxytryptamine (5-HT)] plays many important roles as a neuromodulator in the central nervous system. In our previous studies, 5-HT inhibited the induction of long-term potentiation (LTP) and depression (LTD) of layer 2/3 field potentials evoked by stimulation of layer 4 in rat visual cortical slices. To study the underlying mechanisms, we investigated the effect of 5-HT on the synaptic transmission mediated by the three major neurotransmitter receptors: AMPA receptors, NMDA receptors, and $GABA_A$ receptors. Whole-cell patch-clamp recording was made on the pyramidal neurons of layer 2/3. AMPA and NMDA receptors currents were measured with K-gluconate-based internal solution. $GABA_A$ receptor current was measured with CsCl-based internal solution. AMPA receptor current was measured with a NMDA receptor blocker at -70 mV of holding potential. NMDA receptor current was meas-

ured with AMPA and $GABA_A$ receptor blockers at 0 mV of holding potential. $GABA_A$ receptor current was measured with AMPA and NMDA receptors blockers at -75 mV of holding potential. To study the effect of 5-HT on long-term synaptic plasticity, LTD of excitatory synaptic potential was induced with low frequency stimulation (1 Hz, 900 stimulation) of the paired pulse stimuli (40-ms interval). Stimulation was applied to either layer 1 (L1-LTD) or layer 4 (L4-LTD). In both stimulation pathways, LTD was well induced. The induction of L1-LTD depended on both metabotropic glutamate and NMDA receptors. However, only NMDA receptor was involved in L4-LTD. Application of 5-HT inhibited L4-LTD but not L1-LTD. The most significant effect of 5-HT on synaptic transmission was ~20% increase in the $GABA_A$ receptor current evoked by layer 4 stimulation only. To test the importance of this increase on the suppression of LTD, we investigated the effect of $GABA_A$ receptor modulators with concentration at which $GABA_A$ receptor current increase or decrease by ~20%. The 20% increase in $GABA_A$ receptor current was sufficient to block the NMDA receptor-dependent L4-LTD but could not block L1-LTD. The 20% decrease in $GABA_A$ receptor current was sufficient to reverse the inhibitory effect of 5-HT on L4-LTD. These results suggest that inhibitory role of 5-HT on NMDA receptor-dependent LTD might be mediated by the enhancement of $GABA_A$ receptor current which could suppress the activation of NMDA receptors. The enhancing effect of 5-HT on $GABA_A$ receptor current was input-specific and the specific input depended heavily on NMDA receptors for the induction of LTD.

Exploring undergraduate medical students' self-directed learning readiness

R.R. Abraham[1], M. Fisher[2], A. Kamath[3], T. Izzati[4], S. Nabila[4] and N. Atikah[4]

[1]Physiology, Melaka Manipal Medical College, Manipal Campus, Manipal University, India, Manipal, Karnataka, India, [2]Sydney Nursing School, University of Sydney, Sydney, SA, Australia, [3]Comunity Medicine, Kasturba Medical College, Manipal University, Manipal, Karnataka, India and [4]Undergraduate medical students, Melaka Manipal Medical College (MMMC), Manipal Campus, Manipal University,, Manipal, Karnataka, India

Background: Medical students are expected to possess self-directed learning skills in order to pursue life long learning (1) . Melaka Manipal Medical College (MMMC), Manipal Campus, Manipal University, India offers a Bachelor of Medicine and Bachelor of Surgery (MBBS) twinning program which is of five years duration. The curriculum adopted at MMMC incorporates strategies which require students to spend considerable amount of time in self-directed learning.
Aims: In the present study, we explored the self-directed learning readiness of first year MBBS students (n=130) using Self-directed Learning Readiness Scale (SDLRS) (2) and also determined the correlation between SDLRS scores of high achievers, medium achievers and low achievers with their academic performance in physiology examinations.
Methods: Based on academic performance in three teaching units, students were categorized into three groups; high achievers (>75%; n=10), medium achievers (64 to 74%; n=41) and low achievers (<64%; n=79). Students were requested to respond to each item of SDLRS on a Likert scale. The median scores of three scales of SDLRS (self-management, desire for learning, self-control) were compared across the three groups of students using Kruskall Wallis test. The SDLRS scores of three groups of students were correlated with their marks in theory paper of first, second and third block-end examinations using Spearmann's correlation coefficient.
Results: The total score was found to be 141.7 (out of 200). The total mean score for self- management, desire for Learning and self-control were found to be 126.16, 134.32 and 164.72 respectively. The mean score for self- control was found to be higher followed by desire for learning and self-management. Data analyses showed significantly high ($p < 0.03$) median scores for self-control for high performers compared to medium and low performer groups. Between the groups, high performers had a higher score for all three scales of SDLRS, followed by low performers and medium performers. Nevertheless, SDLRS scores and academic performance of three groups of students were found to exhibit a weak correlation.
Conclusions: Total scores for each subscale reflected a positive attitude towards readiness for self directed learning. The study threw light upon the fact that inspite of having a high desire for learning and ability of self-control, students need to be supported in their self-management skills.

PCA161

Does practical demonstration class help medical students to develop their skill domain?

N. Upadhayay[1], B.H. Paudel[1], A. Kopila[1] and N. Baral[1,2]

[1]Basic and Clinical Physiology, BP Koirala Institute of health Sciences, Dharan, —, Nepal and [2]Biochemistry, BP Koirala Institute of Health Sciences, Dharan, Nepal

Practical demonstration by teachers has been practiced in a medical institute. It is quite difficult to handle and to involve hundred students in the laboratory exercise (Labex) at a particular time. So, practical demonstration class has been practiced in basic medical science discipline (BMSD) to tackle and minimize time and number of students in a labex. But, do practical demonstration class help medical students to develop their skill domain have been questioned by many students and teachers in the institute. So, we aimed to evaluate the importance and efficiency of practical demonstration classes in the institute.
It was a cross sectional descriptive study. Pretested structured questionnaire having both open and close ended questions were administered to MBBS students (n=63) and basic medical science (BMS) teachers (n=24) and their perception were assessed. Data were expressed in frequencies. On the present scenario, both teachers (24/24) and students (57/63) believed that practical demonstrations were very helpful to student for

developing their practical skills. Although most of the students (57/63) and all the teachers (24/24) were satisfied with the lab exercise (Labex) but both gave mixed response on the practical class. Most of the students (53/63) and teachers (17/24) felt and suggested that practical should be demonstration by teachers' followed by practical work by the students, and some of them (students= 8/63 and teachers= 3/24) suggested practical work (Labex) should be briefed and done by the students followed by a feedback.
Almost all the teachers (21/24) responded that they clarify queries raised by the students in the Labex. However, students mention that queries were clarified in few practical classes of BMS disciplines like in anatomy (63/63), biochemistry (61/63) and microbiology (60/63) but in physiology (22/63), pathology (28/63) and pharmacology (37/63) disciplines the clarification of queries perceived by the students was less.
Regarding training on the questions and exam pattern, overwhelming majority of teachers (20/24) agreed to provide training and majority of students (51/63) want to receive the training.
Thus, for the effective students' skill development, practical classes (Labexes) should not be limited to only demonstration by teachers but it should also be done by the students. Moreover, for skill improvement, queries raised during labex should be solved on the spot by the teachers, and it will be more understandable when students involves in practical work, so that students knows how to troubleshoot the problem when they encounter the problems.

New challenge of Physiological Society of Japan – Reform of annual meeting and establishment of Physiology Educator

N. Koibuchi[1,2], A. Nakashima[2], M. Ishimatsu[2], S. Okumura[2], T. Okumura[2], Y. Kawai[2], M. Kuno[2], A. Koizumi[2], M. Shiibashi[2], A. Suzuki[2], T. Matsuda[2], H. Morita[2], T. Yamashita[2] and A. Yamanaka[2]

[1]Department of Integrative Physiology, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan and [2]Education Committee, Physiological Society of Japan, Tokyo, Japan

The major aim of Physiological Society of Japan (PSJ) is to promote research in the physiological sciences by providing free communications to members and by actively committing itself to the national and international scientific communities. Research field of physiological science deals with a wide variety of areas, from cell physiology to system physiology of various organs. Because of development of modern science, sessions of PSJ annual meeting are finely divided and thus researchers who are outside of the area cannot understand the presentation. As a consequence, many researchers tend to attend other meeting that deals with their own area of interest, such as Society for Neuroscience. On the other hand, to obtain a tenure-track position in academic area such as Medical School, ability to teach a wide area of physiology is strongly required. Until recently, however, PSJ has provided little opportunity to learn teaching skill during annual meeting. Furthermore, to promote globalization of PSJ annual meeting, it has been required that all scientific sessions are presented in English since 2006. This reform was effective in developing an international collaboration by increasing the number of non-Japanese attendees. However, many physiology teachers, who mainly do teaching rather than research, have stopped attending the annual meeting. Such teachers may not be able to obtain up-to-date knowledge of physiology. Thus, quality of teaching may be declining. To provide an opportunity to learn a wide range of knowledge that is required for physiology teaching, Education Committee of PSJ has started a lecture course of physiological science together with model lectures that are designed mainly for undergraduates. These lectures are given in Japanese. To obtain Physiology Educator license, applicants must attend sufficient number of lectures. In addition to lecture attendance, there are additional several conditions that fulfill license application. We hope that these systems may improve physiology teachers' quality of teaching, help to promote postdocs to obtain academic positions, and to increase attendees of the annual PSJ meeting.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Performance 2012: Engaging the public with the physiology and pharmacology of sporting success

D.I. Lewis and C. Haigh

School of Biomedical Sciences, University of Leeds, Leeds, UK

There is considerable public interest in sport, with a significant upsurge following any major international competition. The 2012 Olympic Games therefore provided an ideal opportunity to explore, with the public, biomedical aspects of sport. Funding was obtained from the Wellcome Trust for a programme of three public engagement events entitled "The physiology and pharmacology of performance enhancement in sport"[1]. The aim was to provide the public with knowledge and understanding of exercise physiology and pharmacology, and promote debate on the ethical issues which arise when this knowledge is utilised to enhance sporting performance.
The first event, targeted at young people, gave them the opportunity to act as scientists in a mock drug testing laboratory. They then discussed their results and debated the use of gene doping to enhance sporting performance. The second event was targeted at individuals who provide sporting opportunities for young people and comprised of a facilitated debate in which their roles and responsibilities as coaches was explored. Video case studies of social drug use by athletes and the phenomenon of "pushy parents" were created and utilised to promote discussion. The final event, "The science behind sporting success" was a two-day interactive exhibition, the aim of which was to introduce the general public to the physiology and pharmacology of performance enhancement in sport, and give them opportunity to reflect on any ethical issues which may arise. The exhibition combined "have a go" sporting activities such as wheelchair basketball or racing a friend on a Wii rowing game whilst measuring cardio-respiratory changes, with those which focused more on the science of performance enhancement e.g. how do you measure lactate threshold, or an interactive mind-map where the public could contribute their ideas on the harms and benefits of gene doping in sport for different sections of the community. Individual activities were run by undergraduate student interns. The exhibition attracted more than 900 visitors over its two days
Feedback from all three events was excellent. 95% of school pupils would come to a similar event in the future, it made them think about their views on the use of drugs in sport (Lik-

ert 1-4 scale, mean score = 3.18/4) and increased their understanding of the ethics of gene doping (3.73/4). Coaches similarly enjoyed their debate (3.3/4), with it being of benefit to them in their role as a coach (3.06/4) whilst 82 % of the public found the exhibition interesting.
Performance 2012 has successfully engaged the public with the physiology and pharmacology of performance enhancement in sport. To promote sustainability of the project, all resources will be made available as open educational resources via the project website[1].

PCA165

Enhancing feedback provision and use through *in situ* audio commenting

K.L. Colthorpe[1], K. Zimbardi[1], A. Dekker[2], P. Hay[3], C. Engstrom[3], A. Bugarcic[1], P. Long[4], L. Lluka[1], P. Chunduri[1], P. Worthy[1] and J. Marrington[2]

[1]Biomedical Sciences, The University of Queensland, Brisbane, QLD, Australia, [2]Information Technology & Electrical Engineering, The University of Queensland, Brisbane, QLD, Australia, [3]Human Movement Studies, The University of Queensland, Brisbane, QLD, Australia and [4]Centre for Educational Innovation & Technology, The University of Queensland, Brisbane, QLD, Australia

Assessment reforms in higher education recognize the need for effective feedback that is timely, informative, and encourages positive attitudes towards future learning amongst students[1]. Although it is well established that feedback to students is one of the educational practices with large positive impacts on student learning[2], evaluating the actual extent to which students engage with and utilize feedback is difficult. Studies show that when students do receive feedback it is often too brief, too broadly stated, and is often misinterpreted by students[3]. Recent studies have suggested that students find audio feedback more engaging and informative than traditional written feedback[4], and prefer either audio or a combination of text and audio[5] to text alone.
During this study, we have developed a 'rich media' marking system, to help markers provide students with timely, detailed and situated feedback, and to investigate the potential of technology to facilitate new methods of feedback provision, such as *in situ* audio comments. The system can support large cohorts of students, large teams of markers, moderation of markers, and provides learning analytics during the feedback process. It consists of three components: 1) *Administration interface* that processes submissions for marking and moderation, 2) *iPad application* that allows markers to provide feedback as audio, handwritten and typed annotations, and to grade using criteria rubrics, and 3) *Feedback viewer* allowing students to view their feedback on any web browser. In addition, the in-built learning analytics allows for extensive evaluation of the provision and use of feedback, providing empirical evidence of both marker and student behaviors. To date, the system has been trialled on 852 student assignments in two separate trials, the first based on a final student laboratory report, and the second on a draft of a scientific literature review.
Preliminary analysis of the learning analytics data indicates extensive provision of feedback by markers and use of the *in-situ* feedback by students. However, it also revealed differences in the ways in which markers use the annotation modalities, with almost half avoiding use of audio annotations whilst the remainder used audio annotations extensively. Differences were also found in student use of feedback, with students in the second trial viewing their feedback for considerably longer time periods than the first, suggesting there was an effect of timeliness of feedback provision. For audio feedback specifically, students reported in interviews that they (i) favoured audio feedback for its greater detail and personalized nature; (ii) valued contextualized, *in-situ* feedback; and (iii) were concerned if audio comments were too long or lacked meaning. These findings are currently being used to target professional development for markers and to enhance the provision of quality feedback.

PCA166

Development of a wiki of education and training resources in in-vivo sciences

D.I. Lewis

School of Biomedical Sciences, University of Leeds, Leeds, UK

There is a global shortage of individuals with the knowledge, skills and expertise necessary to undertake in-vivo or whole animal research. To address this skills shortage, many countries, including the UK and the US, have committed significant funds towards training the next generation of in-vivo scientists within their respective countries. There is also a need to provide for continued professional development (CPD). Indeed, the new European Union animal welfare directive 2010/63/EU makes such training mandatory. This training and CPD would be best facilitated with short open educational resources (OERs) or learning objects (LO) and therefore the aim of this project was to collate, evaluate and disseminate OERs and LOs that could be used in educational and training in in-vivo sciences.
Open educational resource repositories and websites of professional and other organisations were searched for suitable OERs and LOs (eg video podcasts, guidance notes, statistical packages). A call was also made to colleagues in relevant professional bodies. Individual resources were evaluated and a brief description of each written. These were then collated into an education and training resources in in-vivo sciences (ETRIS) wiki, subdivided into topics across the entire spectrum of resources required by practicing in-vivo scientists including

surgical procedures, animal welfare and husbandry, ethics and the 3Rs, experimental design and analysis. This wiki is now being made freely available to colleagues.
ETRIS will be of significant benefit and a valuable tool for colleagues engaged in education, training or research in in-vivo sciences. It is envisaged that it will be a living wiki, that will grow as colleagues either contribute or provide links to new OERs and LOs.

This project was funded through the award of a University of Leeds teaching fellowship to DIL

PCA167

Optimisation of certainty-based assessment scores

A.R. Gardner-Medwin

Physiology (NPP), UCL, London, UK

Certainty-Based Marking (CBM) rewards students for identifying which of their answers are uncertain and which reliable. Confident answers incur negative marking if wrong, while uncertain answers receive lower credit but no penalty. The scheme at UCL is shown in Table 1 (1,2). In self-tests this encourages reflection and deeper learning, because the student gains from evaluating both doubts and justifications. CBM gives a sound measure of knowledge (1) and enhances the statistical reliability of assessments (3,4). Problems arise, however, with student perception of CBM final scores, because average marks as a fraction of the maximum are lower than the percentage of correct answers ('accuracy'). For example, students with 80% accuracy typically get only 50% of the CBM maximum (Fig.1).
A new strategy is analysed here using data from 17 medical exams with CBM at UCL (250-300 true/false Qs, 320-360 students). In this, a CB bonus (+ or -) is added to conventional accuracy to reflect how well or badly the student has distinguished uncertain from reliable answers. This bonus is a fraction of the difference between average CB mark and the average that would have resulted with a uniform certainty level, appropriate to the student's overall accuracy. The multiplying 'Bonus Factor' (BF) is shown here to be optimally ca. 0.1 to give maximum statistical reliability for the resultant 'CB Accuracy' (accuracy + bonus). Reliability was calculated as the rank correlation (r) between scores on subsets (odd and even questions) in each exam. This increased from a mean of 0.80 with BF=0 (i.e. conventional accuracy) to 0.86 with BF=0.1 (increase = 0.060 ±0.0039), almost as high as for the CBM average (0.87). This reflects an increase of 57% in predictive power (Fig. 2a), equivalent to adding 57% more questions without CBM. The power to predict conventional accuracy was increased by 16% (Fig. 2b), showing greater validity for CBM scores even with accuracy as the standard.
The CB bonuses added to accuracy in exam data are typically 2-5%, though students doing online self-tests while studying often get negative bonuses due to misconceptions (confident errors). Bonuses and CB accuracy scores are implemented online using BF=0.1 in LAPT at UCL (2), available for use by other institutions. CBM is also available in Moodle, though additional code (5) is required to implement the enhanced scoring and feedback to students.

Degree of Certainty:	C=1 (low)	C=2 (mid)	C=3 (high)	No Reply
Mark if Correct:	1	2	3	0
Penalty if wrong:	0	-2	-6	0
Probability correct:	<67%	67-80%	>80%	-

Self-tests with certainty-based-marking in early years of medical course

N. Curtin[1] and A.R. Gardner-Medwin[2]

[1]Molec Med, NHLI, Imperial College London, London, UK and [2]University College London, London, UK

Although our Medical class intake are bright and highly motivated students, they need and seek help in adapting to the differences between teaching and learning in the medical course and what they experienced at school. Even the best-achievers quickly discover that in the medical course they will not be able to learn everything presented to them, as they felt they could do with their school curriculum. Consequently, new students commonly want more (and more) guidance about the level and breadth of knowledge expected of them. To help fill this need within the 6-Yr medical Course at Imperial College London, we have developed Self-tests using the LAPT system (www.ucl.ac.uk/LAPT, Gardner-Medwin (1995)). Self-tests are a set of exercises, each on a specific course or topic within Yr1 and 2 of our 6-yr Medicine program. An important fea-

ture of the LAPT system is use of Certainty Based Marking (CBM) in which the student's answer is marked so as to reward not only correctness, but also identification of whether they think their knowledge is secure. The mark scheme ensures honest reporting of uncertainty. See Table 1. The students easily grasp the rationale: "knowledge is knowing what I know, and what I don't know". It is particularly important in medicine: "As a doctor, I must recognize when I am sure enough to act, and when I need more information or help. Guessing can be a disaster for my patients."

Features for students include:

*Links via BlackBoard Learn for use on personal computers or tablets,

*Approximately 2,100 questions in 58 exercises that map onto the Imperial course,

*Can do any number of repeat attempts,

*Instant marking of each answer as it is entered,

*Instant explanations of answers,

*Student comments are shared, anonymous, and linked to each exercise,

*Personalized spread-sheets of performance, including certainty.

Features for staff include:

*Many questions types can be used (SBA, EMQ, ARQ, T/F, etc.)

*Summary spread-sheets of student performance,

*Analysis of correctness and certainty for each question,

*Editing facilities (which also can be available to students on a wiki basis),

*Comments emailed to designated staff for each Self-test.

Most of the Self-tests were written by students (a 'grass-roots' project), then checked by an academic expert. Self-tests are popular with students. Performance comparisons show that the students who do the Self-tests have better exam results than students who do not do the Self-tests.

Marking Matrix

Certainty level:	C=1	C=2	C=3	no reply
Mark if correct	1	2	3	0
Penalty if incorrect	0	-2	-6	0

Engaging the gen Y students with STD - Speed Triage Dating

L.B. Tee

School of Pharmacy, Curtin University, Perth, WA, Australia

Speed dating "speed networking" was integrated as a tool for interpersonal development (1). Academic sector recognised its potential and adopted speed dating as an educational tool to help students to know each other and share knowledge (2, 3). The main challenge for the pharmacology teaching team is to transform the students' perception of pharmacology as difficult, with a great amount to "know and remember," to an essential and interesting subject which enhances their competency in clinical pharmacology and medication prescription. The aim of this research is to investigate whether the inclusion of the innovative Speed Triage Dating learning method within the Pharmacology modules in the Bachelor of Pharmacy Course at Curtin University enhnaces deep learning in subjects traditionally reliant on memorisation. In this project a modification of speed dating, Speed Traige Dating (STD) is used in tutorial workshop in Pharmacology. Instead of the one-on-one dating, to foster collaborative learning and peer coaching, each "dating" session will involve three students or a triage. Information was relayed from students to students. Before class students undertook a test to assess their prior drug knowledge. At the end of the STD session students undertook another test to assess their improved drug knowledge. For each dating the students were instructed to address different issues pertinent to their individual task with increasing level of thinking progressing from describing the task to critically evaluating and integrating information learned during the process. Students were provided with a drug in which they have to research to develop a comprehensive drug monograph. During the STD session, in Round 1 of the STD, they were instructed to describe their drug. In the subsequent rounds they may be ask to integrate, evaluate and compare and contrast the drugs in various aspects of Pharmacology. There was an increasing spiral of information with increasing rounds of STD with students teaching as well as learning the increasing number drugs. Most importantly students were actively engaging in intergration and communication of knowldege learned. Qualitative data were gathered from eVALUate data of students' feedback on their perception of resources and teaching activities available in the Pharmacology Module including the use of STD during tutorials. Students have valued the STD method and commented positively on STD indicatig that it is engaging, fun and improves their ability to understand the more complex content of pharmacology and foster internalisation of knowledge allowing long term memory to occur more effortlessly.

More than semantics: Moving physiology instruction to learner competencies from learning objectives

R.G. Carroll

Physiology, East Carolina University, Greenville, NC, USA

Preclinical medical education is adopting the 'competency' framework that has been successfully used in the postgraduate medical education community. While learning objectives focus on specific content to be mastered, competencies focus on the learner. In 2002, the American Physiological Society and Association of Chairs of Departments of Physiology CDP published Medical Physiology Learning Objectives, which outlined the physiology content that medical students should master during their preclinical training. In contrast, in 2003 these same groups published the List of Professional Skills for Physiologists and Trainees, which took a competency approach, focusing on the skills and attributed of professional physiologists.

The following is proposed as a set of knowledge-based competencies for medical physiology instruction as a compliment to the more specific Learning Objectives
Medical Knowledge: 1. Identify the range of normal physiological values, i.e., plasma electrolytes (Na+, K+, and Cl-) ; arterial and mixed venous blood gasses, blood pressure in the cardiac chambers, the systemic and pulmonary arteries, capillaries, and veins, and key values in assessing cardiovascular, pulmonary and renal function. 2. Use normal values to interpret clinical data in order to identify the direction and degree of variation from normal. 3. Given an alteration in a physiological parameter, identify potential causes for the alteration and the physiological mechanisms which when effective would correct the alteration. 4. Contrast the regulation of a physiological parameter (i.e., blood pressure, plasma glucose, pH or body temperature) by negative feedback, positive feedback and feed forward control mechanisms. 5. For a physiological variable controlled by multiple redundant systems (i.e., plasma glucose or blood pressure), rank the control systems based on time to effect and overall effectiveness.
Professional Development: 1. Demonstrates a positive attitude and regard for education by demonstrating responsibility and preparedness, 2. Demonstrates maturity in soliciting, accepting, and acting on feedback.
Interpersonal and Communication: 1. Effectively leads group discussions, 2. Creates a supportive environment for conversation, 3. Demonstrates collegiality and respect for group members.
In the shift to competencies, instructors must move from the exclusive focus on knowledge and take responsibility for the development of professionalism in all of their students.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA172

Undergraduate-led practical physiology activities can enhance learning for both university students and A-level school pupils

P. Lillie, A.C. Reid and J.R. Harris

University of Bristol, Bristol, UK

The Undergraduate Ambassador Scheme (UAS; http://www.uas.ac.uk/) enables university students to undertake a final year research project in association with a local school. At the University of Bristol we run UAS projects in which pairs of BSc students (a) design, deliver and evaluate biology lessons in the partner school and (b) design, implement and evaluate a complementary research project that includes collecting and analysing biometric data generated with/from the pupils.
We describe a UAS research project designed to illustrate and extend the respiratory and cardiovascular components of the Salter-Nuffield Advanced Biology A-level curriculum. The impact of pupils' height, weight and breathing pattern on the cardio-respiratory variables of vital capacity, breath-hold breaking point and resting heart rate (RHR) was compared to impact on these variables of regular exercise.
One week before visiting our undergraduate physiology teaching lab, 65 A-level pupils took a test to evaluate their cardio-respiratory physiology knowledge and completed a modified Brunel lifestyle questionnaire[1] quantifying their level of regular physical activity. They were then given worksheets explaining the experiments they would do in the lab and preparatory exercises to work through. In the lab, pupils rotated in small groups through three stations: (a) measuring vital capacity with a Benedict spirometer; (b) using ECG recording to measure RHR; (c) measuring their breath-hold (BH) breaking time at rest and after a period of voluntary hyperventilation while monitoring arterial oxygen saturation (SaO_2) with a finger pulse oximeter. At the end of the lab session they completed the same theory test as before.
Little correlation was found between the physiological variables and the subjects' physical activity scores. However, there was strong correlation between height and vital capacity ($r = 0.72$; $P < 0.001$; $n = 19$). BH breaking time was increased from 39 s (SEM 2.6) to 65 s (SEM 5.1) after voluntary hyperventilation for 15 s ($P < 0.001$, Student's t-test; $n = 22$) but SaO_2 did not change. The results were discussed in the lab session and used to illustrate subsequent school lessons on cardio-respiratory anatomy and physiology delivered by the undergraduates. The average marks (out of a total of 11) for the pre- and post-lab physiology tests increased from 3.6 (SEM 0.36) to 6.8 (SEM 0.40); ($P < 0.001$, Wilcoxon signed-rank test; $n = 60$). The accompanying teachers gave very positive feedback on the benefits of the lab session for the pupils' learning and engagement.
We conclude that this type of BSc research project has significant benefits for the school pupils concerned; involves undergraduates in interesting and novel physiology research that also develops their communication skills; and fosters valuable links between universities and schools.

PCA173

Developing students' advanced scientific thinking skills through effective inquiry-based physiology practical classes

K. Zimbardi[1,2], K. Colthorpe[1], J. Kibedi[1] and P. Long[2]

[1]School of Biomedical Science, University of Queensland, St Lucia, QLD, Australia and [2]Centre for Educational Innovation and Technology, University of Queensland, St Lucia, QLD, Australia

Over the last 30 years there has been a wide-spread implementation of inquiry based classes in science education (1), and in tertiary physiology curricula in particular (2), because these pedagogies have been shown to improve student learning of content (3, 4) and important scientific thinking skills such as experimental design and data interpretation (5). However, a multitude of obstacles face instructors aiming to implement inquiry-based practical curricula (6) where poor implementation (7), and both too much and too little guidance (8) have negative effects on student learning. It is therefore important to understand which specific aspects of inquiry-based curricula engage students in effectively developing scientific thinking skills, and when and why the development of these skills goes awry. We have developed a vertically-integrated set of inquiry-based practical curricula for large cohorts (500-900 students) of first and second year physiology students (9) which facilitate the development of students' skills in scientific thinking (10, 11). Video recordings of students engaged in inquiry in class were analysed using the Australian national academic standards for scientific thinking (12) and the theo-

retical framework for critical thinking developed by Bailin (13). Results from this study showed that students used and developed their critical scientific thinking skills when they needed to make scientific decisions. In our physiology practical classes, these decisions typically involved which hypothesis to test and how, and how to analyse and interpret experimental data. Students employed a range of strategies to make these decisions, from uncritical guesses, to using their prior anecdotal experience and instructions from manuals or teaching assistants, through to more scientifically rigorous strategies that included using evidence from their own experiments and scientific literature. Evidence from video tapes of classes has revealed key factors that impact on the degree of scientific rigour students employ when making their decisions. For example, students must be required to 1) demonstrate feasibility of their experimental proposals with pilot data and primary literature, and 2) to critically compare experimental contexts and specific data values when interpreting their experimental findings. This study provides evidence-based strategies for producing curricula that are effective in helping large cohorts of early stage undergraduate physiology students to develop advanced scientific thinking skills.

A practical class to teach masticatory efficiency for dental students

M.A. Rocha, M. Ferreira, D. Gaspar and W. Mestriner-Júnior

Dental School of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

The aim was to set up a practical class to teach the students about the several factors that can affect masticatory efficiency. Before starting the test we asked the student volunteers to report to the colleagues whether or not they have any masticatory problem and to masticate a piece of parafilm or a sugar-free chewing gum for 20 seconds to remove any resting muscular memory. Subsequently, they are instructed to masticate the way they usually do a Me Mastig® capsule made of polyvinyl acetate filled with beads containing a calcium chlorid fuchsin dye. After 20 seconds, the beads (fragmented or not) are collected and the content is dissolved in 5 ml of water and agitated for 30 seconds. The solution is then filtered through gaze and the fuchsin dye quantified by spectrophotometry. The masticatory force of each volunteer is then calculated by regression analysis of the extracted fuchsin concentration against a standard curve generated from a force-controlled masticatory apparatus. As future dentists, the students are instructed to discuss the problems that the volunteer students reported and discuss the possible factors affecting the respective masticatory efficiency.

PCA175

Quality of essay plans in finals papers correlates with the mark awarded to the essay by independent examiners

P.D. Langton, R. Helyer and F. MacMillan

Physiology and Pharmacology, Univ Bristol, Bristol, UK

Increasingly, students' written work is word processed. Concerns about students' ability to compose written work seem unfounded for essays composed using a word processor (Goldberg, Russell et al. 2003). However, essays written in end of year examinations are traditionally hand written. We were interested to know if the practice of essay planning, that has been suggested to positively contribute to essay quality (Hounsell 1984), correlated with the mark awarded to the essay.
This was investigated by a post-hoc examination of a complete set of recent final examination scripts for the three Units of the Physiological Sciences programme that are examined by a finals paper. Ignoring the mark sheet, so as to remain blind to the mark awarded, each essay booklet was examined to establish if there was an essay plan. Plans were graded according to a four point criteria with a maximum total of 10 marks:

Title present = 0 to 1 mark
Structure evident = 0 to 2 marks
Scope of the plan = 0 to 4 marks
Reference works listed = 0 to 3 marks
Only after the overall mark for the plan was recorded was the mark awarded for each essay determined from the official records of the examination. The essays written for each unit that were not associated with a plan (unit 2, n=12; unit 3, n=10; unit 4, n=8) were excluded from the correlation analysis. Students who choose not to construct a plan are likely to fall into two groups, 1) those who have attempted to question spot and have done their planning before the exam and, 2) those who simply choose not to construct a plan. For this reason it seems sensible to separate these candidates from the correlation analysis.
Each unit had more than 30 students (unit 2, n=31; unit 3, n=33; unit 4, n=34) who had made a plan. In each case the distribution of marks for the plan and the essay mark were normally distributed and the existence of an association between the mark given for the essay and the plan was determined by a Pearson correlation analysis.
For each unit a statistically significant correlation was found to exist ($p=0.0026$; $p=0.0004$; $p<0.0001$ for units 2,3 & 4, respectively). The Pearson correlation coefficient (r2), which indicates the degree of correlation, ranged from 0.27 to 0.44. In summary, there is a statistically robust correlation between the mark awarded to the essay plan and the mark previously awarded to the essay. In each case the mark awarded to the plan and the mark awarded to the essay (moderated mark) were safely normally distributed. Moreover, the r2 values in each case was greater than 0.25 and so the correlation is reasonably strong. Our current interpretation of these finding supports the assertion that students who have thought more about the structure of their essay achieve higher marks.

South East Asian medical students perceive and accept PBL as useful learning process: report from an upcoming medical school in Malaysia

S. Ghosh

Physiology, MAHSA University College, Kuala Lumpur, Selangor, Malaysia

Problem based learning [PBL] has been widely used globally in undergraduate medical education and other professional training programs. Asian students are often found to have aversive reaction to the Problem Based Learning process being introduced in their first year of medical school. The basic apprehension remains that without being told what to learn they will not be able to learn (1). The present study reports that with a proper briefing on the process of PBL first year students appreciate the importance of PBL and accept it as an important teaching learning tool. One week before the real session, a briefing session was conducted for two hours with interactive lecture and video clips to sensitize the first year students of batch 2011 to the process of PBL. A case of an inherited disorder was used for actual training session of the students. 12-14 students were allotted to one facilitator and the case had four triggers. Three sessions of 2 hours each with one week gap were conducted based on the accepted steps of PBL. The second session comprised of presentation and discussion after the students were introduced to the case in the first session. The third session comprised of a mini test, concept map and feedback by the facilitator. After the sessions were over, students were required to give their feedback on a structured questionnaire. Their performance scores in the mini test were correlated with those of the facilitator's during the session.
Students enjoyed this active form of learning alongwith good scores in the minitest. However, the facilitator's scores of their performance did not correlate with the scores of the mini test for some groups. 80% students were aware of the process and accepted it as a good teaching learning activity. 20% students were still unsure of the process and felt lost in studying what they do not know.With proper briefing sessions, most Asian students can be sensitized to the process of PBL and they accept it as a good active learning strategy. The minitest and concept map are good to assess them in PBL objectively.Students are acceptable to newer TLAs which are more active in nature. They can be motivated to undertake such activities with proper briefing and visuals and also feedback being given to make them perform better in subsequent PBL sessions.

Perception of basic medical science teachers and medical students on objective structured practical examination (OSPE) and viva in a medical institute

N. Upadhayay[1], B.H. Paudel[1], N. Baral[2] and K. Agrawal[1]

[1]Basic and Clinical Physiology, BP Koirala Institute of Health Sciences, Dharan, —, Nepal and [2]Biochemistry, BP Koirala Institute of Health Sciences, Dharan, Nepal

OSPE has been practiced in our all under graduate curricula. However, its utility has been questioned by many teachers and students. This study was undertaken to assess the students and teachers perception on OSPE and viva in basic medical science (BMS) disciplines. We administered pre-designed and pretested structured questionnaire on OSPE and viva to MBBS students (n=63) and BMS teachers (n=24). Majority of students (38/63) considered OSPE as a satisfactory practical evaluation tool whereas almost all the teachers (22/24) believed it as a fairly good tool. More than 50% (34/63) of students and 70.83% (17/24) of teachers believed 5-min to each OSPE station is sufficient enough; however, 42.86% (27/63) of students responded that it was not sufficient for stations having calcu-

lation and additional tail questions. Almost all students (58/63) preferred a gap between practical exams and 100% of them preferred having a rest station between OSPE stations in an exam day. Majority of students preferred a gap between practical exams for proper sleep, coping and minimizing their stress and anxiety, and revising contents. However, teachers (11/24) were against giving the students a gap between practical exams, neither they (14/24) favored rest station among many OSPE stations. Students gave almost equal preference to OSPE stations only (46.03%) as well as combined OSPE plus some procedures (47.62%) during practical exams. Majority of teachers (21/24) opined that students must perform some procedures during practical exams, which has declined over the years. Regarding viva as a station, many students (36/63) and teachers (11/24) supported the ongoing structured of fixed number of questions to evaluate all students. Teachers gave major suggestions: careful questions framing directly linking with the practical, having some liberty for examiners with alternative reserve questions so that bias across the examiners is minimized, question uniformity should be maintained and students' opinion has to be taken to explore the issue further. However, majority of teachers (17/24 or 70.83%) and some students (21/63 or 31.74%) preferred open number of questions with respective weight-age, they believed that it tests the students' knowledge in depth, facilitates and motivates them to study meticulously and helps to evaluate them properly in exams. Thus in BMS, well-framed OSPE directly linking with the practical exercises can be a best tool to assess students' skill, but it should include some working stations (procedures) too. During practical exams students should be provided gap between exams to minimize their stress and for revision. Viva questions should be framed carefully by directly linking with the practical, and having some liberty for examiners with alternative reserve questions to minimize examiner bias.

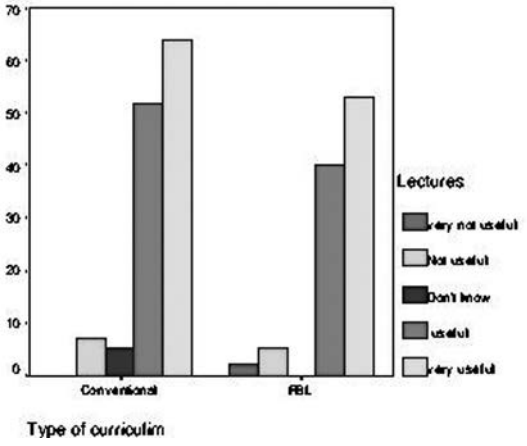
PCA178

Doctors' perception about clinical relevance of physiology to practice in the houseman ship in Sudan. Comparison between graduates from Problem based learning and conventional curricula

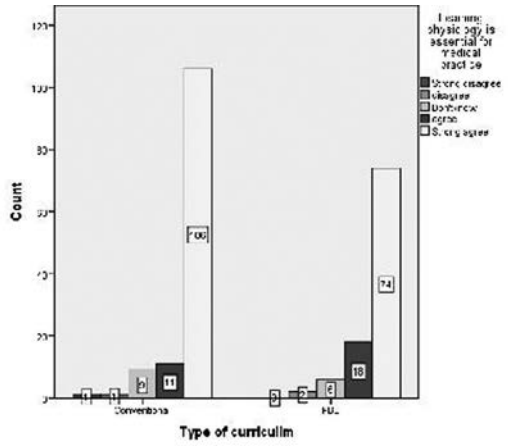
L.A. Kaddam[1], H. Awooda[1], M. Elnimeiri[2], A. Saeed[3] and R. Badi[3]

[1]Physiology, Alneelain University Faculty of Medicine and Health sciences, Khartoum, Khartoum, Sudan, [2]Community Medicine, Alneelain University Faculty of Medicine and health sciences, Khartoum, Sudan and [3]Physiology, University of Khartoum Faculty of Medicine, Khartoum, Sudan

Physiology is s considered as an essential subject in any medical curriculum. There is an increase in studies that showed poor retention of basic sciences in clinical years and students' perceptions of some parts of physiology as "irrelevant". This mandated rethinking about physiology teaching methods to improve students' competence to apply knowledge in clinical practice.Problem Based learning (PBL) is considered as an ideal curriculum where students are able to integrate their knowledge into clinical application and problem solving. However some studies showed no convincing evidence of improved learning using the PBL curriculum. Other studies showed PBL curriculum resulted in significant gaps in students' understanding of basic physiological concepts. In this study we investigated difference in physiology perception between graduated from faculties adopting PBL curriculum and those graduated from faculties adopting conventional curriculum. We focused on their experience in learning physiology and their self-assessed competence to translate knowledge into practice in their clinical work. 400 self administered questionnaires were distributed among doctors who finish houseman ship residency and sat for a license examination to be registered in Sudan Medical Counsel. As they represented all medical schools across the country. Results: 229 questionnaires were returned for analysis (response rate 57%). Differences between the two groups of graduates was determined using chi-square and two-tailed t-tests for categorical and continuous variables, respectively.BPL based curriculum (n=100) and conventional curriculum (n=129). PBL graduates studied physiology for longer time than conventional one (p=0.02). No difference in self evaluation for time spent in studying physiology. 52.8 % declared they were satisfied by the time spent in learning physiology (55.8% conventional PBL 49%). 91% agreed that learning physiology is essential for medical practice.While 80% stated they applied physiological concepts during medical practice (83.6% conventional 76% PBL). 51% stated they recalled the information from their undergraduate study (56%conventional PBL. p=0.2). 44% Graduates from both curricula agreed lectures are useful method to study physiology 91% (90% conventional, 91% PBL) . Regarding case study 70% declared it is useful tool to learn physiology (57% conventional 86% PBL p=0.00). So, here in Sudan we concluded that no significant difference was found between graduates from conventional curriculum and Problem based study in perception of physiology clinical relevance, satisfaction about time spent in learning physiology and application of physiological concepts in clinical practice



Doctors perception about usefulness of different teaching methods utilized in learning physiology



Doctors perception about physiology relevance to clinical practice

Merits and demerits of 'Frequent Discussion Embedded Interactive Lecture (FDEIL)' in learning physiology: a students' opinion

M.U. Khan

Physiology, Noakhali Medical College, Noakhlai, Bangladesh

Background: Lecture is a method of teaching where teacher gives information and the students receive it. Students get less scope to make a point clear (1). Researchers demonstrated that students need to be taught by interactive lectures(2). Frequent discussion interrupted lecture has been preferred as a good method of lecturing in a recent research(3). Interactive lectures are avoided due to time constraints and fear of losing of control over students(4). Objective: To assess the students' opinion about merits and demerits of 'Frequent Discussion Embedded Interactive Lecture (FDEIL)' in learning physiology. Method: This cross-sectional descriptive study was conducted in the Department of Physiology, Noakhali Medical College during March-June'12. By convenient sampling 107 students who attended FDEIL lecture in physiology were enrolled in the study. In FDEIL teachers delivered lecture on a topic for 15-20 minutes and gave a 5-10 minute's discussion-break among students and teacher. A one-hour lecture was divided into 2-3 lecture-discussion cycles. A questionnaire with statements on merit and demerit of FDEIL was distributed to the participants to response. Permission of the authority and consent of the participants were taken. Data was analyzed by a calculator. Result: The number of students chose the statements as follows; 'students get opportunity to understand the topic clearly' 101 (94.4%), 'students can discuss among them about the topic' 92 (86%), 'students can ask question to the teacher before forgotten the critical part, 97 (90.7%), and 'students do not feel tired' 58 (54.2%). The number of students who chose the demerits was as follows; 'students engage in gossiping and chatting' 59 (55.1%), 'teacher may lose attention and time' 34 (31.8%), 'it kills time' 21(19.6%), and 'students attention towards teacher is interrupted' 18 (16.8%), students. 99(92.5%) students thought FDEIL a good learning system. Conclusion: FDEIL was supported as a good lecturing system for large group teaching in Physiology.

Table-I: Summary of response in favor of merits and demerits of FDEIL

Statements in favor of merits of FDEIL system	Frequency (%)
Students get opportunity to understand the topic clearly	101 (94.39)
Students can discuss among them about the topic	92 (85.98)
Students can ask question to the teacher before forgotten the critical part	97 (90.65)
Students do not feel tired	58 (54.21)
Statements in favor of demerits of FDEIL system	Frequency (%)
Students engage in gossiping and chatting	59 (55.14)
Teacher may lose attention and time	34 (31.78)
It kills time	21 (19.63)
Students attention towards teacher become interrupted	18 (16.82)
Comment on FDEIL: it is good for learning Physiology	99 (92.52)

Cooperative learning, a tool to teach physiology in nursing education

M.A. Kanpurwala[1], S. Saleem[2] and A. Faisal[3]

[1]Physiology, University of Karachi, Karachi, Sindh, Pakistan, [2]Nursing, Baqai University, Karachi, Pakistan and [3]Health Management, Institute of Business Management, Karachi, Pakistan

Nurse educators struggle on how to prepare competitive nurses who can provide best possible quality care to their patients in the increasingly complex healthcare environment of the twenty-first century [1]. Different strategies like lecture, discussion, tutorials, cooperate learning etc are used to convey knowledge to the students so that they will be able to work collaboratively, think critically, draw reasoned conclusions, and make complex decisions in their profession more effectively

[2]. Cooperative learning plays a pivotal role to prepare them to face the contemporary challenges and thus can be helpful in improving overall quality in healthcare [3,4]. The tool could also be beneficial to teach physiology which is the backbone of medical sciences. The objectives of this study are to identify the knowledge about cooperative learning strategy among nursing educators and to assess their attitude and practices about integration of these strategies and the barriers they usually faced in implementing them.

It is a Cross-Sectional Survey in which 100 nursing educators were selected from different institutes of Karachi, Pakistan through Convenient Sampling and a self administered questionnaire was used to achieve the research objectives. Consent was taken from each participants and Data was analyzed through SPSS software.

It has been found that nursing educators have knowledge regarding cooperative learning. 72% of the participants have knowledge about cooperative learning. Besides this they also have positive attitude towards it and approximately 43% of the participants always use cooperative learning structures in their practice but they are facing certain barriers in implementing these strategies. Few of the major barriers are workload, lack of motivation and management support. Hence it can be concluded that nursing educators have knowledge and competencies regarding cooperative learning with respect to teaching physiology. But more emphasis should need to be given on training in relation to cooperative learning as it will not only help in professional development of educators and effective teaching but may also results in the production of efficient competitive nurses who have more self reliance and improved interest in physiology.

Teaching acid-base physiology to medical students: A comparison of group work and peer instruction for interpreting arterial blood gases

M.W. Petersen[1,2], L.N. Toksvang[1], R.R. Plovsing[2] and R.G. Berg[1,3]

[1]Centre of Inflammation and Metabolism, Department of Infectious Diseases M7641, University Hospital Rigshospitalet, Copenhagen Ø, Denmark, [2]Intensive Care Unit 4131, University Hospital Rigshospitalet, Copenhagen Ø, Denmark and [3]Renal and Vascular Research Section, Department of Biomedical Sciences, Faculty of Health Sciences, University of Copenhagen, Copenhagen N, Denmark

Background:

Collaborative teaching strategies are associated with enhanced student performance in quizzes when conveying complex physiological phenomena, (Giuliodori *et al*, 2006), and Mazur's peer instruction may enhance transfer and retention of learning in a time-efficient fashion. This may be of particular relevance when conveying complex physiological phenomena, such as acid-base physiology. In the present study, we hypothesized that peer instruction was superior to conventional group work for teaching medical students to diagnose acid-base disorders by means of arterial blood gas analysis.

Methods:

A total of 41 second-year medical students were included during a respiratory physiology course. They were randomised to (A) conventional group work (n=22) or (B) peer instruction (n=19), and were tested by an identical pre- and post-test, which encompassed four arterial blood gases (see Table). Each correctly diagnosed acid-base disorder was awarded with one point (both tests). During the class, students were presented with eight additional arterial blood gasses that were either solved in groups of two (A; 2 minutes for each case) or by using a peer instruction-based approach (B; individual assessment for 1 minute followed by an assessment in groups of two for 1 minute). The percentage of correct answers and the subjective confidence level (0-100 % certainty of the correct diagnosis) in the pre- and post-tests were determined, and data are reported as median with corresponding interquartile range (IQR).

Results:

Pre-test scores were identical in both groups (median, 2; IQR, 1-2), and a significant increase was observed in both the conventional and the peer instruction study group following intervention (median, 4; 3-4 and 3; 3-4, respectively, both $p < 0.0001$), and scores did not differ between the two groups ($p=0.31$). Confidence levels increased in both groups and they evaluated the class similarly (data not shown).

Conclusion:

Collaborative teaching strategies were efficient for teaching students to diagnose acid-base disorders by means of arterial blood gas analysis. In the present time-restricted setup, we found no evidence that peer instruction is superior to conventional group work. However, a larger study is required before any definitive conclusion on this matter can be surmised.

Acid-base disorder	Group A (n = 22)		Group B (n = 19)	
	Pre-test (%)	Post-test (%)	Pre-test (%)	Post-test (%)
Normal	36	100*	79	95*
Respiratory alkalosis with partial metabolic compensation	55	82*	42	79*
Metabolic acidosis with partial respiratory compensation	27	91*	26	89*
Combined metabolic and respiratory acidosis	23	77*	5	58*

Correct answers. *Difference between pre- and post-test within groups ($p<0.0001$). Within group differences were assessed by Wilcoxon rank sum test, and between group differences by Mann-Whitney U-test.

Using a classic paper by Robin Fåhraeus and Torsten Lindqvist to teach basic hemorheology

L. Toksvang and R.M. Berg

Department of Infectious Diseases, Centre of Inflammation and Metabolism, Copenhagen Ø, Denmark

"The viscosity of the blood in narrow capillary tubes" by Robin Fåhraeus and Torsten Lindqvist (Am J Physiol 96: 562-568,

1931) can be a valuable opportunity for teaching basic hemorheological principles in undergraduate cardiovascular physiology. This classic paper reports that a progressive decline in apparent viscosity occurs when blood flows though glass capillary tubes of diminishing radius, which has later been designated the 'Fåhraeus-Lindqvist effect'. Subsequent studies have shown that apparent viscosity continues to decline at diameters that correspond to the arteriolar segments of the systemic vascular tree, where the majority of the total peripheral resistance resides and is actively regulated in vivo. Here we present how the paper by Fåhraeus and Lindqvist can be used as a teaching tool and a platform for a plenary discussion of these concepts with undergraduate students, as well as of the relationship between hematocrit, vessel diameter, red blood cell deformability, resistance to blood flow, and how these factors may affect the work of the heart.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA185

The contribution of Adolf Beck to Physiology (to 150-anniversary from his birth)

O. Zayachkivska[1], M. Gzhegotsky[1] and A. Coenen[2]

[1]Physiology, Lviv National Medical University, Lviv, Ukraine and [2]Biological Psychology, Donders Centre for Cognition, Radboud University, Nijmegen, Netherlands

Professor Adolf Beck (1863-1942), the founder of Physiology Department of the Lviv National Medical University who stood at the cradle of studies of the manifestation of the electrical brain activity, fought political discrimination and racism (anti-Semitism) on his way to becoming one of the XX century's leading but still unknowing in XXI century to a wide audience, scientist.

A. Beck was a pioneer in neurophysiological and psychophysiological methods to investigate cerebral cortex. Beck's fate was closely tied to the turbulent political and war history of Galicia, a region of the Austrian-Hungarian empire, He performed his influential electrophysiological work at the Jagiellonian University in Cracow and was invited to organize Physiology Department at the Medical Faculty in Lviv, where nominated as professor at the University of Jan Casmir in 1895. This Department in nowadays is in Lviv As professor in Physiology he produced 180 publications and was nominated for the Nobel Prize in Physiology. Dr. Beck's initial interest was the electrophysiology of the nervous system. In 1890 his article about the spontaneous and evoked electrical activity in the brain was published in the 'Centralblatt für Physiologie', a leading European Physiology magazine. Beck accurately localised sensory modalities of the cerebral cortex, by electrical and sensory stimulation during recording of electrical activities. In doing this, Beck also found the spontaneous oscillations of the brain potentials, just as Caton (1875) did, and showed that these fluctuations were not related to heart and breathing rhythms, but had to be regarded as genuine electrical brain activities. After Hans Berger's work on human brain waves (1929), these electrical activities were indicated as the EEG. In the 1890s Beck studied parts of the cerebral cortex that reacted upon stimulation with electro-negativity, first recorded 'evoked potentials'. Moreover, Beck discovered a new element: a decrease in the amplitude of the potentials upon sensory stimulation. Thus, he was the first to describe the phenomenon, which is now known as the desynchronization of the EEG. It is important to note that the research of Beck was not limited to neurophysiology, but he also worked in the field of general Physiology, such as visceral, sensory, and laboratory medicine. However, Beck's groundbreaking work and ideas were uknown to wide scientific community due to the diverse factors, including wars, political, ideological grounds and restricted international contacts between different scientific groups. After the WWII Adolf Beck was mainly disregarded, until M.A.B. Brazier (1904–1995), neuroscientist, expert in the history of neuroscience, translated Beck's dissertation into English (1973). The historical lessons of life story and work Adolf Beck on modern science should be widely explored for educational and scientific purpose.

PCA188

Natsudaidain isolated from *Citrus* plants inhibits activation of mast cells in the late phase of immediate allergy

T. Matsui[1], H. Shiono[1], C. Ito[2], M. Itoigawa[3] and T. Okada[1]

[1]Physiology, Aichi Medical University, School of Medicine, Nagakute, Japan, [2]Meijo University, Nagoya, Japan and [3]Tokai Gakuen University, Nagoya, Japan

Mast cells play a central role in the immediate allergic reaction and in chronic inflammation associated with fibrosis. Mast cells also express several genetically encoded pattern recognition receptors including Toll-like receptors, which function in innate immunity. Thus, the roles of mast cells are complex, as they function in both immunity and inflammation. This discrepancy may be due to the fact that numerous bioactive chemical mediators including histamine, prostaglandins, and pro-inflammatory cytokines are released following the discrete reactions of mast cells against various stimuli. To understand the physiological roles of mast cells, studies have focused on the mechanisms of mast cell activation, as well as on the molecules that inhibit mast cell activation. Flavonoids, such as quercetin, are found in many plants and inhibit the activity of chemical mediators released from mast cells. Extracts of *Citrus* plants, which contain many flavonoids, exhibit anti-inflammatory, anti-allergy, and anti-cancer effects. We isolated and identified two polymethoxyflavonoids––natsudaidain and nobiletin––from *Citrus* plants. Although nobiletin has an anti-inflammatory effect, the biological activity of natsudaidain, which closely resembles nobiletin, is not fully understood. Here we examined the inhibitory effect of natsudaidain on histamine release, tumour necrosis factor-α (TNF-α) production, and cyclooxygenase-2 (COX-2) expression in Ca ionophore-stimulated rat basophilic leukemia cells (A23187-stimulated RBL-2H3 cells) using spectrofluorometric, ELISA, and immunoblotting methods. The percent of histamine release from A23187-stimulated RBL-2H3 cells pretreated with natsudaidain at 5, 25, or 50 μM was not altered compared with non-treated A23187-stimulated cells. Pretreatment with 100 or 200 μM natsudaidain resulted in slightly reduced levels of histamine release (89.8 ± 3.5% and 71.5 ± 5.6% histamine release at 100 and 200 μM, respectively). Thus, natsudaidain has little effect on histamine release from RBL-2H3 cells, except at high concentrations. On the other hand, natsudaidain inhibited TNF-α protein and mRNA levels in A23187-stimulated RBL-2H3 cells dose-dependently; a concentration of 6.8 μM was required for a 50% reduction. In addition, all levels of this compound tested also inhibited COX-2 protein expression. The mRNA levels of COX-2 in

A23187-stimulated RBL-2H3 cells treated with natsudaidain were also markedly reduced. The phosphorylated-p38 MAPK protein levels in A23187-stimulated RBL-2H3 cells were lower in natsudaidain-treated cells than in non-treated cells. These findings suggest that natsudaidain inhibits TNF-α and COX-2 production by suppressing p38 MAPK phosphorylation; thus, natsudaidain may alleviate inflammatory diseases.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA189

Mer receptor tyrosine kinase promotes resolution of acute sterile inflammation through upregulation of liver X receptor expression and activation

J. Choi[1,2], Y. Yoon[1,2], J.Y. Seo[1,2] and J.L. Kang[1,2]

[1]Physiology, Ewha Womans University, Seoul, Republic of Korea and [2]Tissue Injury Defense Research Center, Ewha Womans University, Seoul, Republic of Korea

Mer signal plays the central roles in the intrinsic inhibition of the inflammatory response to pathogens by macrophages and dendritic cells. Liver X receptors (LXRα and LXRβ) also have a role for the maintenance of immune tolerance. However, physiological relevance of endogenous activation and transrepression pathways has remained unclear. In the present study, we aimed to understand the impact of endogenous Mer signal on TLR-dependent generalized inflammatory responses and LXR activation in zymosan-treated mice, using anti-Mer neutralizing antibody. Treatment with anti-Mer antibody significantly reduced phosphorylation of Mer and Akt, Mer downstream molecule in peritoneal macrophages and/or spleen and lung at hours 6, 24, and 72 after zymosan treatment. Anti-Mer antibody inhibited apoptotic cell clearance by peritoneal macrophages in vivo and ex vivo, but further enhanced neutrophil number and the levels of protein in peritoneal cavity. Moreover, anti-Mer antibody enhanced zymosan-induced pro-inflammatory mediators, including TNF-α, IL-1β, MIP-2 and MMP-9, but reduced anti-inflammatory mediators, such as TGF-β and HGF in peritoneal fluid. Similar findings with anti-Mer antibody and zymosan were shown at the levels of genes of TNF-α and MIP-2, as well as TGF-β and HGF in spleen and lung tissue. After zymosan injection, LXRα expression in spleen and lung reduced at 6 hours and reached the control level at 24hours and increased at 72 h. The level of LXRβ expression dropped at 6 hours, reached to the control level at 24 h, and remained at 72 h. The levels of LXRα/β at these time points after injection of zymosan were reduced by treatment with anti-Mer antibody. The levels of genes and proteins of LXRα/β target molecules, such as ABCA1 and ApoE, were in parallel reduced by treatment with anti-Mer antibody. Importantly, co-administration of T0901317 with anti-Mer antibody enhanced LXRs expression and activation and reversed the increases in these pro-inflammatory mediators, neutrophil numbers, and the levels of protein in peritoneal fluid at 6 and 24 h after zymosan injection. These findings suggest that Mer signaling contributes for the resolution of generalized inflammation through upregulation of LXR induction and activation.

PCA190

Heterogeneity of commercially available human serum albumin products: thiol oxidation and protein carbonylation

S. Era, T. Terada, T. Minami, T. Takahashi and H. Arikawa

Department of Physiology and Biophysics, Gifu University Graduate School of Medicine, Gifu, Japan

Albumin has been widely served as nutrients for tissue cultures in laboratory field and as plasma expander for blood transfusion in clinical field. Recently, human serum albumin (HSA) is sometime used as supporting materials in medium for human ES and iPS cell culture. In respect of thiol group of the protein, HSA has one highly reactive thiol group at position 34 (Cys-34). When it is a free state, it is called human mercaptalbumin (HMA, reduced form). On the other hand, when the thiol group is modified by oxidation, it is called human non-mercaptalbumin (HNA, oxidized form). HNA is further classified into two forms; HNA-1, mixed disulfide with cysteine; HNA-2, more higher oxidation products. Therefore, HSA in the exracellular fluids (ECF) is a mixture of HMA and HNA, i.e., a protein redox couple in ECF. As a commercially available HSA product is manufactured from large-scale pooled blood, the serum-derived albumin may have a different degree on thiol-redox state and protein carbonylation. By using a convenient HPLC system for the clear separation from HSA to HMA, HNA-1 and HNA-2, we examined the redox state of HSA products from various sources. Protein carbonylation is analyzed by Protein Carbonyl Assay Kit (Cayman Chem. Co.). All HSA products were obtained from Sigma Co. (product No. A1653 (5 lots), A3782 (5 lots) and A9731 (2 lots)). The A1653 is a product corresponding to Cohn Fraction V from serum-derived albumin, which is a starting material from pooled sera. The A3782 is a final product, which is prepared from A1653 through lyophilized and defatted processes. On the other hand, the A9731 is a recombinant HSA product expressed in rice (Cellastim®). Mean HMA values for A1653, A3782 and A9731 were 29.3. 28.2 and 33.1%, respectively. Mean values for carbonyl content of those products were 10.5, 18.7 and 31.4 nmol/mg protein, respectively. In order to evaluate the possible role of HSA as growth-promoting potential for cell culture in vitro, A1653 (lot 030M7034V), A3782 (lot 090M7001V) and A9731 (lot 061M1563) were used for U937 cells. For cell growth response, the ability of A9731 (recombinant albumin) was stronger than those of A1653 and A3782 (serum-derived albumin). These results suggest that the heterogeneity of thiol-redox state and protein carbonylation of various kinds of commercial HSA products appears to occur during manufacturing process of HSA from large-scale pooled blood. However, a recombinant albumin may have a different manner from that of a serum-derived albumin. This is especially important in studies where these products are used to interact with other biological materials in both laboratory and clinical fields.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA191

A fragment of recombinant habutobin inhibited collagen-induced platelet aggregation

M. Nakamura[1], M. Sunagawa[1] and T. Kosugi[2]

[1]Molecular and Cellular Physiology, University of the Ryukyus, Okinawa, Japan and [2]Nursing, Faculty of Human Health, Meio University, Okinawa, Japan

Habutobin is a thrombin-like enzyme isolated from the crude venom of *Trimeresurus Flavoviridis* (the habu snake). We have clarified physicochemical and biological characteristics of habutobin. Habutobin was found to have pleiotropic biological activities such as clotting activity of rabbit fibrinogen, inhibitory activity of platelet aggregation, and stimulatory activity of urokinase release from vascular endothelial cells. In the previous study, recombinat-habutobin (r-habutobin) was produced by the baculoviral expression system from habutobin cDNA. r-habutobin has biological activities such as fibrin forming activity and inhibition of collagen-induced platelet aggregation as native habutobin. It has not been clarified how the structure of habutobin relates to its pleiotropic biological activities, which enable us to develop a reliable antithrombotic drug. We produced four fragments of r-habutobin (F1, F2, F3 and F4) by the truncation of habutobin cDNA in order to identify the functional domain which is responsible for the antiplatelet action of habutobin. We examined whether the r-habutobin fragments prevent platelet aggregation. The effect of two fragments of r-habutobins (F2 and F3) were tested on the aggregation of washed rabbit platelets. Platelet aggregation and ATP release were measured with a light transmission aggregometer using the method of Luciferin-Luciferase reaction. Upon collagen-stimulation of washed platelets, the effect on conformational change of glycoprotein (GP) IIb/IIIa and on the expression of P-selectin were tested by Flow cytometer (FCM) with PAC-1 (which only binds to activated platelets) and P-selectin antibody. The aggregation of washed platelet by collagen was inhibited by F3 r-habutobin. The percent inhibition by F3 r-habutobin was 22.6 ± 5.99 % (n = 7), and that by F2 r-habutobin was 14.75 ± 13.93 (n = 4). F3 r-habutobin also prolonged the lag time of collagen-induced platelet aggregation and slightly inhibited the collagen-induced ATP release from washed platelet. The expression of PAC-1 and P-selectin was decreased by F3 r-habutobin. FCM analysis revealed that F3 r-habutobin decreased FSC/SSC and that platelet membrane expressions of GP IIb/IIIa and P-selectin were decreased by F3 r-habutobin. These results suggested that the reduction of ATP release, decrease of GP IIb/IIIa and P-selectin expression on washed platelets may lead to inhibit the shape change of cytoskeleton in the presence of F3 r-habutobin. The key structure for the inhibition of the expression of P-selectin and the activation of GP IIb/IIIa might be present in F3 r-habutobin.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA192

The effect on anticoagulation by siRNA-mediated tissue factor knockdown in pig aortic endothelial cells in vitro

M. Ji[1] and S.N. Yi[2]

[1]Physiology, Basic medical science school, Central South University, Changsha, Hunan, China and [2]Centre for Transplantation and Renal Research, Westmead Hospital, Sydney, NSW, Australia

Aims: The coagulation disorders leading to the loss of both whole organ xenografts have increasingly been recognized as a critical barrier to successful transplantation. Coagulation is initiated by damage to blood vessel endothelium and the expression of tissue factor (TF). The aim of this study is to determine the effect of TF gene knockdown on pig aortic endothelial cells (SVAP) in coagulation disorders in vitro.
Methods: SVAP were transfected with siRNA specific for TF or a nonspecific control siRNA using lipofectamine 2000. Transfected SVAP were then analyzed for TF gene and protein expression by real-time PCR and FACS respectively. The effect of TF knockdown in SVAP on anti-coagulation was evaluated by incubation with human blood for 60 min. Clots were collected and measured. Platelets, leukocytes and neutrophils were counted by using Beckman Coulter ACT.
Results: TF knockdown resulted in substantially reduced production of TF by SVAP. TF gene level of siRNA transfected SVAP was 22± 4% (n = 4) of naïve SVAP which was determined by real-time PCR. FACS results proved TF protein level of siRNA transfected SVAP had been reduced by 70%(57.1± 5.4% vs13.3±2.4 %, n = 4, $p < 0.01$). Nonspecific
siRNA had no effect (53.6±4.5%, n = 4). When TF siRNA transfected SVAP were
incubated with human blood there was no obvious reduced clot weight (0.42±0.04g vs
0.32±0.05g, n=5, p>0.05) and reduced consumption of platelets (4.1±1.2x10^9/L
vs 6.5±1.3x10^9/L n=5, p>0.05), leukocytes (2.3±0.3x10^9/L vs 2.8±0.5x10^9/L, n=5, p>0.05) and neutrophils (0.94±0.06x10^9/L vs 1.22±0.06x10^9/L, n=5, p>0.05) when compared to that detecte in the well with non-transfected SVAP.
Conclusion: The expression of TF on endothelial cells is involved incoagulation reaction but not the major coagulation factor in xenotransplantation.
Key words: Tissue factor, pig aortic endothelial cells, Anticoagulation, Xenotransplantation
The study was approved by the Sydney West Area Health Service Human and Animal Research Ethics Committees.

Red cell sickling and adhesion are favoured by cellular dehydration, which increases the rate of hemoglobin polymerization and cell sickling. Potassium chloride co-transport and calcium-activated potassium channel (Gardos channel) mediate erythrocyte dehydration in sickle cell disease and β-thalassemia, but their role in vaso-modulation is less defined. We investigated the in-vitro effect of various concentration of K+ ions in physiological solutions (PSS) as well as in cocos nucifera water which is a natural drink known for its natural high potassium content and health benefits. We obtained blood samples of ten (10) sickle cell disease patients (SCD) confirmed by hemoglobin electrophoresis in the Hematology Laboratory of University of Benin Teaching Hospital, Benin city for this study. One part was treated with sodium metabisulphite (Na2S5O7) solution to induce maximum sickling as controls while the other parts were subjected to different high concentrations of K+ in PSS as well as cocos nucifera water (40mM, 80mM and cocos nucifera water -240m/M) respectively. A thin blood smear was made to ascertain the percentage sickled erythrocytes count before and after the treatment. A mean sickle cell count was obtained after a manual count of three different smears. We observed a maximum percentage count of sickled cells after the addition of Na2S5O7 (45%) which decreased significantly ($P<0.05$ respectively) to about 2% with Cocos nucifera and 10% with80mM K+ PSS. The decrease count in 40mM K+PSS was not statistically significant. We conclude that high potassium ion solutions can activate the rehydration of sickled erythrocytes by probably activating the Gardos channel to increase the mean corpuscular haemoglobin concentration(MCHC) and thereby restoring the normal red cell shape. A probable pharmacological value of the cocos nucifera water and high potassium isotonic solutions in SCD management may be indicated.

The roles of Macrophage MHC receptor (MMR)1 in allorecognition: Isolation of a cDNA encoding a novel MHC receptor for HLA-B44, human MMR1

J. Yamaji, T. Shimizu, E. Daikoku, M. Saito, Y. Shiraiwa, R. Yoshida and T. Kubota

Osaka Medical College, Takatsuki, Japan

Previously, we reported that macrophage (H-2D^{b}K^b)-mediated cytotoxicity of allografts [e.g., BALB/c skin (H-2D^{d}K^d)] in the rejection site and that we isolated two cDNAs encoding novel receptors on mouse macrophages or monocytes for H-2D^d and H-2K^d (mouse MHCs) and named them MMR1 and 2. Recently, we identified human homologs of mouse MMR1 and 2 by a search of sequence homology (BLAST) and also isolated two cDNAs encoding human MMR1 and 2 from human PBMCs cDNA library by RT-PCR method. In this meeting, we present the identification and characterization of human MMR1. The predicted amino acid sequence of human MMR1 cDNA (approximately 1.5 kb) encoded a putative single transmembrane protein, and the homology showed 64% identity to the entire mouse MMR1 protein and 96%, 96%, and 98% identity to its respective intracellular, transmembrane, and MHC binding regions. RT-PCR analyses demonstrated that human MMR1 expressed on monocytes in PBMCs. To examine the binding toward HLAs (human MHCs), HEK293T cells expressing human MMR1 were incubated with the beads conjugating 80 kinds of HLA class I or fluorescein-labeled soluble HLA molecules and then were analyzed by flow cytometer. Flow cytometric analyses showed that the mean fluorescence intensity of human MMR1 protein toward HLA-B44 was significantly high and that HEK293T cells expressing human MMR 1 bound specifically to HLA-B44 with a dissociation constant of 3.0×10^{-9} M. These results suggest that human MMR 1 on monocytes or macrophages might be novel receptors for HLA-B44.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

When platelets start to function – insight into primary hemostasis in developing murine fetuses using a new in-vivo microscopy model

A. Margraf[1], C. Nussbaum[1,2], S. Schmidt[1], S. Dietzel[1], E. Quackenbush[3], U.H. von Andrian[4] and M. Sperandio[1]

[1]Walter-Brendel-Centre of Experimental Medicine, Ludwig-Maximilians-University, Munich, Germany, [2]Dr. von Hauner Children's Hospital, Ludwig-Maximilians-University, Munich, Germany, [3]Agennix Inc., Munich, Germany and [4]Department of Microbiology and Immunobiology, Harvard Medical School, Boston, MA, USA

Introduction:
Blood loss resulting from vessel injury is prevented in the mammalian organism through well regulated steps in the process of hemostasis. While a fully functional primary hemostatic system can be found in healthy adults, newborns and especially preterm newborns are at an increased risk for bleeding complications including intraventricular hemorrhage. Recent studies in humans reported decreased platelet reactivity in preterm newborns, opposed to data showing shortened bleeding times in term neonates. However, up to today there is no model to examine the development of the hemostatic system and the impact of maturation on primary hemostasis.
Methods:
To examine platelet function and thrombus formation in yolk-sac blood vessels of developing murine fetuses, pregnant C57/Bl6 mice were anesthetized (5mg/ml ketamine, 1 mg/ml xylazine in 10 ml/kg of normal saline; intraperitoneal injection), the abdominal cavity opened, the uterus prepared and one viable fetus inside the yolk-sac exteriorized. Manual microinjection allowed administration of phototoxic FITC-dextran into fetal yolk-sac vessels, as subsequent excitation with high intensity light was applied to induce thrombus formation. Injection of fluorescent microbeads allowed determination of blood flow characteristics in fetal yolk-sac blood vessels. Time course and steps of thrombus formation were deter-

mined in fetuses of ages E13.5 to E17.5. Multiphoton-microscopy was applied to study distribution patterns of the phototoxic dye within the fetal vasculature. FACS-analysis allowed acquisition of platelet counts as well as further investigation of activation patterns of fetal platelets.
Results:
Rate of onset and firm vessel occluding thrombus formation in murine yolk-sac vessels was significantly lower in youngest fetuses compared to older ones (p<0,05). Additionally, reflow after primary thrombus formation appeared more frequent in youngest fetuses. Time until platelet adhesion and stable thrombus formation was prolonged in E13.5 fetuses compared to older fetuses. FACS-analysis revealed significantly decreased platelet counts in fetal blood samples compared to adult levels. Furthermore, changed platelet activation properties on thrombin stimulation could be noted in fetuses compared to adult values.
Conclusion:
This is the first reported in-vivo observation of platelet function and thrombus formation in the developing murine fetus using a newly established intravital microscopy model. We find that during early fetal development, decreased thrombus formation as well as reduced thrombus stability are present, while a gradual normalization of primary hemostasis can be noted towards more mature gestational ages. Therefore, our results are the first to show a developmental regulation of primary hemostasis in the living fetal mammalian organism.

How carnosine affects cardiovascular parameters in remnant kidney model

H. Yapislar[1] and E. Taskin[2]

[1]Physiology, Istanbul Bilim University, Istanbul, Sisli, Turkey and [2]Pediatric Cardiology Department, New York University School of Medicine, New York, NY, USA

Purpose : Chronic kidney disease (CKD) is a major public health concern affecting millions of people .Oxidative stress is a mediator of systemic complications of chronic renal failure (CRF) and involved in the pathogenesis of hypertension, endothel dysfunction, shortened erythrocyte lifespan and deformability(1). One of the main effects of oxidative stress is the decrease in the biological activity of nitric oxide (NO). Endothelial dysfunction is characterized by a reduced synthesis of bioavailability of NO (2). The remnant kidney (RK) model is widely considered to be the classic model of progressive renal disease and it is known that inhibition of NO synthesis has been known to worsens renal disease is the RK model by hemodynamic changes (3). As we know L-carnosine is an antioxidant known to possess free radical scavenging functions (4). In this study, our aim is to induce renal failure in rats with subtotal nephrectomy (RK model) and observe the effect of carnosine on both hemorheologic parameters and blood pressure levels of nephrectomyzed rats and compare the results with their sham operated control group rats.
Material and Methods: 4 months old Male Sprague-Dawley rats were used in the study. The Animals were divided into 4 groups consisted of 6 rats each. 3 days after the subtotal nephrectomy and sham operations, the surviving rats were divided into the four groups; 1 - Sham (S), 2 - Sham + Carnosine (S-C), 3 - Subtotal nephrectomy (N), 4 - Subtotal nephrectomy + Carnosine (N-C). Carnosine was injected i.p. (50 mg/kg in each injection every day for 15 days). The control group received the same volume of physiological saline.RBC dformability indexes, arterial blood pressure and heart rate, MDA and NO levels were measured.
Results:In N group MDA level was statistically increased compared to sham group as we expected (p<0.05). MDA level was significantly decreased in N-C group compared to N group (p<0.05).NO level of N group was found to significantly decrease compared to S group NO levels(p<0.05). There was significantly decreased in N group EI level than in S group level (p<0.05). N-C group EI level was found to significantly increase compared to N group EI level (p<0.05). EI values demonstrates to us that carnosine shows this effect in all shear stress values.In all systolic blood pressure (SBP), diastolic blood pressure (DBP) and mean blood pressure (MBP) measurements, there was no any significant difference between S and N groups (p>0.05).
S-C group heart rate level was significantly increased compared to S group heart rate level (p<0.05). There is no important difference between other groups in terms of heart rate levels.
Conclusion:As a result, we see that carnosine has important effect o RBC deformability indexes, lipid peroxidation and NO levels but it doesn't affect blood pressure and heart rate levels in RK model in rats.

Lethal and adaptive macroautophagy as typical cellular responses to hypoxia/reoxygenation

A. Kabakov, V. Mosina and K. Budagova

Medical Radiology Research Center, Obninsk, Russian Federation

We investigated consequences of ischemia/reperfusion stress on in vitro models with various types of mammalian cells undergoing hypoxia/reoxygenation. Cultured rat cardiomyocytes (H9c2 line), murine fibroblasts, human vascular endothelium and human kidney epithelium (293 line) were here used for the experiments with prolonged hypoxia (N2 atmosphere, <1% O2, for 18-20 h) followed by reoxygenation under normoxic conditions (21% O2). We found that, independently on cell type, some percentage (8-35%) of the reoxygenated cells dies via mitochondria-dependent apoptosis. Besides, macroautophagic events were clearly observed in all the reoxygenated cells what was manifested in formation of autophagosomes entrapping stress-damaged mitochondria and subsequent formation of large autolysosomes digesting the entrapped mitochondria. Some fraction (5-20%) of those cells underwent autophagic death (i.e. lethal autolysis) afterwards, whereas the other cells survived and even became more resistant to the repeated hypoxia/reoxygenation stress. When we performed stressful preconditioning by means of mild hyperthermia (43 C for 60 min) or shorter (8-10 h) hypoxia, such pretreated cells acquired the enhanced resistance to subsequent (severe) hypoxia/reoxygenation stress: the percentage of apoptotic and autophagic death considerably decreased, although the post-stress macroautophagic processes were not impaired in the preconditioned cells. Furthermore, upon post-hypoxic reoxygenation in the preconditioned (resistant) cells, uptake of mitochondria by autophagosomes began earlier and more intensely as compared with non-preconditioned control; this discrepancy correlated with the decrease in apoptosis and improved survival of the preconditioned cells. In the case of pretreatment with rapamycin, a known inhibitor of macroautophagy, the reoxygenated cells did not exhibit macroautophagic events but, instead, massively died via apoptosis and necrosis. Moreover, rapamycin prevented the acquisition of resistance to the hypoxia/reoxygenation stress after the preconditioning. We suggest that macroautophagy is the characteristic cellular reaction to hypoxia/reoxygenation; this reaction is aimed at compartmentalization of stress-damaged mitochondria into autophagosome followed by their digestion by autolysosomes. Such responses allow some post-hypoxic cells to escape apoptosis resulting from the mitochondrial damage. In some cases, macroautophagy appears to kill the reoxygenated cells if their mitochondrial damage is too severe. According to our observations, the stressful preconditioning may switch the post-hypoxic macroautophagy from its lethal mechanism to the adaptive one. It seems likely that the stress-inducible heat shock proteins are involved in this cytoprotective switching.

MicroRNA let-7i can control TLR4 expression and affect IFN-γ secretion in T cells from patients with ankylosing spondylitis

H. Yu[1,2], W. Liu[1], N. Lai[2,3], H. Chen[4], C. Yu[5], M. Lu[2,3] and H. Huang[1]

[1]Department of Life Science and Institute of Molecular Biology, National Chung Cheng University, Chia-Yi, Taiwan, [2]Division of Allergy, Immunology and Rheumatology, Buddhist Dalin Tzu Chi General Hospital, Chia-Yi, Taiwan, [3]School of Medicine, Tzu Chi University, Hualien, Taiwan, [4]Department of Biomedical Sciences, Chang Gung University, Tao-Yuan, Taiwan and [5]Department of Internal Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan

Ankylosing spondylitis (AS) is a chronic inflammatory disorder characterized by dysregulated T cells. We hypothesized that the aberrant expression of microRNAs (miRNAs) in T cells might involve in the pathogenesis of AS. The expression profile of 270 miRNAs in T cells from five AS patients and five healthy controls were analyzed by real-time PCR. After initial analysis, thirteen miRNAs were found potential differentially expression. After validation using 22 AS patients and 18 healthy controls, we confirmed that miR-16, miR-221 and let-7i were overexpressed in AS T cells and their expression levels were positively correlated with the Bath Ankylosing Spondylitis Radiology Index of lumbar spine in AS patients. In addition, the protein molecules regulated by miR-16, miR-221 and let-7i were measured by Western blotting. We found that the protein levels of Toll-like receptor 4 (TLR4), a target of let-7i, in T cells from AS patients were decreased. Lipopolysaccharide (LPS), a TLR4 agonist, inhibited interferon gamma (IFN-γ) secretion by anti-CD3+ anti-CD28 antibodies-stimulated T cells from healthy controls but not AS patients. After transfection of let-7i into normal T cells, LPS promoted IFN-γ production after stimulated by anti-CD3+anti-CD28 antibodies, but the transfection of let-7i does not have effects on IFN-γ production in AS T cells. In summary, we found that miR-16, miR-221, and let-7i were overexpressed in AS T cells and their expression levels were associated with radiographic change. In the functional study, the increased let-7i expression facilitated the Th1 (IFN-γ) immune response in AS T cells.

ANGII-AT1 receptor antagonizes bone resorption through TLR-4 signaling in an animal model of LPS-induced periodontitis in rat

M. Garrido[1], M. Matos[1], A. Israel[1], L. Perdomo[2] and M. Alvarez[2]

[1]Laboratory of Neuropeptides, Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of and [2]Instituto Anatómico José Izquierdo, Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of

Periodontitis is an osteolytic disease characterized by destruction of the tooth-supporting tissues determined by cytokines induced by T-cells activation by oral bacteria products. Receptor activator of NF-kB Ligand (RANKL) stimulates bone resorption, while its soluble decoy receptor osteoprotegerin (OPG) blocks its action. RANKL activates its receptor (RANK) on monocytic precursors, triggering their differentiation into osteoclasts. Evidence indicates that Toll-like receptor (TLR) signaling regulates bone metabolism. TLRs are expressed in periodontal tissues and triggers a variety of downstream signal transduction pathways, including p-38 MAPK and NF-kB, which controls genes expression linked to inflammation and bone remodeling. Angiotensin II (ANG II) is now considered a pro-inflammatory cytokine since AT1 receptor (AT1R) blockade decreases the progression of inflammatory pathologies. The role of ANGII/AT1R in the periodontal disease is not known. We assessed the effect of valsartan (VAL), an AT1R blocker, on osteoclasts number, RANK/RANKL/OPG system expression, AT1 and TLR-4, and phosphorylation of p38-MAPK and NF-kB, in an experimental model of periodontitis induced by lipopolysaccharide (LPS) in rat. Experiments were conducted according to good practice for the management of laboratory animals of the Bolivarian Republic of Venezuela and the approval of Animal Ethical Committee of the School of Pharmacy. Male SD rats (280-300g) were divided into 4 groups: Control, LPS, VAL, LPS+VAL. LPS interdaily injections (10ul) and VAL (20 mg/kg, p.o.)/7 days were applied. Rats were anesthetized with 10% ketamine (60 mg/kg) and euthanized by decapitation, the maxilla dissected and the connective tissue collected. Immunofluorescent staining was used. Immunostaining was visualized with a confocal microscope. Intensity was quantified with NIH Image J software in 3 representative sections. Values are means ± SEM compared by ANOVA. LPS induced the formation of TRAP-positive multinucleated cells, increased tissue AT1R expression (C=3648±209; LPS=6081±150; L+V=4054±300) and TLR-4 (C=5487±66; LPS=7276±293; L+V=6097±62), RANK/RANKL system (C=5067±34; LPS=6161±48; L+V=5387±48/C=5570±130; LPA=7341±122; L+V=6177±189) and diminished OPG expression (C=5451±181; LPS=1007±42; L+V=5638±108). Also, LPS increased p-p38/p38 (C=1; LPS=1.52; L+V=1.19) and p-NF-kB/NF-kB (C=1; LPS=1.72; L+V=1.1). Conversely, VAL blunted all LPS-induce effects. Our results suggest that LPS, through TLR-4 stimulates MAPK and NF-kB-depentent pathways to induce bone resorption. Our data demonstrate a novel role for ANG II and AT1R in the pathogenesis of periodontal disease.

PCA200

The effect of asthma related allergens in human gingival epithelial cells

A. Son[1,3], S. Lee[1], S. Lee[1], W. Park[2] and D. Shin[1]

[1]Department of Oral biology, Colleage of Dentistry, Yonsei University, Seoul, Republic of Korea, [2]Department of Advanced General Dentistry, College of Dentistry Yonsei University, Seoul, Republic of Korea and [3]Department of Dental Hygiene, Beakseok University, Cheonan, Republic of Korea

Asthma is a chronic inflammatory disease of the airway characterized by variable airflow obstruction and bronchial hyperresponsiveness. In addition, patients with asthma have been reported that high prevalence of dental caries and gingivitis, which are induced by low salivation due to the medication for asthma. However, it is not known that asthma related allergens such as house dust mite (HDM) and German cockroach extract (GCE) have direct effects on the generation of gingival inflammation. HDM and GCE proteases are potent inducers proinflammatory cytokines through protease-activated receptor (PAR). Toll like receptor (TLR) family as the major receptor for endotoxin from GCE and HDM. Furthermore, the NLR family, pyridine domain-containing 3 (NLRP3) inflammasome is activated by a wide rage of danger signals. In the present study, we investigated the level of NLRP3 inflammasone, interlukin-8 (IL-8), IL-6 and IL-1β mRNA expression and the characteristics of Ca^{2+}signal by GCE and HDM in the human gingival epithelial cells. HDM and GCE induced increases in NLRP3 and proinflammatory cytokines mRNA expression level and intracellular concentration of Ca^{2+} ($[Ca^{2+}]_i$), respectively. Endotoxin-free GCE activated PAR2, but endotoxin-free HDM did not activate any PARs. In human gingival epithelial cells, whereas lipopolisacaride, a Gram-negative endotoxin, did not induce Ca^{2+} signal, HDM and GCE containing endotoxins induced Ca^{2+} signal from thapsigargin (Tg), an inhibitor of sarco/endoplasmic reticulum Ca^{2+} ATPase, -sensitive Ca^{2+} stores via phospholipase C (PLC)/inositol 1, 4, 5-trisphosphate (IP_3) pathway. These results suggest that asthma related allergens induce Ca^{2+} signaling and cytokine release in human gingival epithelial cells.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA201

Hypo-osmotic stress regulates RANKL mRNA expression through TRPM3 and TRPV4 in primary cultured human PDL cells

G. Son, S. Lee, Y. Yang, S. Lee and D. Shin

Department of Oral Biology, Yonsei University College of Dentistry, Seoul, Republic of Korea

The periodontal ligament (PDL) is specialized connective tissue fibers for attaching a tooth to the alveolar bone and for supporting the tooth to withstand the mechanical stress occurred during chewing and continuous orthodontic tooth movement. These mechanical stresses induce physiological processes such as inflammatory response, periodontal tissue and bone remodeling. However, the mechanism of hypo-osmotic stress-induced cellular response in PDL cells remains poorly understood. We hypothesized that receptor activator of nuclear factor-kappaB (NF-κB) ligand (RANKL) and osteoprotegerin (OPG) released from PDL cells under hypo-osmotic stress regulate bone remodeling, and investigated the mechanisms of RANKL and OPG expression by primary cultured human PDL cells in response to hypo-osmotic stress. Hypo-osmotic stress increased the mRNA expression of RANKL but not OPG as well as intracellular calcium concentration ($[Ca^{2+}]_i$). This increases in $[Ca^{2+}]_i$ was completely inhibited by gadolinium and lanthanum, non-specific plasma membrane Ca^{2+} channel blockers. We found TRPM3 and TRPV4 expressed in primary cultured human PDL cells and activities of these channels of TRPM3 and TRPV4 were confirmed by a whole-cell patch-clamp technique. Finally, aminoethoxydiphenyl borate and ruthenium red, each blockers of TRPM3 and TRPV4, reduced hypo-osmotic stress-induced increases in $[Ca^{2+}]_i$ and RANKL mRNA expression. These results suggest that hypo-osmotic stress induces increases in $[Ca^{2+}]_i$ through TRPM3 and TRPV4 to regulate RANKL mRNA expression in primary cultured human PDL cells.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA202

Decreased calcium mobility and the lack of secretion in equine sweat gland cells

J. Robertson and D.L. Bovell

Glasgow Caledonian University, Glasgow, UK

Sweat secretion helps maintain the skin surface ecosystem and provides thermoregulation in humans and the Equidae. Mediators of sweat secretion act by activating receptors coupled to phospholipase-C, which results in the breakdown of phosphatidylinositol 4,5-bisphoshate to create inositol 1,4,5-trisphosphate (IP3) which stimulates a Ca2+ signaling process that is biphasic {Putney, 1981; Berridge, 1984}. This biphasic response involves the release of Ca2+ ions from an intracellular organelle, the endoplasmic reticulum (ER), followed by the entry of calcium ions across the plasma membrane. Much is known about the first phase of intracellular calcium release from an intracellular organelle, an effect mediated by IP3 acting on the IP3 receptor {Berridge, 1987}. The resultant rise in calcium is maintained by calcium influx and it is this sustained elevation of calcium which activates the secretory mechanism.

The mechanisms regulating the Ca2+ entry process in sweat glands are not well understood. It is commonly accepted that the degree of emptying of the intracellular Ca2+-stores, generated by IP3 pathway, initiates a signaling process that regulates the rate of Ca2+ entry across the plasma membrane. This process is known as capacitative Ca2+ entry or store–operated Ca2+ entry (SOCE) {Putney, 2005; Parekh, 2005}. Despite the signaling processes underpinning SOCE having been researched over the last two decades, it is only fairly recently that the key molecular components been identified.

We investigated the role of SOCE in horse sweat gland cells from control animals and those that had developed anhidrosis, an inability to produce sweat. The cells used in this study were previously grown from horses destroyed for humane reasons (Wilson et al., 1993) and the methods used to initiate cultures of equine sweat glands are based on protocols elsewhere for human glands (Lee et al., 1986). Western blotting and PCR techniques confirmed the presence of STIM 1 and 2, Orai 1, 2 and 3 and TRPC1 proteins in cell lines derived from control and anhidrotic animals. However, the results indicated a reduction in STIM1 mRNA and protein expression, as well as a decrease in the localisation of STIM1 in the ER of anhidrotic cells compared to control cells. The functionality of the SOCE pathway in both cell lines, in response to agonist stimulation was investigated using FURA-2AM calcium-imaging techniques. Increases in [Ca2+]i could be abolished in the presence pharmacological blockers of SOCE and that anhidrotic cells showed a significant decrease in the [Ca2+]i FURA-2 ratio in response to agonists when compared to control cells. The results suggest that a reduction of STIM1 expression in the SOCE pathway may play a role in anhidrosis in horses.

PCA203

A protein arginine methyltransferase isoform controls the HIF-1-mediated adaptation to hypoxia by reducing de novo synthesis of HIF-1α protein

U. Ju[1], H. Park[1], J. Park[1,2] and Y. Chun[1,3]

[1]Department of Biomedical Sciences, Seoul, Republic of Korea, [2]Ischemic/Hypoxic Disease Institute, Seoul, Republic of Korea and [3]Department of Physiology, Seoul National University College of Medicine, Seoul, Republic of Korea

Hypoxia-inducible factor 1α (HIF-1α), which is regulated oxygen-dependently, transactivates numerous genes essential for cellular adaptation to hypoxia. HIF-1α expression is regulated at multiple steps from transcription to protein degradation. Moreover, the stability of HIF-1α protein has been known to be determined by posttranslational modifications such as ubiquitination, sumoylation, neddylation, and acetylation, but the

HIF-1α regulation by methylation has not been reported. Protein methylation at arginine residues is an essential process to regulate gene expressions and signal transductions, and is catalyzed by PRMT enzymes. While testing which PRMT isoforms participate in the HIF-1 signaling pathway, we found that one of PRMTs modulates HIF-1α expression under hypoxia. When the PRMT was knocked-down in glioblastoma cells, HIF-1α was expressed even under normoxia and further induced under hypoxia. The transcriptional activity of HIF-1 was evaluated in reporter systems using EPO enhancer-luciferase or VEGF promoter-luciferase vector, and the HIF-1-driven gene expressions were checked by RT-qPCR. These assays demonstrated that functional HIF-1 was induced by PRMT knockdown. We next studied the mechanism of the HIF-1α induction, and found that HIF-1α was induced at the translational level through activated PI3K/Akt/mTOR signaling. Based on these findings, we propose that the PRMT negatively controls de novo synthesis of HIF-1α protein regardless of oxygen level. Given many literatures supporting the cancer promoting action of HIF-1α, the PRMT could be a potential target for cancer therapy.

CD73 suppression induces apoptosis and cell-cycle arrest in human breast cancer cells

X. Zhi, M. Xiang, X. Li, L. Yin and P. Zhou

Department of Physiology and Pathophysiology,, Fudan University, Shanghai, China

Ecto-5′-nucleotidase (CD73) is a 70 kDa glycosylated protein that is bound to the outer surface of the plasma membrane by a glycosyl phosphatidyl inositol anchor and co-localized with detergent-resistant and glycolipid-rich membrane sub-domains called lipid rafts. CD73 hydrolyzes extracellular AMP into adenosine and phosphate. Adenosine, a proliferative factor, acting through G-protein coupled receptors, produces a spectrum of physiological functions. In addition, it causes tumor growth, angiogenesis and immune suppression. CD73 upregulation is associated with a highly invasive cancer phenotype, drug resistance and tumor-promoting functions.To date, our knowledge on the mechanisms of CD73 on tumor growth is still limited. The present studies examine the effect of RNAi-mediated CD73 suppression and CD73 overexpression on tumorigenicity in vivo and in vitro on cell growth, and further explore its underlying regulatory mechanisms.

In this study, we tested the hypothesis that increased CD73 may promote tumor progression by examining the effect of CD73 suppression via RNA interference and CD73 overexpression on tumor growth in vivo and in vitro. Using digitized whole-body images, plate clone forming assay and TUNEL assay in frozen tissue sections, we found that the cell growth rate was significantly lowerin vivo and in vitro after CD73 suppression ($n = 3$; $P < 0.05$)and late apoptosis was much higher in xenograft tumors developed from the CD73-siRNA transfected MB-MDA-231 clone (P1) ($n = 10$; $P < 0.01$). By flow cytometry, the P1 cell cycle was arrested in the G0/G1 phase($n = 3$; $^*P < 0.05$). Moreover, Bcl-2 was downregulated, while Bax and caspase-3 were upregulated with CD73 suppression($n = 3$; $P < 0.05$). CD73 inhibitor α,β-methylene adenosine-5′-diphosphate (APCP) functioned similarly with RNAi-mediated CD73 suppression($n = 3$; $P < 0.05$). In addition, in transfected MCF-7 cells, we found that CD73 overexpression increased cell viability and promoted cell cycle progression($n = 3$; $P < 0.05$), depending on its enzyme activity. More intriguingly, CD73 overexpression in MCF-7 breast cancer cells produces a tumorigenic phenotype. We conclude that CD73 plays an important role in breast cancer growth by affecting cell cycle progression and apoptosis.

Key words: CD73; breast cancer; RNA interfere; apoptosis, cell cycle

8,9-epoxyeicosatrienoic acid inhibits antibody production of B lymphocytes in mice

J. Feng[1], Y. Gao[1], Y. Zhu[1], Q. Xu[2] and X. Wang[1]

[1]Peking University Health Science Center, Beijing, China and [2]Cardiovascular Division, Kings College London BHF Centre, London, UK

Epoxyeicosatrienoic acids (EETs), synthesized from arachidonic acid by cytochrome P450 epoxygenases, are converted to dihydroxyeicosatrienoic acids by soluble epoxide hydrolase. EETs exert anti-inflammatory effects. However, the effect of EETs on humoral immunity is poorly understood. The present study is to investigate the potential role of EETs on B cell function and mechanisms. Firstly, we examined the role of EETs on antibody production of splenic B cells from C57BL/6 (male, 8-week-old, n=8) and ApoE-/- mice (male, 8-week-old, n=8) by means of ELISA. Of the 4 EET regioisomers, 8,9-EET (1 uM) significantly decreased the production of IgM (4.2 ± 0.9 vs. 8.0 ± 0.7 ug/ml) and IgG (35.6 ± 1.8 vs. 57.4 ± 1.0 ng/ml). By use of carboxyfluorescein succinimidyl ester (CFSE) dilution assay, we found that the proportion of dividing cells was lower with 8,9-EET (1 uM) (33.2 ± 0.9% vs. 49.3% ± 1.7%). We next examined the effect of 8,9-EET on B-cell survival stimulated with LPS. And the data showed that the percentage of live cells was substantially lower with 8,9-EET (10.2% ± 3.0% vs. 29.9% ± 2.6%). On the other hand, the generation of CD138+ cells was

markedly inhibited by 8,9-EET (28.1% ± 4.5% vs. 39.5% ± 0.5%). Furthermore, we found that 8,9-EET decreased sIgG1+ cell production (3.9% ± 0.3% vs. 7.8% ± 0.3%), which indicated that 8,9-EET inhibits the class-switch recombination of B cells. Molecular events involved in class-switch recombination were significantly inhibited by 8,9-EET. Additionally, nuclear p65 NF-kB level was increased within 5 min after LPS stimulation and was inhibited by pretreatment with 8,9-EET. To determine whether 8,9-EET regulates B-cell function in vivo, sEH-/- mice treated with 8,9-EET were intraperitoneally injected with 4-hydroxy-3-nitrophenyl acetyl-OVA (NP-OVA). The spleen size of mice with 8,9-EET infusion (15 ng/h) was smaller at day 6 pos-timmunization. The colocalization of CD19 and PNA from immunofluorescence analysis of spleens revealed fewer germinal centers and smaller structures. In summary, 8,9-EET may inhibit B-cell function in vitro and in vivo, which suggests a new therapeutic strategy for diseases with excess B cell activation.

A simulation study of the effects of GLP-1 on membrane excitability in pancreatic β-cells

Y. Takeda and A. Noma

Ritsumeikan University, Kusatsu, Shiga-ken, Japan

Upon elevation of plasma glucose concentration, pancreatic β-cells generate bursts of action potentials to induce cyclic changes in [Ca2+]i and regulate pulsatile insulin release. This glucose-dependent insulin secretion is synergistically enhanced by an incretin hormone, gucagon-like peptide-1 (GLP-1). To date, it has been well established that GLP-1 activates adenylate cyclase through binding to its G-protein-coupled receptor and increases [cAMP], the key signal underlying the insulinotropic effects. The increase in [cAMP] subsequently activates protein kinase A (PKA) and cAMP-regulated guanine nucleotide exchange factor (cAMP-GEF or Epac), modulating the activities of ion channels at the plasma membrane and ER, which in turn modify the pattern of burst as well as Ca2+ transients. However, because of complex interactions between multiple cellular factors and ion channels or transporters involved in the GLP-1 effects, quantitative aspects of the molecular mechanisms have not yet been determined. In order to overcome this difficulty, we adopted a strategy of modeling analysis; simulation study and mathematical analysis. First, our β-cells model [1] was updated and GLP-1 receptor signal transduction model [2] was incorporated. The modulatory effects of PKA and Epac on ion channels, voltage-gated Ca2+ channels (VGCC), delayed rectifying K+ channels (KDR), ATP-sensitive K+ channel (KATP) and non-selective cation channels (NSCC), were then reconstructed based on experimental observations in electrophysiological and pharmacological studies. Finally, lead potential (VL) analysis [1] were applied to quantitatively determine the functional role of each ion channel in GLP-1 induced increase in membrane excitability (Fig. 1). The analysis revealed that activation of NSCC strongly contributes to shorten burst interval, whereas deactivation of KATP causes insufficient contribution to hyperpolarization during plateau leading to prolongation of burst duration during GLP-1 stimulation. Simulation studies by constructing a comprehensive model based on experimental records and mathematical analyses of the model behavior provide a deeper and more objective insight into cellular functions.

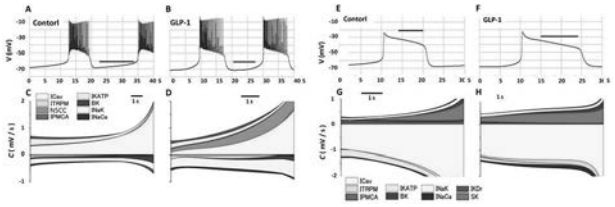

Fig 1. Contribution of ion channel to the interburst and plateau period at 10 mM [Glucose] with and without GLP-1 stimulation. A, B, E, F; Time-dependent changes in Vm trace is overlapped by VL. In order to resolve the change in slow components, action potentials was eliminated by calculating Vm with steady-state solution for gating variables (E,F). C, D, G, H; Time-dependent changes in the contribution (c) of individual currents indicated with different colors. A positive c indicates that the time-dependent change in the corresponding current contributes to depolarization, whereas channels with negative c contributes to hyperpolarization.

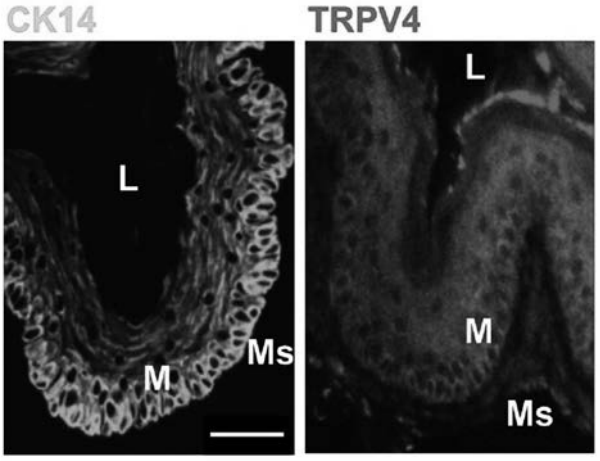
Transient receptor potential vanilloid 4-dependent calcium influx and ATP release in mouse esophageal keratinocytes

A. Boudaka[1,2], H. Mihara[1,3], T. Sugiyama[3], Y. Moriyama[4] and M. Tominaga[1]

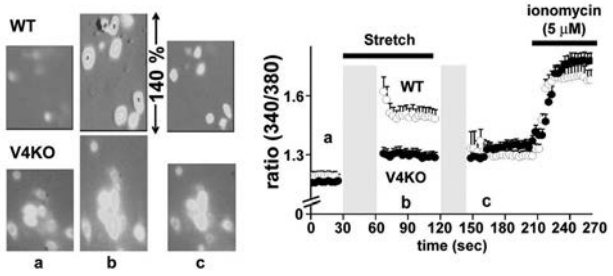
[1]Division of Cell Signaling, Okazaki Institute for Integrative Bioscience (National Institute for Physiological Sciences), National Institutes of Natural Sciences, Okazaki, Aichi-ken, Japan, [2]Department of Physiology, College of Medicine and Health Sciences, Sultan Qaboos University, Muscat, Oman, [3]Department of Gastroenterology, Graduate School of Medicine and Pharmaceutical Sciences, University of Toyama, Toyama, Japan and [4]Department of Membrane Biochemistry, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan

Gastro-oesophageal reflux disease (GERD) is a multi-factorial disease that may involve
oesophageal hypersensitivity to mechanical or heat stimulus as well as acids. Intraganglionic
laminar endings (IGLEs) are the most prominent terminal structures of oesophageal vagal
mechanosensitive afferents and may modulate mechanotransduction via purinergic receptors.
Transient receptor potential channel vanilloid 4 (TRPV4) can detect various stimuli such as warm temperature, stretch and some chemicals, including 4α-phorbol 12,13-didecanoate (4α-PDD) and GSK1016790A. TRPV4 is expressed in many tissues, including renal epithelium, skin keratinocytes and urinary blad-

der epithelium, but its expression and function in the oesophagus is poorly understood. Here, we show anatomical and functional TRPV4 expression in mouse oesophagus and its involvement in ATP release. Methods: Expression studies were performed on mouse esophagus by RT-PCR and immunostaining. TRPV4 channel activities were examined by Ca^{2+}-imaging and Patch-Clamp experiments with primary esophageal keratinocytes isolated from WT and TRPV4KO mice. ATP release from keratinocytes was measured by Luciferin-Luciferase assay. Results: TRPV4 mRNA and protein were detected in esophageal keratinocytes. Several TRPV4 activators such as chemicals, heat and stretch stimulus have increased cytosolic Ca^{2+} concentrations in primary WT keratinocytes, but not in TRPV4KO keratinocytes. GSK and heat stimulus evoked TRPV4-like current responses in WT cells, but not in TRPV4KO cells. The mRNA of a newly identified ATP transporter, VNUT and its protein were also detected in esophageal WT keratinocytes. TRPV4 activators (GSK and heat stimulus) increased ATP release from WT cells, but not from TRPV4KO cells. This release was inhibited by a vesicle-trafficking inhibitor brefeldin A. Conclusion: TRPV4 contributes to ATP release via exocytosis, responding to heat, chemical and possibly mechanical stimuli. TRPV4 could be involved in esophageal mechano- and heat-hypersensitivity and be related to the pathophysiology of GERD.



TRPV4 immunoreactivity in WT mouse esophagus. Bars indicate 50 μm. CK14: keratinocyte marker; L: lumen; M: mucosa; Ms: muscle.



TRPV4-mediated cytosolic Ca^{2+} increase in primary esophageal keratinocytes. Representative pseudocolor images and traces for $[Ca^{2+}]_i$ changes in response to mechanical stimuli (140 %) in WT and TRPV4KO keratinocytes cultured on silicon chambers (mean ± SEM). Images were obtained at points a, b and c indicated on the traces. Mechanical stimulus was applied between the blue boxes (a black bar).

Development of new molecular tools to monitor various inositol compounds in stimulated human HEK-293 fibroblasts

J.T. Tóth, G. Gulyás, D.J. Tóth, L. Hunyady and P. Várnai

Department of Physiology, Semmelweis University, Budapest, Hungary

In recent years it became clear that phosphoinositides (PI) are not only structural lipids in membranes, but they also have important roles in several cellular functions ranging from mediating signalling cascades in the cell by binding to effector proteins, through regulation of ion channels to cell movements. Reversible phosphorylation of the inositol ring at positions 3, 4 and 5 results in the synthesis of seven different PIs. Their levels in the plasma membrane, endomembranes and in the cytoplasm can influence these processes, thus measuring the level of these lipids in living cells can help us to better understand their distinct functions.

Our aim was to develop a highly sensitive method which enables us to follow the dynamic change of these lipids in living cells. For this we performed bioluminescence resonance energy transfer (BRET) measurements between various luciferase-labeled PI-binding domains and a plasma membrane-targeted Venus (yellow fluorescent protein) in HEK-293T cells. To monitor the inositol lipid pools the following domains were used: the PH domain of PLCδ1 for PIP2, the 2xPH domain of OSH2 for PI4P and the PH domain of BTK for PIP3. To measure cytoplasmic IP3 level a recently developed intramolecular BRET sensor, based on the ligand binding domain of the type-1 IP3 receptor, was used.

As expected, stimulation of the cells expressing type-1 angiotensin receptor with 100 nM angiotensin II resulted in a transient response including the decrease of the plasma membrane PI4P and PIP2 level, and increase of the cytoplasmic IP3 concentration, but no change of the PIP3 level. In contrast, more robust, sustained responses could be recorded if 100μM carbachol was applied to stimulate cells expressing M3 muscarinic acethylcholine receptors indicating that cells are able to synthetize huge amount of PI4P and PIP2 upon agonist stimulation. Stimulation of the cells expressing EGF receptor with 100 ng/ml EGF resulted in a sustained increase of the PIP3 and a slowly developing IP3 signal. Both PI4P and PIP2 levels were decreased, but in contrast with Gq-activating hormones, decrease of the PI4P pool was continuous and significantly higher compared to the transient decrease of the PIP2 level.

Our results indicate that this approach is highly sensitive and capable of quantitative and dynamic characterization of inositol lipid changes upon stimulation of the cells with various compounds. Selective measurements of the various lipid pools may result in the discovery of differences between stimuli and therefore the role of inositol lipid pools and inositol modifying enzymes during the activation process.

Cholinergic pathways in human chronic myeloid leukemia cell proliferation

B. Aydin[1], M. Goren[2] and H. Cabadak[1]

[1]Biophysics, Marmara University, Istanbul, Turkey and [2]Medical Pharmacology, Marmara University, Istanbul, Turkey

A role may be attributed to cholinergic system in the development of hematological diseases. Recent studies demonstrated a significant increase in AChE activity together with muscarinic receptor expression in normal human peripheral blood lymphocytes as an early response to various stimuli (Battisti et al 2009). K562 cell line was established from a patient with chronic myeloid leukemia (CML) in terminal blast crisis. We have previously demonstrated the presence of muscarinic receptor subtypes namely M2, M3 and M4 in K562 line (Cabadak et al., 2010). We hypothesized that cholinergic agonist ACh is involved in cell proliferation in CML through muscarinic receptors.
In this present study, we aimed to demonstrate the mechanisms of ACh and carbachol (CCh) in cell proliferation. In order to track the roles of ACh we used hemicholinium, a choline uptake inhibitor, eserine hemisulfate, an acetylcholine esterase inhibitor and vesamicol a vesicular choline uptake inhibitor. We also made experiments with atropine the non-specific muscarinic antagonist to show the contribution of muscarinic receptors. K562 cell counts were performed in response to CCh stimulation where proliferation and cell viability were evaluated by the trypan blue exclusion test and BrDU labeling. AChE activity was determined by QuantiChrom TM Acethylcholine Assay kit. Choline acetyl transferase (ChAT) and AChE levels were quantified by using Western Blotting.
In our experiments we detected an inhibition of K562 cell count after 48 hr incubation in response to CCh at a concentration of 1 uM. Non-specific receptor antagonist atropine failed to reverse the inhibitory roles of CCh and ACh. Eserine also acted similarly on K562 cells and inhibited cell proliferation and atropine could not affect this inhibition (Table 1). Neither hemicholium nor vesamicol affected the cell counts. The effects observed with eserine is specifically dependent on ACh since we demonstrated a dose-dependent decrease in AChE activity concurrently. The experiments performed with vesamicole and hemicholinium imply that ACh secreted form other cells decrease proliferation of K562 cells. In conclusion, all these results may imply that extrinsic ACh activity affects cell proliferation in CML through nicotinic mechanisms, but ACh syhthesized within the cell elicits muscarinic receptor mediated effects.

Proliferation Assay Results

Groups	Optic Density at 405 nm (Mean ± SEM)
Control	0.223 ± 0.005
0.1 uM Eserine	0.186 ± 0.003
100 uM Eserine	0.155 ± 0.016
0.1 uM Eserine + Atropin	0.198 ± 0.017
100 uM Eserine+Atropine	0.178 ± 0.015

Differential beta-arrestin2 requirements for constitutive and agonist-induced internalization of CB1 cannabinoid receptor

P. Gyombolai[1,2], E. Boros[1], L. Hunyady[1,2] and G. Turu[1,2]

[1]Department of Physiology, Semmmelweis University, Budapest, Hungary and [2]Laboratory of Molecular Physiology, MTA-SE, Budapest, Hungary

Background: Desensitization and internalization are key procedures in the regulation of hormone receptors, and beta-arrestins play an important role in these processes. Currently, little is known about the role of beta-arrestins in the regulation of the CB1 cannabinoid receptor (CB1R). Therefore, the interaction between beta-arrestins and CB1R, and its role in receptor internalization were investigated.
Materials and methods: The beta-arrestin binding of CB1R was studied by confocal microscopy and bioluminescence resonance energy transfer (BRET) in HeLa and Neuro-2a cells. To follow CB1R internalization, plasma membrane CB1 receptors were selectively stained using Halo-labeling technique. Internalization of the receptors was also monitored by a BRET assay through measuring non-specific BRET between CB1R and ICAM as a plasma membrane marker.
Results: We found that upon activation CB1R binds beta-arrestin2 (beta-arr2), but not beta-arrestin1, and this binding is transient. We also found that internalization following stimulation with CB1R agonists could be impaired either by a dominant negative beta-arrestin2 (beta-arr2-V54D) or by siRNA-mediated knock-down of beta-arr2. Similar inhibitory effects on agonist-induced internalization were detected with BRET measurements. In contrast, neither beta-arr2-V54D nor beta-arr2-siRNA had a significant effect on the constitutive (i.e. spontaneous) internalization of CB1R.
Conclusions: We conclude that upon activation, CB1R binds beta-arr2 in a transient manner (class A GPCR), and this binding is required for the agonist-induced internalization of the receptor. In contrast, constitutive CB1R internalization is independent of the beta-arr2 binding of the receptor, suggesting that the molecular mechanisms underlying these two processes are different.

PCA214

The role of store operated calcium entry in endocytic vacuole formation in pancreatic acinar cells

D. Collier[1,2], R. Sutton[2,3], A. Tepikin[1,2] and S. Voronina[1,2]

[1]Department of Cellular and Molecular Physiology, University of Liverpool, Liverpool, UK, [2]NIHR Liverpool Pancreas Biomedical Research Unit, University of Liverpool, Liverpool, UK and [3]Department of Molecular and Clinical Cancer Medicine, University of Liverpool, Liverpool, UK

The intracellular activation of trypsinogen in pancreatic acinar cells is an early and probably initiating event in the development of acute pancreatitis (a frequent and life-threatening inflammatory disease). Endocytic vacuoles are the site of trypsinogen activation in pancreatic acinar cells (Sherwood et al 2007).

All inducers of acute pancreatitis trigger prolonged Ca^{2+} responses, involving release of Ca^{2+} from intracellular stores and induction of store-operated Ca^{2+} entry (SOCE). The formation of endocytic vacuoles is a Ca^{2+} dependent process.

The current study examined the specific role of SOCE in the formation of endocytic vacuoles. Fluorescence microscopy and Ca^{2+} sensitive probes (fluo-4 and fura-2) were utilised to test the response of murine pancreatic acinar cells to supramaximal doses of the secretagogue cholecystokinin (CCK), thapsigargin and the bile acid taurolithocholic acid 3 sulphate (TLC-S). All three compounds (known to deplete intracellular Ca^{2+} stores) induced sustained increase in cytosolic Ca^{2+} concentration and endocytic vacuole formation. We observed that pharmacological inhibition of SOCE (verified using fura-2 measurements) resulted in significant (more than 40%) inhibition of endocytic vacuole formation. Inhibition of vacuole formation was observed in experiments utilising supramaximal doses of CCK, TLC-S and thapsigargin, suggesting that SOCE plays an important role in vacuole formation in all three of these models of cellular Ca^{2+} toxicity. It is therefore likely that SOCE is an important component of Ca^{2+} toxicity, responsible for pancreatic acinar cell damage in the early stages of acute pancreatitis, and is a potentially useful pharmacological target in the development of treatment against this disease.

PCA215

BRET titration experiments to study G protein coupled receptor dimerization: New insights into an old tool

B. Szalai[1], P. Hoffmann[2], P. Várnai[2,1] and L. Hunyady[2,1]

[1]MTA-SE Laboratory of Molecular Physilogy, Budapest, Hungary and [2]Institute of Physiology, Semmelweis University, Budapest, Hungary

G Protein Coupled Receptors (GPCRs) can form dimeric or higher ordered oligomeric complexes, which can remarkably influence the signalling of these receptors.

Bioluminsecent Resonance Energy Transfer (BRET) titration experiments are the gold standards to prove the physical interaction between the protomers of a presumed dimer. In this method the energy transfer (BRET signal) is measured between a luminescent (energy donor) and a fluorescent (energy acceptor) labelled receptor. BRET signal can increase not only due to a specific interaction (dimerization) but due to the random, non-specific interactions between donor and acceptor. To distinguish between the specific and non-specific interaction, BRET signal is measured using fixed amount of donor and varying amount of acceptor labelled receptors, and BRET signal values are plotted as a function of acceptor/donor ratio. In the case of specific interaction this plot shows a saturation curve, while in the case of non-specific interactions it shows a lineal relationship.

Maintaining constant amount of donor labelled receptors is strictly required to the correct interpretation of BRET titration experiments, but it is very hard to achieve in a transient transfection system. In our work, we analysed the effects of changing donor levels on BRET titration curves, and set up a system, where it is possible to distinguish between specific and non-specific interaction even in the case of changing donor amount.

To analyse the effects of changing donor levels on BRET titration curves, we performed Monte Carlo simulations. The results showed, that in the case of non-specific interaction, the BRET signal is only dependent on the amount of acceptor, while in the case of specific interaction it depends on the acceptor/donor ratio. Our simulations also showed, that in the case of changing donor levels, even non-specific interaction can lead to saturation BRET titration curves, which can lead to false interpretation of experimental results.

We tested our simulation results in an inducible dimerization system, where the non-specific interaction between FKBP labelled donor and FRB labelled acceptor molecules could artificial changed with the addition of rapamycin into a specific interaction. Our experimental results verified our simulations. With these new analysis methods, we examined the dimerization between various GPCRs (type I and II angiotensin receptor, V2 vasopressin receptor, β2 adrenergic receptor, calcium sensing receptor, CB1 cannabinoid receptor).

PCA216

Assessment of gap junction communication between human umbilical endothelial cells and monocytes in response to tumour necrosis factor (TNF-α)

A.H. Qasem, C.H. Fry and R.I. Jabr

Biochemistry and Physiology, University of Surrey, Surrey, UK

Atherosclerosis is a chronic inflammatory disease characterised by accumulation of monocytic cells and lipids within the subendothelial space. This is facilitated by monocyte (MO) transendothelial (EC) migration early in atherosclerosis development and requires direct MO-to-EC contact. This is enhanced by adhesion molecules in the presence of pro-inflammatory stimuli such as tumour necrosis factor-α (TNF-α). Both cell types express connexin (Cx) 43 isoforms that permit formation of gap junctions (GJ); channels permeable to small molecules

(<1KDa). We hypothesised that MOs and ECs communicate through formation of Cx43 GJs, which is enhanced by TNFα. Human umbilical vein endothelial cell (HUVEC) monolayers were maintained in endothelial growth medium whose functional integrity was assessed by measuring trans-endothelial electrical resistance (43.94±3.32Ω.cm^2;n=6). A dye transfer assay examined functional GJ formation between MOs and ECs. HUVEC monolayers were loaded with 5mM calcein-AM dye: free calcein is membrane impermeable and only permeates through GJs. Suspensions of freshly isolated MOs from peripheral blood were added to HUVEC monolayers. Calcein transfer to MOs was measured by flow cytometry and normalised to positive control values obtained from MOs directly loaded with calcein. A negative control used a Cx43 deficient MO cell-line, THP-1 monocytes. Experiments were carried out in endothelial basal medium (EBM) in the absence and presence of 2ng/ml TNF-α. The efficiency of dye transfer to MOs through GJs was measured in: 1) the presence of GJ inhibitor, 2mM heptanol; 2) THP-1 monocytes; 3) HUVECs transfected with Cx43-siRNA. Data are means ± SEM, compared by ANOVA, the null hypothesis was rejected at p<0.05.

Dye transfer to MOs, after incubation with calcein-loaded HUVECs monolayers for 30 minutes in EBM was recorded in 66.3±2.1% (n=3) of cells. This fraction was attenuated by heptanol (9.9±4.5%;n=3;P<0.001) and was comparable to the fraction of loaded THP-1 cells (8.33±4.66;n=3). For HUVECs transfected with CX43-siRNA, the fraction of calcein-loaded MOs also decreased compared to control,11.3±4.5% vs 74.1±2.1%, respectively (n=3;P<0.05). TNF-α enhanced the fraction of calcein-loaded MOs to 89.6±2.5% (n=3;P<0.001) in control monolayer. Such an effect was prevented in monolayer transfected with Cx43-siRNA (13.70±2.45%;n=3; P<0.001).

These results show that calcein-dye transfer through GJs formed between ECs and MOs. Dye transfer was attenuated by lack of Cx43 in MO, knock down of Cx43 in HUVECS with Cx43-siRNA or application of GJ blockers. TNF-α increased calcein transfer to MOs and had no effects in HUVECs with Cx43-siRNA. In this study we confirm the important role of GJ communication between MOs and ECs as an underlying mechanism for early stages of atherosclerosis development.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA217

Measurement of inositol-1,4,5-trisphosphate in living cells using newly developed resonance energy transfer-based biosensors

G. Gulyás[1], J.T. Tóth[1], D.J. Tóth[1], L. Hunyady[1], T. Balla[2] and P. Várnai[1]

[1]Department of Physiology, Semmelweis University, Budapest, Hungary and [2]Section on Molecular Signal Transduction, Program for Developmental Neuroscience, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, USA

Inositol-1,4,5-trisphosphate (IP3) plays a central role in calcium signalling. Its production is catalyzed by phospholipase C enzymes, which can be activated through receptor stimulation. When investigating these signalling pathways, calcium measurement is not the most appropriate method to detect receptor activation, because several parallel processes can alter intracellular calcium concentrations. To solve this problem, we designed an IP3 probe, which is able to directly reflect the level of this compound, and thus allows a more accurate characterization of these signalling pathways.

To construct this sensor, we used the human type-1 IP3 receptor, in which amino acids 224-605 are responsible for ligand binding. According to crystal-structure data, IP3 binding may lead to a conformational change of this protein domain. Based on this conformational change, we were aiming to construct a resonance energy transfer-based biosensor. In literature, similar probes can be found, but all of them have limitations. In particular, measurement of decreasing IP3 levels is uncertain, due to the high ligand affinity of these sensors. To eliminate this effect, we engineered two lower affinity mutants by impairing the binding site of the protein domain. The arginine in either position 265 or 269 was substituted to lysine (R265K and R269K, respectively). Finally, two appropriate luminescent chromophores were fused to the two ends of the protein domain to enable the monitoring of IP3 concentrations by fluorescence or bioluminescence resonance energy transfer.

To compare our sensors, we needed an experimental system, in which an increase or decrease in IP3 concentration could be equally established. We created a modified HEK-293T cell line, which stably expressed a rapamycin-inducible phosphatidylinositol 4,5-bisphosphate (PIP2) depletion system. To achieve a stochiometric expression of its proteins, the components of this depletion system were cloned into a self-cleaving 2A-peptide containing vector. In addition, type-1 angiotensin receptor was transiently transfected to these cells, so IP3 concentration increased upon angiotensin II stimulus, while a decrease was seen after rapamycin treatment and consequent PIP2 degradation.

Under these conditions both the wild type and the mutant sensors were able to show the increase in IP3 levels, but only the mutants were capable of detecting the decrease of IP3 concentration. Our data suggest that these sensors are suitable to investigate IP3 signalling more accurately by single cell imaging as well as in cell population measurements.

PCA218

A truncated splice variant of LRP1

M. Kolb[1], S. Trettner[1], S. Büttner[1], K. Engel[1], T. Seiboth[2], K. Huse[2] and G. Birkenmeier[1]

[1]Medical Faculty University Leipzig, Institute of Biochemistry, Leipzig, Germany and [2]Leibnitz Institute for Age Research, Fritz-Lipmann-Institute e.V., Jena, Germany

The low-density lipoprotein receptor-related protein-1 (LRP1), identical to the Alpha2-macroglobulin receptor (A2MR), is a member of the LDL receptor superfamily. The ubiquitously expressed LRP1 in particular is a scavenger receptor that mediates clearance of over 50 ligands from the extracellular matrix and the bloodstream among others A2M, proteases, and distinct components involved in modulation of cancer cell dissemination. Moreover, LRP1 is implicated in coordinating cell-matrix interactions, cell migration, as well as tumour promotion. So far, LRP1 was associated with both anti-tumour and recently with pro-invasive functions, thus indicating a more complex functionality. Beyond that LRP1 is involved in regulation of signalling pathways and physiologic processes such

as regulation of lipid metabolism and the proliferation of vascular smooth muscle cells.
NCBI data bank research revealed the expression of a truncated splice variant of LRP1 mRNA (shLRP1). Using standard PCR and Western Blot both its mRNA transcript and protein expression was analysed in human tissues and cancer samples as well as cancer cell lines. In order to localise the shLRP1 protein in cells, shLRP1 protein was over-expressed in cancer cell lines using pcDNA3.1 vector and Lipofectamine and analysed using immune fluorescence microscopy. The gene LRP1 comprising 84.86 kb is localised on chromosome 12q13.3 and is organised in 89 exons coding for a mature mRNA transcript of 14886 nucleotides. Compared to LRP1, the shLRP1 comprises exon 1 – 6 of LRP1 followed by an alternative exon containing a polyadenylation signal. As a result, the respective transcript shLRP1 can escape nonsense-mediated decay. Hence, the shLRP1 mRNA code for a truncated protein of only 296 aa exhibiting a unique C-terminus in contrast to LRP1 comprising 4544 aa. The shLRP1 mRNA was detected to be exclusively present in several solid tumours. Beyond that it was also present in tumours of brain, breast, colon, lung, muscle, and prostate as well as in corresponding tumour cell lines, such as U87-MG, 1321N1 (astrocytoma), MDA-MB-231, HT-29 (colon), A549 (lung), and PC3 (prostate). In contrast, no expression was detected in tumour cells derived from blood cells as well as normal human tissue. Western blot analysis of protein extracts of several cancer cell lines among others 1321N1, PC3, HT-29, and A549 verified translation of shLRP1 mRNA into protein. Consequently, shLRP1, over-expressed in transfected cancer cell lines, was detected in the cytoplasm and the perinuclear region, but not - as the LRP1 - in the cell membrane.
Summarising, these preliminary data offer the possibility to exploit the shLRP1 for tumour diagnosis, and tumour therapy on the one hand. On the other hand, the limited expression of shLRP1 in cancer cells raises the question regarding its involvement in physiological signalling pathways that have to be further investigated.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA220

Effect of the nicotinic acid adenine dinucleotide phosphate antagonist Ned-19 on pancreatic acinar cell calcium signalling

M.R. Charlesworth, O.H. Petersen, J.V. Gerasimenko and O.V. Gerasimenko

Pathophysiology and Repair, Cardiff University, Cardiff, S.Glamorgan, UK

Regulation of the concentration of cytosolic calcium (Ca2+) is vital for the physiological function of many cell types. Three secondary messengers; inositol 1,4,5 trisphosphate (IP3), nicotinic acid adenine dinucleotide phosphate (NAADP) and cyclic adenosine diphosphate ribose (cADPR); have been identified as being able to induce Ca2+ release from organelle Ca2+ stores. Together these messengers allow for temporal and special coordination of Ca2+ signalling.
Acute pancreatitis (AP) is inflammation of the pancreatitis and the surrounding tissue, caused by the improper activation of the digestive enzymes within the acinar cells. This pathological enzymatic activation has been linked to atypical Ca2+ signalling, with mass release from stores; resulting in mitochondrial overload and induction of necrosis. Both the neurotransmitter acetylcholine (ACh) and the hormone cholecystokinin (CCK) induce in release of Ca2+ from stores in pancreatic acinar cells (PAC). ACh has been shown to induce Ca2+ release via generation of IP3, while CCK has been suggested to mobilise Ca2+ via synthesis of NAADP.
NAADP is unique from other secondary messengers as it induces calcium release from a thapsigargin resistant (non-endo/sarcoplasmic) store, shown to be composed of acidic organelles. PAC have a large pool of acidic organelles, mainly composed of zygomorphic granules, creating a significant store of NAADP sensitive Ca2+. Targeting this NAADP sensitive Ca2+ store by manipulating NAADP signalling should allow for an increased understanding of the role of Ca2+ in both the physiological and pathological function of PAC.
Ned-19 is a NAADP antagonist discovered in a screen of the ZINC chemical library using NAADP's 3D electrostatic structure. Its ability to inhibit NAADP induced Ca2+ release has been observed in several different mammalian tissue types and Ned-19 has been used to isolate NAADP's role from that of that the other secondary Ca2+ signalling molecules.
Initial experiments into the effect of Ned-19 on physiological Ca2+ signalling in PAC match the pattern expected by the secondary messengers implicated in the function of the stimulants used. With no changes in ACh induced Ca2+ release observed in the presence of Ned-19, but full to partial inhibition of CCK's ability to increase cytosolic Ca2+ levels.
One of the pathological causes of AP is reflux of bile acid in to the pancreases via the common bile duct. The bile acid taurolithocholic-acid-3-sulfate (TLC-S) has been shown to induces large Ca2+ release via a NAADP depend mechanism; however Ned-19 shows only the ability to delay this release and not inhibit it. Further study into Ned-19's effect on other models of AP and its ability to affect cell fate will provide vital information as to its potential as a treatment for AP.

PCA221

Modulation of calcium entry and extrusion mechanisms in relation to the development of acute pancreatitis

E. Stapleton, J.V. Gerasimenko, O.H. Petersen and O.V. Gerasimenko

Biosciences, Cardiff University, Cardiff, S.Glamorgan, UK

Acute pancreatitis (AP) is a human disease characterised by inflammation and necrosis of pancreatic tissue. The most common causes of AP are excessive alcohol intake, gallstones and a fatty diet. The hallmark of AP is premature intracellular activation of digestive, resulting in the digestion of pancreatic tissues[1,2]. The premature activation of enzymes has been shown to be the result of elevated cytosolic Ca^{2+} concentration[1,2].
Pathophysiological Ca^{2+} signals are typically global, sustained increases in cytosolic Ca^{2+} and deplete Ca^{2+} stores. This sustained elevation of cytosolic results in intracellular activation of enzymes[1,2]. Pathological stimulation depletes the ER of Ca^{2+},

this depletion is determined by a Ca^{2+} sensor located in the ER membrane, STIM1[2]. STIM1 is activated by the depletion of ER Ca^{2+}, it is coupled to Orai-1 located in the plasma membrane (PM). Orai-1 is a store-operated Ca^{2+} (SOC) channel activated via depletion of the ER, resulting in Ca^{2+} influx[2]. Store-operated Ca^{2+} entry (SOCE) serves to refill the depleted ER with Ca^{2+} in non-excitable cells. However, during pathological stimulation additional Ca^{2+} entering the cell will serve to further exacerbate already elevated cytosolic Ca^{2+} concentrations. SOCE, as such, is ideal to target in order to reduce cytosolic Ca^{2+}.

C57BL/6 mice were killed humanely in accordance with the UK Schedule 1 of the Animals (Scientific Procedures) Act, 1986. Pancreatic acinar cells were isolated as described previously[3]. Cytosolic Ca^{2+} measurements were made using intact cells loaded with the Ca^{2+}-sensitive dye Fura-2 in AM form.

Preliminary data, using inhibitory compounds of SOC channels, indicate a significant reduction in Ca^{2+} overload and therefore partial protection of necrosis in acinar cells treated with reported pancreatitis-inducing agents[3,4].

In addition to focusing on SOCE, there are other mechanisms that could serve to decrease Ca^{2+} overload, such as potentiation of the plasma membrane Ca^{2+}-ATPase (PMCA) driving Ca^{2+} extrusion from the cell[4] as well as reducing calcium release through the calmodulin regulation[5]. We have measured the rates of Ca^{2+} entry and extrusion under control and pathological conditions, and compared the potential benefits of interfering with different calcium signalling pathways.

Targeting SOC channels and PMCA in order to reduce cytosolic Ca^{2+} overload could be an attractive strategy to reduce necrosis of pancreatic tissue.

Cytological remodeling of the periodontal ligament tissues due to mechanical stress

T. Kawakami[1], M. Tomida[2], R. Muraoka[3], T. Nakamura[2] and K. Nakano[1]

[1]Hard Tissue Pathology Unit, Matsumoto Dental University Graduate School of Oral Medicine, Shiojiri, Nagano, Japan, [2]Department of Oral Physiology, Matsumoto Dental University School of Dentistry, Shiojiri, Nagano, Japan and [3]Department of Orthodontics, Matsumoto Dental University School of Dentistry, Shiojiri, Nagano, Japan

[Aim] We examined the transplanted bone marrow-derived cell migration into the periodont ligament tissues. Mesenchymal cells in the bone marrow have abilities of cell migration and differentiation into periodontal cells. We examined the cytological remodeling dynamism of the periodontal ligament tissue due to orthodontic mechanical stress, using mouse experimental model.

[Methods] After the approving by Animal Experimental Control Committee of the University, Bone marrow cells from GFP transgenic mice were transplanted into 8 week-old female C57BL/6 mice, which had undergone 10 Gly of lethal whole-body irradiation for the purpose of inactive all bone marrow/white cells of in the recipient mice. After successful transplantation, the mice received orthodontic mechanical stress using the Waldo method; and the mice were compared as control without receiving orthodontic mechanical stress. Paraffin-sections were immunohistochemically (IHC), fluorescence IHC and TRAP staining techniques and analyzed using a primary anti-GFP-polyclonal rabbit antibody. Semi-quantitative evaluation of IHC staining was prepared and pixel density was counted for each image. Then typical IHC positive staining part was defined as positive area. The pixel number of positive area in the periodontal tissue was compared with the previously calculated total pixel number of the periodontal tissue and the ratio was obtained. The examination results were analysed using Mann-Whitney U test.

[Results and Discussion] We examined the transplanted bone marrow-derived cell migration into periodontal tissues. The IHC revealed that GFP-positive cells were detected in the periodontal tissues, both in the experimental and control specimens. The GFP-positive cells histopathologically differentiated into some cell types. The fluorescence IHC and TRAP staining techniques demonstrated these cells were detected as osteoclasts and macrophages. Furthermore, GFP-positive cells gathered adjacent blood vessels. The data suggest that GFP-positive bone marrow-derived cell migration into periodontal ligament tissues and differentiate periodontal tissues component-cells. The GFP-positive cells histopathologically differentiated into some cell types. The fluorescence IHC and TRAP staining techniques demonstrated these cells were detected as osteoclasts and macrophages. Furthermore, GFP-positive cells gathered adjacent blood vessels. The data suggest that GFP-positive bone marrow-derived cell migrate into periodontal tissues and differentiate periodontal component-cells. As a results of the examination group specimens and control group, the ratio of pixel number of GFP-positive cells in the examination group showed 5.77 ± 3.24 % (mean ± SD); and that in the control group, 0.71±0.45 % (mean ± SD). The examination group was greater than that of control group ($p<0.001$).

[Conclusions] These results suggest that orthodontic mechanical stress induces bone marrow cell migration and differentiation into periodontal ligament tissue component cells.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA225

Assessment of blood perfusion as possible tool in differentiating between human benign skin naevi and malignant melanomas

M. Rossi[1], A. Stefanovska[2], G. Vezzoni[1], M. Pesce[1], B. Loggini[3], F. Ghiara[1], G. Rossi[4], F. Pingitore[3] and P. Barachini[1]

[1]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Physics Department, University of Lancaster, Lancaster, UK, [3]Department of Translational Research and New Technologies in Medicine, University of Pisa, Pisa, Italy and [4]Unit of Epidemiology and Biostatistics, Institute of Clinical Physiology, CNR of Pisa, Pisa, Italy

Malignant melanomas (MM) are characterized by hypervascularisation which may affect MM blood flow and its oscillatory dynamic. The hypothesis of this study was that the blood flow assessment at the level of skin melanocytic lesions may aid in differentiating between benign skin naevi and MM. Fifty

one subjects with clinically and dermatoscopically atypical naevi and 23 subjects with clinically and dermatoscopically typical benign naevi underwent blood flow (BF) measurement at the level of the lesion of interest (central and margin lesion site) and at the level of a clinically healthy skin site, contra lateral to the lesion of interest, using a single point laser-Doppler fluxmetry (LDF). After LDF, atypical naevi were excised and underwent histological examination and immuno-histo-chemistry microvessel count. At the histological examination, MM was demonstrated in 9 lesions, atypical benign naevus in 31 lesions and typical benign naevus in 11 lesions. No significant difference in BF was found between clinically benign naevi, histologically benign naevi and histologically atypical naevi (Wilcoxon test), which were then included in a single control group (CG) of 65 naevi. Compared to CG naevi, MM showed a significantly higher BF (at the level of both central and margin lesion site) and a significantly higher ratio in BF between lesion margin site and contra lateral skin site (LMS/CLS ratio), as well as between central lesion site and contra lateral skin site (Wilcoxon test). A LMS/CLS ratio > 1 was observed in 100% of MM and in 60% of CG naevi, with a sensitivity of 100 (95% C.I.: 65.5- 100), a specificity of 40 (95% C.I.: 28.8-52.9) and a ROC area of 0.70 (95% C.I.: 0.64 – 0.76). The results of this study show that MM have a significantly greater BF compared to benign naevi (both typical and atypical) and suggest that a > 1 LMS/CLS BF ratio could be a suitable cut-off for selecting naevi to be examined by histology in order to exclude MM. This last result should be confirmed in a larger group of MM patients.

Results of laser-Doppler blood flow assessment in melanomas and control naevi.

	Melanomas (9)	Control naevi (65)	p
Lesion central site blood flow (PU)	112.0 (39.9-181.6)	15.6 (10.1-29.0)	0.0003
Lesion margin site blood flow (PU)	78.7 (27.6-125.8)	16.8 (10.9-29.3)	0.0004
Contra lateral skin blood flow (PU)	15.9 (13.0-23.0)	12.6 (10.3-16.8)	0.051
LMS/CLS blood flow ratio	3.7 (1.6-6.6)	1.3 (0.8-2.4)	0.006

Data are as median and inter-quartile range. LMS/CLS = margin lesion site/contra lateral skin.

The effect of SDF1- 3'A and CXCR4 gene polymorphisms on the susceptibility and clinicopathological characteristics of prostate cancer

S. Seckin[2,1], C. Kucukgergin[1,2], F. Isman[1,3], D. Selcuk[1,4], . Bedia[1,5] and O. Sanli[1,6]

[1]Department of Biochemistry, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey, [2]Department of Biochemistry, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey, [3]Clinical Biochemistry Laboratory, Goztepe Teaching and Research Hospital, Istanbul, Turkey, [4]Department of Molecular Medicine, Institute for Experimental Medicine Research,Istanbul University, Istanbul, Turkey, [5]Department of Molecular Medicine, Institute for Experimental Medicine Research, Istanbul University,, Istanbul, Turkey and [6]Department of Urology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

Chemokines and their receptors may contribute to pathologic processes such as cell proliferation, angiogenesis, invasion and metastasis of different types of cancers. In the present study, we aimed to investigate the association between SDF1-3A' and CXCR4 gene polymorphisms and the susceptibility and clinicopathological development of prostate cancer.

Consecutive patients with histologically confirmed prostate cancer (n= 152) and healthy controls (n= 149) with normal serum total PSA (< 4 ng/ml) and DRE were prospectively enrolled in this study between 2007 and 2011. SDF1-3'A and CXCR4 gene polymorphisms were assessed by polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP) in all subjects. For the statistical analyses Pearsons's Chi-Squared (χ2), Mann-Whitney U and multiple logistic regression model tests were used where appropriate.

The mean age and smoking status were similar in prostate cancer patients and controls. Total PSA levels were significantly increased in the prostate cancer patients compared with controls. There were no significant differences in the distributions of SDF-1 and CXCR4 genotypes between controls and prostate cancer patients. However, the patients with prostate cancer with AA genotype of SDF1-3'A gene had an increasing risk of 2.02 fold (aOR= 2.02; 95% CI= 1.05-3.90; p= 0.035) to develop high pathological T stage when compared with prostate cancer patients with GG homozygotes of SDF1-3'A gene after being adjusted for age, BMI and smoking status. In addition, the distribution of AA genotype of SDF1-3'A gene polymorphism was found significantly increased in the patients with bone metastasis in comparison to those without bone metastasis (aOR=2.94; 95% CI=1.26-6.82; p=0.012). On the other hand, CXCR4 gene polymorphism was not associated with the clinicopathological characteristics of prostate cancer.

Our results suggest that SDF1-3'A gene polymorphism may be associated with the progression and bone metastasis of prostate cancer.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA227

The role of MCP-1 A2518G and CCR2A V64I gene polymorphisms on the susceptibility and clinicopathological characteristics of bladder cancer

C. Kucukgergin[1,5], F. Isman[2,1], S. Dasdemir[3,1], B. Cakmakoglu[4,1], O. Sanli[5,1] and S. Seckin[6,1]

[1]Department of Biochemistry, Istanbul faculty of medicine, Istanbul, Turkey, [2]Clinical Biochemistry Laboratory, Goztepe Teaching and Research Hospital, Istanbul, Turkey, [3]Department of Molecular Medicine, Institute for Experimental Medicine Research, Istanbul, Turkey, [4]Department of Molecular Medicine, Institute for Experimental Medicine Research, Istanbul, Turkey, [5]Department of Urology, Istanbul faculty of medicine, Istanbul, Turkey and [6]Department of Biochemistry, Istanbul faculty of medicine, Istanbul, Turkey

The gene variants of the chemokine and chemokine receptor genes associated with inflammation may be involved in cancer initiation and progression. The aim of this study was to explore the possible association of monocyte chemoattractant protein-1 (MCP-1) A2518G and chemokine receptor CCR2A V64I gene polymorphisms with the risk and clinicopathological characteristics of bladder cancer (BC) in a Turkish population.

In the present study, 142 individuals diagnosed with histologically confirmed BC between 2008-2011 at the Department of Urology, Istanbul Faculty of Medicine were enrolled as a patient group. The control group (n=197) consisted of urology patients who were treated at our outpatient clinic for various urological complaints but had no evidence of any malignancy based on a detailed evaluation. MCP-1 A2518G and CCR2A V64I gene polymorphisms were assessed by polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP) in all subjects. For the statistical analyses Pearsons's Chi-Squared (χ2), Mann-Whitney U and multiple logistic regression model tests were used where appropriate. There were no significant differences in the distributions of MCP-1 A2518G genotypes between controls and BC patients. However, the carriers with AA genotype or at least one A allele of CCR2 had an increased risk of developing BC (aOR=2.39, 95%CI=1.13-5.03; p=0.022; aOR=1.37, 95%CI=1.04-1.81; p=0.022 respectively). In addition BC patients with AA genotype or at least one A allele of CCR2 had an increased risk of high grade and stage tumors as compared to those with GG genotype (aOR=3.09, 95%CI=1.02-9.34; p=0.045; aOR=1.58, 95%CI=1.07-2.32; p=0.020 respectively). On the other hand, MCP-1 A2518G gene polymorphism was not associated with the clinicopathological characteristics of BC.

Our results suggest that the genetic variants of CCR2A V64I gene polymorphism may modify the BC risk. Furthermore, CCR2A V64I gene polymorphism may contribute to the muscle invasive BC in a Turkish population.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA228

Manganese superoxide dismutase ILE-58THR, catalase C-262T and myeloperoxidase G-463A gene polymorphisms in prostate cancer patients: Relation to advanced and metastatic disease

C. Kucukgergin[1,2], T. Tefik[1,2], O. Sanli[1,2], T. Oktar[1,2], C. Ozsoy[1,2] and S. Seckin[1,2]

[1]Department of Biochemistry, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey and [2]Department of Urology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

Known as a multifactorial disease, prostate cancer (PCa) is considered one of the most frequently diagnosed tumors and second leading cause of cancer related deaths among men. We aimed to evaluate the relationship between manganese superoxide dismutase (MnSOD) Ile-58Thr, catalase (CAT) C-262T and myeloperoxidase (MPO) G-463A gene polymorphisms and the susceptibility and clinicopathological characteristics of PCa.

One hundred and fifty five patients diagnosed with PCa and 195 controls with negative digital rectal examination and PSA<4ng/dl were enrolled in this study. MnSOD, CAT and MPO gene polymorphisms were performed by polymerase chain reaction restriction-fragment length polymorphism (PCR-RFLP) methods. For the statistical analyses Pearsons's Chi-Squared (χ2), Mann-Whitney U and multiple logistic regression model tests were used where appropriate.

No statistically significance regarding demographic data and smoking status was observed between groups. As expected, total PSA levels were significantly elevated in the PCa patients compared with controls. No relationship was found between MnSOD Ile-58Thr gene polymorphism and PCa risk. However, there were significant differences in the genotype distributions of CAT C-262T and MPO G-463A gene polymorphisms between PCa patients and controls (aOR:1.57; 95%CI: 1.11-2.21; p=0.010; aOR:1.78; 95%CI: 1.15-2.76; p=0.009, respectively). MnSOD Ile-58Thr and MPO G-463A gene polymorphisms were not found to be associated with clinicopathological characteristics including pathological grade, T stage and metastasis among PCa patients. However, CAT C-262T gene polymorphism was found to be associated with clinicopathological characteristics including T stage and metastasis among PCa patients. The patients with PCa carrying TT genotype had a significantly increased risk of high pathological T stage disease and metastasis compared to patients carrying CC genotype (aOR:1.94; 95%CI: 1.14-3.23; p=0.014; aOR:3.83; 95%CI: 1.75-6.59; p=0.000, respectively).

It seems that there is no association of PCa and MnSOD Ile58Thr polymorphism, whereas TT genotype in CAT C-262T polymorphism and GG genotype in MPO G-463A polymorphism may be associated with increased PCa risk. The TT genotype in CAT C-262T polymorphism may also play as a risk factor in tumor progression and metastasis among Turkish men.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA229

Antioxidant enzymes in prostate cancer

N. Salmayenli[1,2], C. Kucukgergin[2,1], T. Tefik[3,2], O. Sanli[3,2] and S. Seckin[2,1]

[1]Clinical Biochemistry, Istanbul University Medical Faculty, Istanbul, Turkey, [2]Department of Biochemistry, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey and [3]Department of Urology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

Prostate cancer is the most important malignancy in men with advanced age. Oxidative stress contributes to the etiology and pathogenesis of the prostate cancer. The aim of this study was to determine the relation of antioxidant enzymes with the prostate cancer and to evaluate whether the activities of these enzymes were correlated with different stages and states with or without metastasis of disease. Moreover, we investigated oxidant-antioxidant state in prostate tissue with and without tumor. We also determined MnSOD expression by Western Blot analysis in the tissue protein extracts.

One hundred sixty five men diagnosed with histologically confirmed prostate cancer were included in the study. The control group also consisted of 168 male subjects who were enrolled to Department of Urology for reasons other than lower urinary tract symptoms. Prostate cancer patients were histologically classified into two groups as low and high stage disease according to 2002 TNM classification. Moreover, tumors with Gleason score >7 were classified as poorly differentiated whereas those with Gleason score <7 were classified as well-differentiated tumors. The presence or absence of bone metastasis was determined by bone scanning of prostate cancer patients with serum PSA level> 10 ng/ml. Twenty one prostate cancer and adjacent non- tumorous specimens were resected with transurethral resection of prostate (TURP). Serum and prostate tissue malondialdehyde (MDA), total thiol (-SH) levels and SOD, GPx, CAT activities were determined spectrophotometrically. Western Blot analysis was performed for evaluating MnSOD protein expression. For the statistical analyses, Mann-Whitney U and Kruskal-Wallis tests were used where appropriate. Serum MDA levels, GPX and SOD activities were significantly higher and total –SH levels were significantly lower in patients with prostate cancer compared to those of the controls. Serum MDA levels were significantly increased in prostate cancer patients with high stage. Moreover, serum MDA levels were significantly elevated in bone metastasis group. However, serum total –SH levels and GPX activities were lower in bone metastasis group. We observed that total MDA levels and SOD activities were also higher in prostate tissues with tumor. GPX, CAT activities and total –SH levels were significantly lower in prostate tissues with tumor. Meanwhile, tumors had higher levels of MnSOD protein when the MnSOD protein expression was evaluated by Western analysis.

In conclusion, we suggest that tissue GPX and CAT activities were decreased due to oxidative injuries in patients with prostate cancer and also increased MnSOD expression in cancerous tissue was to be an indicator for progression and stage of the disease.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA230

SIRT1 expression enhanced antitumor effect of Cisplatin decreased by chronic hypoxia in human non-small cell lung cancer

D. Shin

Pharmacology, College of Medicine, Seoul National University, Seoul, Republic of Korea

Hypoxia induced drug resistance is a major obstacle in the development of effective cancer therapy. Hypoxia is also associated with human non-small cell lung cancer (NSCLC), which is highly resistant to chemotherapy. However, the exact mechanisms driving hypoxia induced chemoresistance of NSCLC remain elusive. We first found that NSCLC cell lines showed hypoxia-induced chemoresistance from human several solid tumors treated with Cisplatin. Especially, IC50 values to NSCLC cell lines, H1299 and A549 are significantly more increased under hypoxic condition than these of normoxic condition. To evaluate why IC50 values are significantly increased in NSCLC cell lines, we measured the expression levels of SIRT1 and pAMPK alpha after normoxic and hypoxic condition 48 h with 21 solid tumors by using Western blot analysis. Surprisingly, the levels of SIRT1 and pAMPK alpha in NSCLC cell lines were highly underestimated in hypoxic condition. Cell viabilities, colony numbers, and IC50 values were diminished by SIRT1 overexpression and SIRT1 activator (SRT1720), which was recovered by AMPK alpha knock-down and AMPK alpha inhibitor (Compound C), and also these were increased by SIRT1 knock-down, SIRT1 mutant (H363Y) expression, and SIRT1 inhibitor (EX527), which was re-decreased by AMPK alpha expression and AMPK alpha activator (A769662). These results suggest that hypoxia-induced chemoresistance is correlation with SIRT1-AMPK alpha axis. To elucidate how SIRT1 can overcome hypoxia-induced chemoresistance, we measured mitochondria activity by using mitochondria morphology change, MitoTracker, and ATP/ADP ratio. SIRT1 expression increased the Area, number, perimeter, ferret's meter, ATP/ADP ration of mitochondria, and promoted cytochrome C release from mitochondria, which was diminished by siAMPK alpha. Moreover, our new combination therapy SIRT1 activator and Cisplatin can overcome resistance to hypoxia-induced chemoresistance through activation of mitochondria activity. Actually, these regime synergistically decreased tumor volume and weight in H1299 xenograft model and significantly increased survival rate in H1299 lung orthotopic model in compared with either each single or non-treatment. Our results showed that SIRT1-AMPK alpha axis by chronic hypoxia makes chemoresistance via the inactivation of mitochondria. However, ectopically increased SIRT1 expression or activity in hypoxia can overcome hypoxia-induced chemoresistance via activated mitochondria. It suggests that SIRT1 is an efficient target for reducing chemoresistance in NSCLC.

Key words: SIRT1, AMPK alpha, hypoxia, chemoresistance, mitochondria activity, Cisplatin

Jia-Wey Shiau-Uau San (JWSYS) is the most commonly Chinese medicine prescribed in Taiwan for disorders of menstruation in female and for sleep disturbances in males

J. Yu[1], C. Ho[2] and C. Chang[3]

[1]Department of Chinese Medicine, Chi Mei Medical Center, Tainan, Taiwan, [2]Department of Medical Research, Chi Mei Medical Center, Tainan, Taiwan and [3]Department of Biotechnology, Southern Taiwan University of Science and Technology, Tainan, Taiwan

Jia-Wey Shiau-Yau San (JWSYS), one of the traditional Chinese herbal formulas, is a famous herbal remedy used for the treatment of various menopause-related symptoms and stress-related neuropsychiatric disorders in Korea, Japan and China. Despite the wide use in clinical applications, the scientific literature on efficacy and safety of JWSYS is not available. The present study is a clinical research to evaluate the drug-use patterns of Chinese herbal medicine JWSYS in Taiwan during 2009.The National Health Insurance Research Database (NHIRD) was applied in this study. The Traditional Chinese Medical (TCM) database, a subset database of NHIRD, is the first national population TCM database, including of TCM ambulatory care expenditures by visits and details of TCM ambulatory care orders. The principal diagnosis was based on the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9CM) code. Patients took Jia-Wei-Xiao-Yao powder in 2009 was selected for the study subjects. In a 2009 statistics, it is revealed that a total of 899,712 persons had took JWSYS, and the total prescription number is 2,479,09 times. The age distribution of the 889,712 patients showed that most (30.44%) were between 36 and 50 years of age, and 27.63% were between 21 and 35. In addition, in gender the number of females who take JWSYS is greater than that of males, the ratio is about 4:1 (80.50%:19.50%). As for the top 10 major diseases treated by JWSYS, according to the statistics classified by the Institute with ICD-9 codes, they are different for males and females. The disease treated most with JWSYS for males is disorders of menstruation and other abnormal bleeding from female genital tract (ICD-9:626.9), while for males is sleep disturbances (ICD-9: 780.5). Within the top ten diseases of males and females, five major diseases are the same, including the sleep disorders, contact dermatitis, allergic rhinitis, migraine, and endocrine disorders, and the other remaining five major diseases are not the same. Although our survey tends tio indicate that JWSYS is the most commonly Chinese medicine prescribed in Taiwan of menstruation in female and for sleep disturbances in males, the efficacy and the therapeutic mechanisms of JWSYS in treating disorders of menstruation and sleep disturbances warrant further exploration in future studies.

The photodynamic action is initiated by the absorption of a photon followed by many competing radiative and nonradiative reactions which ultimately result in the oxidation and degradation of vital biomolecules (1). Molecular oxygen plays a key role in propagation the initial molecular damage, resulting in vascular collapse, tissue destruction, cell death. The photodynamic therapy (PDT) induces tumor cell necrosis and/or apoptosis by producing reactive oxygen species through activated photosensitizer that accumulates specifically to the tumor. Thus, PDT has much attracted as less invasive method for treating cancer. The potential applications for fullerenes and their derivatives have increased in recent years, particularly in the fields of biology and medicine, where they can be used as DNA photo-cleaving agents, anti-HIV protease inhibitors, antibacterial agents and photosensitizers for photodynamic therapy. Fullerenes are suitable for application as photosensitizer because they are efficient visible-light triplet-sensitizers and their ability to photoproduce singlet oxygen ($^1O_2$) is considerable. Although carbohydrates play essential roles in biological systems, their usage in fullerene-based PDT has remained virtually unexplored; this is essentially true of fullerene in which an intact carbohydrate moiety is connected to fullerene through an appropriate linker. We previously reported that sugar-pendant C60 derivatives prepared from carbohydrate linked azides, having $^1O_2$ producing ability in DMSO under laser irradiation (355 nm) proved by the direct observation of $^1O_2$ emission at 1270 nm (2). The cytotoxicity of PDT was studied in several cancer cell lines cultured with D-glucose residue pendant fullerene and a maltohexaose residue pendant fullerene (3). These glycoconjugated fullerenes induced significant cytotoxicity against cancer cells. In contrast, PDT with these compunds exhibited no significant cytotoxicity against normal fibroblasts, indicating that PDT with these compounds targeted cancer cells. Ideally, PDT-induced tumour destruction should occur without damage to adjacent normal organs. Therefore, it can be expected to design high functional glycoconjugated fullerene. Here, we wish to report on the synthesis of a novel D-glucose pendant C60 compounds derived from D-glucose linked amine, photocytotoxicity against HeLa cells and unprecedented photo-

physical processes together with previously prepared D-glucose pendant azafulleroids (2).

Hyperbaric oxygen treatment ameliorates the course of DSS-induced colitis in BALB/c mice and reduces the Foxp3+ regulatory T cell expansion

M. Mihalj[1], D. Pojatic[1], E. Ugor[2], Z. Kellermayer[2], S. Novak[1], M. Zulj[1], A. Vcev[3], T. Berki[2] and I. Drenjancevic[1]

[1]Department of Physiology and Immunology, Faculty of Medicine University Josip Juraj Strossmayer of Osijek, Osijek, Croatia, [2]Department of Immunology and Biotechnology, Faculty of Medicine University of Pecs, Pecs, Hungary and [3]Department of Internal Medicine, Faculty of Medicine University Josip Juraj Strossmayer of Osijek, Osijek, Croatia

Several studies in both animals and men showed beneficial effects of hyperbaric oxygenation (HBO2) on the course of experimentally induced colitis and inflammatory bowel disease. However, underling mechanisms of its action remain elusive. It was found that adoptive transfer or induction of CD4+CD25+FoxP3+ regulatory T cells (Treg) can prevent disease and reverse the course of established colitis (1). In addition, recent findings suggest that the mesenteric lymph nodes (mLN) are an important site of Treg induction (2). In the present study, we have assessed the effects of HBO2 on the frequencies of Treg in mLN of mice with DSS-induced colitis.

BALB/c mice at the age of 10-12 weeks were randomized into 4 groups (n=9 mice): control mice, control mice undergoing HBO2, mice receiving dextran sodium sulphate (DSS) and DSS treated mice undergoing HBO2. Mice were fed 5% w/v of DSS (Mr 36.000-50.000, MPBomedicals, France) in drinking water ad libidum for 7 consecutive days. HBO2 was initiated at day 1 and was administered until the end of experiment, twice a day 100% O2 for 60 minutes at 2.3 bars with addition of 15 minutes for gradual compression and decompression. Disease activity (DAI) was assessed by daily recording of animal body weight, stool consistency and the presence of occult or gross blood per rectum. On the day 9 mice were scarified by cervical dislocation and their mLN collected and further processed for flow cytometric assessment of Treg. The data are presented as mean±SEM, and were compared by student t test and one-way ANOVA. The study was approved by the Ethical Committee of Faculty of Medicine Osijek.

Mice treated with DSS exhibited severe symptoms of colitis, including diarrhea and gross rectal bleeding starting from day 6. DSS treated mice that underwent HBO2 presented with occult bleeding at day 8 and only a loose stool starting at day 7. DSS treated mice have lost 14.8±1.9% of body weight, whereas the mice which additionally underwent HBO2 lost 5.9±3.4% body weight. There was a significant difference in disease severity between those two groups, as evidenced by DAI on days 6-8 ($p<0.001$, Figure 1). Frequency of Treg in mLN increased significantly in DSS treated mice ($p=0.026$), and was reduced to control values after HBO2 ($p=0.03$, Figure 2).

DSS induced inflammation of the colon resulted in increased frequencies of Treg cells in the mLN. Consistent to previous studies HBO2 significantly reduced symptoms of disease and severity of colitis, which resulted in reversed frequencies of Treg cells, at comparable levels with those found in control mice. Thus our results suggest that the improved course of DSS-induced colitis in BALB/c mice does not involve Treg expansion.

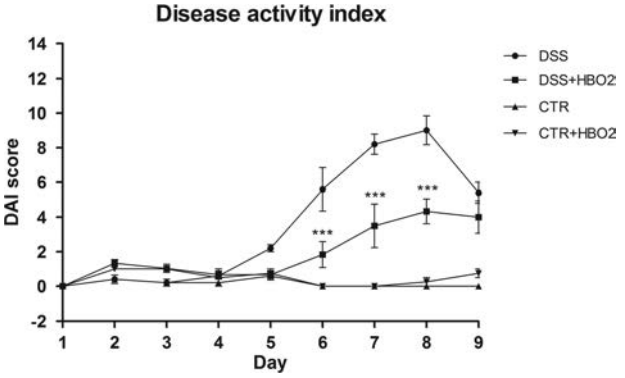

Figure 1. Disease activity index (DAI) was determined by daily assessment of body weight (0-4 depending on % of body weight reduction), stool consistency (0 – normal, 2 – loose stool, 3 – diarrhea) and bleeding (0 – normal, 2 – occult bleeding, 3 – gross bleeding).

Treatment of polycystic kidney disease with PPARγ agonists: Effects of sub-pharmacological doses in rodent models

B.L. Blazer-Yost[1,2], S. Flaig[1], A. Carr[2] and V. Gattone[2,1]

[1]Biology, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA and [2]Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA

The autosomal dominant form of polycystic kidney disease (ADPKD) is the most common renal genetic disease in humans with an estimated incidence of 1:400-1000. Cyst expansion progresses slowly, and renal function is typically not compromised until the fifth decade but then the decline to renal failure is precipitous usually occurring in 5-10 years in 50% of patients. There are currently no drugs approved for the treatment of ADPKD. Based on our previous observations that PPARγ agonists inhibit CFTR synthesis and that pioglitazone feeding ameliorates PKD progression in the PCK rat model, we have hypothesized that the PPARγ agonists, pioglitazone (pio) and rosiglitazone (rosi), could be used to treat ADPKD. CFTR is the Cl^- channel in the epithelial cells lining the cysts that is responsible for Cl^- driven fluid secretion into the cyst lumen causing cyst expansion. Both pio and rosi are insulin sensitizing agents which have been used to treat diabetic patients for many years, albeit with some dose related side effects. We have fed the PCK rat (a slowly progressing PKD model) with super-pharmacological (4.0 mg/kg BW; high dose) and sub-pharmacological (0.04 mg/kg BW; low dose) rosi from week 4 to 28. An alternative, rapidly progressing model of renal cystic disease, the WPK/WPK rats, were fed with high (20.0 mg/kg BW) and low (0.2 mg/kg BW) doses of pio from day 5 to 18. At the end of the appropriate time period, the animals were euthanized with an overdose (i.p.) of sodium pentobarbital. The kidneys were weighed and then prepared for histological sections which were used to determine various parameters including cyst volume. In the PCK rats both super- and sub-pharmacological concentrations of rosi resulted in statistically significant (ANOVA one way, P less than 0.05) decreases in kidney weight and renal cyst volume. The average (±- S.E.M.) kidney weights of the 12 animals on control diet were 4.33 ± 0.18 gr compared to 3.56 ± 0.26 for high dose (n=3) and 3.68 ± 0.14 for low dose (n=8). The average renal cyst volume of the control diet animals was 0.53 ± 0.06 ml compared to 0.27 ± 0.05 for high dose and 0.33 ± 0.09 for low dose. In the Wpk/Wpk animals, the kidney weights and renal cyst volumes of the animals on the high dose were not statistically different from the control diet animals while the animals fed the low dose were significantly different. Kidney weights of control versus low dose = 4.51 ± 0.48 ml (n =11) versus 3.53 ± 0.17 (n =10); renal cyst volume = 3.34 ± 0.36 versus 2.57 ± 0.14. Thus concentrations of PPARγ agonists that are below the doses used to treat diabetic patients are effective in slowing cyst growth in two models of PKD. At these low doses, the drugs are less likely to exert adverse side effects. We suggest that low dose PPARγ agonists may be effective life-long therapy for PKD patients.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA237

Plasmin in urine - a new biomarker and target for renal protection in diabetes

H. Andersen[1,2], U. Friis[1], P. Hansen[1], J. Henriksen[2] and B. Jensen[1]

[1]Cardiovascular and Renal Research, University of Southern Denmark, Odense C, Denmark and [2]Department of Endocrinology, University of Southern Denmark, Odense C, Denmark

Diabetes is often accompanied by hypertension, microalbuminuria and decline in kidney function until renal failure. Diabetic nephropathy is the leading cause of chronic kidney disease. In nephrotic syndrome, aberrant filtration of plasminogen from plasma to preurine with subsequent activation to plasmin may proteolytically activate the epithelial Na^+ channel (ENaC). We hypothesized that plasmin is lost to preurine in diabetic nephropathy and that plasmin in urine may activate ENaC current. This cross-sectional study included patients with type 1 diabetes mellitus with diabetic nephropathy (n=19) and without nephropathy (control, n=20). Patients were matched on age, gender and diabetes duration. Plasma, spot urine samples, 24 h urine collections and 24 h blood pressure recordings were obtained. 24 h urinary protein excretion was 1.8±0.5 (nephropathy, n=17) and 0.07±0.03 g/day (control, n=18, p=0.0007). Urinary plasmin(ogen)/creatinine ratio as assessed by ELISA was significantly higher in nephropathy than control group ($172\pm1.86\times10^{-3}$, n=19, vs. 3.48×10^{-1} $\pm1.32\times10^{-3}$ μg/g, n=18, p<0.0001) and correlated with urine albumin concentration (p<0.0001). Plasma plasmin(ogen) concentration did not differ between nephropathy and control (140±7, n=18, vs. 152±9 μg/ml, n=19). Western immunoblotting supported the presence of urinary plasmin(ogen) in nephropathy, but not in control group. Preliminary data indicated that urine from nephropathy patients (n=3) increased ENaC current more than control group (n=5) as evaluated by whole-cell patch clamp on murine collecting duct cells (67.8±12.8 % vs. 16.5±3.9 %). Mean 24 h systolic, but not diastolic, blood pressure was significantly higher in nephropathy (144/79 mmHg, 95 % confidence interval (CI): 136.0–151.9/74.9-83.2) than control group (132/75 mmHg, 95 % CI: 126.2-137.4/71.8-77.8, p=0.0117) despite being treated with 3.0±0.4 (nephropathy) vs. 1.4±0.3 (control) antihypertensive drugs including diuretics. There was a significant correlation between mean 24 h blood pressure and urine plasmin(ogen) concentration (r^2=0.18, p=0.0102). Furthermore, nephropathy patients dipped significantly less in systolic (7.4±1.8 % vs. 13.3±2.0 %, p=0.04) and diastolic blood pressure (9.1±1.6 vs. 16.1±1.9 %, p=0.008) at night than did the control group.

It is concluded that aberrant presence of plasmin activity in urine in diabetic nephropathy is capable of activating ENaC and may contribute to insufficient hypertension control.

Susanne Hansen and Kenneth Andersen are thanked for excellent technical assistance.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA238

Recruitment mechanisms and anti-inflammatory effects of haematopoietic stem cells in the injured kidney

R.L. White, G. Nash, D. Kavanagh, C. Savage and N. Kalia

Clinical and Experimental Medicine, University of Birmingham, Birmingham, UK

Introduction: Haematopoietic stem cells (HSCs) can migrate to injured kidney and aid in tissue repair. However, clinical success remains poor and can be attributed to limited HSC recruitment. Understanding adhesive mechanisms governing HSC recruitment may allow the development of strategies that enhance their homing, thus improving the efficacy of HSC-based therapies. This study therefore determined the adhesive mechanisms critical for renal HSC recruitment, whether pre-treating HSCs with chemokines enhanced recruitment and the mechanisms by which this occurred and what vasculoprotective effects were being conferred by recruited HSCs.
Methods: Numbers of HSCs, neutrophils and platelet microthrombi in renal peritubular capillaries of sham and ischemia-reperfusion (IR) injured mice (ketamine/xylazine; i.p.) were visualised using dyes that fluoresce different colours. Some HSCs were pre-treated with function-blocking antibodies to surface adhesion molecules (CD49d, CD44, CD18) or chemokines (SDF-1α, KC). Changes in surface expression and clustering of HSC adhesion molecules was determined using flow cytometry and confocally. HSC adhesion to endothelial counterligands (VCAM-1, hyaluronan) was determined using static adhesion assays in vitro.
Results: HSC adhesion was significantly ($p<0.001$) increased in IR kidney when compared to sham controls. This resulted in a significant ($p<0.01$) reduction in adherent neutrophils and platelet microthrombi at 6 hours post-reperfusion when compared to mice receiving no HSCs. Recruitment was dependent on CD49d and CD44, but not CD18. Both SDF-1α and KC pre-treatments significantly ($p<0.01$) enhanced HSC adhesion within IR kidney. Neither pre-treatment strategy increased adhesion molecule expression. However, SDF-1α ($p<0.01$) and KC ($p<0.05$) did increase numbers of CD49d and CD44 surface clusters on HSCs respectively. This likely explained their increased adhesion to VCAM-1 ($p<0.05$) and hyaluronan ($p<0.001$). SDF-1α also significantly ($p<0.01$) increased HSC deformability as demonstrated using a micropipette aspiration method. This resulted in increased ($p<0.01$) numbers of free-flowing HSCs being continuously observed in the renal microcirculation.
Conclusion: Chemokine pre-treatment increased HSC adhesion within injured renal microvessels. Interestingly, it also increased the pool of circulating transplanted HSCs available for renal recruitment. This was possibly due to the increased deformability preventing their entrapment within non-injured tissue (eg. lungs). Our data also demonstrates for the first time that HSCs exhibit marked anti-inflammatory and anti-platelet effects. Ongoing studies will determine whether enhancing their local presence with chemokine pre-treatment confers faster and more efficient vasculoprotective effects.

Simulation of the anti-arrhythmic properties of herbal remedies

P. Noble[2], K. Tasaki[2], D. Gavaghan[1], G. Mirams[1] and D. Noble[2,1]

[1]Computing Science, University of Oxford, Oxford, UK and [2]MAviaSB Project, Physiology, Anatomy & Genetics, University of Oxford, Oxford, UK

Computer models of cardiac cells can identify combinations of actions on ion channels that may avoid arrhythmic side effects (1), thus providing a new, more predictive, biomarker, now used in the pharmaceutical industry.
Herbal remedies are naturally multi-action. In some cases, therapeutic effects have been validated by double-blind clinical trial (2), the chemical composition is known, and the action profiles on multiple targets have also been characterised. The data can therefore be used in the same models as for single compound drugs.
The Figure shows that the profile of action of Shen-song yang-xin (SSYX) (2, 4) accounts for the shortening of the cardiac action potential. When early-after depolarizations (5) are induced in the model the actions of SSYX fully reverse the effect on repolarization (right hand panel). We believe this is the first time that simulation has been used to demonstrate the anti-arrhythmic mechanism of a herbal remedy.

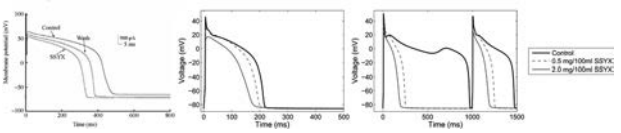

Figure 1. Left: experimental recordings of action potentials of guinea-pig myocytes before, during and after application of SSYX. Middle: simulation of two dose levels using Shannon ventricular cell model (3). SSYX acts on the following six channel proteins with IC50s based on the published data: I_Na: 0.62 g/100ml, I_CaL: 0.83 g/100ml, I_to: 0.49 g/100ml, I_K(mostly s): 1.12 g/100ml, I_K1: 1.01 g/100ml, I_f : 1.02 g/100ml. Right: simulation using the same data on model modified to generate EADs.

Multitargeted therapy of chemotherapy-induced oral mucositis by hangeshashinto, a traditional Japanese herbal medicine

T. Kono[1,2], A. Kaneko[3], R. Nozaki[2], C. Matsumoto[3], C. Miyagi[3], K. Ohbuchi[3], Y. Omiya[3], Y. Mizuhara[3], K. Miyano[4] and Y. Uezono[4]

[1]Faculty of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan, [2]Advanced Surgery Center, Higashi-Tokushukai Hospital, Sapporo, Japan, [3]Tsumura Research Laboratories, Tsumura & Co, Ibaraki, Japan and [4]Division of Cancer Pathophysiology, National Cancer Center Research Institute, Tokyo, Japan

Chemotherapy-induced oral mucositis (COM) is a common disorder but optimal treatment has not yet been established. COM is characterized by painful inflammation and ulceration involving PGE2. Hangeshashinto (TJ-14), a traditional Japanese herbal medicine (Kampo), has been prescribed for oral mucositis in Japan. Recently, a TJ-14 rinse solution (2.5 g/50 mL) was found to significantly reduce ulcer healing time in patients with grade 2 or worse COM in a randomized controlled trial. However, little is known regarding the anti-COM mechanism of TJ-14. The aim of this study was to identify the multiple actions of TJ-14 on the PGE2 system and cell migration by characterizing the action profiles of its main active ingredients, [6]-shogaol (6SG), wogonin (WGN), and berberine (BBR). COM was induced in hamsters by a combination of 5-fluorouracil (5-FU) administration and mild abrasion of the buccal mucosa. Hamsters were fed either a diet containing 2% (wt/wt) TJ-14 or a control diet throughout the experiments. Although buccal lesions were markedly aggravated by 5-FU, TJ-14 fed hamsters had significantly smaller lesions than animals on control diet and the ulcer healing time was also significantly reduced by half to a level comparable to that observed in humans. The amount of prostanoid synthesized by human oral keratinocytes (HOK) after stimulation with IL-1β for 6 h in the presence or absence of a test sample was measured by EIA. RT-PCR, phospho-MAPK, and COX-enzyme assays were performed to determine the mechanism of action. Levels of inducible PGE2 and PGF2α, metabolites of COX pathways, were reduced by TJ-14 (10–300 μg/mL) without inducing cytotoxicity, while LTB4 production was not affected by either IL-1β or TJ-14 addition. Gene expressions of COX-2, phospholipase A2, and PGE synthase were all down-regulated by TJ-14 exposure. Screening of the active ingredients in TJ-14 revealed that 6SG, WGN, and BBR significantly reduced PGE2 production. WGN and BBR inhibited induction of COX-2 mRNA probably through the blockage of c-Jun N-terminal kinase (JNK) and p38 phosphorylation. 6SG inhibited the enzymatic activity in PGE2 synthesis but did not decrease COX-2 mRNA expression, suggesting that 6SG might regulate PGE2 synthesis at the post-transcriptional level. Migration was evaluated after scratch wounding using sterile pipette tips. HOK migration was increased by TJ-14 (30–100 μg/mL) in a concentration-dependent manner. Pretreatment of HOK with IL-1β, which was highly expressed in inflamed sites of COM, resulted in decreased migratory activity. TJ-14 and BBR improved IL-1β-induced down-regulation of HOK migration. These data suggest that TJ-14 exhibits multiple actions against COM via PGE2 inhibition and promotion of wound healing. The main active ingredients, 6SG, WGN, and BBR, appear to exert different mechanistic actions.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Intestinal ischemia, alterations in enteric flora, and pro-inflammatory cytokines (TNF-α and IFN-γ) have been shown to play key roles in the pathogenesis and recurrence of Crohn's disease (CD) (1). Daikenchuto (TU-100), a traditional Japanese medicine (Kampo) composed of processed ginger, ginseng radix, and Japanese pepper, is a pharmaceutical grade multiherbal medicine that is widely prescribed in Japan to improve gastrointestinal disorders such as CD (2). A randomized controlled trial on TU-100 in patients with CD is currently underway in the United States. Basic studies have demonstrated that TU-100 suppresses TNF-α and IFN-γ production in the intestinal mucosa of CD by inducing endogenous adrenomedullin (ADM) release, a potent vasodilatory peptide with anti-inflammatory activity (3,4). We have demonstrated that TU-100 contains transient receptor potential ankyrin 1 (TRPA1) channel ligands, [6]-shogaol and hydroxyl-α-sanshool, which increase intestinal blood flow via enhancing ADM release from the intestinal epithelial cells (5). This shows that TRPA1 present in the intestinal epithelial cells controls intestinal blood flow via ADM release. ADM has also been found to have an antimicrobial effect comparable to that of human β-defensin in the intestinal lumen, suggesting its potential influence on enteric flora. However, little is known regarding the effect of TU-100 on enteric microbiota, which may alter the dynamic relationship between host and microbes to ameliorate colitis. In this study, C57Bl/6 female mice (n=6, 6 weeks old) were housed together to minimize generational and environmental variables that might possibly confound the microbiota analysis. All mice were fed a defined diet (AIN-76A) supplemented with or without 15 g of TU-100 extract/kg diet (1.5% wt/wt) and studied over a 28-day period. Stool samples were analyzed for 16S rRNA gene profiles using terminal restriction fragment length polymorphism (T-RFLP) and 454 pyrosequencing. TU-100 significantly altered the T-RFLP profile of stool microbiota, but only after 28 days of TU-100 treatment. Both taxonomic assignment and operational taxanomic unit (OTU) analysis revealed an expansion of Actinobacteria and Firmicutes at the phylum level and Lactococcus sp. and Clostridium sp. at the genus level. A 28-day supplementation with TU-100 was also investigated in the dextran sulfate sodium (DSS)-induced colitis murine model. TU-100 inhibited weight loss, colon shortening and colonic histological injury, and improved disease activity index in DSS-treated mice, while inducing cytoprotective heat shock pro-

tein expression and suppressing pro-inflammatory cytokine expression, particularly TNF-α. These data address the possibility that TU-100 ameliorates DSS-induced colitis by reshaping the intestinal microbiome, paving the way for a novel therapeutic strategy for CD patients.

Multiple actions via systems biology – ten principles of systems biology and biological relativity

D. Noble, T.W. Tasaki, Y. Mohri, P. Liu, Y. Yang and K.M. Tasaki

Physiology, Anatomy and Genetics, University of Oxford, Oxford, Select State, UK

Systems Biology is the ideal approach for determining the mechanisms of Multiple Actions on biological targets (1) since it is concerned with the interactions following intervention on more than one target (2) and it deals with circular causality in complex systems (3). Computer models can be used to sweep through large parameter spaces, and sensitivity analysis can be used to fine-tune the optimum ratios of the components. The approach is based on the ideas that systems biology is necessarily integrative and multi-scale, or multi-level (4); that "there is no privileged level or scale of causality" (the principle of biological relativity (5); and the idea that causality can be circular (3).

Systems Biology helps illuminate circular processes identified in Multiple Actions, while the systems concept of attractors in complex systems is also important in analysing dynamic balance in the body processes that traditional medicine (sometimes called scholarly medical traditions) is concerned with. Ways of nudging disordered processes towards good attractors can lead to the development of new ways not only of curing disease but also of its prevention, including cost-effective remedies.

This poster discusses the concept of circular causality in Biological Relativity in Ten Principles of Systems Biology (5). It also discusses the relationship between Ten Principles and Multiple Action remedies (1). It shows how the interactions between these ideas and the concepts underlying Multiple Action medicine help to explain why diseases with complex aetiology, which are more prevalent in aging populations, can be treated with multi-component remedies. It also points a way towards new and broader approaches to health and longevity.

PCA244

A reassessment of the linear relationship between VO2max and peak power with age

R.D. Pollock, N.R. Lazarus and S. Harridge

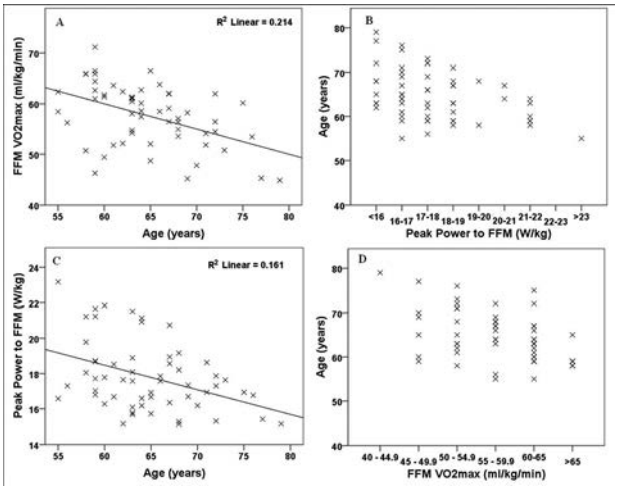
Centre of Human and Aerospace Physiological Sciences, King's College London, London, UK

The majority of research on the effect of age on physiological processes is carried out on subjects that are not physically active. A deficiency with this is that the negative effects of inactivity are implicitly ignored 1 resulting in sub-optimal values being obtained. In order to eliminate this deficiency the use of master athletes, who are less likely to show these negative effects, has been suggested1 as a more objective model of inherent human ageing. Furthermore, as a result of the methods traditionally used to depict physiological changes with age and the use of cross-sectional study designs, it is widely assumed that physiological function shows a linear decline with age. This study set out to test this assumed linear relationship between two aspects of functionality and age on a cohort of endurance trained (but not elite) master cyclists.

57 male subjects (55-79 years) were recruited from an amateur long distance cycling club where the objective of each rider is to complete events in a specified time, irrespective of age. Subjects performed an incremental exercise test to exhaustion on a cycle ergometer, with breath by breath recording of oxygen uptake performed throughout the test (OxyconPro, Jaeger, Netherlands). VO2max was determined as the highest VO2 recorded over a 20s period. Peak (explosive) power output during sprint cycling was also determined using an inertial testing system 2. Both VO2max and peak power were normalised to fat free mass obtained from DXA scans.

When analysed using regression analysis, a modest linear relationship was found between VO2max, power and age (Fig 1 A and C, $r = -.463$ and $-.401$ respectively; $P < 0.003$ in both cases). Thus even in a cohort of individuals performing similar amounts of exercise, where the effects of inactivity are negligible only 21% (VO2max) and 16% (power) of the variability is associated with age. Fig 1 B and D show the same data, but now depicted where each variable is categorised into bandwidths of equivalent function1. Here it can be clearly seen that a wide range of ages (covering up to 2 decades) is present in

the majority of bandwidths. Depiction of the data in this way highlights the spread of data in a manner which suggests functionality and age are not linear processes.
These findings emphasise that even in highly active ageing populations with similar activity patterns, that the relationship between physiological function and age as depicted in cross-sectional studies is not clear and unlikely to be linear. This observation is exemplified when the data are viewed in domains of equivalent function irrespective of age. These data bring in to question the commonly held belief that physiological function linearly declines with age. Longitudinal studies using appropriate models of human ageing are needed to clarify the relationship between age and physiological function.



A and C show the relationship between VO2max and Power displayed in the standard format with regression lines shown. B and C show the relationship displayed in the method described by Lazarus and Harridge1.

PCA245

Selective depletion of high abundance extracellular matrix proteins from the secretome of articular cartilage explant cultures does not facilitate identification of lower abundance proteins

A. Williams[1], J.R. Smith[2], D. Allaway[3], P. Harris[3], S. Liddell[1] and A. Mobasheri[1]

[1]The University of Nottingham, Sutton Bonington, UK, [2]Bruker UK, Coventry, UK and [3]WALTHAM® Centre for Pet Nutrition, Waltham-on-the-Wolds, UK

Age-related changes in articular cartilage lead to extracellular matrix (ECM) degeneration and potentially the development of inflammatory osteoarthritis (OA). OA is characterised by increased expression and activity of pro-inflammatory cytokines, chemokines, catabolic mediators and ECM degrading enzymes. During LC-MS/MS analysis, high abundance of proteins of the ECM in the secretome prevented identification of differentially released low abundance protein with potential involvement in cartilage inflammation and ECM degradation. Here we describe the use of two methods, (cetylpyridinium chloride (CPC) precipitation and conacanavalin A (Con A) chromatography), to bind and deplete negatively-charged glycosylated side chains of high abundance ECM proteins and proteoglycans with the objective of uncovering and identifying lower abundance proteins, which would subsequently be quantified by western blotting.
Articular cartilage explant cultures were established from equine metacarpophalangeal joints (tissues derived from animals euthanased for reasons other than research) and incubated (37°C, 5% CO_2) with the pro-inflammatory cytokine IL-1β (10 ng/ml) for 6 days. CPC (5%) was added (3 mg CPC/mg PG), samples were incubated (RT, 30 minutes), and centrifuged (13,000 rpm, 10 minutes). Con A was added (0.5 ml slurry per 200 μl sample) and centrifuged in spin columns (3,300 rpm, 4 minutes). An amaZon speed ETD (Bruker) was used for nanoLC-MS/MS to analyse the principle protein components of each sample. For protein identifications the NCBInr database was searched using Mascot, only peptides with individual ions scores with a $P<0.05$ or greater were accepted.
Silver stained SDS-PAGE protein profiles confirmed that depletion techniques removed many high abundance proteins, leaving a simplified secretome profile. Sixty proteins were identified in undepleted IL-1β treated samples. After Con A depletion 39 proteins were identified. One ECM constituent, HPLP-1, was enriched by Con A depletion with a mascot score of 796. CPC precipitation identified 34 proteins. Both CPC precipitation and Con A chromatography reduced mascot scores for many proteins, especially small proteoglycans including decorin and fibromodulin. Four additional intracellular proteins were reliably identified after depletion steps, including ferritin heavy chain 1 (score 250) and manganese superoxide dismutase (score 260).
In conclusion, whilst depletion methods removed many abundant ECM proteins they were ineffective in identifying a greater range of inflammatory related proteins and few additional low abundance proteins were detected. Such proteins may have been co-extracted through binding with selectively-removed ECM components, or interacted with CPC/Con A.

PCA246

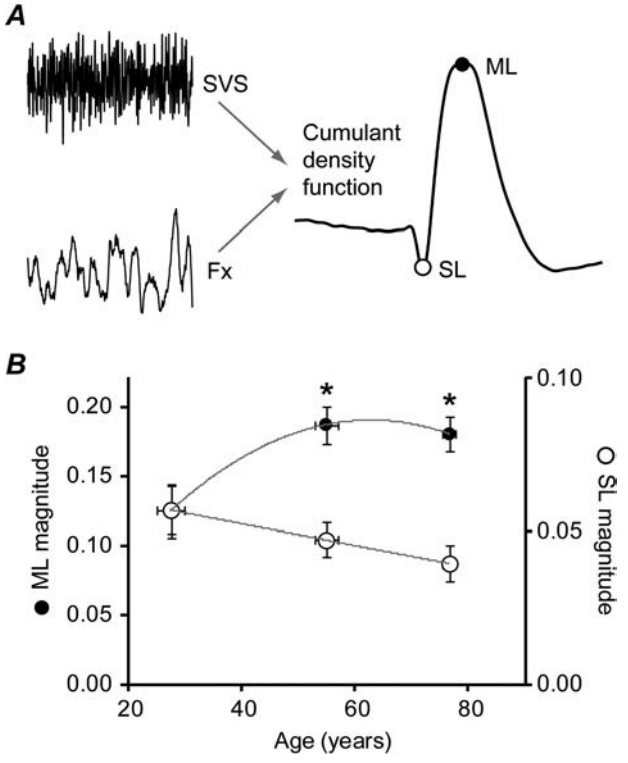
Ageing differentially affects the short and medium latency motor responses evoked by stochastic vestibular stimulation

C.J. Osler, M. Bancroft, H. Southall and R.F. Reynolds

School of Sport and Exercise Sciences, University of Birmingham, Birmingham, UK

Falls are a major problem for older people, but the underlying mechanisms are not well understood. When a balance disturbance is sensed by the vestibular system, a counteractive whole-body motor response is generated. This demonstrates that this system is a key sensory input for maintaining upright posture. Since age-related changes to the peripheral and central vestibular system have been reported (1, 2), the higher incidence of falls in older people may be partially attributable to a vestibular mechanism. We examined balance reflexes evoked by stochastic vestibular stimulation (SVS) in three groups of human subjects; young (n=9, 28±7years), middle-aged (n=9, 55±6years) and older adults (n=14, 77±4years) (mean±SD). A randomly varying current (filtered white noise, 0-20Hz; RMS amplitude, 0.6mA) was passed between the mas-

toids of subjects stood with feet together and eyes closed. Medio-lateral ground reaction shear force (Fx) was measured for the duration of each trial (6 x 30sec). The relationship between the stimulating waveform and the evoked motor response was then calculated using the cumulant density function (3). As shown in Figure 1A, the resulting SVS-Fx relationship clearly shows that SVS precedes an initial negative peak (average magnitude=0.05±0.02) followed by a larger positive peak in Fx (average magnitude=0.17±0.05). These two components are termed the short latency (SL) and medium latency (ML) responses, respectively. We found the magnitude of these components to be differentially affected by ageing (mixed design ANOVA, age group x component; $F_{2,29}$=10.4, p<0.001, n=32). As shown in Figure 1B, the SL response tended to decrease in older adults, though this effect was not significant. In contrast, the ML response was substantially and significantly increased in middle-aged and older adults (pairwise comparisons, both p<0.04). Although the origin of the SL motor response is unclear (4), the ML response has been attributed to a virtual semicircular canal signal of head roll, and its direction is congruent with the resulting body sway. Our results therefore demonstrate that the functional balance response evoked by electrical activation of semicircular canal afferents is increased in older people. Since the site of electrical activation bypasses the end organ mechanics, this finding may reflect an increased afferent or central sensitivity in order to compensate for an age-related loss of peripheral vestibular hair cells (1).



A, The relationship between the stimulating current (SVS) and motor response (Fx) was calculated using the cumulant density function. The short latency (SL) and medium latency (ML) components of the SVS-evoked response are indicated by open and filled markers, respectively. B, SL response magnitude tended to be reduced in older adults. In contrast, the ML response was significantly increased. * indicates a significant difference when compared to the young age group (p<0.04). Grey lines indicate 2nd order polynomial fits.

PCA247

The impact of age on upper airway morphology: a risk factor for obstructive sleep apnoea?

E. Carthy[1,2], T. Carlisle[2], M. Glasser[1,2], P. Drivas[3], A. McMillan[1,2], N. Ward[1,2], A.K. Simonds[1,2] and M.J. Morrell[1,2]

[1]Academic unit of sleep and breathing, National Heart and Lung Institute, Imperial College London, London, UK, [2]NIHR Respiratory Biomedical Research Unit, Royal Brompton and Harefield Foundation Trust, London, UK and [3]NIHR Cardiovascular Biomedical Research Unit, Royal Brompton and Harefield Foundation Trust, London, UK

Obstructive sleep apnoea (OSA) is a common disorder, affecting 2-4% of middle-aged adults and rising to >25% in older people. Reduced upper airway calibre and greater pharyngeal length are both associated with an increased risk of OSA; however, the effect of age on upper airway morphology in people with and without OSA is unclear. The aim of this study was to investigate the impact of age on upper airway morphology in healthy older and younger people. **Methods:** Upper airway morphology was assessed using magnetic resonance (MR) imaging in healthy older (>60 years) and younger (<40 years) people who were screened to exclude OSA, and matched for body mass index (BMI) plus neck circumference (NC). MR scans of the upper airway were performed using a 1.5 Tesla MR scanner (Siemens Avanto; T1 weighted, 2D Axial and Sagittal spin echo sequences). Selected upper airway parameters were analysed using ImageJ software (version 1.46r, National Institutes of Health, USA) to determine any group differences; group mean differences were tested using Man Whitney U tests (SPSS, IBM Statistics 19, SPSS Inc., USA). **Results:** Fourteen younger (median (quartile 1-quartile 3): age 27.5 (26.3-31.8)years, BMI 25.9 (23.9-27)kg.m-2; NC 38.5 (37.5-41.0)cm) and 11 older (age 65.0 (63.0-68.5)years, BMI 26.6 (25.2-28.8)kg.m-2; NC 39.6 (38.9-40.4)cm) healthy males were studied with ethical approval. Older subjects had significantly longer pharyngeal airways (older: 8.8 (7.8-9.0)cm, younger: 7.7 (7.0-8.3)cm; p=0.025) and greater soft palate cross-sectional area (older: 43.1 (36.0-48.8)cm2, younger: 35.2 (30.5-40.5)cm2; p=0.003) compared to younger subjects. Moreover, there was a significant increase in parapharyngeal fat-pad thickness and fat-pad cross sectional area in the older group despite controlling for BMI and NC (thickness, older: 1.7 (1.4-2.2)cm, younger: 1.2 (1.0-1.8)cm; p=0.029. Cross sectional area, older: 13.8 (9.1-17.1)cm2, younger: 7.4 (5.9-13.0)cm2; p=0.018). **Conclusion:** Ageing was associated with soft tissue enlargement and lengthening of the pharyngeal airway. We speculate that these changes in upper airway morphology result in a greater propensity to airway collapse during sleep, predisposing older people to an increased risk of OSA.

PCA248

Evidence for refractoriness in a whole-body human balance task

C. van de Kamp[1], P. Gawthrop[2], H. Gollee[2] and I. Loram[1]

[1]HSRI, Manchester Metropolitan University, Manchester, UK and [2]School of Engineering, University of Glasgow, Glasgow, UK

In a sustained movement task, such as human balance, continuous peripheral and serial ballistic intermittent control mechanisms might be integrated [1]. This implies that feedback mechanisms might not act continuously "closed loop" but can be intermittently "open". Intermittent control limits the frequency bandwidth of the human operator and makes it refractory in nature.
Classic experiments by Craik [2] revealed refractoriness in tracking responses to unpredicted, discrete step stimuli closely spaced in time. Recently, we employed a new method of analysis [3] and successfully identified refractoriness in the sustained visuo-manual control of unstable second-order systems [4]. It is, however, unclear whether the observation of refractoriness would generalize to a whole-body movement task like human balance.
In the current study we designed an experimental setup (Fig 1 A) in which participants, standing on both feet, were strapped to a rigid structure that pivots at the ankle joint. This inverted pendulum model of human balance was actuated by a linear motor as a marginally stabilized second order system that run on a computer in real time. Participants controlled the system's position through a myoelectric force signal derived from the combined EMG activity measurements of the tibialis anterior and the gastrocnemius medialis muscles. Visual feedback information about their human-attached-to-structure position was fed back to the participants by means of a sphere displayed on a large TV screen in front of them. The position of the pursuit tracking target was represented by a second sphere on the display (see Fig 1B for the step sequence).
Our method of analysis showed that the goodness of fit of an appropriate order, zero delay ARMA model relating the control signal to the series of paired stimuli step disturbances could be improved by sequentially and individually adjusting the instant of each second step disturbance. This procedure resulted in a distribution of first- and second response times. Results show that the mean (n= 14) response time was significantly higher for the second than for the first stimulus (RT2: 311 ± 145 ms, RT1: 245 ± 145 ms, $F(1, 13) = 15.9$, $p < .005$). The interaction between Stimulus Number and Inter Step Interval, ($F(7, 91) = 9.4$, $p < .0001$) indicates that reducing the ISI had different effects on RT1 compared to RT2 (the two separate post-hoc tests both showed a significant ISI effect). Post-hoc test at each ISI level revealed that first and second response times were significantly different for ISIs up to 500 ms.
These findings suggest that also for this whole-body balance task, the stimulus-response mechanism is refractory in nature; findings that might be better explained by an intermittent- than by a continuous control model.

PCA249

Position played affects cervical spine range of motion of elite female rugby union players

B.B. Zietsman and P.W. McCarthy

Health, science and Sport, University of Glamorgan, Pontypridd, Wales, UK

Elite male rugby union players have a decreased active cervical range of motion the severity of which correlates to years of playing and position played (Lark and McCarthy; 2007, 2010). Although the female game has yet to attain full professional status, the players are still generally subjected to the same game related activities and therefore might be expected to also accumulate degenerative changes in vertebral joints. This study was therefore designed to determine if playing a contact sport such as rugby union decreases cervical (neck) active flexion/extension in the elite female game.
Methodology
The protocol used in this study is the same as that described previously (Lark and McCarthy, 2007). Female Welsh interna-

tional Rugby Union players in the 2011 pre-season training camp squad were invited to participate (age 24 ±4yrs) volunteered. Exclusion criteria included: current neck pain or trauma, previous surgery or serious pathology/trauma to the cervical spine. A cervical range of motion device (CROM device; Performance Attainment Associates, Minnesota, USA: Capuano-Pucci et al, 1991; Youdas et al,1991) was used to measure active cervical range of motion (ACROM) following a warm up procedure. From the neutral point full flexion and full extension were measured in no set order, (to reduce potential order effects). Ethical approval was granted by The Faculty of Health Science and Sport's Ethics Committee, University of Glamorgan, written informed consent was obtained.

Statistical Analysis

The data was normally distributed (Shapiro-Wilkes), therefore, unpaired T-tests and Cohen's d coefficient of effect size were used to compare Forwards and Backs: see Table 1, all data presented as mean ±1 standard deviation (SD).

Results

Of 35 volunteers, 29 were included. Exclusions: 4 pain on extension, 2 recent severe trauma (whiplash). The 15 Backs (age 24±5 yrs: 3.7±3.9 yrs playing elite) were compared to the 14 Forwards (age 24±4 yrs; 3.8±3 yrs playing elite); see Table 1.

Discussion

These findings confirm that playing in the forward position in elite rugby union is especially associated with a decrease in ACROM regardless of sex. Neck girth is unlikely to be responsible for the difference (Reynolds et al, 2009). This suggests that female elite rugby union players have a similar risk of accelerated degeneration of the vertebral joints as their male counterparts. Further research is needed to determine cause.

Anthropomorphic and ACROM data for position of play

Table 1	Mass(Kg)	Height(m)	Neck(cm)	Age(yrs)	Flexion (degrees)	Extension(degrees)	Total ACROM (degrees)
Forwards (n=14)	78.0±8.3	1.7±0.1	35.7±1.4	24.2±4.2	46.7±16.7	57.3±8.8	104.0±16.6
Backs (n=15)	65.0±8.4**	1.7±0.1	33.8±1.3**	24.1±5.0	56.0±17.5	66.1±17.2*	122.1±19.9**

Data presented as mean ±1SD: * indicates $p<0.05$ and ** $p<0.01$ (t-test; 2-tailed). Effect size (Cohen's d): extension ACROM 0.65 and total ACROM 0.99.

Physics-based soft-tissue modelling and simulation

M.A. Warburton and S.C. Maddock

Computer Science, The University of Sheffield, Sheffield, South Yorkshire, UK

Introduction

Physics-based techniques enable more accurate simulations to be produced [1]. We present an approach for easy automatic model creation and efficient GPU-based finite element (FE) simulation of gross and fine-scale soft-tissue behaviour, including skin wrinkles. Focussing on the forehead region of the face, we simulate both large areas of soft tissue, and detail such as skin layers (necessary to produce wrinkles [2]), unlike current approaches [3]. Our approach could be used in a variety of fields, from animation to surgical simulation, and it can be used to simulate any multi-layered soft body.

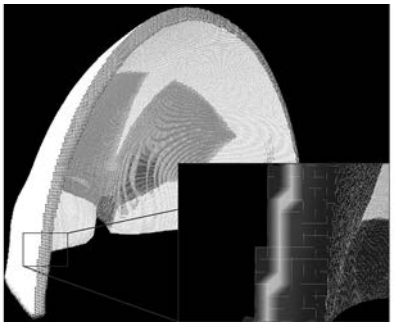
Simulation Approach

Our simulation approach involves three stages: creating the multi-surface mesh, creating a suitable simulation model, and simulating the model over time. Any surface mesh can be used. The model creation system then automatically constructs simulation-ready non-conforming (voxel-based) hexahedral FE simulation models with bound surface meshes [4]. This includes automatic computation of skin layers and material properties, muscle properties (such as fibre directions) from NURBS volumes, and boundary conditions.

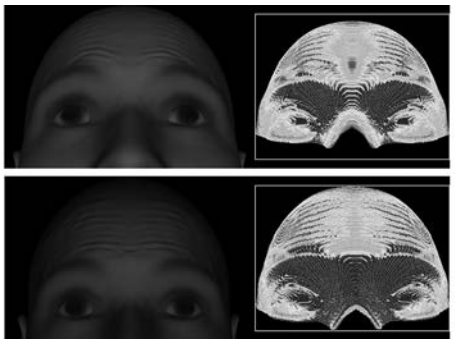
Our GPU-based non-linear total Lagrangian explicit dynamic (TLED) FE system includes procedures for muscle contraction, and to enable the non-conforming elements to slide along a surface, such as the skull or deep tissue boundary (a phenomenon often neglected [5]), facilitated using a GPU-based semi-brute-force broad-phase collision detection algorithm. The solver has also been optimised for use with our non-conforming models [4]. Figures 1 and 2 show some example models and simulations.

Conclusions

Examples have demonstrated the complexity of models that our approach can generate, and their ability to simulate gross and fine-scale soft-tissue behaviour. Improvements could be made, for example, by using shell elements to better model the thickness of the epidermis. Future work will focus on simulating different-aged skin, and using different material models.



Rear view of a forehead model. Dark spheres represent rigid (fixed) nodes, light spheres represent sliding nodes, and coloured elements overlap a muscle. The material stiffness of the skin layers is visualised in the inset.



Simulation examples of forehead models with different muscle structures under contraction of the frontalis. Insets visualise the stresses.

Pointing at and tracking falling targets: Directional aspects of an internal model of gravity

J.C. Flavell, I.D. Loram and D.E. Marple-Horvat

School of Healthcare Science - IRM, Manchester Metropolitan University, Manchester, Greater Manchester, UK

Gravity acts vertically downwards in the real world. By internalising that reality as an internal model we should perform better when relating to objects 'falling' naturally downwards rather than in some other direction. Several studies have shown that expectation of gravity's effect on vertically descending or ascending targets can over-rule visual information to the contrary (1-3), but this has not been explored for other 'unnatural' directions. We sought evidence for an internal model of gravity by comparing visually guided tracking of objects accelerating at *g* (9.81m/s^2) in straight lines vertically downwards, upwards and horizontally. If a model exists, differences should exist between tracking natural versus unnatural trajectories.

For each direction, 17 subjects executed 3 tracks of a 15cm diameter realistic visual target 'falling' from stationary for 2.475m. The target was back-projected onto a screen 3m ahead of subjects. Tracking was by extending the dominant hand's index finger and pointing at the moving target. Tracking intercept (indicated position on the screen) was determined using a vector from the dominant eye past the fingertip to the screen. Vicon tracked movements. The instantaneous error (tracking position minus target position) was summed in 10ms steps over the time taken for the target to traverse 2.475m (730ms) as a measure of performance. Tracking ahead produced negative error values, and tracking behind positive values.

Direction significantly affected error (one-way ANOVA: F=31.57, p<.001). Post hoc tests revealed all errors were significantly different from one another (p<.001): descending M=-8.405m SD=2.342; ascending M=18.426m, SD=10.022, horizontal: M=7.755m SD=6.965). Tracking, the output of the manual tracking controller, was below the target: leading descending targets and lagging behind ascending targets. Starting errors were also below the target in all conditions. To judge one's tracking position, one is required to keep both finger-tip and target in sight. Due to the physical presence of the arm/hand/finger one must ensure that the target is above the tracked location to prevent total or partial target occlusion. Error when tracking a target accelerating upwards was more than double that for a target accelerating naturally downwards, and tracking fell behind for a horizontally accelerating target. These different errors for different directions suggest that subjects expected non-descending (rising or horizontally moving) targets would not accelerate in the same way as a free-falling target.

This pattern of results suggests subjects used an internal model of gravity to predict the future position of 'free-falling' targets and that the model is directionally tuned. Also, such tuning is evidence that subjects did not use either feedback or direct perception when tracking.

Effects of diabetic peripheral neuropathy on muscular activations during stair descent

J.C. Handsaker[1], A.J. Boulton[2], F.L. Bowling[2], S.J. Brown[1], G. Cooper[1], C.N. Maganaris[3,1] and N.D. Reeves[1]

[1]IRM, Manchester Metropolitan University, Manchester, UK, [2]University of Manchester, Manchester, UK and [3]Liverpool John Moores University, Liverpool, UK

Introduction

People with diabetic peripheral neuropathy (DPN) are more likely to fall than age-matched controls, and are particularly at risk during the physically demanding task of stair descent. The timing of lower limb muscle activations is fundamental to controlling joint movement and enabling a safe descent, but such timings may be adversely affected by diabetes and DPN. The aim of this study was to investigate the effect of DPN and diabetes on muscular activations during stair descent.

Methods

12 DPN patients, 12 diabetic patients without neuropathy (D) and 10 age and BMI-matched controls (C), descended a 7 step staircase. Electromyographic (EMG) activity was recorded from the vastus lateralis (VL) and biceps femoris (BF), medial gastrocnemius (MG) and tibialis anterior (TA) muscles, from which onset, cessation, and duration timings relative to footstep contact (FSC) were obtained (Figs. 1 & 2). A one-way ANOVA was used to analyse between group differences (significance p<0.05).

Results

The MG muscle was activated significantly earlier relative to FSC by the DPN group compared to controls, but the D group displayed similar activation timings to controls (Fig. 1). Both the DPN and D groups activated the TA muscle significantly closer to FSC than the C group. The DPN group activated the MG and TA muscles for significantly longer than the C group (Fig. 1).

There were no significant differences between groups for the onset of VL or BF muscle activation (Fig. 2). DPN and D patients activated the VL muscle for a similar duration to the C group, but the DPN group activated the BF muscle for a significantly longer duration compared to the C group (Fig. 2).

Discussion

Differences in muscle activation strategy were observed primarily at the ankle joint, with the DPN group activating MG and TA muscles significantly earlier and later, respectively, than the C group. This modified activation strategy may indicate increased dependence on the plantar flexors to control ankle dorsiflexion upon FSC during stair descent. The DPN group also activated the MG and TA muscles for longer compared to controls, which is likely a mechanism to improve ankle stabilisation. The D group displayed alterations to muscle activation in the same pattern to that of the DPN group, but to a lesser extent, highlighting the progressive nature of diabetes.

The DPN group activated the BF muscle for a longer duration than the C group, but no other differences in muscle activation were observed between groups at the knee joint, further highlighting the predominantly distal adaptation of the stair descent strategy adopted by patients with DPN.

Low-dose L- arginine supplementation improved total antioxidant activity and erythrocyte integrity in sickle cell anaemia subjects

S.I. Ogungbemi[1], C.N. Anigbogu[1], M.O. Kehinde[2] and S.I. Jaja[1]

[1]Department of Physiology, University of Lagos, Lagos, Nigeria and [2]Medicine, university of Lagos, Lagos, Nigeria

Low L- arginine concentration ([R]) has been reported in sickle cell anaemia (SCA). L- Arginine supplementation may be a cheaper alternative to the very expensive inhalation of nitric oxide in the management of SCA in Nigeria. The study investigated the effect of low-dose (1 g/day), oral L- arginine (Mason Vitamins, INC. USA) supplementation on plasma [R], lipid peroxidation (LPx), total antioxidant activity (TAA), red cell osmotic fragility and irreversibly sickled cell (ISC) count. 33 male and female non-sickle cell anemia subjects (NSCAS) and 28 sickle cell anaemia subjects (SCAS) were studied. A written ethical approval was granted for the study (Medical Research Grant and Experimentation Ethics Committee, College of Medicine University of Lagos, Nigeria). Each subject gave informed consent. 5 mL of venous blood was withdrawn from an ante-cubital vein of each subject for the measurements of plasma [R] (Li et al., 2008), malondialdehyde ([MDA] for LPx), TAA (Koracevic et al., 2001), osmotic fragility and ISC count. L- Arginine was then taken orally (1 g/day/6 weeks, Tanimura, 1967) by each subject. Measurements were made before and after L-arginine supplementation. Before supplementation, TAA (1.0±0.1 vs 1.5±0.2 mM/L, P<0.05) and [R] (8.3±0.7 vs 12.4±0.5 mg/dL, P<0.001) were low in SCAS compared to NSCAS while [MDA] (41.4±0.4 vs 33.0±2.0 mM/mg prot, P<0.001), initial lysis (IL: 0.86±0.01 vs 0.63±0.02 g%, P<0.001) and mean corpuscular fragility (MCF: 0.40±0.01 vs 0.45±0.01 g%, P<0.05) were high in SCAS compared to NSCAS. L- Arginine increased TAA (1.0±0.1 vs 1.6±0.2 mM/L in SCAS and 1.5±0.2 vs 2.0±0.1 mM/L in NSCAS, P<0.05) and [R] (8.3±0.7 vs 15.2±0.4 mg/dL in SCAS and 12.4±0.5 vs 18.8±0.6 mg/dL in NSCAS, P<0.001). However, [MDA] (41.4±0.4 vs 14.9±1.1 mM/mg prot in SCAS and 33.0±2.0 vs 14.2±0.7 mM/mg prot in NSCAS, P<0.001), IL (0.86±0.01 vs 0.57±0.02 g% in SCAS and 0.63±0.02 vs 0.49±0.02 g% in NSCAS, P<0.001), MCF (0.40±0.02 vs 0.23±0.01 g% in SCAS and 0.45±0.01 vs 0.22±0.02 g% in NSCAS, P<0.001), complete lysis (0.21±0.02 vs 0.11±0.02 g% in SCAS and 0.22±0.02 vs 0.01±0.01 g% in NSCAS, P<0.001), (and ISC count: 7.9±1.2 vs 2.0±0.3 %, P<0.001 in SCAS only) were reduced after supplementation. L- Arginine caused a greater percent increase in TAA (60.0±10 vs 33.0±6.7 %, P<0.05) and [R] (83.1±3.6 vs 51.6±0.8 %, P<0.001) while reduction in IL was greater (0.29±0.01 vs 0.14±0.01 g%, P<0.001) in SCAS than in NSCAS. Δ[R] correlated with ΔTAA (r=+0.8), Δ[MDA] (r=-0.7) and ΔISC (r=-0.6) in SCAS. Δ[R] correlated with ΔTAA (r=+0.6) and Δ[MDA] (r=-0.5) in NSCAS. Low-dose, oral L- Arginine improved TAA, red cell resistance to osmotic haemolysis and [R] but suppressed LPx in both groups of subjects and reduced ISC count in SCAS. L- Arginine may have beneficial implications in cost effective therapy in the management of SCA.

The change in diastolic blood pressure during autonomic blockade is associated with T50 and error signal in young and older women

A.B. Peinado[1,2], E.C. Hart[3], N. Charkoudian[4], M.J. Joyner[2] and J.N. Barnes[2]

[1]Department of Health and Human Performance, Technical University of Madrid, Madrid, Spain, [2]Department of Anesthesiology, Mayo Clinic, Rochester, MN, USA, [3]Department of Physiology and Pharmacology, University of Bristol, Bristol, UK and [4]Thermal and Mountain Division, U.S. Army Research Institute of Environmental Medicine, Natick, MA, USA

Background: Understanding age-related changes in blood pressure regulation is key to preventing and treating hypertension. The blood pressure error signal represents the difference between resting diastolic blood pressure (DBP) and the T50 value, the DBP at which 50% of cardiac cycles are associated with bursts of muscle sympathetic nerve activity (MSNA). We have previously shown that both the T50 and the error signal are different between young men and women, suggesting that sex hormones may have an important influence. The purpose of the present study was to evaluate whether T50 and the error signal relate to the extent of change in blood pressure during autonomic blockade (AB) in young and postmenopausal women. Methods: In 12 young women (YW; 25 ± 1 yrs) and 12 postmenopausal women (PM; 61 ± 2 yrs), we measured MSNA using microneurography, and intra-arterial brachial blood pressure before and during complete AB with trimethaphan camsylate. Relationships between MSNA, T50, error signal (T50-DBP) and ΔDBP with AB were measured using linear regression analysis and Pearson's correlation coefficient. For mean data comparison between YW and PM an unpaired t test was used. Results: ΔDBP was associated with baseline T50 (r=-0.739, p<0.001), indicating that a greater reduction in DBP during AB was associated with higher T50 values in PM women (74.4±7.6 mmHg; r=-0.725, p=0.008) but not in young women (65.7±5.1 mmHg; r=-0.337, p=0.285). There was also an inverse relationship between ΔDBP and the error signal, but only when all women are grouped together (r=-0.715, p<0.001). This means that women who operate at a higher BP than their T50 (i.e. a negative error signal) have a smaller change in DBP when autonomic tone is removed. Women with the most negative error signal (DBP much higher than T50) had the lowest average MSNA (r=0.910, p<0.001) in both groups (YW: r=0.886, p<0.001; PM: r=0.870, p<0.001). Young women had more negative error signals than PM women (-7.6±5.2 versus 2.1±4.6 mmHg, p<0.001; respectively), and lower average MSNA (15.5±4.9 versus 32.9±10.2 bursts/min, p<0.001; respectively). Conclusions: Using T50 and error signal analysis, we have identified important differences in control of MSNA between young and PM women. Postmenopausal women had higher T50 values, more positive error signals, and greater drops in DBP during autonomic blockade. These data are consistent with recent reports from our laboratory regarding greater autonomic support of blood pressure in PM women, and provide further evidence of the importance of reproductive hormone influences on sympathetic mechanisms controlling blood pressure in women.

Stimulation of the otolith organs by ultrasonic bone stimulation of the mastoid increases muscle sympathetic nerve activity in humans

C.A. Ray and C.L. Sauder

Medicine, Penn State College of Medicine, Hershey, PA, USA

Muscle sympathetic nerve activity (MSNA) is altered by stimulation of the vestibular system. Studies indicate that the otolith organs mediate increases in MSNA when engaged by head-down rotation (HDR). These findings are important with regards to postural blood pressure regulation on earth and post-spaceflight orthostatic intolerance. It is currently unknown if nongravitational activation of the otolith organs can mediate increases in MSNA. One method believed to stimulate the otolith organs is ultrasonic bone stimulation (UBS) of the mastoid. To test the hypothesis that UBS can augment MSNA we measured leg MSNA, heart rate, and arterial blood pressure during gravitational stimulation of the otolith organs by HDR and during stimulation of the mastoid via UBS in 14 healthy subjects (4 men and 10 women; age: 25 ± 4 yr; BMI: 24 ± 4 kg/m2). UBS of the mastoid elicited a significant increase in leg MSNA (3 ± 1 bursts/min, 31 ± 10% total activity; P < 0.05). This increase in MSNA via UBS was comparable to HDR (4 ± 1 bursts/min, 35 ± 8% total activity; P < 0.05). UBS of the clavicle (n=10), which served as a control, did not increase MSNA. In all studies, HDR and UBS did not change heart rate or mean arterial blood pressure. These results indicate that UBS stimulation can elicit sympathetic outflow and may assist in maintaining peripheral resistance and arterial blood pressure during orthostatic challenges.

PCA258

Evidence for beat-to-beat myogenic responses in the regulation of resting limb blood flow in man

P.J. Fadel[1], S.T. Fairfax[1], M. Takahashi[2], M.J. Davis[1] and J. Padilla[1]

[1]Medical Pharmacology & Physiology, University of Missouri, Columbia, MO, USA and [2]Institute of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan

Previous work assessing the presence of myogenic responses in humans has primarily used experimental manipulations to evoke robust changes in transmural pressure. Although providing evidence for a myogenic response, such manipulations do not provide information about potential contributions of myogenic responses to beat-to-beat limb blood flow control during unprovoked resting conditions. Therefore, we explored spontaneous beat-to-beat relationships between arterial blood pressure (Finapres) and limb blood flow (duplex Doppler ultrasound in brachial and popliteal arteries) during 10 min of quiet supine rest in 15 young men. In addition, considering previous work demonstrating the presence of a myogenic response in the cutaneous circulation, measurements in the brachial artery were repeated with a wrist cuff inflated to 220 mmHg to occlude the hand circulation and thus, eliminate a major portion of skin blood flow. Cross correlations between mean

arterial pressure (MAP) and blood flow were determined using Pearson correlations in which MAP values were systematically offset by ±10 cardiac cycles relative to its real time associated blood flow. Repeated measures ANOVA was used for comparisons and data are presented as means ± standard errors. For both the brachial and popliteal artery, limb blood flow was negatively influenced by MAP such that higher pressures were associated with lower blood flows and vice versa. Indeed, significant negative correlations between MAP and blood flow were observed in both arteries (Figure 1A). Furthermore, the strongest negative relationship was observed when MAP was offset by 2 preceding heartbeats suggesting a consistent time-lag was present. Interestingly, the negative relationship between MAP and brachial artery blood flow was significantly attenuated by wrist occlusion (Figure 1B). These preliminary findings suggest that myogenic responses are detectable on a beat-to-beat basis in human limbs and contribute to the regulation of resting limb blood flow. Furthermore, it appears that the cutaneous circulation is necessary to fully observe the influence of the myogenic response in the forearm. However; partitioning the contributions of cutaneous and skeletal muscle circulations to the observed myogenic responses requires further investigation.

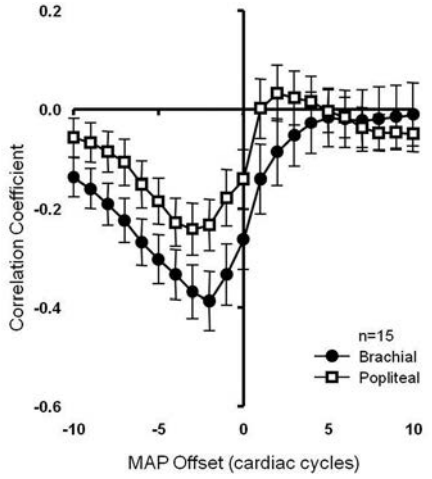

Figure 1A: Correlation coefficients relating MAP and blood flow in the politeal and brachial artery as MAP is offset by ±10 cardiac cycles relative to its real time associated blood flow (0 on x-axis).

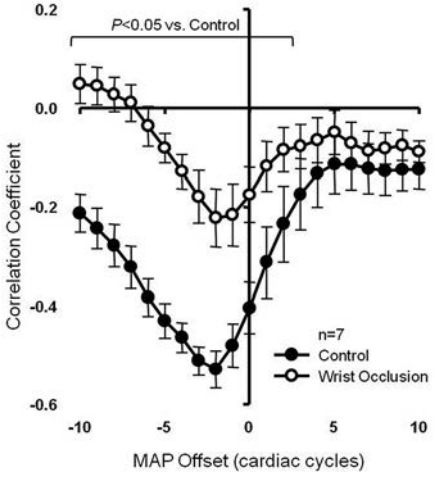

Figure 1B: Correlation coefficients relating MAP and blood flow in the brachial artery before (control) and during wrist cuff occlusion.

Cardiovascular response to aerobic exercise training is attenuated in middle-aged adults with polymorphism of eNOS gene at position intron 4 a/b: A double-blind study

A. Zanesco, C.H. Sponton, R. Esposti, C.M. Rodovalho, M.J. Ferreira, A.P. Jarrete, C.P. Anaruma and M. Bacci

UNESP, Rio Claro, Sao Paulo, Brazil

We have demonstrated that postmenopausal women with endothelial nitric oxide synthase (eNOS) gene polymorphism at position -786T>C are less responsive in lowering blood pressure after exercise training than those who are not polymorphic (TT genotype),[1]. This response was accompanied by lower nitric oxide (NO) production, measured by plasma nitrite/nitrate. Interestingly, variable number of tandem repeat Intron 4b/a of the eNOS gene has also been associated with reduction in plasma NO levels, decreased eNOS expression or reduced enzyme activity[2]. However, no studies exist evaluating the influence of Intron 4b/a of the eNOS gene in the cardiovascular responses and oxidative stress biomarkers in response to aerobic exercise training (ET) in adults. Therefore, we investigated the relationship between eNOS polymorphism at position Intron 4 a/b and the effect of ET on the blood pressure (BP), nitrate/nitrite levels (NOx-) and oxidative stress biomarkers (superoxide dismutase - SOD, catalase - CAT and malondialdehyde - MDA) in middle-aged adults. Eighty-one subjects (51.1±0.6 yrs) were trained in treadmill, 3 days/week, for 30-40 min/session at moderate intensity, during 24 sessions. A comparison between sphygmomanometer-based and ambulatory BP monitoring (ABPM) was carried out before and after ET. Genotype analysis was performed using sequencing method (ABI3500–Applied Biosystems). All the data acquisition and analysis were performed in a double-blind manner. The volunteers were divided into non-polymorphic (Intron 4bb, n=55) and polymorphic (Intron 4ba+aa, n=26). ET were effective in lowering BP measured by sphygmomanometer-based for both systolic (-4.6mmHg) and diastolic BP (-2.6 mmHg) whereas in ABPM measurements only systolic BP values were significantly reduced (-2.4mmHg) in non-polymorphic group (genotype bb). These beneficial effects were accompanied by increased SOD (+11.7 U/ml) and CAT (+7.9 nmol/ml/min) enzymes activity. In contrast, adults who carry eNOS gene polymorphism for intron 4 a/b (genotype 4ba+aa) showed no changes in BP for both methods, acute and measurement during 24 hr. Interestingly, an increase in SOD (+12.1 U/ml) and CAT (+10.2 nmol/ml/min) enzymes activity were found in polymorphic group. No changes were observed in plasma NOx- and MDA concentrations in response of ET for both genotypes (intron 4bb and 4ba+aa). Our findings show that the polymorphism of eNOS gene at intron 4b/a position attenuated the benefits of the exercise training in lowering blood pressure, but did not affect the antioxidant enzymes activity.

Young adult asian males have a lower baro-reflex gain compared to matched caucasians, as measured by heart rate variability analysis

D.A. Saint, L. Casey and A. Elliott

University of Adelaide, Adelaide, SA, Australia

INTRODUCTION: Racial and ethnic differences in risk for cardiovascular morbidity and mortality are well documented. The relative role of genetic vs environmental influences is unclear. A non-invasive measure of autonomic balance, Heart Rate Variability (HRV) has been shown to be correlated with cardiovascular risk in some populations. Whether there are underlying differences in HRV between racial and/or ethnic groups, and whether this might therefore affect cardiovascular risk, is largely unknown.
HYPOTHESIS: Young Asian males will have a higher HRV than matched Caucasians and will show a lower response to postural changes.
METHODS: Subjects were in two groups; 1) Caucasian males aged 18 to 25 living all their life in Australia (n=20) and 2) age and BMI matched Asian males ("Asian" being defined as south east Asia, excluding the Indian sub-continent) resident in Australia (n=30).
Subjects abstained from exercise, consuming alcohol, caffeine or guarana for 2 hours prior to the experiment. After 2 min acclimatisation, either standing or supine, the subject's ECG was recorded for 15 min and HRV analysis conducted with AD Instruments (Australia) Chart 5/HRV module. The time domain measure used was SDdeltaNN, Frequency domain analysis used power spectral analysis to derive LF:HF ratio.
RESULTS: There were no significant differences in age, BMI, hip:waist ratio or heart rate between the groups. There were no differences in blood pressure, except standing systolic blood pressure (137.2 ± 5.2 mm.Hg in Caucasian vs. 123.8 ± 2.8 mm.Hg in Asians; P<0.05).
For both groups there was a significant decrease in SDdeltaNN and an increase in LF:HF ratio when standing compared to supine. Each of these changes was significantly larger for Caucasians compared to Asians for both measures (table 1).
CONCLUSIONS: When moving from supine to standing, Asian subjects showed a lesser fall in HRV by both time domain and frequency domain measures compared to Caucasians. This appears to be because they have a larger reduction in vagal tone during this postural change. This may indicate a genetic difference between groups, and provide insight to the racial differences in risk for cardiovascular mortality and morbidity.

Table 1

SD delta NN	supine		standing		change	
	mean	SD	mean	SD	mean	SD
Asian	46.10	3.85	26.76	6.09	-19.35	5.29
Caucasian	72.47	8.07	24.88	1.96	-47.59	7.44
p	**		ns		**	
LF:HF ratio	supine		standing		change	
Asian	1.43	0.77	4.76	2.55	3.32	2.23

PCA262

Capsaicin-based analgesic balm attenuates the skeletal muscle metaboreflex in humans

L.C. Vianna, I. Fernandes, T. Barbosa and A. Nóbrega

Physiology and Pharmacology, Fluminense Federal University, Niterói, Rio de Janeiro, Brazil

While it is well established that the exercise pressor reflex (EPR) is one of the principal mediators of the cardiovascular response to exercise, the receptors activating the group III and IV fibres that are important to EPR function remains unclear. Recent animal studies have reported that either capsaicin balm or infusion of capsazepine attenuates the pressor response to muscle contraction, indicating the transient receptor potential vanilloid1 (TRPv1) receptor (localized on the group IV afferent neuron) as an important mediator of the EPR via its metabolic component (named muscle metaboreflex). Whether these findings can be extended to human remains to be determined. To begin to address this question, blood pressure (BP, Finometer), muscle sympathetic nerve activity (MSNA, peroneal microneurography) and femoral blood flow (FBF, Doppler Ultrasound) were measured in five male subjects (24±2 yrs) at rest, during static handgrip exercise at 40% maximal voluntary contraction, and during post-exercise muscle ischemia (PEMI) to isolate the metabolic component of EPR. Trials were performed before (T0) and at 30 (T30) and 60 min (T60) after application of a commercially available analgesic balm, containing capsaicin as the active ingredient (0.1%, CAPZASIN-HP), on the volar forearm of the subject's non-dominant arm in a similar manner to that described in the manufacturer's directions. Statistical comparisons of all physiological variables were made utilizing paired t-tests and data are presented as means ± SE. Static exercise evoked increases in mean BP (+32±4 mmHg, P<0.05), MSNA (+26±5 bursts/min, P<0.05; +19±5 bursts/100 heart beats, P<0.05). The BP and MSNA responses to forearm static contraction were not affected by the application of capsaicin balm. During PEMI at T0, BP (+31±4 mmHg, P<0.05), MSNA (+27±5 bursts/min, P<0.05; +36±5 bursts/100hb, P<0.05) remained elevated compared with rest. Additionally, femoral vascular conductance (the ratio of FBF to BP) was slightly but significantly attenuated from rest during PEMI (-0.72±0.2 mL/min/mmHg, P=0.05), indicating reflex vasoconstriction. After application of capsaicin balm, the BP (+25±4 mmHg at T30; +25±2 mmHg at T60, P<0.05 vs. T0) and MSNA (+17±4 bursts/min and +21±5 bursts/100hb at T30; +15±2 bursts/min and +21±4 bursts/100 hb at T60; P<0.05 vs. T0) responses to PEMI were all significantly less than those observed at T0. Capsaicin balm also attenuated vasoconstrictory responses to PEMI (+0.27±0.18 mL/min/mmHg at T30; -0.24±0.18 mL/min/mmHg at T60, P<0.05 vs. T0). In conclusion, capsaicin-based analgesic balm effectively attenuated BP, sympathetic and vasconstrictory responses evoked by metabolically sensitive skeletal muscle afferents in humans. These data are consistent with the concept that TRPv1 receptors contribute to the EPR in humans, via its metabolic component.

Enhanced cardiovascular responses is associated with increased orthostatic tolerance in young men following oral glucose and Vitamin C ingestion

T. Usman, V.A. Olatunji, A.O. Adah and L.A. Olatunji

Physiology, University of Ilorin, Ilorin, Nigeria

Background — Recent studies have shown that ingestion of glucose or vitamin C lowers blood pressure in patients with autonomic dysfunction, and modestly reduce blood pressure in normal subjects. Whether oral glucose loading with vitamin C ingestion affects cardiovascular responses during orthostatic stress in normal young subjects is yet to be determined. We therefore hypothesized that co-administration of glucose and vitamin C will reduce orthostatic tolerance in normal young male volunteers. Methods: In a randomized controlled cross-over fashion, nine non-obese (19.3 ± 0.6 kg/m2), young (21.9 ± 0.6 yr) men ingested nothing (control), glucose (75g) alone and with Vitamin C (1g) 10 min before standing on three separate days of appointment. We measured supine and standing blood pressure, heart rate, haematocrit and blood glucose levels. Orthostatic tolerance was evaluated as the time to presyncope during motionless standing or until presyncopal symptoms were observed. Results: During the first 60 min of standing, 89%, 78% and 0% of subjects experienced presyncopal symptoms when ingested nothing, glucose alone and glucose+vitamin C, respectively. Ingesting glucose alone did not affect orthostatic tolerance (61.4 ± 1.4 vs 63.0 ± 1.7min; $p < 0.05$) while ingesting glucose with vitamin C significantly improved orthostatic tolerance (86.6 ± 2.2 vs 63.0 ± 1.7 min; $p< 0.001$). Increases in systolic blood pressure and heart rate induced by standing were significantly enhanced when glucose+vitamin C was ingested, while changes in diastolic blood pressure were not significantly affected. Ingestion of glucose alone or with vitamin C led to a comparable significant increase in blood glucose levels after standing. However, significant increase in haematocrit level was observed after standing when glucose+vitamin C but not when glucose alone was ingested. Conclusion: The results of the present study demonstrate that oral glucose loading with vitamin C ingestion improves orthostatic tolerance, and the improvement is associated with enhanced systolic blood pressure, heart rate and haematocrit level.

Yogic practices can increase estrogen and progesterone levels and heart rate variability in peri-menopausal women

R. Khadka[1], B.H. Paudel[1], S. Majhi[2], N. Shrestha[3], M.C. Regmi[4], S. Chhetri[4], A. Das[1], D. Sharma[1], V. Gautam[1] and P. Karki[3]

[1]Basic and Clinical Physiology, BP Koirala Institute of Health Sciences, Dharan, Nepal, [2]Department of Biochemistry, BP Koirala Institute of Health Sciences, Dharan, Nepal, [3]Department of Internal Medicine, BP Koirala Institute of Health Sciences, Dharan, Nepal and [4]Department of Obstetrics and Gynecology, BP Koirala Institute of Health Sciences, Dharan, Nepal

Higher death rate has been reported in postmenopausal or perimenopausal women with cardiovascular events than in men. Reduced estrogen production from ovaries has been suggested as one of its factors. Studies with estrogen therapy have shown cardio-protective effects. However, estrogen has proliferative effect on breast and its long-term use may be carcinogenic. One of the alternative therapies, yoga has been found to reduce the levels of testosterone and luteinizing hormone in hirsutism. Therefore, we aimed to study the effect of yoga on female sex hormone level and heart rate variability in perimenopausal women. Consenting twenty perimenopausal women were randomized into yoga (n=10, age 44±2.64 years) and control (n=10, age 46±5.09 years) groups. Subjects suffering from any diseases or on medication were excluded from the study. Yoga group practiced meditation, pranayama (breathing exercise) and few easy asnas (postures) for 30 min/day for a month. Control group did not do any yoga/relaxation or any active relaxation procedures. Short-term heart rate variability was recorded in all subjects at zero and one month. Institutional ethical committee approved the work. Both groups were comparable in term of their age, height, weight, BMI, systolic BP, diastolic BP, heart rate, and respiratory rate. Time domain measures of HRV, which are primarily markers of cardiac parasympathetic activity [SDNN: 23.93(18.5-35.4) vs 43.2(34.4-50.1) ms, p=0.014; rMSSD: 17.3(12.45-21.85) vs 30.6(25.15-38.05) ms, p=0.022; NN50: 1(0.25-8.5) vs 34(11-60.5) count, p=0.022] were found increased in yoga group as compared to control group after yoga. High frequency power, which is also one of the markers of parasympathetic activity, increased in yoga group as compared to control group. Both serum estrogen [11.95(5.05-41.32) vs 24.47(12.54-64.90) pg/ml, p=0.036] and progesterone [0.24(0.10-1.02) vs 2.0(0.25-9.73) ng/ml, p=0.012] levels were found increased in yoga group after yogic intervention. In conclusion, parasympathetic activity, estrogen and progesterone levels increased in perimenopausal women after a month of yoga practice. Increased parasympathetic activity and female sex hormone levels indicate that yoga can be a cardioprotective alternative therapeutic measure in perimenopausal women.

Cerebrovascular reactivity is associated with central pulse wave characteristics in healthy adults

J.N. Barnes[1,2], J.L. Taylor[1] and M.J. Joyner[1]

[1]Anesthesiology, Mayo Clinic, Rochester, MN, USA and [2]Physiology and Biomedical Engineering, Mayo Clinic, Rochester, MN, USA

Cerebrovascular reactivity determines the responsiveness of the cerebral vessels to vasoactive stimuli. However, acute changes in blood pressure may augment the calculated cerebrovascular reactivity. If autoregulatory mechanisms within the brain are intact, fluctuations in blood pressure will not alter cerebral blood flow. Because aging and hypertension may reduce autoregulation, cerebrovascular reactivity is often calculated using conductance to account for changes in mean arterial pressure (MAP). Yet, MAP may underestimate the influence of central hemodynamics on cerebral blood flow. In this context, we investigated whether central pulse wave characteristics were associated with cerebrovascular reactivity in healthy humans. Hypercapnia was used to determine cerebrovascular reactivity of the middle cerebral artery (MCA) in 28 adults (14 men and 14 women) using transcranial Doppler. MAP was measured using finger photoplethysmography and central pulse wave characteristics (i.e. aortic blood pressure, augmented pressure, augmentation index) were determined using arterial tonometry. Baseline MCA velocity was 48.6 ± 3.9 cm/s and cerebrovascular reactivity was 0.79 ± 0.08 AU. Aortic systolic (110 ± 2 mmHg) and diastolic (72 ± 1 mmHg) blood pressure were not associated with cerebrovascular reactivity. However, cerebrovascular reactivity was inversely associated with augmented pressure (8.3 ± 1.0 mmHg; r = -0.43; p<0.05), augmentation index (21.1 ± 2.3 %; r = -0.52; p<0.01), and augmentation index corrected for heart rate (12.1 ± 2.6%; r= -0.50; p<0.01). In conclusion, higher augmentation of the central pulse wave is associated with lower cerebrovascular reactivity in healthy adults. Our results suggest that cerebral blood flow regulation may be affected by central pulse wave characteristics.

Heart rate variability: the impact of hypoxia and gender

D. Hodson, C.J. Marley, L. Fall, K. Evans, D. Whitcombe, J.V. Brugniaux, K.J. New and D.M. Bailey

University of Glamorgan, Pontypridd, UK

Introduction:
Non-invasive measurements of heart rate variability (HRV) are used to assess cardiovascular autonomic regulation. HRV can be measured using time and frequency domain indexes; changes in these indexes are considered to reflect changes in the parasympathetic and sympathetic modulation (1). A reduction in HRV, with an increase in low frequency (LF) component and LF/HF (high frequency) ratio are common findings when at high altitude, highlighting a shift towards sympathetic modulation and a decline in the vagal activity (2), Little is known regarding the impact of gender on HRV. And existing literature is inconclusive suggesting that females exhibit either an increase (3) or a decrease (4) in HRV measurements when compared to males in normoxia. Therefore, the present aim was to investigate the effect of acute hypoxia and gender on the cardiovascular autonomic function.
Methods:
Sixteen healthy physical activity subjects (6 males, 10 females) aged 26 ± 7 years, 29 ± 6 years (respectively) underwent a 5-minute supine HRV measurement in normoxia (21% O2) and following 4 hour exposure to normobaric hypoxia (12% O2). The following parameters of HRV were calculated: Time domain indexes: standard deviation of RR intervals (SDNN), root-mean-square of successive normal RR interval differences (RMSSD); Frequency domain indexes: Total power (TP, 0.0 – 0.40Hz), LF/HF ratio, HF normalised power (HFnu) calculated as the HFnu =(absolute HF power/TP)x100 and LF normalised power (LFnu) calculated as LFnu = (absolute LF power/TP)x100. Following confirmation of distribution normality using Shapiro-Wilks W tests, data were analysed using a 2-way repeated measures analysis of variance. Significance was established at a level of P<0.05 and data were expressed as mean ± SD.
Results:
Hypoxia induced a reduction in all the time domain indexes (P<0.05) as well as in HFnu, TP, but an increase in LFnu and a significant increase in LF/HF (P<0.05) in all groups. There was no gender difference in any measured HRV index (P>0.05).
Conclusion:
The findings are consistent with the concept that hypoxia induces modifications of the cardiac autonomous nervous system (5). However, the effect of gender remains undetermined in the current study both in normoxia and hypoxia, hence warranting further assessment.

Table 1: Heart Rate Variability indexes in Normoxia and Hypoxia for both male and female.

	Male		Female	
	Normoxia	Hypoxia	Normoxia	Hypoxia
Time Domain Indexes				
SDNN (ms)	82 ±42	59 ±24	91 ± 39	45 ±20
RMSSD (ms)	70 ±49	36 ±22	83 ±52	31 ±19
Frequency Domain Indexes				
HFnu (%)	40 ± 17.7	27.6 ± 20.5	41.9 ± 14.7	25.4 ± 11.9
LFnu (%)	60 ± 17.7	72.4 ± 20.5	58.1 ± 14.7	74.6 ± 11.9

Autonomic dysfunction is implicated in cardiovascular disease, with studies reporting an exaggerated blood pressure response to sympathoexcitatory stress in individuals with resting hypertension (1-3). It is not clear whether this response is associated with changes in cardiac autonomic modulation or altered peripheral cardiovascular dynamics. The aim of this study was to compare blood pressure (BP), heart rate variability (HRV) and limb blood flow between normotensive (N: mean±SD; BP 116.9±1.4/73.4±0.9mmHg; age 49.4±10.4years, BMI 26.4±4.5kg.m-2; n=49) and mildly hypertensive participants (H: BP 141.3±2.0/88.8±2.2mmHg; age 51.7±11.4years, BMI 30.5±5.0kg.m-2; n=17) at rest and in response to sympathoexcitatory stress. Participants performed a cold pressor test (CPT) and an ischaemic handgrip test (IHGT) and were assessed for BP, forearm blood flow and HRV at rest and in response to the tests. Data are expressed as mean±SD and comparisons were made using ANOVA (SPSS Version 19, IBM Statistics, SPSS Inc., USA). The CPT evoked greater increases in systolic blood pressure (SBP; H: 18.13±13.01mmHg; N: 8.84±12.38mmHg; p=0.011) and mean arterial pressure (MAP; H: 10.13±9.55mmHg; N 4.65±8.16mmHg; p=0.026) in hypertensive compared with normotensive participants. The IHGT evoked greater increases in diastolic (DBP; H: 6.88±5.48mmHg; N: 0.32±7.20mmHg; p=0.001) and MAP (H: 9.24±4.85mmHg, N: 3.26±6.24mmHg; p=0.001) in hypertensive compared with normotensive participants. Hypertensive participants had significantly lower levels of resting cardiac parasympathetic modulations measured as the high frequency power of HRV (H: 31.7±4.1nu; N: 42.1±2.2nu; p=0.026). There were no significant differences in the HRV or blood flow responses to the CPT or IHGT between hypertensive and normotensive participants. This study demonstrated that sympathoexcitatory stress triggered an augmented blood pressure response in hypertensive participants, in line with previous studies (1-3). However, we found no evidence to support stress-activated hyper-reactivity in HRV or forearm blood flow in hypertensive participants. These findings lend support to the notion that sympathetic dominance contributes to the pathogenesis of hypertension. From the findings, we propose that more direct markers of autonomic function be investigated to better understand the role of the autonomic nervous system on the stress induced blood pressure response.

PCA268

A novel integrated tilt table-lower body negative pressure box to investigate differential arterial baroreflex responses with tilt in humans

M. Tymko, N. Ingram-Cotton, M. Howatt, R.J. Skow and T.A. Day

Mount Royal University, Calgary, AB, Canada

The arterial baroreflex responds to acute reductions in mean arterial pressure (MAP) by eliciting a heart rate response, maintaining MAP at normal levels. In the case of traumatic blood loss, Trendelenburg position (i.e., head-down tilt) is often used clinically to help compensate for reductions in MAP through gravity-dependent shifts in blood volume distribution toward the central cavity, but its use is controversial. A lower-body negative pressure (LBNP) box can be used to study baroreflexes by eliciting acute reductions in MAP through shifts in blood volume distribution toward the lower extremities, reducing venous return. We developed a novel integrated tilt table-LBNP box to investigate the cardiovascular and cerebrovascular effects of head-up and head-down tilt (HUT, HDT) on LBNP-induced hypotension. We hypothesized that 45° HUT would elicit a larger arterial baroreflex heart rate response to acute -50 mm Hg LBNP than supine or 45° HDT. Additionally, we hypothesized that there would be differential cerebral autoregulation (CA) between the middle cerebral artery (MCA) and posterior cerebral artery (PCA) during acute LBNP. 13 male volunteers (BMI 26.4±3 kg/m2; 24.2±4.8 yrs) were recruited. Following familiarization and consent, subjects were instrumented for measurement of instantaneous heart rate (IHR; ECG), MAP (mm Hg; finometer), end-tidal (PET)CO2 (Torr) and MCA and PCA cerebral blood velocity (CBV; cm/s; transcranial Doppler ultrasound). Subjects were placed in the tilt-table-LBNP box in supine position, underwent a 10-min baseline period, and exposed to -50 mmHg of acute LBNP for a maximum of ten minutes. The protocol was then repeated in 45° HUT and HDT in randomized order. Subjects were coached to maintain PETCO2 to resting values (±2 Torr). LBNP was terminated if systolic blood pressure was reduced 30% from resting values (pre-syncope; PS). We found that the arterial baroreflex-mediated IHR responses were linear and tilt-dependent. The slopes of the IHR responses were largest in 45° HUT, but less effective at protecting MAP than in supine and 45° HDT during acute LBNP. 10/13 subjects in 45° HUT reached PS in 427.7s, 3/13 subjects in supine position reached PS in 450.3s and no subjects reached PS in 45° HDT. PETCO2 was unchanged during LBNP in all three positions with coached breathing, eliminating the confounding effects of cerebrovascular CO2 reactivity on CBV. Although MAP was unchanged during LBNP prior to PS in all positions, there were differences between baseline and LBNP MCA in 45° HDT and 45° HUT, but there were no differences in the PCA between baseline and LBNP in any body position. Our findings suggest (a) Trendelenburg may be a useful application to prevent hypovolemic shock, and (b) CA may be different between anterior and posterior cerebral arterial circuits during acute LBNP.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Implications of enhanced kynurenic acid and extracellular tryptophan during fatigue

T. Yamamoto

Psychology, Tezukayama University, Nara, Japan

Serotonin, a neurotransmitter synthesized from tryptophan(TRP), has been proposed to play a key role in central fatigue. Here, we examined whether TRP itself and/or its two metabolites, kynurenic acid (KYNA) and quinolinic acid (QUIN), are involved in central fatigue. Experiments were conducted using Sprague-Dawley rats (SDR, 200–250 g, n = 21) and Nagase analbuminemic rats (NAR, 210–255 g, n = 3). Central fatigue was assessed by treadmill running and a Morris water-maze test. First, a microdialysis guide cannula (CMA/12) was inserted into the left striatum under anesthesia with sodium pentobarbital (25 mg/kg i.p.; Abbott Laboratories, USA), and microdialysis (Yamamoto et al, 2012) was used to collect samples for measurement of extracellular concentrations of TRP, serotonin, and 5-hydroxyindoleacetic acid (5-HIAA) in real time as rats (SDR and NAR) ran to exhaustion on the treadmill. Rats (SDR) were first treated with either saline or Branched-chain amino acids (BCAA, valine:leucine:isoleucine, 5:3:2, 250 mg/kg i.p.) 30 min before the exhaustion test. Second, the rats (another group of SDR) were trained in four daily sessions for 10 consecutive days on a Morris water-maze (a circular water tank 147 cm in diameter fitted with a refuge platform 250 mm in height). Rats were tested 6–7 days after injection with 180 nmol QUIN or QUIN plus 20 nmol KYNA into the hippocampus CA3-region through a guide cannula (CMA/12). All animal procedures were conducted in accordance with guidelines of the Japanese Neuroscience Society for animal experiments, and sanctioned by the animal-research ethics committee of Tezukayama University. The concentration of TRP secreted into the extracellular space of the striatum was higher during fatigue, and quickly returned to basal (free moving) levels with recovery from fatigue. Intracerebral TRP levels were directly associated with the time-to-exhaustion and were shown to be easily reduced with BCAA treatment. Compared with the saline group (133 ± 6.3 min), time-to-exhaustion for the BCAA group was clearly prolonged via the dramatic reduction in extracellular TRP caused by BCAA treatment (187 ± 21.5 min) ($t = 2.404$, d.f. = 7, $p < 0.05$). Moreover, return to basal TRP levels was associated with recovery from exhaustion, with real-time release of TRP in extracellular fluid showing that this response was sensitive and specific. Time-to-exhaustion was shorter in NAR, which maintain a higher extracellular level of striatal TRP than do SDR. Impaired memory performance in a water maze task after TRP treatment was attributable to high levels of KYNA and QUIN in the hippocampus acting synergistically on N-methyl-D-aspartic acid receptors. Our findings demonstrate that the increase in fatigue that occurs because of elevated brain TRP can be further amplified with synthetic KYNA and QUIN.

PCA270

PKC-dependent regulation of mTOR activity is mediated through TSC2/Rheb signaling in C2C12 myoblasts

M. Miyazaki

School of Rehabilitation Sciences, Department of Physical Therapy, Health Sciences University of Hokkaido, Ishikari-gun, Hokkaido, Japan

The enhanced rates of protein synthesis overcoming to the protein degradation resulted in a net increase in cellular protein accumulation that leads to skeletal muscle growth and hypertrophy. It has been well documented that mammalian target of rapamycin (mTOR) plays an essential role for the regulation of protein synthesis and subsequent hypertrophy in skeletal muscle. The protein kinase C (PKC)-dependent regulation of mTOR activity and subsequent protein synthesis/cell growth has been suggested, however, the exact molecular mechanisms underlying this regulation are poorly defined in skeletal muscle. The purpose of this study was to determine the regulatory mechanism in PKC-dependent pathway leading to mTOR activation in skeletal muscle cells. C2C12 murine myoblasts were treated with serum/antibiotics free media for 120 min and then stimulated with PKC activator phorbol 12-myristate 13-acetate (PMA) for 20 min (100 nM in serum/antibiotics free media), co-incubated with/without mTOR-specific inhibitor rapamycin (50 nM) and PKC-specific inhibitor bisindolylmaleimide I (BIM-I) (10 μM). Phosphorylation of the p70 ribosomal S6 kinase 1 (S6K1) at both Thr389 and Ser421/Thr424 sites, which show the functional activity of mTOR signaling, were markedly increased (6.21 ± 0.44 fold increase in Thr389 and 12.53 ± 0.59 fold increase in Ser421/Thr424 compared to the control, $p > 0.01$) in response to the PMA treatment. Conversely, inhibition of PKC-dependent pathway by BIM-I treatment completely blocked PMA-induced activation of mTOR signaling. Phosphorylation of tuberous sclerosis complex 2 (TSC2) at S664 site (ERK-specific residue), an upstream regulator of mTOR, was also prevented by PKC inhibition. Overexpression of Ras homolog enriched in brain (Rheb), a downstream target of TSC2 and an mTORC1 activator, was sufficient to activate mTOR signaling. We also identified that, in the absence of Rheb with using siRNA gene knock down, PMA-induced activation of mTOR signaling was significantly prevented (67% decrease in S6K1-Thr389 phosphorylation and complete inhibition of rpS6-Ser240/244 phosphorylation compared to the negative control). These observations demonstrated that, in C2C12 myoblasts, the PKC-dependent activation of mTOR signaling is mediated through TSC2 phosphorylation and its downstream target Rheb. It was also confirmed that Rheb is essential regulator of mTOR activation and enhanced protein synthesis in skeletal muscle cells.

PCA271

Skeletal muscle damage from eccentric exercise: protective effect of nitric oxide II

Y. Lomonosova[1], B. Shenkman[1] and T. Nemirovskaya[2]

[1]Institute for bio-medical problems, Moscow, Russian Federation and [2]Faculty of basic medicine, Moscow State University, Moscow, Russian Federation

It was shown that eccentric contraction is associated with skeletal muscle damage including cytoskeletal proteins degradation. Moreover, muscle pain and weakness are present that is probably the reason of decrement in muscle performance. We suggested that NO level decreases during eccentric contraction which leads to cytoskeletal proteins degradation in skeletal muscle. Our study was aimed to determine if NO level increase during muscle eccentric contraction can prevent proteolysis and improve work capacity after the contraction. Male Wistar rats were divided into 5 groups: control group (C group, 260-302g, n=8), control group treated with L-arginine, NO precursor (500 mg/kg body wt. per os for 2 days; CA group, 270-305g, n=8), downhill motor-driven treadmill running group (40 min of treadmill running downhill at 16°, 20 m/min; R group, 280-310g, n=10), groups of treadmill running rats with L-arginine (500 mg/kg body wt. per os for 2 days before the running; RA group, 270-298g, n=10) or L-NAME, nNOS inhibitor, administration (90 mg/kg body wt. per os for 2 days before the running; RN group, 265-289g, n=10). The experiment was conducted according to the rules of biomedical ethics (protocol No. 264 of March 5, 2009 was approved by the Russian Academy of Sciences Committee on Bioethics). The rats were sacrificed by nembutal overdose (75 mg/kg body wt.) next day after the running, the m. soleus was immediately frozen in liquid nitrogen. EPR spectroscopy revealed that NO level in CA group was significantly greater than that in C group ($p<0,05$). When tested work capacity it was considerably greater in C and RA groups as compared to R and RN groups ($p<0,05$). Contents of cytoskeletal proteins dystrophin and desmin were tested by immunohistochemistry and western blotting respectively. Degradation of the proteins was significantly greater in both R and RN groups. L-arginine administration in RA group prevented the proteolysis after eccentric contraction. We determined by means of real-time RT-PCR that contents of μ-calpains mRNA in R and RN were significantly greater in comparison with C group. L-arginine administration in RA group considerably decreased μ-calpains mRNA expression as compared to R group ($p<0,05$). Having analysed E3-ligases, MAFbx and MuRF-1, we showed that its mRNA expressions in RA group didn't differ from that in control group, but it was significantly lower in R and RN groups than that in C and RA groups ($p<0,05$). nNOS mRNA expression was greatly higher in R and RN groups as compared to C group ($p<0,05$). It is concluded that NO precursor administration in time of eccentric contraction increases work capacity and prevents proteolysis of cytoskeletal proteins, dystrophin and desmin. However nNOS inhibition at the eccentric contraction lead to dystrophin and desmin degradation and the capacity decrease.

Activity of anabolic and catabolic signaling pathways in rat soleus during recovery following gravitational unloading

T. Mirzoev, O. Turtikova, E. Kachaeva and B. Shenkman

State Scientific Center of Russian Federation - Institute of Biomedical Problems of Russian Academy of Sciencies, Moscow, Russian Federation

Nowadays the problem of muscle recovery from disuse atrophy (caused by gravitational unloading or hypokinesia) is urgent for rehabilitation and space medicine. Therefore the aim of the study was to analyse intracellular signaling pathways which are responsible for protein synthesis (anabolic markers – ribosomal kinases p-p70s6K and p-p90RSK) and protein breakdown (markers of proteolysis – E3 ubiquitin ligases MuRF-1 and MAFbx/atrogin-1) in rat soleus muscle.

The experiment was carried out in accordance with the rules of biomedical ethics certified by the Russian Academy of Sciences Committee on Bioethics. Thirty-five male Wistar rats weighing 190-210 g were randomly assigned to the 5 groups (n=7 for each group): ground control (C), hindlimb suspension for 14 days (14HS), hindlimb suspension for 14 days followed by 3-day recovery (14HS+3R), 7-day recovery (14HS+7R) and 14-day recovery (14HS+14R). Gravitational unloading was simulated by hindlimb suspension of rats (Morey-Holton, Globus, 2002). Animals were anaesthetised with 10% avertin (8ml/kg). Ribosomal kinases content was established by gel electrophoreses with immunoblotting. Expression of mRNA of E3 ligases was assessed by RT PCR. Values were expressed as means ± S.E., compared by 2-way ANOVA.

The unloading resulted in 30% decrease of p-p70s6K content but increase of expression of E3 ligases ($p<0.05$) vs. (C). At the same time content of p-p90RSK was 50% higher compared to (C). Content of E3 ligases mRNA was increased after 3 days of recovery ($p<0.05$). The content of p-p90RSK and p-p70s6K was reduced by the 7-th day of recovery vs. 14HS group. Expression of MuRF-1 and MAFbx/atrogin-1 returned to control level after 7 days of recovery. By the 14-th day of recovery period content of both ribosomal kinases retuned to control levels.

Thus, activity of anabolic signaling pathways demonstrated irregular dynamics during recovery period following gravitational unloading. At the same time increased activity of the ubiquitin-proteaosome pathway contributes to degradation of structural and functional proteins in rat soleus. These data can explain low rates of protein restoration in soleus muscle at early stages of recovery from disuse atrophy.

PCA273

Responses of elongation factor 2 and its kinase to short- and long-term hindlimb unloading in rat skeletal muscle

Y. Lomonosova, A. Krasnuy, E. Lysenko and B. Shenkman

Institute of bio-medical problems, Moscow, Russian Federation

Loss of skeletal muscle mass happens under catabolic conditions of gravitational unloading because of combination proteolysis increase and synthesis decrease processes. Increase of proteolytic enzymes expression namely calpains and E3-ligases, MuRF-1 and MAFbx, was shown in soleus at short-time hindlimb unloading of rats. The aim of our study was analysis of protein synthesis elongation mechanism in rat soleus in conditions of different periods of hindlimb unloading. Male Wistar rats were divided into 4 groups: control group (C group, 221-225 g, n=10), hindlimb unloaded group during 3 days (3HS group, 226-240g, n=8), 7 days (7HS group, 223-232g, n=8) and 14 days (14HS group, 227-242g, n=8). Hindlimb unloading was carried out according to Ilyin-Novikov's design with Morey-Holton's modification. The experiment was conducted according to the rules of biomedical ethics (protocol No. 180 of April 6, 2011 was approved by the Russian Academy of Sciences Committee on Bioethics). The rats were sacrificed by nembutal overdose (75 mg/kg body wt), each soleus was weighted, immediately frozen in liquid nitrogen and stored at -80°C until analysis. Atrophy of soleus was found in all hindlimb unloaded groups, the most profound loss (by 40% vs. C group, $p<0,05$) of soleus mass was revealed after 14 days unloading. eEF2 is one of the important member of eEF family catalyzing simultaneous translocation tRNA and mRNA on a 80S ribosome. It's known that eEF2 phosphorylation by its specific eEF2-kinase leads to prevention of elongation translation. We observed two-fold increase of eEF2k mRNA expression in rat soleus as early as 3 days unloading and it's remained high till 14 days unloading as compared to control group ($p<0,01$). Moreover, eEF2k protein content was significantly greater than that in control ($p<0,05$) after unloading lasting 7 and 14 days. P-eEF2 level was also increased since 3 days unloading in comparison with the control group and remained so till 14 days unloading ($p<0,05$). It was shown significant decrease of eEF2 protein content after 7 and 14 days unloading relative to the control ($p<0,05$). However, it wasn't found any changes in eEF2 mRNA level during all periods of unloading. Hereby, inhibition of eEF2 elongation factor function is a result of post-translational regulation by its eEF2-kinase which takes part in decrease of protein synthesis in soleus of rat after short- and long-term hindlimb unloading. Evaluation of serum and salivary immunoglobulin classes A, G and M in patients with orofacial squamous cell carcinoma

T.J. Lasisi[1], O.A. Lasisi[2], B.K. Kolude[3] and E.E. Akang[4]

[1]Physiology, University of Ibadan, Ibadan, Oyo, Nigeria, [2]Otorhinolaryngology, University of Ibadan/University College Hospital, Ibadan, Oyo, Nigeria, [3]Oral Pathology, University of Ibadan/University College Hospital, Ibadan, Oyo, Nigeria and [4]Pathology, University of Ibadan/University College Hospital, Ibadan, Oyo, Nigeria

Background: Changes in the humoral immune system of patients with orofacial squamous cell carcinoma are considered important factors in the pathophysiology, prognosis and management of the disease in these individuals[1].
Method: This is a cross sectional human study[2], undertaken to evaluate serum and salivary immunoglobulin levels in patients with histologically diagnosed orofacial squamous cell carcinoma (OSCC) attending the University College Hospital, Ibadan, Nigeria (Ethical approval number: UI/UCH/EC/09/014). Seventy subjects comprising 22 cases of untreated OSCC, 18 cases of OSCC receiving treatment and 30 healthy individuals were included. Levels of IgA, IgG and IgM in serum and saliva samples from subjects were determined using ELISA technique[3].
Results: Values are means ± SD compared by ANOVA and Dunnet's tests. Subjects receiving treatment showed a significant reduction in the mean values of serum IgA, IgG and IgM compared with healthy controls ($p= 0.03$, 0.001 and 0.01 respectively). However, the mean values of serum IgA, IgG and IgM in untreated OSCC subjects were not significantly different from those of treated carcinoma subjects and healthy controls. Mean value of salivary IgG was significantly higher ($p = 0.001$) in untreated OSCC subjects compared with treated OSCC subjects and healthy controls. There was no significant difference in the mean values of salivary IgA and IgM among the groups. Correlation (Pearson's correlation test) between serum and salivary immunoglobulins (IgA, IgG and IgM) showed no significant relationship.
Conclusion: These findings may suggest that elevated salivary IgG probably plays a role in the pathophysiology of orofacial squamous cell carcinoma and hence, may be a reliable marker. In addition, serum IgA, IgG and IgM may be useful in the monitoring of patients undergoing treatment.
Key words: saliva, serum, immunoglobulin, orofacial, squamous cell carcinoma

PCA275

Ethnic differences in heat adaptation and autonomic tone during intensive exercise in elite athletes

J. Dalzell[2] and A. Datta[1]

[1]Medicine, Hull York Medical School, York, UK and [2]formerly Portsmouth FC, Portsmouth, UK

INTRODUCTION: Athletic performance may be compromised in extreme heat; this was relevant for the Athens and Beijing Olympics and may be for the 2014 (Brazil) and 2022 (Qatar) FIFA World cups; under those conditions prior determination of required fluid intake is vital for athlete safety. Thompson (1954) described lower sweating rates in Bantus compared with Caucasians.

AIMS

1.To determine the English Football Premiership ethnic mix.

2.To establish fluid intake, sweat production and sweat evaporation during exercise in extreme heat and their ethnic differences.

3.To establish cardiorespiratory and other physiological factors contributing to any putative ethnic differences

METHODS: Using Scout 7 software, the English Football Premiership was analysed for ethnic background in 2012. 34% players were of African origin(**AO**) and 66% of European origin(**EO**). On two successive years, studies were performed in Dubai after four days acclimation, during 80 minutes training at 40 ± 2°C ambient temperature; 25 ± 8% relative humidity on 29 professional Premiership footballers from a single team with Ethics clearance. 15 were **AO** and14 **EO**. Players could drink ad libitum. RESULTS: There was no difference between **AO** and **EO** in height, weight, body surface area, skin fold thickness, resting or average heart rate during exercise, QT interval, cardiac chamber dimensions, left ventricular ejection fraction or maximum VO2. During exercise, fluid intake in **AO** ranged from 1.1- 3.0l (1.6 ± 0.63l, median + SD) and in **EO** ranged from 0.5-2.4 l (1.35 ± 0.50; p=0.40; unpaired t-test). Sweat production in **AO** ranged from 1.8 – 3.9 l (2.3 ± 0.54 l) higher than 1.3 – 2.7 l in **EO** (2.00 ± 0.43 l; p = 0.03; Figs. 1&2). Mean ± SD of Peak Heart Rate (Polar Electro) during training in the heat was 186 ± 7 bpm (range 170-197 bpm) in **AO** footballers, significantly higher than **EO** players (178 ± 7 bpm, range 165-188 bpm ; p=0.007). Heart rate variability (HRV; Akselrod, 1981) was calculated from a five minute collection of resting ECG using bespoke frequency domain analysis software using American Heart Association guidelines (Omega Wave; Oregon USA). (Mean ±SD) LF/HF ratio, an index of sympatho-vagal tone balance was 1.07 ± 0.48 in **AO** and significantly higher in **EO** 2.0± 1.27 (p= 0.03).

CONCLUSIONS

1. A large proportion of the English Premiership footballers are **AO**

2. Sweat production during exercise in extreme heat may be up to 3.25 L/hr, and fluid intake 2L/hr. This can lead to significant dehydration of up to 2.4% naked body mass.

3. There is greater sweat production in **AO** players, despite a similar fluid intake to **EO** players; this may confer a performance advantage to exercise in the heat.

4. Increased sweat production in **AO** players appears to be associated with an increased sympathetic tone, which has also been related to an increased risk of cardiac events (Tsuji et al, 1996)

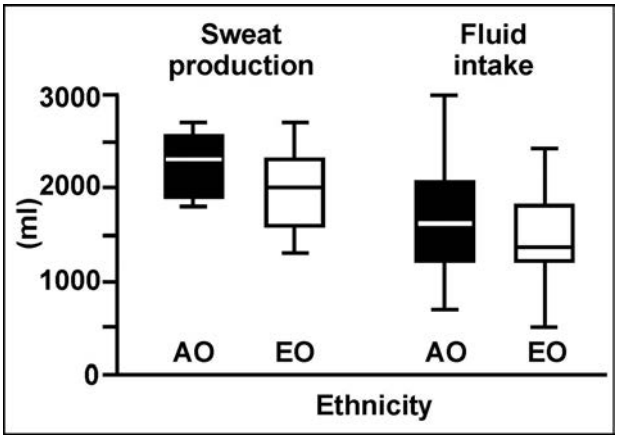

Fig. 1 Sweat production and fluid intake during exercise in the heat for AO (n=15, filled boxes) and EO (n=14, open boxes). Box represents interquartile range, horizontal line represents median vertical line shows range.

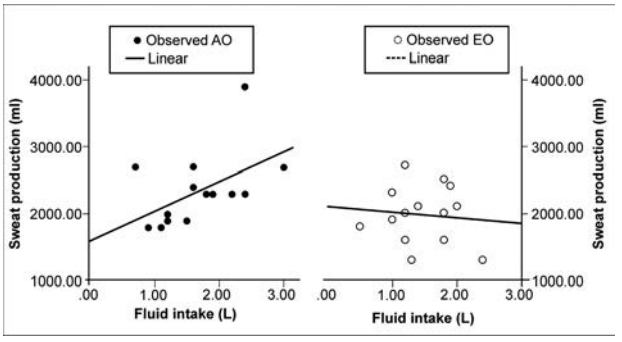

Fig. 2 Sweat production (ordinate) and fluid intake (abscissa) for 15 AO players (Left hand panel, shaded symbols) and 14 EO players (Right hand panel, open symbols) during exercise in the heat. Lines depict linear regression.

Exercise training activates behavioral thermoregulation in mice

K. Nagashima[1,2] and C. Lin[3]

[1]Human Sciences, Waseda University, Tokorozawa, Japan, [2]Institute of Applied Brain Sciences, Waseda University, Tokorozawa, Japan and [3]Sport Sciences for the Promotion of Active Life, Waseda University, Tokorozawa, Japan

Aims Dehydration, factors of hypvolemia and plasma hyperosmolality, attenuates heat tolerance in humans and mice. Themoregulation are achieved by autonomic and behavioral responses. However, we know a little about if and how the behavioral responses in heat, such as heat escape behavior or seeking cooler environment are activated by the exercise training. We evaluates the role of behavioral thermoregulation in heat tolerance. Methods All experimental procedures were conducted under the guidelines of the Japanese Physiological Society and Waseda University in Japan. Male ICR mice (6 w age) were housed with/without a running-wheel for 8 wks (WR and NWR groups, n=40 each). In the 5th week, under inhalation anesthesia with 1% isoflurane, they were placed a datalogger with temperature sensor for the measurement of body temperature (Tb) in the abdominal cavity. Mice were got familiarized with being in an experiment box (50 x 10 x 15 cm; made of Plexiglas with 5 temperature-controllable Peltier boards at the bottom), and learned either of following settings: 1) board temperature of 28˚C or 39˚C; 2) operant-behavior setting; each board was set at 39˚C, and the right-end board was changed at 20˚C within 60 sec only when a mice moved on the left two board; and 3) thermal mosaic setting; each board was set at either 15˚C, 22˚C, 28˚C, 35˚C, or 39˚C with a 6-min interval. After the 8-wk training period, a mouse had subcutaneous injection of isotonic- or hypertonic-saline with 0.1 ml 0.5% lidocaine (1 ml/100 g of body wt; 154 or 2,500 mM, IS or HS subgroup), and was exposed to either of the setting for 2 h after 1.5 h baseline (Experiments 1 – 3). Results In Experiment 1, after the 39˚C board exposure, Tb in both subgroups of the WR group was higher than that in the NWR group without any significant differences. In Experiment 2, the NWR group showed smaller operant counts in the HS subgroup than the IS subgroup; however, the WR group did not. In Experiment 3, the WR group had lower temperature of thermal preference than the NWR group without any differences between the subgroups (e.g. 33.4 ± 0.3˚C and 34.7 ± 0.1˚C in the IS subgroups of the WR and NWR groups, respectively). Conclusions Hyperosmotic condition was a stimulus decreasing heat tolerance in heat. However, exercise training in mice may have resulted in 1) lower thermal preference, and 2) greater activation of behavioral thermoregulatory response. Therefore, the training contributes to increase in the heat tolerance.

PCA277

The changes of the cardiovascular function and its hormones regulation of the 28th chinese inland expeditioners at antarctic dome-A environment of hypoxia and extreme cold

Y. Xiong[1], L. Lin[2], H. Gong[1], X. Chen[1], N. Chen[1] and C. Xu[1]

[1]Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences (CAMS); School of Basic Medicine, Peking Union Medical College, Beijing, China and [2]Hua Dong Hospital Affiliated to Fu Dan University, Shanghai, China

Antarctic Dome-A(80°22′02″S, 77°22′23″E) is a place of extreme cold and hypoxia, with average altitude of 4000m and average temperature -58.4 degree Centigrade. We investigated the effect of Dome-A environment on the cardiovascular function and its hormones regulation of the 28th Chinese Antarctic Inland expedition, so as to providing scientific data for making measures of prevention and cure of mountain sick. This study was approved by Institutional Review Boards of the Peking Union Medical College, Informed consent was obtained from each participant after the study objectives and data collection procedures had been fully explained. Using Cardiodynamics monitor to detect cardiovascular function of the 25 members (male, average age 33.9±6.7yr) of the expedition at departure from Shanghai, stayed 2 weeks at Kunlun Station and returned to Shanghai (2012/3/30), synchronously collecting blood sample. Plasma erythropoietin (EPO), angiotensin II (ANG II), brain natriuretic peptide(BNP), atrial natriuretic peptide (ANP) and endothelin (ET-1) were measured by ELISA. Compared with departure, the heart rate(HR), systolic pressure(SBP), diastolic pressure(DBP), mean arterial pressure(MAP), systemic vascular resistance(SVR) and resistance index(SVRI) significantly increased, the stroke volume(SV), stroke index(SI), cardiac output(CO), cardiac index(CI), velocity index(VI), acceleration index(ACI), left ventricular ejection time(LVET) significantly decreased at Dome-A. Two weeks exposure to the hypoxia and extreme cold environment at Dome-A induced significant decrease in cardiac function. HR and left ventricular work (LCW) increased so as to offset the reduction in SV and arterial oxygen saturation. However, this may further increase the oxygen consumption of cardiomyocyte and increase the risk of ischemic cardiovascular diseases. Although obvious changes in cardiac function were observed in expeditioners, no significant change in plasma ANP, BNP, ANGII, BNP and EPO was observed during residence at Dome A. It might be that the exposure time of Chinese expeditioners to Dome A is too short to induce obvious changes in vasoac-

tive peptide. Upon their return to Shanghai, DBP, MAP, CO, CI, SV, SI, VI and ACI remain at lower levels; SVR, SVRI remain at higher levels comparing with departure. Our data suggested that cardiac function significantly decreased after 2 weeks exposure to Dome A. Moreover, cardiac deadaptation process existed 1 month after return to Shanghai. Thus, further monitoring of cardiac function in inland expeditioners is needed after evacuation from Dome A environment .

PCA279

Exercise stimulates lactate disposal and monocarboxylate transporter expression in rainbow trout

T. Omlin, L. Teulier and J. Weber

University of Ottawa, Ottawa, ON, Canada

In mammals, exercise is known to stimulate glycolysis, lactate production and lactate disposal. Monocarboxylate transporters (MCTs) mediate inter-tissue lactate trafficking and orchestrate recovery. By contrast, the effects of swimming on lactate kinetics and the existence of MCTs have never been characterized for rainbow trout (Oncorhynchus mykiss), an essential animal model in ectotherm physiology. Therefore, our goals were: (1) to determine the rates of lactate appearance (Ra) and disposal (Rd) during steady-state swimming at 1.7 body lengths/s (BL/s) and graded swimming at 0.5-2.8 BL/s by in vivo continuous infusion of [U-14C] lactate as described in (Omlin and Weber, 2010); (2) to clone trout MCTs, and to determine their tissue distribution and the effects of exhausting exercise on their level of mRNA expression. We reasoned that such measurements would prove important to understand the mechanisms underlying the classic "lactate retention" of trout white muscle after maximal exercise. Results show that steady-state exercise increased Ra and Rd lactate in parallel from resting values of 23 μmol kg-1 min-1 to maximal levels of 29 μmol kg-1 min-1, maintaining plasma lactate concentration below 1.5 mM. For graded exercise, lactate fluxes stayed at baseline below 2.2 BL/s, but both Ra and Rd lactate were stimulated at higher speeds, reaching maximal values of 40 and 35 μmol kg-1 min-1, respectively. Plasma lactate reached 5 mM at high swimming speeds because the increase in lactate use was insufficient to match the increase in lactate production. We also show for the first time that rainbow trout possess MCTs by cloning MCT1a, MCT1b, and MCT2. These lactate transporters are present ubiquitously, but their expression varies greatly between tissues and isoforms. Exhausting exercise increased the expression of MCT1a (+90%) and MCT1b (+50%) in the heart, as well as the expression of MCT2 in the brain (+260%). Other tissues showed no changes after exercise, and we could not clone MCT4, the isoform mainly dedicated to lactate efflux from glycolytic muscles in mammals. The stimulation of MCT expression in heart and brain is consistent with an accelerated use of lactate by these oxidative tissues, and with the observed increase in Rd lactate. Results also provide a possible functional explanation for lactate retention because: (1) white muscle shows the lowest MCT expression of all trout tissues, (2) white muscle MCTs are not stimulated by exercise, and (3) rainbow trout may not express MCT4. All procedures were approved by the Animal Care Committee of the University of Ottawa. This research was supported by an NSERC discovery grant.

PCA280

Maternal diet influences circadian cardiovascular function in the offspring

C. Gray[1], S.M. Gardiner[2] and D.S. Gardner[1]

[1]School of Veterinary Medicine and Science, University of Nottingham, Loughborough, UK and [2]School of Biomedical Sciences, University of Nottingham, Nottingham, UK

Background: Contemporary diets are typically high in salt and fructose and such a refined diet has been proposed to contribute significantly to the overall burden of non-communicable disease in the population. Exposure to salt diet throughout fetal and neonatal development via maternal diet induces hypertension in the adult offspring. No study has explored potential interactions between maternal intake of salt and/or fructose and characterised offspring cardiovascular response through the circadian cycle.
Methods: Pregnant rats were fed purified food (±4% salt) with freely available water (±10% fructose) before (4 weeks), during (21 days) and after gestation to weaning (21 days). Offspring (n=5/6 males/females from n=5/6 dams per treatment; 4 treatment groups) were weaned onto standard chow diet and from 10 weeks of age acute and chronic cardiovascular responses to anxiety (becoming singly-housed i.e. removal of paired rat from cage), salt-loading (5 days 4% salt in the diet), fructose loading (5 days 10% fructose in drinking water) nitric oxide blockade (with L-NAME) and voluntary physical activity were assessed by in-dwelling telemeters (DSI International).
Results: Prenatal exposure to high salt diet elicited hypertension (142/103 vs. 128/88 ± 3 mm Hg; P=0.003) and an exacerbated baroreflex during an acute episode of anxiety in male, but not female offspring. These effects were unrelated to tonic nitric oxide activity, since chronic blockade with L-NAME elicited similar physiological responses between groups. Prenatal exposure to high fructose diet elicited increased resting heart rate (by 15-20 ±8 beats min-1) and greater pressor responses to fructose intake in both male and female offspring, despite one magnitude greater voluntary physical activity in female vs. male offspring (≈957 vs. 81 m day-1). Furthermore, fructose-exposed offspring displayed a blunted circadian variation (i.e. non-dipping) cardiovascular pattern.
Conclusions: This study has revealed long-term circadian cardiovascular effects of increased maternal salt or fructose intake in the adult offspring, despite little direct exposure themselves. The delayed cardiovascular effects are distinctly sex-specific and thus any anticipated cardiovascular deterioration with age for example with prolonged, rather than short-term, exposure to such refined nutrients is likely to manifest differently in males vs. females.

The authors express their gratitude for the help and support provided by the BioServices Unit on the Sutton Bonington Campus and Julie March for performing the radiotelemetry transmitter implantations. Novel protein and mRNA expression of voltage-dependent potassium channels in first trimester human placentae

H.D. Mistry[1], L.O. Kurlak[2], G.S. Whitley[3], J.E. Cartwright[3], F. Broughton Pipkin[2] and R.M. Tribe[1]

[1]Women's Health, King's College London, London, UK, [2]Obstetrics & Gynaecology, University of Nottingham, Nottingham, UK and [3]Biomedical Sciences, St. George's University of London, London, UK

Background: Potassium channel α-subunits encoded by KCNQ1-5 genes (Kv7) form voltage-dependent channels which can be modulated by KCNE1-5 encoded accessory proteins. These channels are known to play a role in regulating the reactivity of blood vessels. We have previously shown that both mRNA and protein data indicates a novel combination of KCNQ3 and KCNE5 expression in placentae from preterm and term pre-eclampsia; the expression of these specific KCNQ and KCNE isoforms in early placental tissue remains to be elucidated.
Objectives: The aims of this study were to determine whether KCNQs and KCNEs mRNA are expressed in first trimester placental tissue and to assess protein expression and localisation of the KCNQ3 and KCNE5 isoforms.
Methods: Placental samples were obtained from women undergoing elective surgical termination of pregnancy (TOP) at ≤10 weeks' (early TOP; n=6) and >10 weeks' (late TOP; n=7) gestations following informed written consent. Expression of mRNA for all KNNQ and KCNE isoforms were measured by qRT-PCR and normalised to three housekeeper genes using geNorm. Protein localisation/expression of KCNQ3 and KCNE5 were assessed by immunohistochemistry.
Results: Expression of mRNA (normalised copy number) of both all KCNQs and KCNEs were observed at all gestations. KCNE5 expression (median [IQR]) was increased in late TOP (239.5 [135, 305]) versus early TOP samples (77.6 [57.5, 111.8], P=0.01). No other significant differences were detected for other KCNQ and KCNE genes (P>0.05).
KCNE5 mRNA expression remained constant between 6 and 10 weeks' (median: 77.6) with a subsequent rise at 11 and 12 weeks' and a larger increase after 13 weeks' (median: 239.5). KCNQ3 mRNA expression was initially lower than KCNE5, but increased at 10 weeks (median: 153.1) and then fell below KCNE5 vales by 12 weeks' (median: 22.3).
Protein expression for both isoforms was localised predominantly to the syncytiotrophoblast with some expression in the mesenchyme.
Conclusion: KCNQ3 and KCNE5 channel isoforms are highly expressed in first trimester human placenta. The changes in mRNA expression mirror temporal changes in the placental tissue oxygen tension which increases between 8-10 weeks'. This precedes the dislocation of the spiral artery plugs, which enables maternal blood to flow freely and continuously into the intervillous spaces. We speculate that mesenchymal protein expression may be related to angiogenesis during this critical window of feto-placental vascular development. We will perform functional studies to determine the potential role of this channel complex in the syncytiotrophoblast. Future work will characterise the complete KCNQ/KCNE profile in first trimester tissue and assess their potential functional roles both in early placentation and in relation to pre-eclampsia.

Evaluation of physical fitness of subjects with sickle cell trait: effects of ad libitum fluid intake on thermoregulatory responses in heat environments

A. Samb, M. Diaw, A. Sow, F. Sar, G. Seck, A. Ba and M. Niang

Faculté de Médecine, de Pharmacie et d'Odontologie, UCAD, Laboratoire de Physiologie et d'Explorations Fonctionnelles, Dakar, Senegal

The practice of physical exercises under certain environmental conditions in carriers of sickle cell trait (SCT) may be associated with microvascular injury such as renal vasculary disease (1, 2, 3) . The increase in ambient temperature and high humidity seem to play a significant role in the occurrence of rhabdomyolysis reported post exercise in these individuals (2, 3).
However, adequate fluid intake during exercise would limit the sickling process and therefore reduce the risk of microvascular injury (2).
Our study assessed the effect of hydration ad libitum on thermoregulatory responses during two football matches in carriers of sickle cell trait in tropical climates.
Twenty two students from the Higher National Institute of Popular Education and Sport (INSEPS) of Dakar, male, black, aged 26 ± 2.16 years and weighing 65 ± 5.45 kg, for a size of 1.75 ± 0.08 m, participated to the study.
Eleven (11) subjects were genotype AA (control group) and 11 were of genotype AS (sickle cell trait: SCT). A hemoglobin electrophoresis led to the discovery of the presence of abnormal hemoglobin HbS of SCT carriers.
Subjects were randomized into two teams: A team of 11 players consisting of 6 subjects AA and 5 SCT carriers, and a B team of 11 players, including six SCT and five AA. These teams competed in two football games separated by two weeks in comparable environmental conditions (temperature: 24.5 to 25 ° C, humidity: 65-68%).
In the first game, only players of Team A could drink water freely without restriction during the match (6AA hydrated and 5SCT hydrated), while the players of Team B were not allowed to drink during the match (5AA no hydrated + 6SCT no hydrated). Conditions were reverse in the second match. Rectal temperature of subjects in both groups was taken before and after football matches with a thermometer. Body weight was assessed at rest and recovery in both groups. Our results showed that sickle cell trait is not a limiting factor in thermoregulation and that great hydration during physical exercise can significantly reduce the increase in rectal temperature and weight loss in both groups.

PCA282

Changes of AMPK and SirT1 activity in the trophocytes and fat cells of young and old worker honeybees (Apis mellifera)

C. Hsu[1,2] and Y. Chuang[2]

[1]Department of Biomedical Sciences, Chang Gung University, Tao-Yuan, Taiwan and [2]Graduate Institute of Biomedical Sciences, Chang Gung University, Tao-Yuan, Taiwan

Trophocytes and fat cells of honeybees (Apis mellifera) have served as targets for cellular senescence studies; their changes of aging-related molecules and mitochondrial energy utilization with advancing age have been clarified (Hsieh and Hsu, 2011; Chuang and Hsu, 2012). However, the changes of energy-regulated molecues with advancing age in workers are unknown. In this study, young (2-day-old) and old (50-day-old) workers were selected from the same colony in hive on the same days for the experiments. The expression of adenosine monophosphate-activated protein kinase (AMPK), phosphorylated AMPK (pAMPK), silent information regulator 1 (SirT1), and peroxisome proliferator-activated receptor-α (PPAR-α) were evaluated in the trophocytes and fat cells of young and old workers reared in a field hive by Western blotting. The activity of AMPK and SirT1 were evaluated by analytic Kits. The concentration of AMP, ADP, ATP, and AMP/ATP ratio and ADP/ATP ratio were evaluated by ultra performance liquid chromatography. The results showed that (1) AMPK expression increased with advancing age (n = 18, P < 0.01, two-sample t test), whereas pAMPK expression decreased with advancing age (n = 18, P < 0.05, two-sample t test), pAMPK/AMPK ratio decreased with advancing age (n = 18, P < 0.05, two-sample t test), and AMPK activity decreased with advancing age with 0.62 ± 0.11 and 0.14 ± 0.03 450 nm mg-1 protein in young and old workers (n = 48, P < 0.01, two-sample t test); (2) ATP concentration decreased with advancing age with 44.39 ± 3.50 and 30.51 ± 2.43 nmol mg–1 of protein in young and old workers (n = 10, P < 0.01, two-sample t test) and ADP concentration decreased with advancing age with 4.60 ± 0.39 and 2.78 ± 0.26 nmol mg–1 of protein in young and old workers (n = 10, P < 0.005, two-sample t test), whereas AMP concentration was not different with 1.45 ± 0.16 and 1.61 ± 0.28 nmol mg–1 of protein in young and old workers (n = 10, P > 0.01, two-sample t test). ADP/ATP ratio was not different with advancing age (n = 10, P > 0.05, two-sample t test), whereas AMP/ATP ratio increased with advancing age (n = 10, P < 0.005, two-sample t test); (4) SirT1 expression increased with advancing age (n = 21, P < 0.05, two-sample t test), whereas their activity decreased with advancing age with 73.2 ± 0.9 and 59.7 ± 3.7 fluorescence μg–1 of protein in the trophocytes and fat cells of young and old workers (n = 30, P < 0.01, two-sample t test); and (5) PPAR-α expression decreased with advancing age (n = 18, P < 0.01, two-sample t test). These results show that young workers express higher AMPK and SirT1 activity than old workers and that aging results in a decline in AMPK and SirT1 activity in worker honeybees.

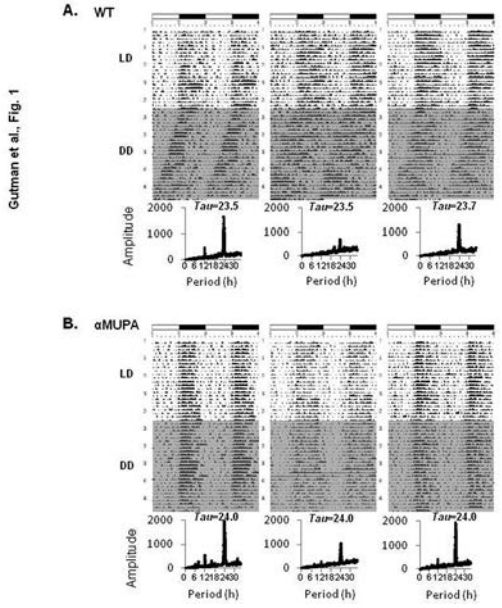
PCA283

Long-lived and obesity resistant mice exhibit 24 h locomotor circadian rhythms at young and old age

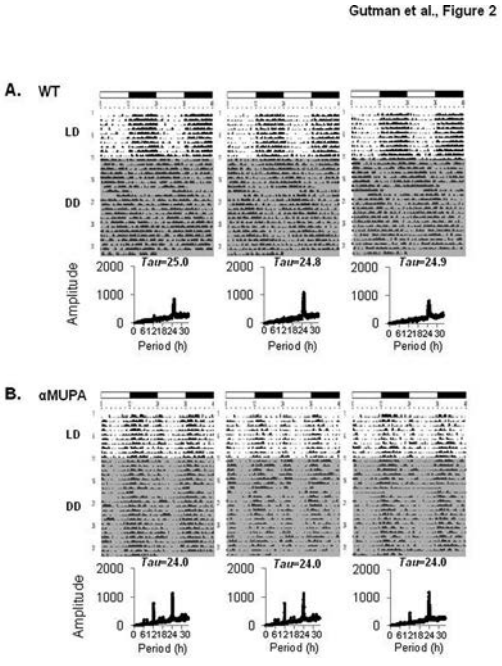
R. Gutman[1,2] and O. Froy[3]

[1]Departments of Nutritional Sciences and Zootechnology, Tel-Hai College, Kiryat Shmona, Israel, [2]2. Unit of Integrative Physiology (LIP), Laboratory of Human Health and Nutrition Sciences., MIGAL - Galilee Research Institute, Kiryat Shmona, Israel and [3]3. Institute of Biochemistry, Food Science and Nutrition, The Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University of Jerusalem, Rehovot, Israel

Ageing is associated with disruption of circadian homeostasis, including reduced entraiment to light-dark cycles, reduced amplitude and desynchronization of circadian physiological rhythms, and shortening or lengthening of the endogenous circadian period length (tau). αMUPA mice carry a transgene encoding the urokinase-type plasminogen activator, an extracellular protease implicated in fibrinolysis, tissue remodeling, and brain plasticity. Female αMUPA mice spontaneously eat ~25% less, live ~20% longer, and show high-amplitude circadian rhythms in food intake, body temperature, and in hepatic clock gene expression levels, compared with WT mice. Herein we examined the tau of locomotor activity of mature (8-month old) and aged (18-month old) female αMUPA and WT mice under total darkness. We show that tau changed in WT mice from a period <24 h at 8 months to a period >24 h at 18 months. However, tau of αMUPA mice was ~24 h at both ages. Deviation of tau from 24 h has shown to be inversely related to life span of rodents and non-human primates. Hence, our results suggest that the sustainable endogenous period of ~24 h in αMUPA mice may contribute to their longevity. These results support the hypothesis that although a non-24-h tau has an adaptive significance in allowing a better response to natural daylight changes, such a lack of resonance between tau and external period length entails a life-shortening metabolic cost.



Locomotor activity of representative 8-month-old αMUPA (n=12) and WT mice (n=12) under 12:12 light-dark (LD) regime followed by constant darkness (DD, gray background). Representative double-plotted actograms presenting locomotor activity of FVB/N WT mice (A), αMUPA mice (B) during LD (light area) and DD (dark area). Individual chi-square distribution of activity period length during 28 days in DD is presented below each actogram. White and black bars at the top of each actogram represent the light and dark cycles. Double plotted actograms were generated using Actogram software. Period length of circadian activity rhythms in DD (tau) were calculated individually by Chi-square analyses using Tau software. Actogram and Tau softwares kindly provided by Refinetti R., University of South Carolina.



Locomotor activity of representative 18-month-old αMUPA (n=10) and WT (n = 9) mice under 12:12 light-dark regime (LD) followed by constant darkness (DD, gray background). Representative double-plotted actograms presenting locomotor activity of WT mice (A) and αMUPA mice (B) during 10 days under LD (light area) followed by 28 days under DD (dark area). Individual chi-square distribution of activity period length during the corresponding days in DD is presented below each actogram. White and black bars at the top of each actogram represent the light and dark cycles.

PCA284

Oxidant-antioxidant balance and homocysteine in postmenopausal women: the role of hormone replacement therapy

C. Gokkusu[1,2], S. Seckin[1,2] and S. Tamer[2,1]

[1]Biochemistry, Istanbul Medical Faculty, Istanbul, Turkey and [2]Physiology, Istanbul Medical Faculty, Istanbul, Turkey

The plasma homocysteine (Hcy) concentration is an independent risk factor for cardiovascular disease (CAD). The increase of plasma Hcy levels at menopause suggests a close relationship between Hcy metabolism and estrogen status and proposes one of the mechanisms through which menopause unfavorably affects CAD risk in women. It has been suggested that hyperhomocysteinemia may promote the production of hydroxyl radicals, through Hcy autooxidation and thiolactone formation. Some investigators have suggested that Hcy may cause atherosclerosis by damaging the endothelium either directly or by altering oxidative status during aging. In this study, the effects of hormone replacement therapy (HRT) on plasma levels of endogenous malondialdehyde (MDA) formation, Hcy and total thiol (t-SH) were investigated in healthy postmenopausal women who received HRT for 1 year. We also determined the enzymatic antioxidant activities, such as superoxide dismutase (SOD) and glutathione-S transferase (GST). We hypothesized that HRT would relate positively with antioxidant status.

A number of 80 unrelated healthy postmenopausal women (aged 45–56 years), and 40 unrelated healthy control subjects (aged 30–45 years) were included in the study. Postmenopausal women were selected from the outpoint clinic of the Department of Obstetrics and Gynecology. All participants underwent clinical, biochemical and hormonal screening procedures including gynecologic and physical breast examination. Postmenopausal women were divided into two groups. HRT group involved 45 healthy postmenopausal women who were receiving hormone replacement therapy for 1 year: oral estradiol valerate 2 mg/day plus continuous cyproterone acetate 1 mg/day. NHRT group included 35 healthy postmenopausal women who received orally placebo but not received HRT. In the samples, levels of MDA, t-SH and activities of GST and SOD were measured before and after treatment.

There was no significant change in plasma Hcy levels between HRT and NHRT groups. However, Hcy concentration is significantly elevated in both NHRT and HRT groups as compared to control. MDA and t-SH correlated significantly with Hcy (p=0.388 and p= 0.478, respectively) content and there was a significant negative correlation between E2 level and GST activity (p= -0.425) in HRT group. SOD and HDL-C correlated significantly with t-SH level (p=0.339 and p= 0.336, respectively) in plasma after HRT in women.

Our data have supported the hypothesis that elevated Hcy levels stimulate production of hydroxyl radicals. In addition, our findings are important as it indicates that HRT may reduce oxidative stress in postmenopausal women.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA285

Tissue specific modification of clock methylation in aging mice

Y. Cai, L. Zhang, Q. Lin and L. Li

Xuanwu Hospital, Beijing, China

Circadian rhythms in humans, rodents and other animals tend to change as they age. The molecular mechanisms underlying these age-related changes in circadian rhythms are yet to be elucidated. DNA methylation is a chemical modification of DNA structure and an important epigenetic regulator of gene expression. In addition, DNA methylation differences have been observed to be acquired in multiple tissues with age [1]. To investigate whether DNA methylation of clock genes changed with age, and contributed to circadian dysfunction in aged animals, we examined the methylation of eight clock promoters (Per1, Per2, Cry1, Cry2, Clock, Npas2, Bmal1 and Bmal2) in the stomach, kidney, striatum and spleen using a methylation-specific PCR assay (MSP) [2]. Young (3-months-old, n = 14) and old (24-months-old, n = 14), male C57BL/6 mice were housed at an animal facility on a 12-h light–dark cycle (lights on at 08:00; lights off at 20:00) and allowed to feed ad libitum. Animal treatment was in accordance with the National Institutes of Health (NIH) guidelines for animal experimentation. All mice were sacrificed at 09:00 and samples of stomach, kidney, striatum and spleen were collected for DNA extraction. Methylation frequencies of clock genes in different age groups were compared and analyzed using Pearson Chi-square tests. We compared eight clock genes, using Bonferroni correction for multiple comparisons. Significance levels were established at a P-value less than 0.00625. Partial methylation was present at the Cry1 promoter in all tissues examined, at the Per1 and Bmal1 promoters in the stomach, and at the Bmal2 and Npas2 promoters in the spleen. Regarding age related changes, methylation frequency decreased significantly in the old mice at the stomach Per1 promoter ($p = 0.006$), but was significantly increased in old mice at the Cry1, Bmal2 and Npas2 promoters of the spleen ($p = 0.001$; $p = 0.006$; $p = 0.002$, respectively). Actually, no methylation was detected in the spleen of young mice, while 11/14 old mice demonstrated methylation in at least one locus, suggesting the spleen may be particularly prone to age-related circadian dysfunction. Indeed, circadian rhythms of cell proliferation in the spleen are reduced in aged rats [3]. These results indicated that methylation of some clock promoters were affected with age at least in the spleen and stomach; in turn this may lead to dysregulation of clock expression and changes in circadian rhythms [4]. In conclusion, our data supports the hypothesis that DNA methylation plays a role in age-related circadian dysfunction.

PCA286

Steroids hormone and nitrite/nitrate levels are unchanged in normotensive and hypertensive postmenopausal women after aerobic exercise training

I. Novais, G. Puga, H. Araújo, R. Esposti, A. Jarrete, C. Sponton, M. Delbin and A. Zanesco

Biosciences Institute, São Paulo State University Júlio de Mesquita Filho, Rio Claro, São Paulo, Brazil

Evidences have shown that the incidence of cardiovascular disease (CVD) increases in women after menopause compared with men of similar age. Estrogen deficiency was ascribed as the main cause of increased rate of CVD in postmenopausal women, but data are not conclusive since clinical trial failed to show beneficial effect of hormonal replacement therapy in the incidence of CVD in this population. Additionally, evidences show a positive relationship between testosterone levels and increased abdominal adiposity as well as arterial hypertension in women after menopause. Although, it is well known that physical exercise promotes beneficial effects in the cardiovascular system with increased nitric oxide (NO) production and/or up-regulation of antioxidant enzymes, no studies evaluated the effect of exercise training (ET) on the steroids hormone levels associated with nitrite/nitrate and redox status in postmenopausal women. Therefore, the aim of this work was to investigate the effects of ET on the cardiovascular biomarkers and steroids hormone in normotensive (NT; n=29) and hypertensive (HT; n=21) women. Women were undergone to twenty-four sessions of ET on a treadmill at moderate intensity. Total testosterone, cortisol, cyclic GMP (cGMP), nitrite/nitrate (NOx-) and malondialdehyde (MDA) levels were measured before and after ET. Superoxide dismutase (SOD) and catalase enzymes activity was also evaluated. Blood pressure was significantly reduced after ET (approximately 5%) for NT and HT. In contrast, no changes were observed in the cardiovascular biomarkers, NOx- (basal: 28.5±4.0, ET: 28.6±3 μM for NT; basal: 38.9±8.0, ET: 55.4±10.4 μM for HT) and cGMP (basal: 5.0±0.5, ET: 6.3±0.7 pmol/mL for NT; basal: 5.5±0.7, ET: 6.4±1.0 pmol/mL for HT). Similarly, serum concentrations of cortisol (basal: 16.6±4.8, ET: 17.5±5.1 μg/dL for NT; basal: 15.7±5.4, ET: 16.4±4.5 μg/dL for HT) and testosterone (basal: 22.7±3.2, ET: 23.6±3.3 ng/dL for NT; basal: 25.2±3.0, ET: 23.4±2.7 ng/dL for HT) were not different in both groups. MDA levels were not different in both groups (basal: 13.8±1.6, ET: 12.2±1.2 μM for NT; basal: 14.2±1.3, ET: 13.3±1.1 μM for HT) as well as catalase activity (basal: 40.2±3.5, ET: 36.5±3.3 nmol/min/mL for NT; basal: 36.5±3.0, ET: 39.1±3.5 nmol/min/mL for HT). In contrast, a marked increase in SOD activity was found in both NT (basal: 12.5±1.4; ET: 24.8±2.3 U/mL) and HT groups (basal: 12.5±1.7; ET: 29.5±1.8 U/mL) after 24 sessions of ET. Our findings show that ET was effective in lowering blood pressure in postmenopausal women that was associated with up-regulation in SOD activity even though we failed to show any changes in NO/cGMP levels. Steroids hormone levels were similar between NT and HT postmenopausal women at baseline and after ET.

PCA287

Adding arginine to an essential amino acid (EAA) feed reverses age-related impairments in vascular responsiveness but does not offset age-related anabolic blunting

W. Mitchell[1,2], J.P. Williams[1,2], B. Phillips[1], D. Rankin[1], J.N. Lund[1,2], K. Smith[1] and P.J. Atherton[1]

[1]School of Graduate Entry Medicine, University of Nottingham, Derby, UK and [2]Royal Derby Hospital, Derby, UK

Impaired vascular function in older age compromises the positive effects of nutrition on limb blood flow, perhaps impacting on maintenance of healthy muscle mass. Herein, we explored: (i) the effect of age upon macro and micro-vascular limb blood flow responses to nutrition, and (ii) the potential for arginine, a substrate of nitric oxide synthase, to improve nutrient-mediate vascular responsiveness in older people. Using contrast enhanced ultrasound (CEUS) with Sonovue™ SF_6 microbubbles, along with phase shift Doppler, we measured: changes in leg blood flow (LBF), muscle microvascular blood volume (MBV), microvascular flow velocity (MFV) and their product microvascular blood flow (MBF), in response to a 15g oral mixed EAA feed in 8 young (~20y) and 8 older (~70y) men. An additional 8 older men (~70y) had the same 15g mixed EAA feed, supplemented with 3g L-arginine. Using $^{13}C_6$-phenylalanine tracer, muscle protein synthesis (MPS) was also measured. Measurements were made 2hr before and 4hr after feeding. Young men showed marked vascular responses to EAA feeding with an early increase in MBV (45±13%, P<0.001) due to capillary recruitment. This was achieved by 45 min post feed, preceding changes in LBF, MFV and MBF, which were observed 120-180 min post feed. LBF increased 44±11% (P<0.001), MFV increased 78±31% (P<0.01) and MBF increased 130±52% (P<0.001) from fasting. In contrast, older men fed 15g EAA had no significant changes in LBF or any index of muscle microvascular flow. Older men receiving 15g EAA with 3g arginine displayed increases in LBF (25±5%, P<0.05), MFV (88±48%, P<0.001) and MBF (110±70%, P<0.05, all mean±SEM, 2-way RM ANOVA) though MBV remained unchanged from fasted. Fasting MPS rates were similar in young (0.054%/hr) and older men (0.052%/hr). Young men demonstrated a total synthetic response of 0.27% in 4hrs after 15g EAA feeding. Older men had a blunted anabolic response of 0.22% (P<0.05 vs. young) in the same period, which was not augmented by 3g arginine (0.20%, P<0.05 vs. young, 1-way ANOVA). Oral EAA feeding achieves early recruitment of muscle capillaries (increasing MBV) with little change in flow; this is consistent with dilatation of terminal arterioles and would promote nutrient delivery by increasing exchange surface area and decreasing capillary-to-fiber distance. The later increase in LBF, MFV and MBF is consistent with a proximal shift in the level of regulating vessels. That arginine restores late, but not early, microvascular responses to feeding suggest different underlying mechanisms. Arginine's failure to augment MPS responses to feeding despite restoring LBF and MBF calls into question the physiological significance of the late circulatory response to feeding and promotes interest in early MBV changes.

PCA288

The effects of bolus versus pulse feeding strategies on muscle anabolism in older men

W. Mitchell[1,2], J.P. Williams[1,2], B. Phillips[1], D. Rankin[1], J.N. Lund[1,2], K. Smith[1] and P.J. Atherton[1]

[1]School of Graduate Entry Medicine, University of Nottingham, Derby, UK and [2]Royal Derby Hospital, Derby, UK

A topical advancement in understanding the control of muscle protein synthesis (MPS) was the discovery of a "Muscle-Full" phenomenon, whereby feeding stimulates only transient increases in MPS, which return to postabsorptive values despite sustained availability of plasma and muscle essential amino acids (EAA) including leucine.

We have explored this phenomenon in relation to aging by measuring MPS using a $^{13}C_6$-phenylalanine stable isotope tracer method. Measurements were made over a 6hr period (2hr fasted and 4hr during / after feeding), using two distinct feeding regimens: 16 older men received either a single 15g mixed EAA feed (N=8, 70±2 y; 'BOLUS') or the same dose in 4 x 3.75g fractions at 45 min intervals (N=8, 70±3 y; 'PULSE').

While MPS was unchanged from fasting in either group 0-90 min after EAA ingestion, it was elevated 90-180 min, irrespective of feeding strategy (BOLUS: 0.051 to 0.084 vs. PULSE: 0.047 to 0.073%/hr). In contrast, while MPS returned to baseline rates in BOLUS between 181-240 min (to 0.052%/hr) this was not the case in PULSE (0.070%/hr, P<0.05 vs. fasting, 2-way RM ANOVA). Despite these temporal differences, equal total MPS responses to feeding regimens were revealed by area under the curve analysis (0.22% vs. 0.23% in 4 h, P>0.05 1-way ANOVA).

While equal total MPS between regimens suggests a dose, rather than time-dependent mechanism regulates the muscle-full state in older men, these data point towards sustainment of the anabolic response over longer durations with PULSE feeding regimens.

Optimization and extraction of antioxidants from *Aloe vera* using response surface methodology

S. Kim, A.D. Assefa and S. Park

Biotechnology, Dept. of Molecular Biotechnology College of Life & Environmental Sciences, Konkuk University, 1, Hwayang-dong, Gwangjin-gu, Seoul 143-701 Korea., Seoul, Seoul, Republic of Korea

Antioxidants obtained from the plants are very popular trend in the world and has been utilised for development of functional foods. The natural antioxidant like phenolics and flavonoids help to prevent diseases like diabetes, cardiovascular diseases, arthritis and cancer etc. The main objective of this work is to search for natural antioxidants and optimization of process for *Aloe vera* extract as an antioxidant by using RSM (Response Surface Methodology). The independent vari-

ables were the extraction time (X1) varying within a 1-4 h range, the ethanol percentage X2 of water-ethanol extracting solvent (0-100 % v/v), temperature X3 X3 (25-60 °C), and the liquid-to-solid ratio X4 (30-60 mL/g). The response variables like extraction yield, concentrations of aloins A and B, aloesin, total polysaccharides, total phenolics and their antioxidant activities (FRAP and CUPRAC) were evaluated. The experimental value for yield, aloin A, aloin B, aloesin, total polysaccharide, total phenol and antioxidant activity (FRAP, CUPRAC) of *Aloe vera* extract were varied from 7.711 to 83.486%, 0.098-0.397mg/g extracted solid, 0.288-0.99mg/g extracted solid, 0.047-0.905mg/g extracted solid, 47.296-350.497mg D-mannose equivalent/g extracted solid, 0.477-3.604mg gallic acid equivalent/g extracted solid, 1.617-14.783mg trolox equivalent/g extracted solid, 11.422-104.532μM trolox equivalent/g extracted solid, respectively. Depending on this data in this study we observed that the optimum conditions for extraction of antioxidants from *Aloe vera* with different parameters are, the required time was 1hour, ethanol concentration were 34.34% v/v, extraction temperature were 60 °C, and the liquid-to-solid ratio was 45.75ml/g. The experimental values agreed with those predicted by RSM models, thus indicating suitability of the model employed and the success of RSM in optimizing the extraction conditions for *Aloe vera* antioxidants.

PCA290

Studying molecular physiology of DNA cruciforms with a coarse-grained computational model

C. Matek[1], T.E. Ouldridge[1], J.P. Doye[2] and A.A. Louis[1]

[1]Rudolf Peierls Centre for Theoretical Physics, Oxford University, Oxford, UK and [2]Physical and Theoretical Chemistry Laboratory, Oxford University, Oxford, UK

Cruciform structures of DNA occur in sequences exhibiting an inverted repeat (IR) structure. They are known to play a role in several regulatory processes of cellular physiology, and have been linked to the development of diseases such as Werner's syndrome and certain types of cancer (1).

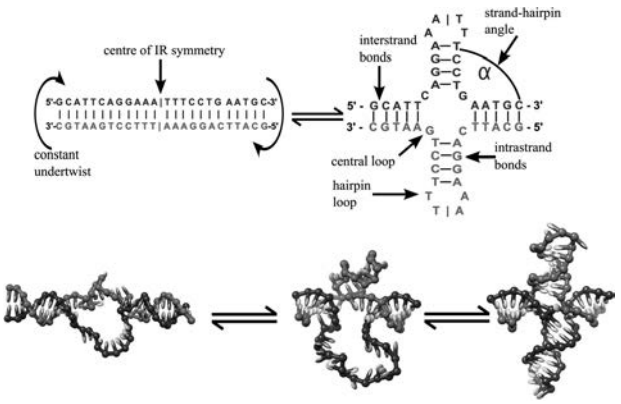
Magnetic tweezer assays have enabled the study of these non-canonical DNA structures on a single-molecule scale (2).However, a detailed understanding of structural and kinetic properties of DNA cruciforms is still lacking.

We used a coarse-grained computational model of DNA (3) to study thermodynamic stability and formation kinetics of cruciform structures in a superhelically stressed DNA strand at physiological temperatures.

Thermal quantities of the structures in the DNA model were obtained using a cluster-move Monte Carlo (MC) method. Free-energy landscapes governing the cruciform formation process in a 34bp IR sequence were calculated using umbrella sampling. Kinetic properties of cruciform formation were studied in direct, unbiased MC simulations for 34bp and 64 bp IR sequences.

In the simulations of the cruciform structures we find an asynchronous, but cooperative extrusion mechanism (4). First, a bubble has to diffuse to the centre position of the IR sequence. Then, a size fluctuation of the bubble must be large enough to allow for rearrangement of its single strands, leading to formation of a first hairpin. Upon formation of the first cruciform arm, the second arm rapidly grows to a similar size. This initial asynchronous formation is followed by a synchronous growth mechanism of both cruciform arms, which resolves the remaining superhelical stress. The asynchronous formation mechanism is reflected in the free energy landscapes of the system, which we calculated as a function of the number of base pairs in the system. For all parameters studied, the free energy barrier lies at 8-9k_BT. At a temperature of 39.4°C, we observe that the fully extruded cruciform structure is thermodynamically more stable than the corresponding bubble state of the DNA strand. This result consistent with the *in vivo* genetic instability observed for perfect IR sequences (2).

We have used numerical simulations of a coarse-grained model of DNA to study thermodynamic and structural properties of DNA cruciforms at a length and time resolution presently inaccessible to experimental setups. Our results show a complex asynchronous extrusion behaviour driven by DNA supercoiling and ambient temperature. The genetic instability of perfect IR sequences may be due to the high thermodynamic stability of cruciform structures under physiological conditions of temperature and supercoiling. This highlights the importance of physical properties of the DNA heteropolymer in physiological processes on a molecular scale, such as cruciform extrusion.



Cruciform extrusion was observed to follow a correlated, but asynchronous cooperative mechanism.

PCA293

Pattern of immunogenicity in a representative group of canines following anti-rabies immunization

M. Gunatilake[1], R.M. Pimburage[2], O. Wimalaratne[3], A. Balasuriya[4] and D. Perera[5]

[1]Physiology, Faculty of Medicine, University of Colombo, Colombo, Western, Sri Lanka, [2]Public Health Veterinary Services, Ministry of Health, Public Health Veterinary Services, Ministry of Health, Colombo, Western, Sri Lanka, [3]Department of Rabies Research and Vaccine Quality control, Medical Research Institute, Colombo 08, Colombo, Western, Sri Lanka, [4]Community Medicine, Faculty of Medicine, General Sir John Kotelawala Defense University, Ratmalana, Western, Sri Lanka and [5]Department of Rabies Research and Vaccine Quality control, Medical Research Institute, Colombo 08, Colombo, Western, Sri Lanka

Immunization of dogs against rabies plays a very vital role in reducing mortality due to rabies in humans as well as in animals. In this context, it is important to know whether a representative group of canines; specially Sri Lankan local breed/mongrel breed have antibody titres above the protective level recommended by the WHO following anti-rabies immunization and also whether the antibody titres are maintained above the protective level until the time of annual booster. Healthy domestic, stray dogs and puppies (N = 510) in Kalutara district, Sri Lanka were recruited initially and allocated into 8 groups based on pre-established criteria. A monavalent (inactivated) vaccine recommended by the Government Rabies Control Programme was used to immunize all recruited canines. On the day of vaccination 3-5 ml of venous blood (D0) was collected from each animal and post immunization blood samples were collected on days 30, 180, 360 (D30, D180 and D360). Rapid Fluorescent Focus Inhibition Test (RFFIT) was used to determine the virus neutralizing antibody titres in serum samples, at the Department of Rabies Research and Vaccine Quality Control, Medical Research Institute (MRI), Colombo 08. Total number of blood samples analyzed was 1520 collected from 380 canines that were available until D360 after immunization. The Ethics approval for the study was obtained from the Ethics Review Committees of the Faculty of Medicine, Colombo and MRI. The number (and percentage) of canines in Groups A to H that had antibody titres below the protective level of 0.5 IU/ml on D0, D30, D180 and D360 are indicated in table 1 (Mean antibody titres are not shown here). This is the first descriptive and comparative study involving a representative group of canines done in Sri Lanka. This indicates that a single dose of anti-rabies immunization fails to generate a protective level of immunity which lasts until 1 year in 40.42% of stray dogs in Group A and 57.14% of domestic dogs in Group D. The pattern of antibody titre development in adult domestic dogs in Groups E and F seems to be closely similar irrespective of regularity in immunization. Almost all puppies in Groups G and H need more than one immunization until the time of annual booster. It is evident that maternal antibodies do not protect puppies against rabies until the first anti-rabies immunization.

Table 1

Group	D0	D30	D180	D360
A (n=47) - Stray dogs without previous immunization history against rabies	44 (93.6)	06 (12.76)	06 (12.76)	19 (40.42)
B (n=47) - Stray dogs with previous immunization history against rabies	14 (29.79)	0 (0)	0 (0)	08(17.02)
C (n=47) - Young domestic dogs with previous immunization history	10 (21.28)	02 (4.26)	03 (6.38)	10 (21.28)
D (n=63) - Young domestic dogs without previous immunization history	01 (1.59)	04 (6.35)	04 (6.35)	36 (57.14)
E (n=51) - Adult domestic dogs with regular annual immunization history	12 (23.53)	02 (4)	06 (12)	11 (22)
F (n=48) - Adult domestic dogs without regular annual immunization history	11 (22.92)	0 (0)	02 (4.16)	08 (16.67)
G(n=40) - Puppies of previously immunized domestic bitches	40 (100)	01 (2.5)	07 (17.5)	37 (92.5)
H (n=37) - Puppies of unimmunized domestic bitches	37 (100)	02 (5.41)	08 (21.62)	33 (89.19)

PCA294

Gabexate mesilate mitigates coagulopathy and organ dysfunction in rats with endotoxemia

C. Tsao[1,3], H. Tsai[2], W. Liaw[3] and C. Wu[4]

[1]Anesthesiology, Taipei Veterans General Hospital and National Yang-Ming University, Taipei, Taiwan, [2]Department of Anesthesiology, Mackay Memorial Hospital, Taipei, Taiwan, [3]Department of Anesthesiology, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan and [4]Department of Pharmacology, National Defense Medical Center, Taipei, Taiwan

Sepsis and its complications, including multiple organ failure are associated with high mortality in patients in intensive care unit. Coagulation abnormalities, such as thrombocytopenia, prolonged clotting time and consumption coagulopathy, occurred in nearly all patients with severe sepsis. Gabexate mesilate (GM), a synthetic serine protease inhibitor, is known to be an anticoagulant by competitively inhibiting activities of

thrombin and factor Xa as well as plasmin and plasma kallikrein. Several studies report that GM has protective effects against tissue injury in models of endotoxemia. The aim of this study was to examine whether GM could attenuate organ dysfunction and improve survival rate in an animal model of lipopolysaccharide (LPS)-induced endotoxemia (Tsai et al, 2012). LPS (30 mg/kg over a 4-h intravenous infusion) was administered to male adult Wistar rats (250-300 g). Bacterial LPS (E. coli serotype 0127:B8, L3127) was used in this study. Some of rats received a continuous infusion of GM (10 mg/kg/h for 8.5 h) at 30 min prior to the infusion of LPS as the treatment group. Variables of hemodynamic and biochemistry were measured during the subsequent 6 h after the start of LPS infusion. Parameters of thrombelastography, hemostasis and inflammatory response were also measured, and survival rate was monitored every 30 min during the 8-h experiment. The administration of LPS rats with GM (i) alleviated hypotension, (ii) attenuated the LPS-induced liver and kidney dysfunction, (iii) minimized consumptive coagulopathy displayed by thrombelastography, (iv) attenuated the rises in serum tumor necrosis factor-α, interleukin-6, and plasma thrombin-antithrombin complex as well as plasminogen activator inhibitor-1, (v) reduced neutrophils infiltration score in lung, liver and kidney, and (vi) significantly increased the 8-h survival rate (58.3%), when compared to the LPS group (25.7%, $p<0.05$). These results suggest that the pre-treatment of LPS rats with GM not only reduces organ injury but also improves survival rate. These protective effects of GM may be attributed to its anti-inflammation and anti-coagulation properties.

PCA295

Erythrocyte osmotic fragility and lipid peroxidation in experimental hyperthyroidism

N. Dariyerli, R. Yucel, S. Ozdemir, S. Toplan, M. Akyolcu and G. Yigit

Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Erythrocyte osmotic fragility and lipid peroxidation in experimental hyperthyroidism
Thyroid hormones have multifaceted effects on humans. Among others, they influence the basal metabolic rate; the overproduction of thyroid gland hormones results in an increased rate of metabolism and oxygen consumption by cells. Increased thyroid hormone concentrations affect the oxidant/antioxidant equilibrium and may cause harm to the cell. Thyroid hormones, while leading to increase in free radicals also activate the antioxidant enzymes. The purpose of this study is to determine the structural integrity of red blood cells in experimental hyperthyroidism by assessing the osmotic fragility of erythrocytes in primary hyperthyroidism and its relation between lipid peroxidation. In this study, twenty-two Spraque-Dawley-type female rats weighing between 160 and 200 g were divided into two, as control (n=10) and experimental (n=12), groups. The experimental group animals have received tap water and L-Tiroksin (0.4 mg/100 g fodder) added standard fodder for 30 days to induce hyperthyroidism. Control group animals were fed tap water and standard fodder for the same period. At the end of the experimental period, blood samples were drawn from the abdominal aorta of the rats under light ether anesthesia. Triiodothyronine (T3), thyroxine (T4), and thyroid stimulant hormone (TSH) levels, osmotic fragility, malondialdehyde (MDA), glutathione (GSH) levels and superoxide dismutase (SOD) activity were measured. Statistical analysis was done by Mann-Whitney U test. Data were expressed as means ± SD. Differences between groups were considered significant at the ($p<0.05$) level. The statistically significant increase in T3, T4 and the significant decrease in TSH) of experimental group is the evidence of induced primary hyperthyroidism. There was a statistically significant increase found in erythrocyte MDA($p<0.001$) levels, and SOD activity ($p<0.001$), but statistically a significant decrease was detected in GSH ($p<0.05$) levels in hyperthyroid group when compared to controls. In the controls, the osmotic fragility levels were found to be maximum at 0.32 % NaCl and minimum at 0.56 % NaCl, whereas in experimental group reached a maximum at 0.40 % NaCl and minimum at 0.64 %. When statistical evaluations were compared, statistically important increases were detected in maximum and minimum osmotic fragility limits between both the groups ($p<0.001$). This finding, which shows maximum hemolysis ratio, is the evidence of increased osmotic fragility of the erythrocytes in hyperthyroidism. As a result of our study, it may be concluded that hyperthyroidism may led to an increase in osmotic fragility of erythrocytes and this situation may possibly originate from the increased lipid peroxidation in hyperthyroidism.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA296

The effects of experimental hypothyroidism on hemorheology and plasma fibrinogen concentration

S. Toplan, N. Dariyerli, S. Ozdemir, M. Akyolcu, H. Hatemi and G. Yigit

Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

The effects of experimental hypothyroidism on hemorheology and plasma fibrinogen concentration
Thyroid hormones are responsible for arrangement of general body metabolism. In their deficiency pathological findings arise related to various physiological systems. In hypothroid cases it has been observed that blood rheology alters. Hematological changes, especially anemia, are common and well characterized in hypothyroidism. This study has been planned with the purpose to determine the effects of experimental hypothyroidsm on hemorheological parameters and fibrinogen concentration. In this study, twenty Spraque-Dawley type albino female rats weighing 160-200g were used in both control and experimental group animals. Both control (n=10) and experimental group (n=10) animals were kept in same physical conditions during experimental period and were fed with standard fodder and tap water. To induce hypothyroidism, methimazole (75-mg/100g fodder) was given to experimental group rats for 20 days. At the end of the experimental period, blood samples were drawn from the abdominal aorta of the rats under the light ether anesthesia. Thyroid stimu-

lant hormone (TSH), triiodothyronine (T3), thyroxine (T4) hormone levels, hematocrit (% Hct), hemoglobin (Hb), blood viscosity, erythrocyte rigidity index, plasma viscosity and plasma fibrinogen concentration values of both control and experimental group animals were determined and evaluated. Statistical analysis was done by the Mann-Whitney U test. Data were expressed as means ± SD. Differences between groups were considered significant at the $p<0.05$ level. According to results of our study when values of control group and experimental groups were compared: While T3 and T4 levels of experimental group were found lower ($p<0.001$) but TSH level higher ($p<0.001$) than that of the control group. Statistically significant decreased T3, T4 and increased TSH values in experimental group were taken as the indicator of the primary hypothyroidism. Plasma viscosity and fibrinogen concentration of hypothyroid group were found significantly higher than controls ($p<0.01$). Hematocrit and hemoglobin values were also found lower in experimental group than the control group animals ($p<0.01$). However, there was no significant difference found in blood viscosity at the original Hct value but there was a significant increase at standart Hct value ($p<0.01$). There was also no change in erythrocyte rigidity index between control and experimental groups. According to results of our study it may be concluded that in the early phase of hypothyroidism, changes in hemorheology are only seen as an increase in plasma viscosity. Such an increase may be dependent on increased fibrinogen concentration.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA297

Reference haemoglobin value in apparently healthy Sudanese children in Khartoum state, Sudan

I.M. Hamad[1] and O.A. Musa[2]

[1]physiology, Bahri university, Khartoum, Khartoum, Sudan and [2]physiology, Ribat university, Khartoum, Khartoum, Sudan

The WHO in 1997(5) stated that 12 gm/dl is the borderline for normal Hb level for adult and 15 as a normal mean (16 and 14 gm./dl for male and female respectively) .Dacie & Lewis stated Hb value of 13.0+1.5 gm./d for children 10-12 yl,(4).Few researchers in Sudan worked in reference Hb value, among them Abdella et al in 1987 (1) found the mean of Hb reference value of 12.00gm/dl for children between 6 to 12 y. with no sex difference. Atig in 1995 (3) stated Hb reference value of 11.63+ 0.89gm/dl for Sudanese children between 5 to 12 y. in Khartoum state. Agabeldour (2) in 1997 worked out Hb reference value of 13.18+ 1.46gm/dl for adult males and a value of 11.17 + 2.03 gm/dl for adult females in Sudan
Objective:- The objective of this study is to estimate the reference Haemoglobin value in apparently healthy Sudanese children in Khartoum state, Sudan. To achieve this objective, using stratified random sampling, 1000, capillary blood samples were collected from apparently healthy Sudanese children in Khartoum state within the age group 12 – 14 years, 550 females and 450 males. The subjects were interviewed according to a designed questionnaire, clarifying tribe, nutritional and socioeconomic status as main variables, Haemoglobin (Hb) value was determined for each, using Hb-cyanide method. The mean reference Haemoglobin value for both sexes was 11.69g/dl+ 2.13 while in males and females was 11.67g/dl+ 2.13, and 11.70g/dl+ 2.13 respectively. About 50% of the children reported value less than 12g/dl, while 6.3% showed a value of 9.4g/dl or less, without any symptoms of anemia. Gender and income has no Significant effect on Haemoglobin value in this study, while nutrition and ethnic background affect Hb value, Southerners have the lowest Hb value, while Kordofan tribes have the highest.
Conclusion :- the mean reference Haemoglobin value for both sexes within the age group 12 – 14 years in Sudan is considerably lower than the standard ones stated in books and, differ according to tribes

Tribes, their individual numbers, %, and mean Hb of different Sudanese

tribe	NO.	%	mean Hb in g/l
North	668	66.8%	12
South	107	10.7%	10.68
Noba	45	4.5%	11.41
Darfour	101	10.1%	11.84
Kordufan	79	7.9%	12.05
Total	1000	100%

I am thankful to the Sudanese children and their parents who signed the agreements to conduct this research, and to all those who helped me in to do this work and declare that the whole research investigations were entirely my sole work and effort

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA298

Determination of hematological and biochemical blood parameters in kitten and adult Angora cats

S. Arikan[1], M. Cinar[2] and O. Simsek[1]

[1]Department of Physiology, Faculty of Veterinary Medicine, Kirikkale University, Kirikkale, Turkey and [2]Department of Biochemistry, Faculty of Veterinary Medicine, Kirikkale University, Kirikkale, Turkey

The purpose of this study was to investigate the reference values of haematological and biochemical blood parameters on kitten and adult Angora cats. In this study, blood samples were taken from a total of 24 Angora cats, 16 adults (1 to 3 year old) and 8 kittens (1.5, 3, 4.5, 6, 7.5, 9 ve 10.5). In the serum, alanin amino transferase (ALT), alkanine phosphotase (ALP), gama- glutamil transpeptidase (GGT), creatine kinase (CK), cholesterol, total protein, calcium (Ca), magnesium (Mg), phosphor (Pi) levels were measured, and from the blood, erythrocyte (RBC), leukocyte (WBC), monocyte (MON), lymphocyte (LYM), hemoglobin (HGB) and hematocrit (HCT) values were determined. Data were analyzed using general linear model in SAS. Fisher's least significant difference (LSD) test was used for mean comparisons. All values are presented as the mean ± S.E.M. The animal care and use protocol was approved by Local Ethical Committee of Kirikkale University.

Monocyte level was found to be high in adult cats, ALP, CK activities were lower in adult cats compared to the kittens. Total protein, RBC, HGB and HCT in kittens (1.5-3 months old) were lower, GGT activity and WBC value in kittens (1.5-3 months old) were higher than other kittens. Concentration of cholesterol, Ca, Pi and Mg was higher in kittens (1.5-3 months old) than in adult cats. As a result of this study, it is the first time these reference values of haematological and biochemical blood parameters in kitten and adult Angora cats were determined. The results of present study will be helpful and an excellent reference document for clinicians.

Dose dependent effects of fish oil on oxidative stress

M.A. Martins[1], M.B. Moss[1], I.K. Mendes[1], C.O. Chamma[1], W.V. Mury[1], M.B. Águila[2], T.M. Brunini[1] and A. Mendes-Ribeiro[1]

[1]Department of Pharmacology and Psychobiology, State University of Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil and [2]Department of Anatomy, State University of Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil

Introduction: Despite the cardiovascular benefits provided by polyunsaturated fatty acids (PUFA), there has been concern that these fatty acids exhibit the highest sensitiveness to peroxidation, which in turn could enhance production of reactive oxygen species. Here, we investigated the effects of different amounts of fish oil on oxidative status in red blood cells (RBC) from mice fed a high fat diet.
Methods: C57BL/6 male mice were divided into six groups based on the diet offered; the control group was fed with a standard diet (10% lipids) and the others groups were fed with isoenergetic high fat diets (50% lipids) containing 0%, 10%, 20%, 30%, or 40% of fish oil. The high fat diets were composed of a mixture of lard and fish oil, with a gradual replacement of lard by fish oil. At the end of the experimental period (12 weeks), the animals were anaesthetized with intraperitoneal sodium pentobarbital (0.42 mg/g). Blood samples obtained by cardiac puncture were collected into a tube containing heparin and RBC were isolated by centrifugation. Oxidative damage in RBC was evaluated by determination of carbonyl groups and by the concentration of malondialdehyde (MDA). The activity of catalase (CAT), glutathione peroxidase (GPx) and superoxide dismutase (SOD) enzymes was analysed to evaluate the antioxidant status. The experimental protocols were approved by the local Ethics Committee (CEUA/033/2011). Comparisons among groups were done by one-way ANOVA followed by a Holm-Sidak post-hoc test. Significance level was set at 5%.
Results: Table 1 shows the results of the oxidative stress parameters. Diets absent (F0) or with high concentrations of fish oil (F20, F30, F40) induced an increased RBC lipid peroxidation than standard chow diet. F0 mice also showed an increased protein oxidative damage, assessed by the quantification of carbonyl groups, compared to control, F20, F30, and F40 mice. No significant difference in protein oxidation was observed among none of the fish-oil fed mice. The antioxidant enzyme analysis showed that SOD activity in RBC from F0 and F10 groups was decreased compared to control group. The activity of the other antioxidant enzymes, CAT and GPx, did not differ among groups, except for a reduction in GPx levels from the F40 group compared to the F20 group.
Conclusion: Lipid peroxidation of RBC rises linearly with increasing amounts of fish oil in the diet, however this increased susceptibility was not reflected in protein damage. The use of antioxidant products during dietary fish oil supplementation could be an alternative to ensure that their consumption does not result in detrimental secondary effects.

Beneficial effect of Cinnamomum burmannii in streptozotocin-induced type 1 diabetic rats

M.L. Silva[1,2], P. Pereira[1], A. Bernardo[1], M. Moncada[1], J. Singh[2] and F. Mesquita[1]

[1]BioquiLab - Centro de Investigação Interdisciplinar Egas Moniz (CiiEM), Instituto Superior de Ciências da Saúde Egas Moniz, Almada, Portugal and [2]School of Forensic and Investigative Sciences and School of Pharmacy and Biomedical Sciences, University of Central Lancashire, Preston, UK

Cinnamon is a traditional plant which is used as a spice, tea, for flavour and for the taste of food preparation. This spice possesses therapeutic properties to treat diabetes mellitus (DM), acting both as an anti-antioxidant and an anti-inflammatory mediator. There are different spices of cinnamon which can induce hypoglycaemic, protective and beneficial effects in DM, regulating blood glucose and lipid profiles. However, not much work has been done on the species, Cinnamomum burmannii. This study investigated the effect of aqueous C. burmannii extract on streptozotocin (STZ)-induced type 1 diabetic (T1DM) rats.

Aqueous cinnamon extract (CE) of cinnamomum burmannii was adapted from Shen et al method (Biosci. Biotechnol. Biochem. 74(12), 2010). T1DM was induced by a single ip injection of STZ (60 mg/Kg body weight) to young adult male rats (125-149g) and maintained with 12 h:12 h light/dark cycle, at temperature and humidity controlled room. Two weeks following STZ-induction both diabetic and age-matched control rats were administrated daily with 150 mg/Kg bw of CE by gavage method during 11 weeks. Control groups (STZ and control) received the same volume of water. The study had ethical clearance of UCLAN and Veterinary Medicine Faculty of Portugal. Blood glucose level (BGL), body weight and food consumption were measured on a weekly basis. At the end of the experimental protocol, the biochemical parameters and the antioxidant status were determined in each rat. The results show that diabetic rats treated with CE showed no significant decrease ($p>0.05$) in BGL and food consumption compared with control group. However, body weight was significantly (ANOVA; $p<0,05$) increased in diabetic rats treated with CE (363.91±17,80 g) compared with control (257,68±18,08) group. The results also show that C. burmannii had no significant effect on either blood lipid profiles or on HbA1c in STZ-induced diabetic rats compared to control. However, the antioxidant status of C. burmannii was markedly improved in diabetic rats compared to control group, but this was not significant. The results suggest that aqueous C. burmannii extract possesses beneficial effects on T1DM rats through improvement in body weight and via its antioxidant properties. Nevertheless, the mechanism via which cinnamon exerts its antidiabetic effect has to be clarified.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Hypertrophic cardiomyopathy and impairment mitochondrial function in insulin-resistant obese mice

A.S. Santos, C.S. Costa, A.C. Santana, E. Cortez, V.M. Soares, E.P. Garcia-Souza, A.S. Moura and C.A. Nascimento-Saba

Physiological Sciences, State University of Rio de Janeiro, Rio de Janeiro, Brazil

Obesity involves co-morbidities as dyslipidemia, cardiovascular disease, insulin resistance and type 2 diabetes. One characteristic of obesity is the propensity for increased circulating fatty acids. However, a loss of synchronization between fatty acid availability and oxidation would result in accumulation of fatty acid derivatives in non specific tissue such the cardiomyocyte, inducing lipotoxicity that is associated with contractile dysfunction and heart failure. It is also observed mitochondrial dysfunction playing key role in cardiac hypertrophy and failure, that can indicate defects at specific sites in electron transport chain (1, 2, 3, 4). The aim of the study was to investigate how lipid and glucose metabolic alterations affect the ventricular contractile function in mice fed high fat diet, through mitochondrial bioenergetics. After weaning, mouse C57Bl/6 received diet containing 7% (C) or 19% (HF) of soybean oil, until 135 days old. Food intake and body mass were monitored, and glucose tolerance test was realized. At 135 days, body composition was evaluated by Dual-energy X-ray Absorptiometry (DEXA) and after, animals were sacrificed by exsanguination. Lipid profile, leptin, insulin, HOMA-IR and the adiposity index were evaluated. The heart, the pancreas and intraabdominal adipose tissue were collected, weighted and processed to morphological analysis. Left ventricular myocardial fibers were used to analyze mitochondrial respiration by technique of high resolution respirometry. Cardiac hemodynamic was evaluated by Langendorff technique of isolated heart perfusion and proteins related to cardiomyocytes bioenergetics (CPT1, UCP2, GLUT1, GLUT4, AMPK and pAMPK) were analyzed by Western blotting. The group HF presented differences in adiposity (130%) with adipocyte hypertrophy (200%),, glucose intolerance, hyperinsulinemia (80%), insulin resistance and pancreatic islet hypertrophy (200%); hyperleptinemia (22%), increase of triglycerides (49%), LDL (29%) and VLDL (51%), without difference in food intake. The hypertrophic cardiomyopathy observed reflected in hemodinamic alterations as increased contractility (78%), higher ventricular pressure (63%) and impaired diastolic function (-36%). Oxidation of carbohydrates (-47%) and fatty acids (-60%) was decreased in cardiomyocytes, however, the expression of proteins co-related to cardiomyocytes bioenergetics did not differ between the groups. Obesity induced metabolic disorders in series, leading to dyslipidemia, type 2 diabetes mellitus, besides impairment of mitochondrial oxidative capacity and cardiac hypertrophy, causing hemodynamic dysfunction. However, these alterations are dissociated of energetic cardiac sensor.

PCA303

Hypothalamic AMP-activated protein kinase is implicated in leptin-induced sympathetic nerve activation

M. Tanida[1], T. Shibamoto[1] and K. Rahmouni[2]

[1]Department of Physiology II, Kanazawa Medical University, Uchinada, Japan and [2]Departments of Pharmacology and Internal Medicine, University of Iowa Carver, College of Medicine, Iowa city, IA, USA

[Introduction] In mammals, leptin released from the white adipose tissue acts on the central nervous system to control feeding behavior, cardiovascular function, and energy metabolism. Central leptin activates sympathetic nerves that innervate the kidney, adipose tissue, and some abdominal organs in rats [1,2]. AMP-activated protein kinase (AMPK) is essential in the intracellular signaling pathway involving the activation of leptin receptors (ObRb) [3]. We investigated the potential of AMPKα2 in the sympathetic effects of leptin
[Method] We used in vivo siRNA injection to knockdown AMPKα2 in rats, and produced reduced hypothalamic AMPKα2 expression. Under urethane anesthesia (1.2g/kg), effects of

leptin (10μg) injection into the ventricle on sympathetic nerve activities were investigated by electro-physiological recording. Effects of leptin on feeding behavior and blood papameters were examined in conscious rats.
[Result] Leptin effects on body weight, food intake, and blood FFA levels were eliminated in AMPKα2 siRNA-treated rats. Leptin-evoked enhancements of the sympathetic nerve outflows to the kidney, brown and white adipose tissues were attenuated in AMPKα2 siRNA-treated rats. To check whether AMPKα2 was specific to sympathetic changes induced by leptin, we examined the effects of injecting MT-II (600pmol), a melanocortin-3 and -4 receptor agonist, on the sympathetic nerve outflows to the kidney and adipose tissue. MT-II-induced sympatho-excitation in the kidney was unchanged in AMPKα2 siRNA-treated rats. However, responses of neural activities involving adipose tissue to MT-II were attenuated in AMPKα2 siRNA-treated rats.
[Conclution] These results suggest that hypothalamic AMPKα2 is involved not only in appetite and body weight regulation but also in the regulation of sympathetic nerve discharges to the kidney and adipose tissue. Thus, AMPK might function not only as an energy sensor, but as a key molecule in the cardiovascular, thermogenic, and lipolytic effects of leptin through the sympathetic nervous system.

PCA305

Improvement of structural and functional microvascular abnormalities after central sympathetic nervous system modulation in a rat model of metabolic syndrome

A. Nascimento[1,2], M. Lessa[1], M. Machado[1], B. Antunes[1], I. Bonomo[1], P. Bousquet[2] and E. Tibiriçá[1]

[1]FIOCRUZ, Rio de Janeiro, RJ, Brazil and [2]University of Strasbourg, Strasbourg, France

Motivation: We investigated the effects of a chronic anti-hypertensive treatment using centrally-acting sympatho-inhibitory drugs on microvascular parameters in a rat model of metabolic syndrome (MS) induced by long-term high-fat diet with salt supplementation.
Methods: Fifty male adult Wistar rats were used in conformity with the guidelines of the Animals Care and Use Comitee of the Oswaldo Cruz Foundation, Brazil (Autorization P 31-11). They were maintained under normal (CON, n = 10) or high-fat diet (HFD, n = 40) during 20 weeks. Thereafter, the HFD group received oral clonidine (HFD-CLO, 0.1 mg/kg), rilmenidine (HFD-RIL, 1 mg/kg), LNP 599 (HFD-LNP, 10 mg/kg) or vehicle (HFD-CON). Functional capillary density (FCD) was evaluated in the gracilis muscle and skin of the ear using intravital videomicroscopy and structural capillary density (SCD) was studied in the skeletal muscle and left ventricle using histochemical analysis. Systolic blood pressure was evaluated by photo-plethysmography and plasma catecholamines by HPLC determination. Plasma glucose, triglycerides and cholesterol were determined by enzymatic assays.
Results: There was an increase in systolic blood pressure (178±2 vs. 138±3 mmHg, P<0.05) and heart rate (412±8 vs. 336±5 bpm, P<0.05) in the HFD-CON compared to the CON group. The HFD-CON group also presented a decrease in FCD and SCD in the gracilis muscle, compared to CON group (153±8 vs. 253±16 capillaries/mm2 and 1.5±0.08 vs. 1.8±0.04 capillaries/fiber, P<0.05, respectively). However, there were no alterations in FCD in the skin. The SCD was reduced in the left ventricle of the HFD-CON group when compared to the CON group (0.18±0.01 vs. 0.33±0.01 Vv[cap]/Vv[fib], P<0.05). The groups of animals submitted to HFD and treated with clonidine, rilmenidine and LNP 599 presented a similar reduction in systolic blood pressure (155±4, 161±4 and 156±4 mmHg, respectively, P<0.05) when compared to the HFD-CON group (178±2 mmHg) and in adrenaline levels (68±7 and 64±8 and 64±8 pg/mL, respectively, P<0.05) when compared to the HFD-CON group (89±4 pg/mL). These reductions in systemic catecholamines were accompanied by an increase in the FCD and SCD in the skeletal muscle when compared to the HFD-CON group. Moreover, there was an increase in the SCD in the left ventricle in the HFD-RIL group when compared to the HFD-CON group.
Conclusions: The modulation of sympathetic activity using chronic anti-hypertensive treatment with centrally-acting drugs results in a simultaneous reduction of arterial pressure and plasma catecholamines accompanied by an improvement of capillary rarefaction in the skeletal muscle and left ventricle in an experimental model of MS in rats.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA306

Resveratrol induces central hypotensive effect via AMPK-mediated signaling to eliminate fructose induces NADPH oxidase overexpression

P. Cheng[1], C. Tseng[1,2] and L. Ger[1]

[1]Medical Education and Research, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan and [2]Biomedical Sciences, National Sun Yat-sen University, Kaohsiung, Taiwan

Reactive oxygen species (ROS) in the brain are thought to contribute to the neuropathogenesis of hypertension by enhancing sympathetic nervous system activity. The nicotinamide-adenine dinucleotide phosphate (NADPH) oxidase and its regulatory subunit Rac1 (a small GTPase) play important roles in ROS production in the brain. Resent evidences reported that resveratrol activates AMP-activated protein kinase (AMPK) to suppress oxidative stress. Therefore, we examined whether promotion of AMPK in the brain decreases Rac1-derived ROS generation, thereby reducing blood pressure in fructose-induced hypertensive rats (F rats). In this study we elucidated the ROS level in the nucleus tractus solitarii (NTS) and rostral ventrolateral medulla (RVLM) were greater in F rats than in Wistar-Kyoto rats (WKY). Inhibitions of ROS, oral resveratrol for one week decrease blood pressure and increase NO production in F rats but not in WKY. Diminutions of Rac1 through resveratrol also reduce NADPH oxidase subunit expression (p22-phox and p67-phox) and induce SOD2 production. In addition, inhibition of AMPK by an AMPK inhibitor (compound C) abolished resveratrol-induced decreases in Rac1 and NADPH oxidase activities and resveratrol-induced increases in SOD2 expression, suggesting that AMPK is an important mediator of the resveratrol-induced regulation of these enzymes. Interestingly, abolish Rac1 by overexpression of AMPK that decrease blood pressure through reduced extracellular signal-regulated kinases 1/2 (ERK1/2), ribosomal protein S6 kinase (RSK), and

nNOS phosphorylation in in F rats. These results indicate that the activation of Rac1 in the brain generates ROS via induced NADPH oxidase, which cause dysfunction of ERK1/2-RSK-nNOS signal pathway in F rats, and this mechanism might be important for the neuropathogenesis of hypertension in fructose-induced hypertension.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA307

Neuronal nitric oxide synthase activation is involved in midkine-mediated cardiovascular effect in the nucleus tractus solitarii

H. Chen[1] and C. Tseng[1,2]

[1]Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan and [2]Department of Medical Education and Research, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan

The renin-angiotensin system (RAS) plays a central role in the regulation of blood pressure. Neuronal nitric oxide synthases (nNOS) is distributed throughout the central nervous system (CNS) and has been proposed to modulate neuronal activity in the nucleus tractus solitarii (NTS). Previous studies demonstrated that Ang II may modulate central blood pressure effects via (Reactive oxygen species) ROS to downregulate ERK1/2, RSK and nNOS in the NTS. Recent evidence has suggested that midkine is produced in the lung and in turn upregulates angiotensin-converting enzyme (ACE) expression. However, the signalling mechanisms involved in midkine-mediated depressor effects in the NTS remained uncertain. Hence, the aim of this study was to investigate these signalling mechanisms. Male Wistar-Kyoto rats (WKY) were anesthetized with urethane, and blood pressure was monitored intra-arterially. Microinjection of midkine into the NTS produced a dose-dependent decrease in BP and HR, and increased nitrate levels in anesthetized WKY. Midkine was unilaterally microinjected into the NTS, and the cardiovascular effects were evaluated before and after microinjection of the N(5)-(1-imino-3-butenyl)-L-ornithine (vinyl-L-NIO), nNOS-specific inhibitors. This depressor effect of midkine was attenuated after pretreatment with an ACE antagonist. Immunoblotting and immunohistochemical analysis further showed that microinjection of midkine significantly increased the expression of ERK1/2 and also increased nNOS phosphorylation. In contrast, L-NIO, eNOS-specific inhibitor, did not diminish these midkine-mediated effects. However, midkine did affect the nNOS phosphorylation level or nNOS upstream ERK1/2 phosphorylation levels. Furthermore, microinjection of nNOS-specific inhibitor did attenuate midkine-induced depressor effects in the NTS. Taken together, these results suggest that the ERK1/2- nNOS signaling pathway may play a significant role in midkine–mediated central blood pressure regulation.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA308

Cross-talk between Wnt and insulin signaling in central blood pressure regulation

W. Cheng[1,2] and C. Tseng[1,2]

[1]Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan and [2]Department of Medical Education & Research, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan

The Wnt signaling pathway has implicated in numerous physiological and pathophysiological activities. In addition, recent clinical and in vitro studies reveal that aberrant Wnt signaling is thought to play an important role in the onset of diabetes. Our previous studies also mentioned that insulin plays a role in central blood pressure regulation in the nucleus tractus solitarii (NTS), located at the dorsal part of the brainstem. Nevertheless, the relationship between Wnt signaling and insulin pathway and related modulation of blood pressure in the central nervous system has not been established. In the present study, we postulated that Wnt signaling pathway may improve neuronal insulin resistance and that neuronal insulin resistance is a core mechanism involved in triggering hypertension. Intracerebroventricular administration of Wnt3a (0.9 pmol/per day) produced depressor in both spontaneously hypertensive rats (SHRs) and fructose-fed rats (FFRs). Pretreatment with a low density lipoprotein receptor-related protein (LRP) antagonist, Dickkopf-1 (DKK-1) (1 μg/per day) significantly attenuated the depressor effect and nitric oxide (NO) production evoked by Wnt3a. Additionally, immunoblotting and pharmacological studies further showed that inhibition of LRP6 activity by DKK-1 significantly abolished Wnt3a-induced glycogen synthase kinase 3beta (GSK-3beta)S9, extracellular signal-regulated kinases 1/2 (ERK1/2)T202/Y204, ribosomal protein S6 kinase (RSK)T359/S363, AktS473, insulin receptor substrate (IRS)Y612 phosphorylation and increased IRS1S332 phosphorylation. GSK-3beta was also found to direct bind to IRS1 and induced Ser332 phosphorylation in the NTS. Likewise, administration of GSK-3beta inhibitor (TWS119, 0.173 μg/per day) into the brain decreased blood pressure of SHRs and FFRs through enhancing IRS1 activity. Taken together, these results suggest that the Wnt-LRP6-GSK3beta signaling may as a key regulator of insulin pathway and a potential therapeutic target for essential hypertension.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA309

Neuroprotective effects of acetyl-L-carnitine against ischemia-reperfusion injury: a spin resonance study

O. Tokumaru[1], M. Shimada[2,1], Y. Mizutani[2,1], K. Ogata[1], T. Kitano[3] and I. Yokoi[1,3]

[1]Neurophysiology, Oita University Faculty of Medicine, Yufu, Oita Pref., Japan, [2]Medical Student, Oita University Faculty of Medicine, Yufu, Oita Pref., Japan and [3]Medical Education Center, Oita University Faculty of Medicine, Yufu, Oita Pref., Japan

Acetyl-L-carnitine (ALCAR), a guanidino compound, is reported to be neuroprotective against ischemia-reperfusion injury (IRI).[1,2] Energetically, ALCAR provides acetyl-CoA to TCA cycle to maintain aerobic energetic metabolism in electron-transport system. In addition, it is speculated that ALCAR inhibits

peroxidation of tissue as an antioxidant. The mechanism of neuroprotective effects of ALCAR was investigated by spin resonance analyses; phosphorous NMR (^{31}P-NMR)[3,4] and electron spin resonance spectroscopy (ESR). [4]

Wistar rats (male, 6-wks, 200g, n=5 per group) were used. In each experiment, a rat was deeply anaesthetised with diethyl ether and then decapitated. 400-μm-thick brain slices were loaded into a NMR sample tube and superfused with well oxygenated ACSF with ALCAR (0, 0.1, 1 mM) at 27.5°C. High-energy phosphates in brain slices, phosphocreatine (PCr) and ATP, were non-destructively measured by ^{31}P-NMR (DRX300wb, Bruker, Germany). Brain slices were exposed to IRI by halting the perfusion for 1 hr, followed by the reperfusion for 3 hrs. The ESR measurement of the radical scavenging activity of ALCAR was based on the competitive reaction with spin trapping agent DMPO or *g*-CYPMPO.[5] Antioxidant activity of ALCAR on peroxidation in brain homogenate was also evaluated by thiobarbituric acid reactive substances (TBARS) assay. All experiments were repeated 3-5 times. Values are means ± SEM, compared by ANOVA.

^{31}P-NMR demonstrated significantly better recovery of PCr in brain slices superfused with 0.1 mM ALCAR (72±5%) than control (59±1%; $p<0.05$). But no better recovery was observed with 1 mM ALCAR (59±3%). In ESR study, ALCAR exhibited direct radical scavenging activity for ascorbate free radicals (EC_{50} 0.34 mM), DPPH radicals and methyl radicals in dose-dependent manners ($p<0.05$). On the other hand, ALCAR at mM-order concentrations increased amounts of superoxide anion ($O_2^{\bullet-}$) and hydroxyl radicals (•OH) than control. TBARS assay demonstrated that ALCAR inhibited peroxidation by carbon-centered radicals at concentrations between 0.1 μM and 1 mM ($p<0.05$), whereas peroxidation was doubled at 10 mM. ALCAR did not inhibit peroxidation by •OH. In conclusion, it is speculated that ALCAR might be neuroprotective against IRI in a limited range of concentration (*i.e.* μM-order) through its antioxidant activity attributable to its free radical scavenging activity. Interestingly, ALCAR increased amounts of $O_2^{\bullet-}$ and •OH at concentrations in mM-order which might support the findings by NMR and TBARS assay that ALCAR might not be neuroprotective at mM-order concentration.

Supported by JSPS KAKENHI to OT (#24592304), TK (#23592259 and IY (#23592099).

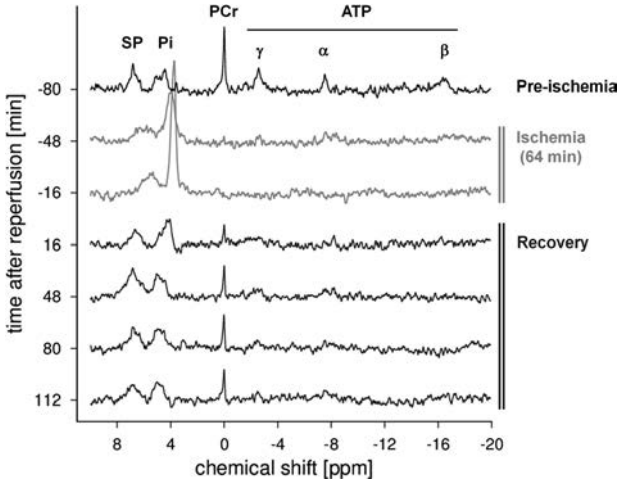

Figure 1. ^{31}P-NMR spectra of rat brain slices. The peaks correspond to, from left to right, sugar phosphate (SP), inorganic phosphate (Pi), phosphocreatine (PCr), γ-, α- and β-phosphate of ATP. During the ischemia, high-energy phosphate substrates, PCr and ATP, were decreased to undetectable levels. After the reperfusion, the peak amplitudes of PCr and ATP recovered to about 60% of the pre-ischemic levels.

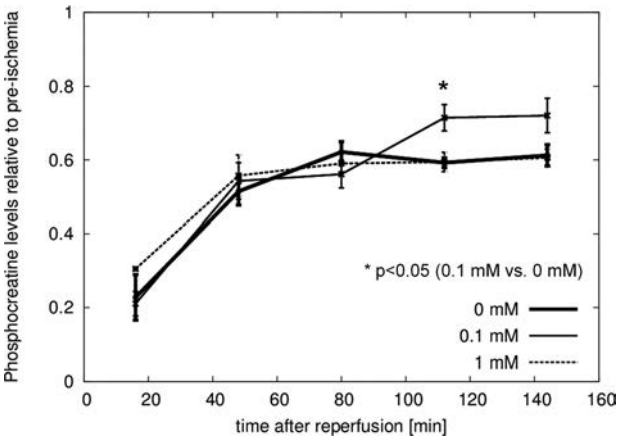

Figure 2. Recovery of phosphocreatine levels after ischemia-reperfusion injury. Values are given relative to pre-ischemic level. PCr had a significantly better recovery when superfused with ACSF with 0.1 mM ALCAR than control ($p<0.05$).

PCA310

BACE1 overexpression shifts glucose metabolism toward aerobic glycolysis in SH-SY5Y cells

J. Findlay, D. Hamilton, P. Meakin and M. Ashford

Medical Research Institute, University of Dundee, Dundee, Angus, UK

Alzheimer's Disease (AD) is the most common cause of dementia and currently there is no cure or means to slow disease progression. This represents a clear, unmet medical need in light of the ageing population worldwide. While much of the current AD research focuses on the hallmark pathologies (amyloid plaques and neurofibrillary tangles), their appearance is extremely end stage and therapeutic interventions aimed at alleviating them have failed to halt symptom progression. It may therefore be beneficial to look at earlier events, with reduced glucose metabolism and a regional switch to aerobic glycolysis among the earliest changes reported in the AD brain (1, 2). Glucose is a required substrate for neuronal function and important for the induction of long-term potentiation (3) and the consolidation of short to long-term memories. Evidence suggests the aspartyl protease β-site Amyloid precursor protein Cleaving Enzyme 1 (BACE1) as a key enzyme in the aetiology of AD. Previous work from our laboratory has also suggested a role in metabolism, with BACE1 knock out mice displaying enhanced whole-body glucose disposal and insulin sensitivity (4). We have also previously shown that BACE1 overexpression impairs glucose metabolism in neuronal cells (5). This study aimed to further investigate the role of BACE1 in neuronal glucose metabolism. We utilised the human SH-SY5Y neuronal cell line stably overexpressing BACE1. Pyru-

vate dehydrogenase (PDH) activity was determined by activity assay (Mitosciences). A Seahorse extracellular flux analyser was used to determine cellular respiration in real-time. All data are expressed as mean ± standard error of the mean, and statistical significance determined by Student's t-test. Chronic elevation in BACE1 resulted in impaired functioning of a key fuel-partitioning enzyme, PDH (activity reduced to 69 ± 8 per cent, $p < 0.05$, n=6). This reduced substrate delivery to the mitochondria and increased reliance upon aerobic glycolysis for ATP generation (oxygen consumption rate (OCR) reduced to 65 ± 9%, $p < 0.01$, n=7 and extracellular acidification rate (ECAR) increased to 165 ± 16%, $p < 0.01$, n=7). These deficits were significantly attenuated by treatment with the PDH kinase inhibitor dicholoracetate (DCA, 10μM). Thus BACE1 overexpression impairs neuronal glucose oxidation resulting in an increased reliance upon aerobic glycolysis for ATP generation. Therefore this BACE1-dependent change in metabolism may account for some of the earliest clinical observations in people who later develop AD.

Recurrent low glucose exposure attenuates α1AMPK activity and reduces basal metabolism in GT1-7 neurons

E.A. Haythorne, D. Hamilton, C. Beall, J. Findlay, M. Ashford and R. McCrimmon

Medical Research Institute, University of Dundee, Dundee, Angus, UK

The major limiting factor in the successful management of type 1 diabetes is Recurrent Hypoglycaemia (RH), resulting from supraphysiological insulin supplementation, which attenuates the Counterregulatory Response (CRR) to future hypoglycaemic episodes. It is now widely accepted that the hypothalamus contributes to hypoglycaemia detection and activation of the CRR (1). Within the hypothalamus, glucose-sensing (GS) neurons exist which are thought to contain the same glucose sensing cellular machinery as pancreatic β-cells, such as ATP-sensitive K+ channels (K_{ATP}), glucokinase, glucose transporter proteins and AMPK (2). Therefore, we hypothesise that disruption of normal function in these specialised neurons may occur following RH. We have previously shown that mouse hypothalamic GT1-7 cells are GS neurons (3) and display impaired electrical activity to low glucose following RH, independent of changes in glucose uptake/oxidation (4). Here we have investigated AMPK activity and mitochondrial function as possible mediators of altered electrical activity following RH.

GT1-7 cells were exposed to 3 hours of low (0.1 mM) glucose for 3 days to model RH, with cells being assayed on day 4. AMPK activity was measured by radiolabelled kinase activity assay. Cellular Oxygen Consumption Rate (OCR) was measured under euglycaemic conditions using an XF24 extracellular flux analyser (Seahorse Bioscience, Inc.). All data sets are expressed as means ± standard error of the mean. Statistical analysis was performed using either Student's t-test or ANOVA.

Following RH of GT1-7 cells, the normal increment in α1AMPK activity to 0.1 mM glucose stimulus was significantly attenuated after 15 minute (RH = 0.97 fold ± 0.31 vs. Cont = 1.48 fold ± 0.09, $p<0.01$; n = 7) and 3 hour incubations (RH = 1.07 fold ± 0.20 vs. Cont = 3.98 fold ± 0.67, $p<0.001$; n=7). α2AMPK activity was not significantly perturbed and no change in AMPK subunit expression was observed following RH. Additionally there were no significant changes in total or phosphorylated protein levels of the upstream AMPK activating kinases, TAK1 or LKB1. Examination of mitochondrial function following RH showed no change in spare respiratory capacity or the proportion of OCR contributing to ATP synthesis. However, RH significantly reduced basal OCR of GT1-7 cells (RH = 4.85 ± 0.87 vs. Cont = 8.10 ± 0.60 pmoles O_2/min/μg, $p<0.05$; n=5).

We conclude that blunted α1AMPK activation to low glucose following RH reduces substrate flux through the oxidative phosphorylation pathway in association with defective GS of hypothalamic neurons.

A novel role for IL-6 in the suppression of hypothalamic glucose sensing

G.T. Denwood, K.R. Watterson, A.H. Gardiner, K.L. Ward, E.A. Haythorne, L. Hamilton, K.A. Wright, F.B. Ashford, M.L. Ashford and R.J. McCrimmon

Medical Research Institute, University of Dundee, Dundee, UK

Repeated exposure to hypoglycemia leads to suppression of normal counter-regulatory responses (CRR) to hypoglycemia; increasing severe hypoglycemia risk. The mechanism underlying this is unknown, but believed to result primarily from defective glucose-sensing within the ventromedial hypothalamus (VMH). Hypoglycemia evokes a significant systemic and local stress response with an increase in inflammatory mediators such as interleukin-6 (IL-6). In this study, we sought to determine if IL-6 affected hypothalamic glucose-sensing by examining its action on hypoglycemia-induced changes in membrane potential and AMPK activity in a mouse hypothalamic glucose-sensing cell line (GT1-7) and mouse hypothalamic *ex vivo* slices.

Perforated-patch electrophysiological recordings of GT1-7 cells investigated the acute and chronic effects of IL-6 (5ng/ml and 20ng/ml) on acute hypoglycemia (0.5mM glucose)-induced membrane hyperpolarization. Acute exposure of GT1-7 cells to 5ng/ml and 20ng/ml IL-6 had no significant hyperpolarizing effect during hypoglycemia (0.5mM). Contrastingly, antecedent 3 hour exposure to 5ng/ml IL-6 followed by a 24 hour recovery period significantly attenuated the response of GT1-7 cells to 0.5mM ($\Delta V_{Control}$ = 13.4 ± 1.3mV vs ΔV_{IL6} = 8.6 ± 2.0mV, $p<0.05$; n=10-13). Additionally, IL-6 was found to significantly increase acute AMPK activity in mouse VMH *ex vivo* slices and GT1-7 cells, as demonstrated by increased AMPK phosphorylation, increased phosphorylation of ACC and direct AMPK activity assay compared to controls. Moreover,

antecedent 3 hour exposure of GT1-7 cells to 5ng/ml IL-6 attenuated subsequent hypoglycemia-induced AMPK phosphorylation.
Thus, prior exposure of hypothalamic GT1-7 cells and VMH *ex vivo* slices to IL-6 reduced their responsiveness to a subsequent hypoglycemia challenge. We conclude that rises in systemic or local IL-6 may contribute, at least in part, to hypoglycemia-induced suppression of hypothalamic glucose-sensing.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA313

Role of (Pro)renin receptor in cell proliferation

K. Ohba[1], K. Kaneko[1], H. Nishiyama[1], T. Hirose[2], K. Totsune[3] and K. Takahashi[1]

[1]Department of Endocrinology and Applied Medical Science, Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Department of Planning for Drug Development and Clinical Evaluation, Tohoku University Graduate School of Pharmaceutical Sciences and Medicine, Sendai, Japan and [3]Department of Social Welfare, Tohoku Fukushi University, Sendai, Japan

(Pro)renin receptor ((P)RR) is a specific receptor for renin and prorenin, and is a new component of the renin angiotensin system (RAS) (1, 2). When bound to prorenin, (P)RR activates the angiotensin I-generating activity of prorenin in the absence of cleavage of the prosegment. Moreover, binding of (pro)renin to (P)RR directly activates MAPK ERK1/2 independently of the RAS. The gene encoding for PRR is named ATP6ap2 (ATPase 6 accessory protein 2), and (P)RR was initially found as a truncated form co-purifying with V-ATPase (vacuolar H^+-ATPase). The association of (P)RR and V-ATPase has been shown to be functional and essential for the survival of certain cells. Furthermore, (P)RR is involved in the Wnt/β-catenin pathway. It is therefore likely that (P)RR has an important role in the physiology and pathophysiology of cell proliferation. The aim of the present study is therefore to clarify the role of (P)RR in cell proliferation. Cultured human breast carcinoma cell lines were used in the present study. Western blot analysis (3) showed expression of (P)RR protein in all 4 breast carcinoma cell lines examined; MCF-7, T47D, SK-BR-3 and MDA-MB-231. Transfection of (P)RR specific small interference RNA decreased cell proliferations in breast carcinoma cell lines. Treatment with angiotensin II did not stimulate cell proliferation or phosphorylation of ERK1/2 in cultured breast carcinoma cells, suggesting that the stimulatory effect of (P)RR on cell proliferation occurred independently of the RAS. By contrast, treatment with prorenin increased phosphorylation of ERK1/2 in these cells. Treatment of bafilomycin A_1, an inhibitor of V-ATPase, greatly inhibited cell proliferation of human breast carcinoma cells. These findings suggest that (P)RR stimulates cell proliferation independently of the RAS, possibly via the stimulation of ERK1/2 and/or the function of V-ATPase. The present study has raised the possibility that (P)RR is a novel target for the development of the new therapies, not only in cardiovascular, renal diseases including diabetic nephropathy (4), but also in proliferative diseases including cancers.

PCA314

A central role of E3 ubiquitin ligase MG53 in insulin resistance and metabolic disorders

Y. Zhang[1], R. Song[1], W. Peng[1], F. Lv[1], C. Cao[1] and R. Xiao[1,2]

[1]Institute of Molecular Medicine, State Key Laboratory of Biomembrane and Membrane Biotechnology, Peking University, Beijing, China and [2]Center for Life Sciences, Peking University, Beijing, China

Insulin resistance is a fundamental pathogenic factor shared by various metabolic disorders[1]. While skeletal muscle accounts for 70-90% of insulin-stimulated glucose disposal, the mechanism underlying muscle insulin resistance is poorly understood. MG53, also named TRIM72, is expressed in striated muscle and implicated in cell membrane repair and cardiac ischemic pre- and post-conditioning[2-4]. Here we show that MG53 acts as an E3 ligase targeting insulin receptor (IR) and insulin receptor substrate 1 (IRS1) for ubiquitin-dependent degradation, and when upregulated, causes metabolic disorders.
MG53 is markedly elevated in the skeletal muscle of insulin resistance models. After 35 weeks on high fat diet (HFD), wild type (wt) mice developed metabolic syndrome featuring obesity, hypertension, hyperglycemia and hyperinsulinemia. In contrast, MG53-difficient (mg53-/-) mice were resistant to HFD-induced metabolic disorders. Concomitantly, 35-week HFD induced significant glucose intolerance and insulin resistance in wt, but not in mg53-/-, mice. Furthermore, MG53 transgenic (mg53 TG) mice on regular chow diet developed metabolic syndrome characterized by obesity, hypertensive, hyperinsulinemia, along with severe glucose intolerance and insulin resistance at 38 weeks of age. These results indicate that upregulation of MG53 is both necessary and sufficient to cause systemic insulin resistance and metabolic syndrome.
Insulin signaling involves tyrosine phosphorylation of IR and IRS1, and subsequent activation of PI3K-Akt signaling pathway[5]. Mechanistically, MG53 acts as an E3 ligase which targets IR and IRS1 for ubiquitin-dependent degradation, constituting a central mechanism controlling insulin signal strength in skeletal muscle. Specifically, in skeletal muscle from mg53 TG mice or wt mice on HFD, insulin-stimulated activation of IR, IRS1 and Akt was profoundly impaired. The suppressed insulin signaling is associated with posttranscriptional downregulation of IR and IRS1 via ubiquitin-dependent degradation. Importantly, in mg53-/- mice, HFD had no significant effect on IR and IRS1 protein abundance or insulin signaling efficiency. Taken together, we have shown, for the first time, that elevated MG53 expression is sufficient and necessary for HFD-mediated downregulation of IR and IRS1 and subsequent suppression of insulin signaling in skeletal muscle. These findings define MG53 as a novel therapeutic target for treating metabolic disorders and associated cardiovascular complications.

Connexin 36 signalling during intercellular communication within pancreatic islets

D. Penko[1,2], H.S. Peiris[3,4], P.H. Coates[1,2], C.S. Bonder[1,5] and C.F. Jessup[3,4]

[1]School of Medicine, University of Adelaide, Adelaide, SA, Australia, [2]Central Northern Adelaide Renal and Transplantation Service, Royal Adelaide Hospital, Adelaide, SA, Australia, [3]Department of Human Physiology, Flinders University of SA, Bedford Park, SA, Australia, [4]Centre for Neuroscience, Flinders University of SA, Bedford Park, SA, Australia and [5]Centre for Cancer Biology, SA Pathology, Adelaide, SA, Australia

Type 2 diabetes mellitus remains an enormous health burden – there are over 300 million sufferers worldwide (1) and 20% of the US healthcare budget is spent on caring for people with diabetes (2). Pancreatic islet dysfunction underlies the development of diabetes. While it is recognised that communication between cells within the islet is essential for proper function, the mechanism responsible is unknown. Connexin 36 is expressed on insulin-producing beta cells, is important for coordinated pulsatile insulin release and may be involved in intercellular communication within pancreatic islets (3). The interaction between pancreatic islets and endothelial cells was investigated *in vitro*. Pancreatic islets were isolated from male C57B6 mice by infusion of collagenase into the pancreatic duct *in situ* followed by digestion at 37°C and density purification. Endothelial cells were grown from C57B6 bone marrow by culture on fibronectin in defined media for one week and confirmed to express endothelial markers (CD31 and E-selectin), bind lectin and uptake acetylated low-density lipoprotein by flow cytometry. To investigate soluble mechanisms, islets were cultured (10 islets per well) with endothelial cell-conditioned medium for 3 days and tested for glucose-stimulated insulin release. Secreted insulin was detected by high-sensitivity ELISA and corrected for total protein and stimulation indices were calculated as insulin secretion at high glucose (20 mM) divided by basal insulin secretion (at 3 mM glucose). Values are means±SEM compared by unpaired t-tests. Endothelial cell-conditioned islets had an increased level of basal insulin release (0.7±0.22 ng/min/mg total protein; n=7) compared to controls (0.2±0.04 ng/min/mg total protein; n=6; p=0.05). However, they had a reduced ability to upregulate insulin release in response to high glucose (stimulation index = 1.3±0.5 compared to 4.2±0.9 for controls; p=0.01). Effects on gene expression were analysed by real-time PCR using Taqman primers (normalizing to the house-keeping gene *B2m*) following 3 day non-contact co-cultures where islets (25 islets per well) were cultured in transwells (0.4 μm pores) above endothelial monolayers. Co-cultured islets significantly down-regulated the expression of connexin 36 (0.4±0.05 fold relative to control islets; n=18; p=0.04). There was no difference in expression of the Insulin gene between groups. These data suggest that connexin 36 expression is modulated during intercellular communication between beta cells and endothelial cells, resulting in dysregulated insulin *release*. We suggest this represents a 'survival' islet phenotype, where baseline insulin secretion is maintained during vascular remodelling. This mechanism may have relevance for islet physiology, where the function and survival of beta cells is critically dependent on the presence of intra-islet vascular endothelium.

PCA316

Estrogenic effects of ginsenoside Rg1 in endometrial Ishikawa cells and neuroblastoma SK-N-SH cells were not observed in preosteoblast MC3T3-E1 cells

W. Chen and Q. Gao

Physiology, Qingdao University, Qingdao, China

Ginseng has been used as a medicine for over two thousand years. Studies have showed that ginseng could relieve menopausal symptoms, bleeding disorders, sleeping disorders, depression, anxiety etc. Ginsenoside Rg1 is the major pharmacologically active compound of ginseng. Our previous studies clearly demonstrated the estrogenic activities of Rg1 in human breast cancer MCF-7 cells. However, it is unclear if Rg1 exert selective estrogenic effects in other cell types in vitro. The present study was designed to determine the selective estrogenic effects of ginsenoside Rg1 by using endometrial, neuroblastoma and preosteoblast cell lines. The endometrial Ishikawa cells, neuroblastoma SK-N-SH cells and preosteoblast MC3T3-E1 cells were cultured in phenol-red free DMEM supplemented with 5% sFBS and were treated with different dosage of Rg1(0.0001-1μM, n=3) and 17β-estradiol (0.01μ M, n=3). MTT method was used to detect the cell viability. The western blot was used to detect the protein expressions of mitogen-activated protein kinase kinase (MEK) and estrogen receptor α (ERα). The activity of estrogen responsive element (ERE) promoter was detected by Dual Luciferase Assay. Treatment of three kinds of cells with various concentrations of Rg1 (0.0001-1μM) had no stimulatory effect on cell number. Rg1 significantly increased estrogen receptor-dependent alkaline phosphatase activity in Ishikawa cells (0.0001μM: 1.34±0.081, 0.01μM: 1.28±0.049, 1μM: 1.22±0.023 vs control 1.00±0.018, P<0.01) but not in MC3T3-E1 cells. Similar to estrogen, Rg1 treatment induced the phosphorylation of MEK

(0.0001μM: 1.42±0.075, 0.01μM: 1.42±0.103, 1μM: 1.65±0.117 vs control 1.00±0.030, P<0.05) and ERα (0.0001μM: 1.47±0.049, 0.01μM: 1.72±0.035, 1μM: 2.02±0.100 vs control 1.00±0.029, P<0.05) in a dose-dependent manner in Ishikawa cells. Similar effects were obtained in neuroblastoma SK-N-SH cells. Cells transfected with the ERE-luciferase reporter construct exhibited significantly increased ERE-luciferase activity in the Rg1 presence in Ishikawa cells (0.0001μM: 1.69±0.094, 0.01μM: 1.79±0.108, 1μM: 2.03±0.194 vs control 1.00±0.134, P<0.05) and neuroblastoma SK-N-SH cells (0.01μM: 2.70±0.235 vs control 1.00±0.231, P<0.01), suggesting that the estrogenic effects of Rg1 were mediated through the endogenous ERs. In contrast, Rg1 did not induce any estrogenic responses in preosteoblast MC3T3-E1 cells. Our results suggest that the estrogenic effects of Rg1 are distinct from those of estradiol and are cell type selective. Further study is needed to characterize the action by which Rg1 exerts tissue-selective estrogenic effects in vivo.

Effect of secretory products of colon cancer cells on the cancer-associated fibroblasts: The reverse Warburg effect

Y. Kim[1], H. Shin[1,3], Y. Chun[1,2], C. Cho[1,3] and J. Park[1,3]

[1]pharmacology, Seoul National University College of medicine, Seoul, Republic of Korea, [2]physiology, Seoul National University college of medicine, Seoul, Republic of Korea and [3]Ischmic/hypoxic disease institute, Seoul National University college of medicine, Seoul, Republic of Korea

Tumor microenvironment is composed of malignant epithelial cells and stromal components including fibroblasts, endothelial cells, and inflammatory cells. Especially, cancer-associated fibroblasts (CAFs) are known to play a key role in tumor progression, metastasis as well as drug resistance. Cancer cells utilize the high-energy metabolites from aerobic glycolysis in fibroblast cells for tumor growth and metastasis, which was called as the reverse Warburg effect. To confirm whether the secretory products from cancer cells induce the reverse Warburg phenomenon in CAFs, we incubated mouse embryonic fibroblasts (MEFs) and human colon fibroblast cells (CCD-18CO) with the HCT116 colon cancer cell conditioned media. Then we observed that cancer conditioned media indeed induced the autophagy and/or mitophagy in fibroblast cells. After treated with the cancer conditioned media, the induction of LC3, a marker of autophagy, in fibroblasts were confirmed. The autophagophores as well as autophagosomes were visualized by GFP-LC3 system and Transmission electron microscopy (TEM). Also, we found that the conditioned media from normoxic HCT116 cells could lead to the autophagy in fibroblasts, but that from hypoxic HCT116 cells could not, which means that hypoxic microenvironmental milieu also may influence the tumor-fibroblasts interactions. Interestingly, both HIF-1/2αs were upregulated in normoxic MEFs when they were treated with the conditioned media from normoxic status of cancer cells. But the conditioned media from hypoxic cancer cells increased the HIF-1/2αs much less than that from normoxic ones. In addition, the cancer conditioned media increased the migration potential of fibroblsts, which was observed by F-actin staining. In summary, the secretory products from epithelial cancer cells may induce the autophagy of fibroblasts including mitochondrial degradation and dysfunction. The illumination of key factors in cancer secretome could help to understand the cancer-fibroblasts interaction as well as acquire the novel therapeutic targets in oncologic fields.

PCA318

SIRT1 differentially regulates HIF-1a and HIF-2a activities under hypoxia

H. Yoon and J. Park

pharmacollogy, the college of medicine, seoul national univercity, Seoul, seoul, Republic of Korea

Cancer cells should accommodate to oxygen- and energy-deficient microenvironment to keep growing. The transcription factors HIF-1a and HIF-2a sense the oxygen state, and express hypoxia-induced genes. The deacetylase SIRT1 senses the energy or redox state, and modulates activities of transcription factors that express metabolic genes. Previously, two studies demonstrated that SIRT1 deacetylates HIF-1a at K674 or HIF-2a at K741 and that SIRT1 inactivates HIF-1a but activates HIF-2a. Yet, how SIRT1 differentially regulates HIF- as is uncertain so far. We here tried to clarify the roles of SIRT1 in HIF-1a and HIF-2a regulations. In the present study, we established two assay systems to separately evaluate SIRT1's actions on two HIF-a s; that is, immnoblotting with specific antibodies to acetylated HIF-1a_K674 or acetylated HIF-2a_K741 and reporter assay using Gal4(DBD)-HIF-1a(TAD) or Gal4(DBD)-HIF-2a(TAD), both of which contain the SIRT1 target sites. Consequently, PCAF acetylated the two lysine residues of HIF- as, which was reversed by SIRT1. Also, we confirmed the opposing actions of SIRT1 on HIF-1 and HIF-2 driven transcriptions, namely, it negatively and positively regulated HIF-1 and HIF-2, respectively. RT-PCR analyses showed that SIRT1 reduced mRNA levels of HIF-1 target genes but enhanced those of HIF-2 target genes. These results further support the differential roles of SIRT1 in HIF-1 and HIF-2 signaling under hypoxia. As one of two HIF- as tends to be chosen as a major adaptive factor during tumor evolution, the selective modulation of HIF-1 and HIF-2 signaling can be a promising strategy for cancer therapy. In this aspect, SIRT1 could be a candidate target to develop tailor-made cancer therapy for patients.

Green tea (GMB4 clone) catechins influences the retinoid-related orphan receptor α (ROR-α) and CCAAT/enhancer binding protein-α (C/EBP-α) expression in primary cultured of preadipocyte

R. Ratnawati[1], F.K. Hasniy[1], D. Lyrawati[2] and C. Ciptati[3]

[1]Physiology, Brawijaya University, Malang, Jawa Timur, Indonesia, [2]Clinical Pharmacy, Brawijaya University, Malang, Jawa Timur, Indonesia and [3]Chemistry Devision, Institute Technology Bandung, Bandung, Jawa Barat, Indonesia

Background: Obesity is a major risk factor for the development of chronic diseases and mortality. At the cellular level, increasing number and size of adipocytes diferentiated from preadipocytes characterized the obesity. Excess intake of sugars and lipids causes obesity, but certain food components have been reported to reduce the risk of obesity. Catechins, the active constituent of green tea has been regarded beneficial as an anti-obesity. Our previous study has showed that catechins from green tea GMB4 clone inhibited differentiation of preadipocytes, reduced PPARy and increased the adiponectinn level in preadipocytes culture (Ratnawati et al, 2011) and EGCG also decreased C/EBPα and leptin (Ratnawati et al, 2012). Therefore in this study, we investigated the effect of catechins on the positive and negative regulators of lipogenesis and adipogenesis; ROR-α and C/EBP-α.
Method: This study is done in primary cultured of preadipocyte with 4 groups of treatment : (1) control, (2) treated with catechins 5 μM, (3) treated with catechins 10 μM and (4) treated with catechins 30 μM. 2 days post confluence, cell were induce to differentiate into adipocyte with IBMX, DEX and insulin. On days 3 during differentiation, cells were treated with catechins for 24 hour. Cells then harvested and measurement of ROR-α and C/EBP-α were done by ELISA and Immunocytochemistry.
Results: In this study we found that catechins significantly reduced the expression of C/EBP-α by 20%, 24% dan 26,43%. . We found that ROR-α expression increased, but not reach statistical significance.
Conclusion: This results suggested that catechins at least in part inhibit adipogenesis through C/EBP-α. Studies are needed to see whether higher doses of catechins will exert further increase on ROR- expression and/or its activity.

The use of bioinformatics to prioritise palmitoylation enzyme isoforms as novel research targets

B. Adeyileka, L. Davies, A. Dempsey, S. Falconer and N. Donohoe

Pharmacy and Life Sciences, Robert Gordon University, Aberdeen, UK

Post-translation lipid modification has been shown to alter the trafficking, targeting and function of a wide range of membrane proteins. Palmitoylation, one type of lipid modification, involves the thioester linkage of palmitate molecules to specific cysteine residues. Palmitoylation is undertaken by a group of 23 palmitoyl-acyl-tranferase (PAT) enzymes which contain a ZDHHC (zinc-finger and aspartate-histidine-histidine-cysteine) motif(1). The potential role of PAT enzymes in physiological control mechanisms, in the causation of disease and as therapeutic targets is the focus of considerable research (2,3,4). This study uses a bioinformatics approach to screen the genomic and proteomic data available for human PATs in order to identify and prioritise isoforms for future laboratory and clinical investigation.
Genomic and proteomic information from the National Centre for Biotechnology Information (NCBI), GeneCards and Uniprot databases was collated and analysed to identify: (a) the number of non-synonymous single-nucleotide polymorphisms (nsSNPs) in PAT genes; (b) their location; and (c) PAT splice variants. The potential of nsSNP to produce damage was analysed using the pre-formulated prediction software systems SNAP, SIFT, Panther, PolyPhen and MutPred as well as damage-prediction scoring system that assigns a damaging score based upon the nature of resulting amino acid (AA) substitutions and their location on functionally important motifs on proteins. An initial screen identified 21,291 nsSNPs, with ~1% displaying high scores (> 50% threshold or equivalent) on the damage–prediction scoring system. Further analysis lead to the prioritisation of six nsSNP candidates; rs111416789 (zDHHC8), rs137852214 (zDHHC9), rs138835172, rs11552044, rs149584176 and rs147199543 (zDHHC24). These nsSNPs are of particular interest due to the nature of the resulting AA substitutions, the close proximity of the substitutions to the enzyme active site and areas involved in post-translational modification, such as palmitoylation and phosphorylation sites.
Prioritised nsSNPs will be examined to determine the functional impact of the resulting amino acid changes in the PAT proteins in laboratory based expression systems and assays; those found to alter PAT function will be investigated with respect to their distribution and incidence within appropriate populations and disease groups.

The metabolic profile of pregnant mice fed a diet high in sugar and fat

B. Musial[1,2], S.E. Ozanne[2], A.L. Fowden[1] and A.N. Sferruzzi-Perri[1]

[1]Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK and [2]Institute of Metabolic Sciences, University of Cambridge, Cambridge, UK

Background: Diets high in sugar and fat (HSHF) are commonly eaten by women of reproductive age and contribute to the increasing prevalence of obesity during pregnancy. In animals, obesogenic diets fed during pregnancy alter the metabolic phenotype of the adult offspring (1) but little is known about the mechanisms involved prenatally. Preliminary work has shown that feeding a HSHF diet throughout mouse pregnancy increased maternal adiposity, glucose and insulin levels, but reduced insulin like growth factor (IGF-I) and fetal growth (2). This project examined the effect of a HSHF diet on the fat content and expression of proteins involved in insulin/IGF-I signalling and lipid metabolism in the maternal liver, muscle and white adipose tissue (WAT) in late pregnancy.

Methods: C57BL6 mice were fed a control diet (energy from fat 11%, sugar 3%) or a HSHF diet (energy; fat 30%, sugar 36%) from day (D)1 of pregnancy (term D20). On D16 and D19, dams were killed and maternal liver, biceps femoralis and retroperitoneal WAT and were dissected and snap frozen for Western blotting. The content of hepatic and muscle fat was measured by the modified Folch method (3). Dietary differences were assessed using ttest and considered significant when, $P<0.05$.

Results: Relative to the control diet, HSHF feeding increased hepatic abundance of specific proteins involved in insulin/IGF signalling in the dam on D16 and D19 (Fig1, $P<0.05$). In contrast HSHF feeding reduced expression of several proteins involved in this signalling pathway in skeletal muscle (Fig2, $P<0.05$) and WAT (IGF1R, PI3K p110α/β and p85α, total Akt and pAkt, $P<0.03$), at both ages. Hepatic lipid metabolic markers were unaffected by HSHF feeding on D16, but PPARα was reduced and LPL, PPARγ, and FAS were increased by D19 (Fig1, $P<0.04$). In maternal skeletal muscle, a HSHF diet increased expression of FAS on D16, and decreased FATP on both D16 and D19 (Fig2, $P<0.05$). HSHF diet reduced FATP, PPARα and FAS on D16 and PPARα and FAS on D19 in maternal WAT ($P<0.04$). The content of fat in maternal liver and muscle was increased by a HSHF diet at D19 ($P<0.001$) but not day 16.

Conclusion: The current study shows that HSHF feeding during mouse pregnancy induces tissue-specific changes in the expression of proteins involved in insulin/IGF signalling and lipid metabolism, consistent with the hyperinsulinaemia and indicative of muscle insulin resistance. These dietary-induced changes in maternal metabolic profile may influence the partitioning of nutrients to fetal growth and thereby explain the intrauterine programming of adult metabolic phenotype.

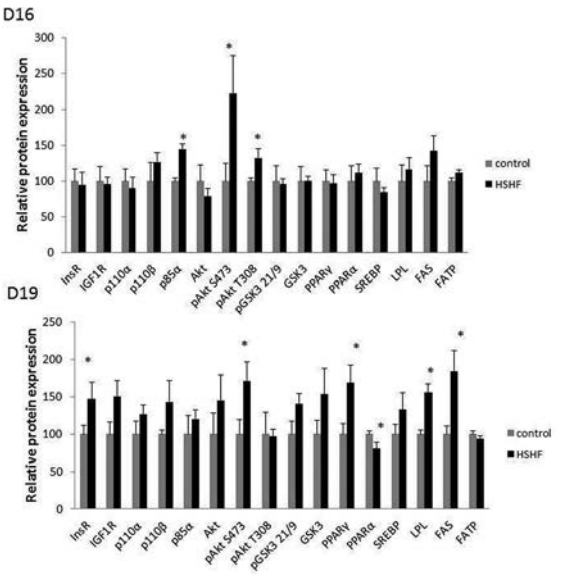

Figure 1. The effect of HSHF feeding on hepatic expression of insulin/IGF signalling pathway and markers of lipid metabolism at D16 and D19 of pregnancy. Data are expressed as mean +/-SEM (control, n=5; HSHF, n=5). The protein expression is relative to the control group.

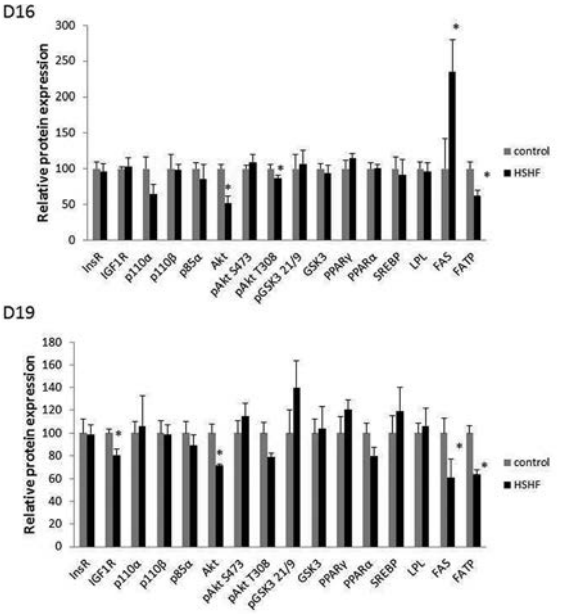

Figure 2. The effect of HSHF feeding on muscle expression of insulin/IGF signalling pathway and markers of lipid metabolism at D16 and D19 of pregnancy. Data are expressed as mean +/-SEM (control, n=5; HSHF, n=5). The protein expression is relative to the control group.

Asymmetric dimethylarginine causes adipocyte hypertrophy through NO-independent upregulation of the mTOR lipid biosynthesis pathway

L.B. Dowsett, O. Boruc and J.M. Leiper

MRC Clinical Sciences Centre, Imperial College London, London, UK

Metabolic syndrome is a major healthcare and economic burden. Cardiovascular disease and obesity are major symptoms of metabolic syndrome. Asymmetric dimethylarginine (ADMA) is an endogenously produced inhibitor of nitric oxide synthesis that is an established biomarker of cardiovascular disease. Increased plasma concentrations of ADMA have been reported in obese individuals in whom it is thought to contribute to cardiovascular dysfunction. However, at present little is known about the direct effects of ADMA on adipocytes and obesity. In the present study we examined the effects of ADMA on 3T3-L1 cells *in vitro* and on adipose tissue *in vivo*.
Mouse 3T3-L1 cells were fully differentiated to adipocytes and treated with exogenous ADMA (10μM) after which intracellular neutral lipid was stained with oil red O and adipocyte area quantified by microscopy. To specifically elevate ADMA concentrations in adipocytes in vivo we deleted the enzyme dimethylarginine dimethylaminohydrolase 1 (DDAH1, the predominant enzyme responsible for intracellular ADMA metabolism) in adipocytes using adiponectin driven Cre expression[1]. In vitro treatment with ADMA caused adipocyte hypertrophy (control area 27.65μM^2 ± 1.41, 10μM ADMA area 33.85μM^2 ± 1.62, p>0.01, n=6, all results ±SEM and student T test) which was independent of NO blockade as the nitric oxide synthase inhibitors L-NAME (1mM) and PB-ITU (20μM) had no effect on lipid accumulation (28.02μM^2 ± 1.52 and 25.73μM^2 ± 1.27 respectively). ADMA treatment of 3T3-L1 cells (10μM, 48h) resulted in increased expression of mTOR RNA and protein (2.4X ±0.47, and 1.73X ±0.22 respectively, p>0.05, n=3). Downstream of mTOR the targets of the transcription factor SREBP1c including ACC and FASN were upregulated (4.6±0.8 and 1.4±0.16 fold respectively, p>0.05, n=6) suggesting that ADMA increases adipocyte size through the upregulation of lipid biosynthesis in an NO independent manner. Adipocytes isolated from AdCre-DDAH1$^{-/-}$ mice were found to have increased intracellular ADMA (control 72.1 ±22.36 nmol/mg, KO 85.24 ±11.90 nmol/mg) which caused a corresponding decrease in intracellular NO concentration (control 30.66μM/mg ± 4.9, KO 18.22μM/mg ± 3.86, p>0.05, n=4). Immunohistochemistry revealed that adipocytes within the epididymal depot were larger in AdCre-DDAH1$^{-/-}$ mice than wildtype littermates (18.05±1.01μM^2 and 14.47±0.52μM^2 respectively, p>0.05, n=4). The physiological consequence of this adipocyte hypertrophy was increased macrophage infiltration (control 17.9±0.9, KO 22.2±1.2 cells per frame, p<0.05, n=4). These data suggest that ADMA is a novel regulator of lipid biosynthesis within adipocytes independent to its actions as a nitric oxide synthase inhibitor. Adipocyte hypertrophy causes increased inflammation and is likely to contribute to insulin resistance.

Interleukin-induced calcium channel current modulation in osteoblasts

H. Kobayashi[2], T. Endoh[1], M. Tazaki[1] and K. Sueishi[2]

[1]Dept of Physiol, Tokyo Dental College, Chiba, Japan and [2]Department of Orthodontics, Tokyo Dental College, Chiba, Japan

Interleukin-1β (IL-1β) and -6 (IL-6) are inflammatory cytokines that are involved in bone resorption under pathological conditions. The cytokines are also involved in bone remodeling under physiological conditions. Voltage sensitive Ca2+ channels (VSCCs) serve as crucial mediators of membrane excitability and many Ca2+-dependent functions such as growth of bone, regulate proliferation, differentiation, enzyme activity and gene expression. The effects of IL-1β and -6 on VSCCs in osteoblast cell line (MC3T3-E1) were investigated using patch-clamp recording. Our results showed that application of 50 pM-50 nM IL-1β facilitated VSCCs current (ICa) carried by Ba2+ (IBa). Application of 50 pM-5 nM IL-6 facilitated IBa. In contrast, 50 nM IL-6 inhibited IBa in MC3T3-E1 cells.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA324

Birth weight is a strong independent determinant of white-to-white corneal diameter of newborns

V.A. Olatunji[1], D.S. Ademola-Popoola[1,2], G.F. Adepoju[1,2] and L.A. Olatunji[3]

[1]Department of Ophthalmology, University of Ilorin Teaching Hospital, Ilorin, Kwara, Nigeria, [2]Department of Ophthalmology, College of Health Sciences, University of Ilorin, Kwara, Nigeria and [3]Department of Physiology, College of Health Sciences, University of Ilorin, Kwara, Nigeria

Measurement of corneal diameter (CD) in children is pertinent in the diagnosis and monitoring of some ocular diseases, especially anterior segment anomalies and congenital glaucoma (1-3). Nonetheless, normal values of CD in African children are not well documented. The present study therefore sought to establish normative values of CD in full-term newborns and to assess relationship with some birth parameters. Horizontal and vertical CD were evaluated with Castroviejo mm caliper in 1000 eyes of 500 normal full-term babies within the first week of life, in a cross-sectional hospital-based study in the North Central zone of Nigeria. The relationship between CD and perinatal variables were assessed by using univariate and multiple linear regression models. A total of 254 (50.8%) male and 246 (49.2%) female babies were involved in the study. The mean value (mean ± SD) of horizontal CD in the right eyes was 9.87±0.40mm (ranged from 9.00-10.50mm) while it was 9.86±0.40mm in the left eyes (range of 9.00-10.75mm). Mean values of vertical CD was 9.59±0.38mm in the right eyes (range 8.75-10.50mm) and 9.62±0.41mm in the left eyes (range 8.75-10.75mm). There were no significant differences between those of the right and left eyes. The horizontal and vertical CD in males were not significantly different from those in females. The study showed a significant association between birth weight and CD irrespective of baby sex, maternal age, birth length, head circumference and postnatal age. The study also indicated that an increase of 0.36 mm for each kg increase

in the birth weight. The results from the present study demonstrate that birth weight is an important independent determinant of CD in newborns. These results would provide useful references for the eye care of newborns in Africa, particularly in Nigeria. Furthermore, the CD values in this study are not consistent with some data from studies in children in other parts of the world. It is therefore plausible to put into account geographical difference when utilizing or interpreting CD values at least in newborns.

Alterations in intrauterine electrical impedance in mice measured by four-electrode methods

M. Yamamoto[1], T. Hosono[1], C. Igi[1], M. Arakawa[1], M. Nakamoto[1], K. Akasaka[1], H. Nakamura[2] and T. Kimura[2]

[1]Graduate School of Bimedical Engineering, Osaka Electro-Communication University, Shijonawate, Osaka, Japan and [2]Graduate School of Medicine, Osaka University, Suita, Osaka, Japan

Introduction. Recently, biological electrical impedance (EI) has been widely used as a method to assess body constituents. There are two methods for EI measurement: two-electrode (TEM) and four-electrode (FEM) methods. The apparatus for the TEM is generally simple and inexpensive comparing with the FEM, but the accuracy of measurement in the TEM is lower than in the FEM. The FEM involves two pairs of electrodes, an outer pair and an inner pair. Electrical current passes between the outer pair (current electrode), and the voltage between the inner pair (voltage electrode) is measured. The uterine endometrium (UE) changes its conditions chemically and histologically in each menstrual phase. Since EI varies depending on tissue conditions, EI of UE (UEI) may also vary according to menstrual phases. However, to the best of our knowledge, UEI has been rarely reported. The aim of this study was to clarify the characteristics of UEI using mice. Methods. Animals. Twenty 10-week-old Slc:ddy female mice were used in this study. We checked the estrus cycle of mice by cytological evaluations of vaginal smears using Giemsa staining. The cycle of the mice used consisted of proestrus (PES, n=4), estrous (ES, n=7), metestrus (MES, n=5), and diestrus (DES, n=4). Equipment. We used an impedance checker using the FEM (MLT-50, Toray Medical, Japan). The MLT-50 measures impedances at 140 points between 2.5 and 350 kHz automatically and calculates characteristic parameters such as the impedance at 0 Hz (R0) and infinity Hz (Ri), critical frequency (fc), and resistance (Rfc) and reactance (Ifc) at fc. The intrauterine probe (IUP) was composed of two electrodes and a core of tungsten wire of 0.3 mm in diameter. We rolled platinum wire on the core wire as voltage electrodes at two sites: 2.5 - 5.0 and 7.5 - 10.0 mm from the tip end. We pricked two thin needles into the skins of the fore- and hind-feet and used them as current electrodes. Procedure. Under anesthesia with continuously inspired isoflurane, we performed laparotomy in a supine position, and exposed the uterus. We inserted the IUP into the vagina and advanced its tip into the uterine cavity, and then measured UEI. Results. Our preliminary experiments revealed that there was little difference in values of UEI at the points where the tip of the IUP was located 15, 30, and 45 mm from the external uterine os. UEI at 1 kHz at ES (3.5 ± 0.3 kΩ, mean ± SEM) was significantly larger ($p<0.05$, Kruskal-Wallis test) than those at PES (1.6 ± 0.2 kΩ), MES (0.6 ± 0.1 kΩ), and DES (0.9 ± 0.1 kΩ). There were no significant differences in R0, Ri, fc, Rfc, and Ifc regardless of menstrual stages. Discussion and Conclusion. We measured UEI at various estrous stages using the FEM successfully. The UEI parameters measured by the FEM might be new parameters for evaluating UE conditions.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA326

An increase in intellectual activity during menstruation by abdominal warming using a heat- and steam-generating sheet

C. Igi, T. Hosono, M. Yamamoto, M. Nakamoto, M. Arakawa and K. Akasaka

Graduate School of Biomedical Engineering, Osaka Electro-Communication University, Shijonawate, Osaka, Japan

Introduction. About 80% female school students suffer dysmenorrhea and sometimes experience a decrease in academic performance due to dysmenorrheal pain. Warming the abdomen has been widely used for pain relief as a non-pharmacological method. The heat- and steam-generating (HSG) sheet, which keeps the attached skin area around 40°C for 5 - 8 hours, relieves dysmenorrheal pain with comfort (Hosono, 2010). The comfort may promote the intellectual ability and thus prevent such a decrease in academic performance. The aim of this study was to clarify the effects of abdominal warming using the HSG sheet on the intellectual ability during simple calculations. The protocol of this study was approved by the local ethics committee. Methods. Ten female university students (age 21.5 ± 0.4, mean ± SEM) were included in this study. During menstruation periods, a subject sat in a room of 25°C and attached an HSG sheet (HSGS group) or a non-warming sheet (NWS group, control), as large as the HSG sheet, to the lower abdomen. Measurement was performed only once during a subject's menstruation. When a subject participated in HSGS at the first measurement, the subject participated in NWS in the next menstruation. For the evaluation of the intellectual ability, we used a randomly generated simple single-digit addition similar to the Kraepelin psychodiagnostic test. The subject performed the test just before and 1 hr after attaching the HSG sheet. The subject solved as many questions as possible for 15 min. We counted the number of correct answers (A) per total number of answered questions (B), and obtained the solution rate (SR) as A/B x 100. We also measured the thumb temperature (Tt) for evaluating sympathetic nerve activities (SNS). The subject also recorded her dysmenorrheal pain level using a integral score of zero (no pain) to three (severe pain). Results. The SR in the HSG group (32 ± 25%) significantly increased ($p<0.05$, Wilcoxon signed-rank test) compared to the control (-3 ± 9%). The increase rate of SR in the HSGS was significantly higher than in the NWS. The rate

of subjects with pain scores of more than two after 1-hr HSG sheet application was also significantly lower (Fisher's exact test, $p<0.05$) in the HSG group (50%) than in the control group (71%). The Tt in the HSGS (33.9 ± 1.3°C) was higher than in the NWS (25.6 ± 3.6°C), indicating a decrease in SNS. Discussion and Conclusion. Lower abdominal warming using the HSG sheet was effective for increasing intellectual activities. Interestingly, although three of the subjects did not feel dysmenorrheal pain during the measurements, all of them also experienced an increase in SR. Thus, the increased intellectual activities may not be completely due to only relief from dysmenorrheal pain. The increase in intellectual activities might be related to SNS decrease.

PCA327

Phenolic compounds content, antioxidant and antibacterial activities of green / black tea decoction as affected by cooking treatment

K. Dhaouadi[2], H. Jlassi[1], S. Fattouch[2] and M.H. Hamdaoui[1]

[1]Research Unit, high School of Health Sciences and Technical, Tunis, Tunisia and [2]Food Biochemistry Laboratory, INSAT, Tunis, Tunisia

Green or black tea decoction is a popular beverage in Tunisia, Libya and Algeria. It is prepared by cooking the dried tea leaves for a relatively long period of time, which is different from the infusion. The aim of our study was to evaluate the phenolic compounds content and the antioxidant and antibacterial activities of tea extracts after different cooking times, in comparison to tea infusion. Green or black tea leaves (40 g per L of water) were cooked for three times (15, 30 and 60 min) with two different methods (continuously and discontinuously). Tea decoctions obtained were extracted by acetone/water (v/v) according to the method described by Dhaouadi et al. (2011). Phenolic compounds were quantified by Folin –Ciocalteu method and their identifications were obtained by RP-HPLC/LC-MS technique. The antioxidant activities were evaluated by ABTS, DPPH and FRAP methods using Trolox as standard. The analysis of antibacterial activities of the tea preparations were assessed by using collection of microorganisms strains, commercially available as references. Values are means ± S.E.M., compared by ANOVA. Our results showed that the green tea cooked for 15 min contained the higher quantity of phenolic compounds (1388 ± 52 mg / gallic acid equivalent (GAE)/100mL of tea decoction). For the black tea, the higher phenolic compounds content were obtained 30 min after continuously cooking (953 ± 40mg /GAE /100 ml of tea decoction). Detailing of phenolic compounds peaks from different tea decoction extracts was described in the poster. The stronger antioxidant properties corresponded to those obtained from green tea cooked for 15 min (4975 mmol/ equivalent Trolox /100 mL of decoction). The antibacterial potential of tea extract showed that staphylococcus aureus and staphylococcus epidermidis were the most sensitive studied strains. Phenolic compounds of tea extracts from green tea cooked for 15 min are more powerful on the antioxidant and antibacterial activities, followed by black tea decoction obtained 30 min after continuously cooking, than tea infusion or decoctions of other cooking times.

Oxidative Stress and antioxidant response in rats exposed to permethrin, a pyrethroid insecticide, and ameliorating effect of vitamin C

F.M. El-Demerdash[1], H.M. Nasr[2] and A.B. Jebur[3]

[1]Environmental Studies, Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt, [2]Pest Control and Environmental Protection, Faculty of Agriculture, Damanhour, Egypt and [3]Environmental Studies, Institute of Graduate Studies and Research, Aleexandria, Egypt

Pyrethroids are important insecticides used largely because of their high activity as an insecticide and their low mammalian toxicity. The present study was designed to investigate the propensity of permethrin to induce oxidative stress and biochemical perturbations in rat liver and the role of vitamin C in alleviating its toxic effects. Male Wister Albino rats were randomly divided into four groups of 7 each, group I served as control; group II treated with vitamin C (200 mg/kg BW), group III received permethrin (150 mg/kg BW) and group IV treated with permethrin plus vitamin C. Rats were orally administered their respective doses daily for 28 days. The local committee approved the design of the experiments, and the protocol conforms to the guidelines of the National Institutes of Health (NIH). The administration of permthrin significantly caused elevation in lipid peroxidation (LPO) and reduction in the activities of antioxidant enzymes including catalase (CAT), superoxide dismutase (SOD), glutathione S-transferase (GST), glutathione peroxidase (GSH-Px) and glutathione reductase (GSH-Rx). A significant decrease in glutathione (GSH) content was also observed. Liver aminotransferases (AST and ALT) and alkaline phosphatase (AlP) were significantly decreased while lactate dehydrogenase (LDH) was increased. Vitamin C treatment to permethrin intoxicated rat decreased LPO level and normalized CAT, SOD, GST, GPx and GR activities, while GSH content was increased. Also, liver AST, ALT, AlP and LDH were maintained near normal level due to vitamin C treatment. In conclusion, vitamin C has beneficial effects and could be able to antagonize permethrin toxicity.

PCA329

Protective effect of vitamins C and E on abamectin-induced oxidative stress in rats

H.M. Nasr[1] and F.M. El-Demerdash[2]

[1]Pest Control and Environmental Protection, Faculty of Agriculture, Damanhour University, Damanhour, Egypt and [2]Environmental Studies, Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt

The present study was designed to investigate the impact of abamectin to induce oxidative stress and biochemical perturbations in male albino rat (Rattus norvegicus) serum and the role of vitamin C and vitamin E in ameliorating its toxic effects. Rats were randomly divided into 6 groups of 10 each, group I served as control; group II treated with vitamin C (VC; 20 mg/kg BW), group III treated with vitamin E (VE; 200 mg/kg BW/day), group IV received single dose of abamectin (2.175 mg/kg BW/day, 1/4 LD50), group V treated with abamectin plus vitamin C and group VI treated with abamectin plus vit E. Rats were orally administered their respective doses of VC and VE daily for 10 days. The local committee approved the design of the experiments, and the protocol conforms to the guidelines of the National Institutes of Health (NIH). After 10 days of treatment, serum aspartate amino transferase (AST), alanine amino transferase (ALT), gamma-glutamyl transferase (GGT) alkaline (AlP) and acid phosphatase (AcP) as well as malondiadehyde (MDA), glutathione (GSH), glutathione-S-transferease (GST), catalase (CAT) and superoxide dismutase (SOD) were measured. The results revealed significant increase in serum AST, ALT, AlP and AcP activities in abamectin group as compared to the control. Also, the level of MDA was significantly increased in abamectin treated rats. On the other hand, abamectin induced a significant inhibition of GST, CAT SOD and GSH contents as compared with the control group. Supplementation of vitamin C and vitamin E to abamectin - treated rats reduced the toxic effect of abamectin on the above measured parameters and lipid peroxidation in serum. In Conclusion, the findings data suggested that administration of vitamins C and E ameliorated the abamectin -induced oxidative stress in albino rats and the effect of vitamin E in preventing abamectin - induced toxicity was superior to that of vitamin C.

PCA330

The role of adrenergic receptors in nicotine-induced hyperglycemia in the common african toad (*Bufo regularis*)

G.O. Isehunwa, G.O. Adewunmi and A.A. Alada

Physiology, University of Ibadan, Ibadan, Oyo, Nigeria

The role of adrenergic receptors in nicotine-induced hyperglycaemia has not been well studied in amphibians. Thus, this study investigated the effects of alpha and beta adrenergic receptor blockers in nicotine-induced hyperglycaemia in the common African toad *Bufo regularis*. Each toad was fasted for 24hr and anaesthetized with sodium pentobarbitone (3mg/100g i.p). The animals received intravenous (i.v) injection (abdominal vein cannula) of 0.7% amphibian saline, or nicotine (50μg/kg) and thereafter, blood samples were collected for estimation of blood glucose level. In the treated groups, the toads were pretreated with prazosin (0.2mg/kg i.v), propranolol (0.5mg/kg i.v) or prazosin (0.2mg/kg i.v) combined with propranolol (0.5mg/kg, i.v) 30 minutes before i.v. injection of nicotine (50μg/kg i.v). Thereafter, blood samples were also collected from truncus arteriosus for estimation of blood glucose level using the modified glucose oxidase method.

Nicotine caused significant increase ($P<0.01$) in the levels of blood glucose in the common African toad. Pre-treatment of the toads with prazosin (0.2mg/kg i.v) or propranolol (0.5mg/kg, i.v) significantly ($p < 0.01$) reduced the hyperglycaemia induced by nicotine (50μg/kg i.v). However, the combination of prazosin (0.2mg/kg i.v) and propranolol (0.5mg/kg, i.v) abolished the hyperglycaemic effect of nicotine (50μg/kg i.v). The results of this study suggest that both alpha and beta adrenoceptors are involved in nicotine-induced hyperglycaemia in common African toad *Bufo regularis*.

Thyroid hormones in high altitude natives

O. Nepal and B.R. Pokhrel

Physiology, Kathmandu University Medical School, Dhulikhel, Nepal

The endocrine changes related to altitude adaptation in human have attracted physiologists around the globe for long. A number of high altitude studies to detect the physiological changes have been performed now and then. But, the study to see the hormonal changes to compare populations residing at different high altitudes is a scarce. Hence, we have performed a study in native populations of different high altitude comparing changes in thyroid hormones in western Nepal. The Jharkot population included in this study is at altitude of 3760m and Jomsom population at 2800m height from sea bed.
To compare thyroid status between high altitude natives at two different altitudes a cross sectional study is performed by random sampling method. The blood sample was collected in a vacutainer from fifty eight individuals after obtaining the informed consent of participants. The blood collected from antecubital vein was centrifuged in an hour and the plasma obtained was used for biochemical analysis of free triiodothyronine, free thyroxine and thyroid stimulating hormone. ELISA technique was used for bioanalysis of the serum samples collected in this study. Mean free thyroxine (fT4) of Jharkot population is significantly larger ($p = 0.001 < 0.05$) than Jomsom population. Mean thyroid stimulating hormone (TSH) with $p = 0.597 > 0.05$ does not indicate the difference between this two population. There is no significant difference between mean free triiodothyronine (fT3) of Jharkot and Jomsom population ($p = 0.345 > 0.05$). The rise in free thyroid hormone at high altitude is not dependent on the thyroid stimulating hormone released from anterior pituitary. The rise in free thyroxine may be the cause for the rise in free triiodothyronine at higher altitude and low plasma fT3 is not found in population studied at high altitudes.

PCA332

Effects of exposure to Bisphenol A on Expression of obesity-related genes in zebrafish

T.Y. Kostrominova

Anatomy and Cell Biology, Indiana University School of Medicine-Northwest, Gary, IN, USA

In recent years, environmental pollutants/endocrine disrupting chemicals (EDCs) have received special attention as metabolic disruptors that produce adverse developmental, reproductive, neurological, cardiovascular, metabolic and immune effects, including predisposition to metabolic syndrome, obesity and type 2 diabetes. Many EDCs are found in everyday products, such as plastic bottles, metal food cans, pesticides, detergents, toys, cosmetics, etc. The knowledge on cellular mechanisms behind the biological effect of EDCs exposure on the development of obesity and type2 diabetes is very limited.
Bisphenol A (BPA) is one of the most abundant EDCs present in the environment. BPA is present in the tested samples of human serum and urine worldwide and is considered to be an “obesogene” that interferes with lipid and glucose metabolism (reviewed in Umar et al., 2013). We focused our study on the effects produced by the exposure to BPA on the expression of obesity-related genes using zebrafish as an experimental model. We have chosen the zebrafish model based on several criteria: 1) recent studies have used zebrafish as a model for studies of the effects of EDCs (Chow et al., 2012); 2) a review by Holtta-Vuori at al. (2010) described zebrafish as an excellent model organism for lipid research; 3) studies of diet-induced obesity show that zebrafish and mammals share common pathophysiological pathways (Oka et al., 2010).
Our experiments showed that exposure of 7dpf zebrafish larvae to 5mg/L of BPA for 24 hours significantly decreased adiponectin and ghrelin mRNA expression (by 29±7% and 26±6 %, respectively, N=5, t-test $p<0.05$) assessed by quantitative RT-PCR using RPLO mRNA expression for the normalization. In the same experiments vitellogenin mRNA expression was increased (by 96±11%, N=5, t-test $p<0.05$) and there were no changes in the mRNA expression of PDK4, perilipin and UCP3. Exposure of 7dpf zebrafish larvae to 5mg/L of BPA for 72 hours decreased adiponectin and ghrelin mRNA expression by 56±4% and 38±5 %, respectively (N=5, t-test $p<0.05$). The data presented here are the first to show that exposure of zebrafish to BPA decreases adiponectin and ghrelin expression. Adiponectin increases fatty acid oxidation and glucose metabolism in muscle, reduces glucose output and enhances insulin sensitivity in liver, and exposure of mammalian adipocytes to BPA inhibits adiponectin release (reviewed in Ben-Jonathan et al., 2009). Ghrelin is involved in regulation of feeding and has potent growth hormone stimulation activity in zebrafish. Our data on increased vitellogenin mRNA expression correlate well with previously reported data on the zebrafish response to BPA (Chow et al., 2012). Overall our data suggest that exposure of zebrafish to BPA displays similarities with obesity-promoting effects of BPA previously documented in mammalian models.

PCA334

Changes in hsp mRNA dynamics are involved in HSP72 level regulation during one month of heat acclimation decline

A. Abbas and M. Horowitz

The Hebrew University of Jerusalem, Jerusalem, Israel

We have previously shown in rats (Rattus norvegicus, Sabra strain) that during heat stress (at 41°C), upon heat- acclimation decline, HSP72 maintained heat-acclimatory protein levels despite of the transition to normothermic ambient temperature (at 24 °C). Both basal and heat stress hsp transcripts were profoundly higher than those measured during heat acclimation (continuous exposure at 34 °C, Tetievsky et al., 2008). Increased hsp mRNA/HSP72 protein ratio promoted the hypothesis that dynamic changes in mRNA are responsible for HSP72 proteo-stasis. To test this hypothesis, given that Eif2α is associated with initiation of translation, we measured during 15d and 30d of acclimation decline vs. acclimation: (i) the levels of Eif2α and its phosphorylated form, (ii) the effect of Eif2α dephosphorylation inhibition (using Sal 003, TOCRIS Cat No. 3657) on hsp 72 and 27 transcripts and the encoded HSPs. Our data demonstrated that heat acclimation induced increased Eif2α protein level with decreased phosphorylation. With acclimation decline, Eif2α-phosphorylation gradually increased. Basal and heat-stressed hsp 72 transcripts were elevated whereas HSPs levels were stable, suggesting HSPs proteo-stasis. Daily SAL administration (IP 0.1mg/kg b wgt) during acclimation decline elevated profoundly (vs. non SAL administered groups) hsp 72 transcripts and the mRNA/protein ratio under both basal and heat stress conditions, thus confirming our hypothesis on the importance of mRNA dynamics in HSPs adjustment during heat acclimation decline.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

High-performance thermogenesis of brown adipose tissue under hypothermic condition during hibernation in Syrian hamsters

M. Hashimoto[1], H. Ohinata[1] and N. Kitao[2]

[1]Department of Physical Therapy, Teikyo University of Science, Faculty of Medical Sciences, Tokyo, Japan and [2]Public Health Center, Sakai, Japan

Hibernation under extreme cold environment needs a preparation period of some length in which most physiological functions are thought to be remodelled in wide range to adapt to hibernation. Brown adipose tissue (BAT) is an indispensable organ to complete the hibernation behavior, particularly in arousing from hibernation of hypothermia. Taking into consideration the restraint of most physiological functions by low body temperature, remodelling before hibernation occurs possibly in BAT function too. A concrete mechanism of the 'preparation' is still unclear, but the molecular-level remodelling of BAT must be performed during the preparation period of hibernation, because most gene expression stops during deep hibernation. The dominant pathway of BAT thermogenesis occurs through the β3-adrenergic receptor. We investigated the role of the β3-adrenergic system in BAT thermogenesis during arousal from hibernation both in vivo and in vitro. Necessary surgical procedures were carried out under isoflurane anesthesia. Stimulation of BAT by CL316,243 significantly facilitated arousal from hibernation and it also induced arousal in deep hibernating animals, while the β3-antagonist SR59230A inhibited arousal from hibernation. Syrian hamsters in the hibernation group (H) contained BAT that was significantly greater in overall mass, total protein, and thermogenic uncoupling protein-1 than BAT from the warm-acclimated group (WA). Although the ability of the β3-agonist CL316,243 to induce BAT thermogenesis at 36°C was no different between H and WA, its maximum ratio over the basal value at 12°C in H was significantly larger than that in WA. Forskolin, adenylyl cyclase activator, stimulation at 12°C produced equivalent BAT responses in these two groups. These results suggest that BAT in hibernating animals has potent thermogenic activity with a highly effective β3-receptor mechanism at lower temperatures. Hence we hypothesized that the high effectiveness of the receptor mechanism may be due to an increase in number of the receptor that possibly occurs during the preparation period. To investigate the hypothesis, we measured β3-receptor mRNA of BAT removed from animals in 4 stages of activity, WA, CA (cold-acclimated), H and IBA (inter-bout arousal, awake phase during hibernation) by using RT-PCR method. Gene expression of the β3-receptor in BAT of hibernating hamster was significantly smaller by about 40% and 60% than that of WA and CA respectively, but was not different from that of IBA. Results showed that the facilitation of BAT function in hibernating animals may be due to remodelling of the messenger pathway between two molecules, β3-receptor and adenylyl cyclase.

Endothelial SHIP2 confers age-dependent contrasting affects on whole body glucose homeostasis and vascular function

M. Gage[1], S. Wheatcroft[1], A. Abbas[1], H. Imrie[1], H. Viswambharan[1], S. Galloway[1], P. Sukumar[1], R. Cubbon[1], J. Smith[1], S. Schurmans[2], M. Jacoby[2], E. Dubois[2] and M. Kearney[1]

[1]DCDR, Leeds University, Leeds, UK and [2]IRIBHM, Université Libre de Bruxelles, Brussels, Belgium

Aging is an important risk factor for diabetes and cardiovascular disease (1). Although the vascular implications of endothelial insulin resistance are well understood (2) the effect of enhanced endothelial insulin signaling on glucose regulation and vascular function remain poorly characterized. To investigate this we generated mice with endothelial-specific downregulation of the lipid phosphatase SHIP2 (3). We deleted exons 18-19 of the ship2 gene using Cre-Lox technology under control of the Tie2 promoter generating an inactivate protein. Male heterozygotes (EC-SHIP2+/-) were compared to sex-matched littermate controls. At 8 weeks of age EC-SHIP2+/- mice displayed increased glucose tolerance after glucose challenge (P=0.03) and improved insulin sensitivity (P=0.02) after insulin challenge (glucose/insulin administration via intra-peritoneal injection, blood sampling from tail vein). By 40 weeks of age this phenotype was reversed; EC-SHIP2+/- mice revealed significant insulin resistance 60 min after insulin challenge (P=<0.05). This phenotype was confirmed by euglycemic hyperinsulinemic clamping. In young mice ex vivo aortic vasomotor studies in both controls and EC-SHIP+/- revealed similar contractile responses to phenylephrine and displayed decreased contraction after insulin incubation (Emax 0.88 ± 0.05g vs 0.62 ± 0.05g P=0.002 and 0.83 ± 0.05g vs 0.69 ± 0.05g P=0.025 respectively). Both groups displayed increased contraction after NO synthase inhibitor LNMMA incubation (Emax 0.88 ± 0.05g vs 1.31 ± 0.11g P=0.01 and 0.83 ± 0.05g vs 1.28 ± 0.02g P=<0.0001 respectively). However, at 40 weeks old in EC-SHIP2+/- mice the vasodilatory aortic ring response to insulin was abolished (Emax controls 0.59 ± 0.04g vs 0.47 ± 0.03g P=0.04, EC-SHIP2+/- 0.64 ± 0.04g vs 0.63 ± 0.06g P=0.9) and EC-SHIP2+/- displayed no increase in contraction to LNMMA incubation (Emax controls 0.59 ± 0.04g vs 0.82 ± 0.08g P=0.02, EC-SHIP2+/- 0.64 ± 0.04g vs 0.69 ± 0.07g P=0.5) indicating insulin resistance and lower basal nitric oxide production (NO), suggesting changes in glucose homeostasis may be mediated by NO bioavailability. In conclusion; endothelial functional downregulation of SHIP2 augments whole body glucose disposal in young mice but attenuates whole body glucose disposal in older mice. Our data suggest a previously unrecognised age dependent role for the vascular endothelium in whole body glucose regulation and a novel spatial and temporal specific affect of the lipid phosphatase SHIP2.

PCA338

The impact of advanced maternal age on the initiation and progress of parturition in a pregnant mouse model

R. Patel

Division of Women's Health, Women's Health Academic Centre, King's College London, London, UK

Rima Patel1, Lucilla Poston1 and Rachel M Tribe1. 1Women's Health Academic Centre, King's College London. London SE1 7EH, UK.

Background: Advanced maternal age (defined as ≥35 years at delivery) is associated with adverse obstetric risks including operative delivery, stillbirth, and post-term labour induction. The physiological causes for such complications remain to be ascertained, although myometrial function has been implicated (Smith GC et al., 2011; Arrowsmith et al., 2012). To address the hypothesis that maternal age directly influences successful parturition, we assessed timing of birth and fetal outcome in a pregnant mouse model. The function of myometrium and cervix ex-vivo was also examined.

Methods: Gestation length (days) and parturition duration (hours) in young (3 months old, n=8) and old (8 months old, n=8) nulliparous pregnant C57/BL6 mice were monitored using infrared cameras. The number of viable pups delivered per mouse was recorded. Isolated myometrial tissues from pregnant (day 18) C57/BL6 mice (3 months and 8 months; n=10 each group) were used for isometric tension recording [spontaneous contractility; mean integral tension (g) and contractile frequency (Hz)]. Oxytocin induced contractility (n=5 for both groups) was also measured [mean integral tension(g)]. Maximal cervical distensibilty (mm) was recorded in cervices from pregnant (day 18) C57/BL6 mice (3 months and 8 months, n=5 per group).

Results: Older pregnant mice compared to 3 month old mice had a longer mean (±SEM) gestation (20.08 ±0.49 days vs. 19.05 ±0.25; p<0.001) and significantly longer labours (3.68 ±0.83 hours vs. 1.01 ±0.41; p<0.001). The 3 month old mice gave birth to a greater number of viable pups compared to older mice (7.5 ±0.53 vs. 4.8 ±2.2, p<0.01); 50% of older mice had at least one stillborn pup. The contractile frequency of myometrium ex-vivo was faster in older pregnant mice (0.05 ±0.0098 vs. 0.02 ±0.0046 Hz, p<0.05); however mean integral tension was similar. The 8 month group appeared to exhibit a greater sensitivity to oxytocin (n=5, 10-10 - 10-9 M), but this did not reach significance. Cervical distensibility was significantly greater in older pregnant mice (19.4 ±0.60 vs. 16.6 ±0.75 mm, p<0.05).

Conclusions: Gestation length, labour duration and stillbirth risk were increased in older pregnant mice suggesting that there is an intrinsic problem with parturition processes in older mice. This is unlikely to be due to delayed cervical ripening as evidenced by enhanced distensibility in older mice. However, the increased contraction frequency seen in older mice ex-vivo could potentially result in poorly coordinated myometrial contractions in-vivo.

PCA339

Phosphodiesterase-5 activity exerts a coronary vasoconstrictor influence in awake swine that is partly mediated via an increase in endothelin production

Z. Zhou[1], V.J. de Beer[1], S.B. Bender[2], H. Laughlin[2], D. Merkus[1] and D.J. Duncker[1]

[1]Cardiology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands and [2]Biomedical Sciences, University of Missouri, Columbia, MO, USA

Nitric oxide (NO)-induced coronary vasodilation is mediated through production of cyclic guanosine monophosphate (cGMP), and through inhibition of the endothelin (ET) system. We previously demonstrated that both phosphodiesterase-5 (PDE5) mediated cGMP breakdown and ET each exert a vasoconstrictor influence on coronary resistance vessels. However, little is known about the integrated control of vascular tone of these two vasoconstrictor mechanisms. In the present study, we investigated the contribution of PDE5 and ET to the regulation of coronary resistance vessel tone in swine at rest and during graded treadmill exercise. ET-A/ET-B receptor blockade with tezosentan (3 mg/kg iv) and PDE5 inhibition with EMD360527 (300 μg/min/kg iv) each produced coronary vasodilation at rest that waned with incremental levels of exercise. Interestingly, however, tezosentan failed to produce further coronary vasodilation in the presence of EMD360527. Similarly, tezosentan and EMD360527 each produced concentration-dependent vasodilation in preconstricted porcine coronary small arteries in vitro, while tezosentan again failed to produce additional vasodilation in the presence of EMD360527. Importantly, EMD360527 (3×10-6 M) significantly attenuated BigET-induced, but not ET-induced coronary contraction. In conclusion, PDE5 activity exerts a vasoconstrictor influence on coronary resistance vessels that is in part mediated via an increase in ET production.

PCA340

A toxicity profile of the aqueous calyx extract of Hibiscus sabdariffa in Sprague Dawley rats

F.B. Mojiminiyi

Physiology, Usman Danfodio University, Sokoto, Nigeria

The aqueous calyx extract of Hibiscus sabdariffa (HS) doubles as a beverage and an agent for treating hypertension in Traditional Medicine in Nigeria and other places (Hopkins et al., 2013). Its antihypertensive effect has been scientifically validated (Mojiminiyi et al., 2007) and may be due to its antioxidant properties (Frank et al., 2012). It contains organic acids such as citric acid, anthocyanins, polyphenols and hibiscus acid (Hopkins et al., 2013). However more toxicological studies are needed before the emergence of a drug(s) from it. This study was designed to carry out a toxicological study of HS. 10g of the dry calyces was boiled in 1 litre of water at 100oC for two hours and the cold decoction filtered. The filtrate was evaporated to dryness and the powder was used to prepare the HS solutions. Thirty six inbred Sprague Dawley (SD) rats of either sex weighing 112-140g were randomly divided into three groups (n=12 each): control, HSLD (HS Low dose) and HSHD (HS High dose). All groups received the rat chow while the control drank tap water and HSLD and HSHD drank 1750mg/kg and 3500mg/Kg HS respectively for twelve weeks. Rat Chow, water and HS solutions were available ad libitum. The rats were then anaesthetized individually by means of chloroform inhalation in a jar. Each was removed and blood was obtained rapidly by cardiac puncture into EDTA or plain bottles. In some cases additional chloroform in cotton wool encased in a cone-shaped filter paper was applied to the nose to maintain anaesthesia during the procedure. Blood in EDTA was used for estimation of haematological parameters (packed cell volume: PCV, white blood cell count: WBC, red blood cell count: RBC and Haemoglobin: Hb) in the QBC machine while serum was extracted from the rest and used for cation (Na+and K+) and biochemical (alkaline phosphatase:ALP, aspartate amino transferase: AST, alanine amino transferase: ALT, albumin, total protein and urea) analyses. Results are expressed as mean±SEM and statistical analyses were done by means of one way ANOVA and a post hoc Tukey Kramer multiple comparison test. $P<0.05$ was considered statistically significant.

Haematological and biochemical parameters and serum cation levels remained similar in the HS groups compared to control except WBC count and urea. These rose significantly in the HSHD group (14.03±1.9 x103/ml and 7.63±0.50 mmol/dl; $P<0.001$ and $P<0.05$ respectively) compared to control (7.25±0.76 x103/ml and 5.10±0.96mmol/dl) but remained similar in HSLD group (10.2±0.16 x103/ml and 5.92±0.44mmol/dl). These results suggest that chronic consumption of HS at low doses may be safe. Higher doses may be associated with reactive leucocytosis and renal injury which may be secondary to subtle inflammatory processes in the body following its consumption.

PCA341

Endothelial relaxation mechanisms dysfunction are reversed by atorvastatin or metformin in animals with estrogen deficiency state

I.F. Caliman, P.W. Oliveira, A.Z. Lamas, S.G. Figueiredo, P.L. Dalpiaz, G.J. Sousa and N.S. Bissoli

Physiological Sciences, Federal University of Espirito Santo, Vitória, Espirito Santo, Brazil

Deleterious effects in cardiovascular system (CVS) have been reported in females with estrogen deficiency. However, stud-

ies with hormone replacement therapy (HRT) are not concise. Thus, estrogen receptor independent therapies, such as atorvastatin (ATO) and metformin (MET), could be new strategies to substitute HRT. These drugs have been showed pleiotropic effects, but there are limited data comparing ATO and MET with estrogen on the CVS. This study was performed to evaluate the effects of ATO and MET on mesenteric vascular bed (MVB) reactivity from ovariectomized (OVX) female rats. All procedures were approved by Ethics Committee in Animal Experimentation of the Federal University of Espirito Santo (069/2011). All the surgical experiments were carried out under anesthesia (Ketamine 70 mg/kg + xylazine 10 mg/kg, i.p). Female Wistar rats (180-200g) were divided into five groups (n=6): control (SHAM); ovariectomized (OVX), OVX treated with 17βestradiol (EST, 0.5μg/Kg/day), ATO (ATO, 20mg/Kg/day) or MET (MET, 300mg/Kg/day), 21 days after bilateral ovariectomy. On day 35, the MVB was isolated, perfused and constricted with noradrenaline. Dose–response curves of ACh (10-12 to 10-3 M) were obtained in absence or presence of L-NAME (NOS inhibitor) and L-NAME plus Indometacin (COX inhibitor). Inducible NOS (iNOS), endothelial NOS (eNOS) and NADP(H) oxidase type 2 (NOX 2) protein expression were analyzed by western blot (n=6). The data are reported as means ± SEM, compared by ANOVA. OVX showed decreases in vasodilator response to ACh, and all treatments improves this response (Emax - %relaxation SHAM: 80 ± 3; OVX: 54 ± 4*; EST: 82 ± 3; ATO: 88 ± 5; MET: 68 ± 4; *P<0.05 vs SHAM). L-NAME reduce the relaxation to ACh in all groups (Emax - %relaxation SHAM: 32 ± 8; OVX: 24 ± 7; EST: 34 ± 4; ATO: 35 ± 5; MET: 25 ± 4). L-NAME and Indometacin blockade failed to further reduce ACh-induced relaxation (Emax - %relaxation SHAM: 47 ± 10; OVX: 43 ± 7; EST: 40 ± 7; ATO: 36 ± 7; MET: 25 ± 3). OVX showed elevated levels of iNOS and NOX2 protein expression (iNOS: SHAM: 0.84 ± 0.05; OVX: 0.99 ± 0.04* and NOX2: SHAM: 0.76 ± 0.10; OVX: 1.12 ± 0.13*, *p<0.05), and reduced levels of eNOS (SHAM: 1.07 ± 0.10; OVX: 0.71 ± 0.10**, **p<0.01). All Treatments were able to restore the protein expression values (iNOS: EST: 0.81 ± 0.05; ATO: 0.84 ± 0.03; MET: 0.73 ± 0.04; NOX2: EST: 0.80 ± 0.05; ATO: 0.96 ± 0.09; MET: 0.44 ± 0.07; eNOS: EST: 1.13 ± 0.08; ATO: 1.13 ± 0.09; MET: 0.93 ± 0.05). The relaxation dysfunction caused by estrogen deficiency were improved by ATO and MET treatments, through mechanisms related to nitric oxide pathway, by increase eNOS and decrease iNOS levels and by reduction in NOX2/oxidative stress, providing evidence that non-estrogen therapies could be used to improvement the CVS in estrogen deficient state, such as menopause.

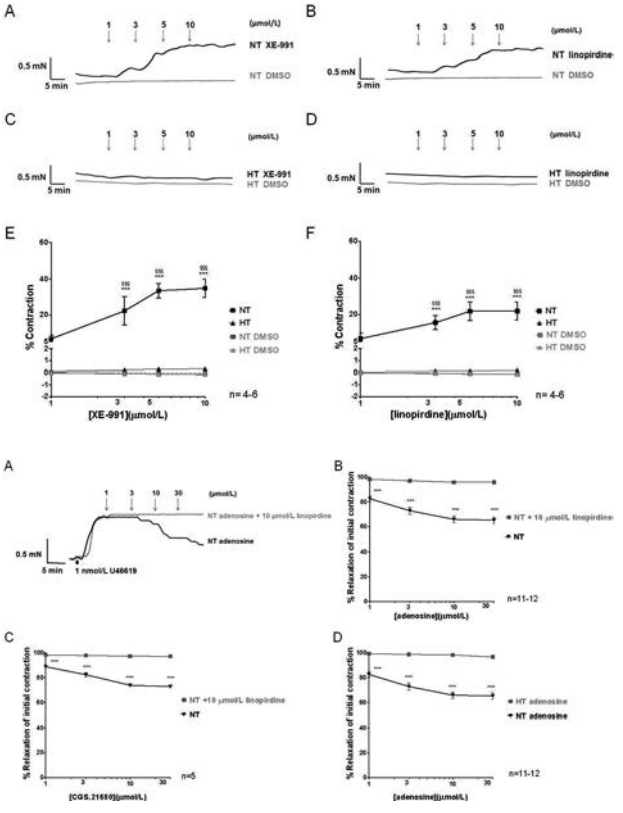
Kv7 channels are major determinants of basal coronary flow and active response to ischemia

S. Khanamiri[1], E. Soltysinska[1], T.A. Jepps[2], B.H. Bentzen[1], P.S. Chadha[2], N. Schmitt[1], I.A. Greenwood[2] and S. Olesen[1]

[1]Danish National Research Foundation Centre for Cardiac Arrhythmia and Dept. of Biomedical Sciences, Copenhagen University, Copenhagen, Denmark and [2]Division of Biomedical Sciences, St. George's University of London, Pharmacology & Cell Physiology Research Group, London, UK

The small coronary arteries constitute the primary site for regulation of vascular resistance in cardiac muscle and mediate the increased blood flow by metabolic substrates such as adenosine. The goal of the present study was to determine the role of KCNQ-encoded KV channels (KV7 channels) in the passive and active regulation of coronary blood flow in normotensive and hypertensive rats. In normotensive rats different KV7 activators and inhibitors caused dilatation or constriction of left anterior descending coronary arteries, which were not observed in hypertensive rats. In isolated, perfused heart preparations, coronary flow rate increased in response to the KV7 activator (S)-1, and was significantly diminished in the presence of a KV7 inhibitor. The expression levels of KCNQ1-5 and their known accessory KCNE1-5 subunits in coronary arteries were similar in normotensive and hypertensive rats as measured by quantitative PCR. However, KV7.4 protein expression was reduced in hypertensive rats. Application of adenosine or the protein kinase A mediated A2A receptor agonist CGS21680 produced concentration-dependent relaxations of coronary arteries from normotensive rats. However, the effects of adenosine, A2A receptor and CGS21680 were abolished in presence of KV7 inhibitors. KV7 blockers also attenuated the ischemia-induced increase in coronary perfusion in Langendorff studies. Overall, these data suggest that KV7 channels are crucial regulators of coronary blood flow and utilised by adenosine receptor activation to contribute to metabolic hyperemia.



Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Cardioprotection from cold stress and subsequent fatty diet is mediated by Epac-1 in the isolated mouse heart

F. Edland

Dept of Biomedicine, University of Bergen, Bergen, Hordaland, Norway

Background
Cold stress and subsequent fatty diet reduce infarct size (IS) in the isolated mouse heart when subjected to ischemia and reperfusion. We assessed the hypothesis that Exchange protein directly activated by cyclic adenosine monophosphate 1 (Epac-1) is necessary for cold- and fat stress induced cardioprotection.
Methods
Epac-1 knock-out mice (-/-) (Epac-1 KO) and wild type littermates (WT) were subjected to cold stress (week 5-9) and a fatty diet (week 10-termination) or control environment with room temperature and normal diet. At age 42-43 weeks the mice were sacrificed and the hearts were excised and mounted on a Langendorff perfusion system. The hearts were subjected to 30 min of global ischemia and 1 h of reperfusion, before IS was measured. Hemodynamic parameters were measured at regular intervals.
Results
IS is reported as necrotic tissue/left ventricle ± S.E.M. (%). All groups were n≥6, and group differences were tested by one-way ANOVA combined with Fischer's post-hoc test. WT animals were cardioprotected from cold/fat (WT cold/fat 42±3,5% vs. WT controls 61±6,9%, $p<0.05$, while Epac-1 KO were not (Epac-1 KO cold/fat 65±9,8% vs. Epac-1 KO ctrl 56±5,5%, ns.). Hemodynamic parameters, such as left ventricle developed pressure (LVDP), also suggests a better recovery of the WT cold/fat group, compared to the other groups. LVDP recovery in % of baseline at 30 min of reperfusion, baseline set at 20 min of stabilization: WT cold/fat 94,8±7,4%, WT ctrl 69,9±8,1%, Epac-1 KO cold/fat 59,8±9,1%, Epac-1 KO ctrl 64,8±6,3% ($p<0,05$).
Conclusion
Epac-1 seems to be necessary for the cardioprotective effect of cold stress and fatty diet.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA345

Flow-mediated outward remodeling and NO-dependent dilation of resistance arteries are both determined by sex and age with a key role of timing in estradiol replacement therapy

K. Tarhouni[1], A. Guihot[1], L. Grimaud[1], B. Toutain[1], L. Loufrani[1], F. Lenfant[2], J. Arnal[2] and D. Henrion[1]

[1]BNMI, INSERM, Angers, France and [2]I2MC, INSERM, Toulouse, France

Flow (shear stress)-mediated outward remodeling of resistance arteries is a key adaptative process [1], which declines with age [2]. We recently demonstrated the essential role of 17beta-estradiol in flow-mediated remodeling of resistance arteries in vivo [3]. We now sought to assess the impact of age and timing of estrogen treatment after ovariectomy for better efficacy on this process.
Rats of various ages (3 to 18 months) were submitted to surgery in order to increase locally blood flow in one mesenteric artery in vivo [4, 5], and the arteries, were collected 2 weeks later.
Arterial diameter increased by 27% in high flow arteries of 3-months old male and female rats compared to normal flow vessels. In 12-month old rats, flow-mediated remodeling was absent in males, while it still reached 21% in females. Ovariectomy (3 weeks of estrogen deprivation) of 3, 9 and 12 month-old rats abolished flow-mediated remodeling, that was restored by immediate 17beta-estradiol replacement. Nevertheless, this permissive effect of E2 was attenuated or even abrogated if 17beta-estradiol replacement was delayed by 3 to 9 months respectively. This absence of remodeling was associated with reduction in both estrogen receptor alpha and endothelial nitric oxide (NO) synthase expression levels, associated with reduced NO-dependent dilation in high-flow mesenteric resistance arteries.
Thus, long deprivation of 17beta-estradiol leads to a rapid decline in FMR, that can be prevented by early exogenous 17beta-estradiol supplementation, while delayed substitution of 9 months impairs 17beta-estradiol action. These data underline the importance of "timing" of 17beta-estradiol effect on this vascular process.

PCA346

Optimal ROS level is essential for induced pluripotent stem cell adhesion, transendothelial migration, and trafficking in mice

D. Meng[1], Y. Wu[1,2], R. Wang[1,2], N. Li[1], W. Yuan[2] and S. Chen[1]

[1]Department of Physiology and Pathophysiology, Fudan University, Shanghai, China and [2]Department of Physiology, Ningxia Medical College, Shanghai, China

Cell trafficking is essential for cell-based therapy. Reactive oxygen species (ROS) regulate cell proliferation, differentiation, and survival. However, it is not yet known how ROS affects induced pluripotent stem cell (iPSC) trafficking. We found that ROS inhibitor N-acetylcysteine decreased iPSC adhesion, transendothelial migration, and proliferation, and down-regulated major adhesion and migration-related molecules. Exogenous ROS inhibited iPSC adhesion and induced cell apoptosis

and senescence.Male C57BL/6J mice were subjected to operative unilateral hind limb ischemia-reperfusion injury under anesthesia with sodium pentobarbital (50 mg/kg i.p.). The left femoral artery and vein were isolated and clamped for 5 h. After clamp removal, mice were immediately assigned to the following experimental groups (n=9): the MEF (mouse embryonic fibroblasts) group, the iPSC group, the iPSC-NAC group (iPSCs pretreatment with 10 mM NAC for 24 h), the iPSC-H_2O_2 group (iPSCs pretreatment with 50 μM H_2O_2 for 24 h) or the vehicle group (PBS). In each animal, 2.5x10^6 cells/kg body weight (200 μl) or medium was administered through the tail vein 0 h and 24 h after the operation. We found that intravenously administered iPSCs selectively homed to the ischemic tissue and improved blood perfusion and limb function while NAC- or H_2O_2-pretreated iPSCs did not. Our results showed either increased or decreased ROS levels damaged iPSC function. ROS-facilitated IPSC trafficking is essential for their therapeutic effect.

The effect of l-arginine on microvascular reactivity in normotensive subjects with family history of hypertension

Z. Melik, P. Zaletel, T. Virtic and K. Cankar

Institute of Physiology, University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Introduction: Arterial hypertension is the leading risk factor for mortality worldwide. The increasing number of studies support the hypothesis that endothelial dysfunction due to reduced availability of nitric oxide plays a key role in initiation, development and progression of essential hypertension. The aim of our study was to determine whether the ingestion of the food supplement L-arginine actually improves endothelial function, which could be beneficial in the treatment of essential hypertension.

Methods: 30 normotensive healthy men, aged 20-30 years, were divided into two groups according to the family history of hypertension (FN - healthy, not genetically predisposed, FH - normotensive subjects with family history of hypertension). We measured ECG, heart rate, systolic and diastolic blood pressure, cardiac output, stroke volume, total peripheral resistance (Task Force Monitor) and laser Doppler (LD) flux in the microvessels of the skin of the forearm, at rest before and after administration of 0.9 g L-arginine. Endothelium-dependent vasodilation was assessed by iontophoresis of acetylcholine and endothelium-independent vasodilation by iontophoresis of sodium nitroprusside. Values are expressed as mean ± SEM. The study was approved by the National Medical Ethics Committee; written informed consent was obtained from each subject.

Results: After the ingestion of L-arginine the heart rate (FN 67.7 ± 4.3 vs. 62.7 ± 3.3; FH 63.2 ± 2.2 vs. 60.3 ± 2.0 beats/min) and the cardiac output (FN 7.07 ± 0.5 vs. 6.53 ± 0.4; FH 7.19 ± 0.3 vs. 6.38 ± 0.2 L/min) statistically significantly decreased in both groups (paired t-test, $p<0.05$), while arterial blood pressure did not change significantly. In contrast, stroke volume decreased (116.0 ± 6.5 vs. 108.2 ± 5.9 mL) and total peripheral resistance increased (868.9 ± 96 vs. 1114.4 ± 48 MPa s/m3) only in the group of subjets with family history of hypertension (paired t-test, $p<0.05$). We demonstrated that the ingestion of L-arginine in genetically predisposed normotensive subjects acutely improved endothelium-dependent vasodilation (68.8 ± 4.4 vs. 95.4 ± 9.3 PU) (Dunnett's test, $p < 0.05$), which

is consistent with the assumption that endothelial dysfunction is already present in these subjects.
Conclusions: In genetically predisposed normotensive subjects in comparison to healthy subjects without predisposition, L-arginine increased nitric oxide production and improved endothelial function. That justifies L-arginine as a potential therapeutic agent for treatment of arterial hypertension.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA348

Improvement of blood-retinal barrier breakdown in type 2 diabetic rats by alpha-mangostin

C. Areebambud[1], C. Mekseepralard[2] and A. Jariyapongskul[1]

[1]Physiology, Faculty of Medicine, Srinakharinwirot University, Bangkok, Thailand, Bangkok, Thailand and [2]Microbiology, Faculty of Medicine, Srinakharinwirot University, Bangkok, Thailand, Bangkok, Thailand

The blood-retinal barrier (BRB) breakdown is a common feature of diabetic retinopathy. In this present study, effects of long-term supplementation of alpha-mangostin (α-MG), a xanthone isolated from mangosteen fruit, on the ocular blood flow and blood-retinal barrier were investigated in type 2 diabetic rats. Type 2 diabetes was induced in male Sprague-Dawley rats by feeding with high-fat (HF) diet for two weeks followed by intravenous injection of low dose streptozotocin (STZ; 35 mg/kg body weight). The rats were divided into three groups: control group (CON; n=7), type 2 diabetic (HF-STZ; n=7) group and type 2 diabetic rats supplemented with α-MG (HF-STZ-MG; n=7). The use of animals was approved by Faculty of Medicine, Srinakharinwirot University Animal Ethic Committee. Alpha-mangostin was prepared by dissolving in corn oil in the volume of 1 mL per rat. The daily gavage feeding of α-MG 200 mg/kg body weight/day was performed for 40 weeks. At the start of experiment, the rat was anesthetized with pentobarbital sodium (60 mg/kg BW, i.p.) and a tracheotomy was performed to allow for mechanical ventilation with both room air and supplemented oxygen. A catheter was inserted into the femoral vein to inject Evans blue (EB) dye and a femoral artery was cannulated for measurement of arterial blood pressure. After cannulation was performed, ocular blood flow (OBF) was monitored using Laser Doppler flowmeter. The blood-retinal barrier (BRB) leakage was quantified using Evans blue (EB) dye technique. The effect of α-MG on glycemia was assessed by evaluating glycated hemoglobin (HbA1c). The blood sample for HbA1c assessment was obtained from femoral vein. Values were mean ± S.E.M., compared by ANOVA. In type 2 diabetic rats, HbA1c and MAP were increased significantly, whereas OBF was decreased markedly as compared with control group ($p < 0.01$). All of these abnormal parameters were improved by α-MG supplementation (HbA1c = 7.31±0.16 mg/dL for HF-STZ vs 4.31±3.33 mg/dL for HF-STZ-MG, $p < 0.01$; MAP = 132±2.1 mmHg for HF-STZ vs 107.28±3.33 mmHg for HF-STZ-MG, $p < 0.01$; OBF (arbitary unit) = 173.67±5.0 for HF-STZ vs 230.50±1.68 for HF-STZ-MG, $p < 0.01$). Additionally, the leakage of EB dye from retinas was significantly decreased in type 2 diabetes supplemented with α-MG as compared with type 2 diabetes (BRB leakage = 47.84±4.67 μg/mg of retina for HF-STZ vs 30.56±1.75 μg/mg of retina for HF-STZ-MG, $p < 0.01$). These results demonstrated that alpha-mangostin supplementation improved glycemic state, mean arterial pressure and exerted beneficial effects on the ocular blood flow and blood-retinal barrier integrity in type 2 diabetes.

PCA350

Neuropilin-1 regulates endothelial focal adhesion turnover via p130Cas phosphorylation

I. Evans, W. Pickworth, G. Schey, P. Frankel and I.C. Zachary

Medicine, University College London, London, UK

Neuropilin-1 (NRP1) is a non-tyrosine kinase receptor for vascular endothelial growth factor (VEGF) and a co-receptor for VEGF receptor 2 (VEGFR2) signalling in the endothelium. There is increasing evidence that NRP-1 plays a pivotal role in endothelial migration and angiogenesis, but the mechanisms involved are unclear. Recently, we have shown that NRP-1 is required for VEGF-mediated phosphorylation of the adaptor protein, p130Cas, a critical signalling hub in the regulation of cell motility, and this novel NRP-1-p130Cas pathway is important for endothelial cell migration (Evans et al 2011). Here we show that knockdown of either p130Cas or NRP-1 inhibits the VEGF-induced decrease in endothelial adhesion to fibronectin. Furthermore, NRP-1 and p130Cas are required for VEGF-induced focal adhesion kinase (FAK) phosphorylation, and NRP-1/p130Cas knockdown reduces immunofluorescent staining of focal adhesions by an anti-paxillin antibody. These findings indicate a key role for a NRP-1/p130Cas pathway in VEGF-induced focal adhesion turnover. NRP-1 modulation of focal adhesion turnover is likely to be an important mechanism mediating its role in endothelial migration and angiogenesis.

PCA351

The role of Na+/H+ exchanger-1 during ischemia-induced cerebrovascular dysfunction

Y. Jung

Ajou University, Suwon, Republic of Korea

The present study has investigated the role of Na+/H+ exchanger-1 (NHE-1) during cerebrovascular endothelial dysfunction during ischemia in a rat cerebral ischemia model in vivo and in mouse brain microvascular endothelial cells (bEnd.3 cells) in vitro. This study shows that specific inhibition of NHE-1 by sabiporide, a well-known NHE-1inhibitor, ameliorates brain edema in vivo, and attenuates cerebrovascular endothelial hyperpermeability induced by ischemia in vivo and in vitro. Occludin and Zonular Occludens-1 (ZO-1) were found to be damaged in the ischemic rat brain, but the inhibition of NHE-1 reversed these damages. Furthermore, during aglycemic hypoxia in bEnd.3 cells, the subcellular distributions of occludin

and ZO-1 were found to be altered, but these changes were also reversed by NHE-1 inhibition. Sabiporide also inhibited aglycemic hypoxia-induced increases in intracellular Ca2+ levels. These findings suggest that NHE-1 plays a critical role during ischemia-induced cerebrovascular hyperpermeability and TJs alteration, and that NHE-1 inhibition can be therapeutic target to protect against cerebrovascular dysfunction during brain ischemia.

Figure. 1

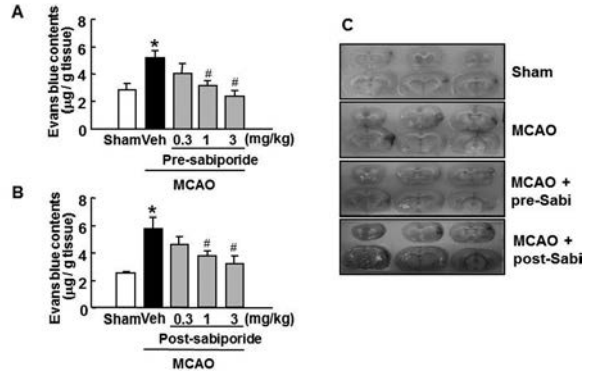

Figure. 1 Effects of sabiporide on ischemia-induced Evans blue extravasation in vivo

Quantitative analysis of Evans blue contents in brain tissues. Evans blue contents were measured 24 h after MCAO in ischemic hemispheres after i.v. pre-treatment (A) or post-treatment (B) with saline (Veh) or sabiporide (0.3, 1, or 3 mg/kg). Data shown are mean ± SEM. (n=5). *p<0.05 vs. the sham control (sham), #p<0.05 vs. vehicle-treated MCAO (Veh). (C) Representative photographs of the sequential cross sections of the brain.

PCA352

Assessment of arterial distensibility in patients with sarcoidosis

H. Balci[1], S. Sipahi Demirkok[2], M. Yildiz[3], G. Metin[3], M. Hacibekiroglu[1] and G. Simsek[3]

[1]Fikret Biyal Central Research Laboratory, Istanbul, Turkey, [2]Internal Medicine, Istanbul University, Cerrahpasa Faculty of Medicine, Istanbul, Turkey and [3]Physiology, Istanbul University, Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Oxidative stress plays an important role in the pathophysiology of cardiovascular disease. Studies show that sarcoidosis increases oxidative stress. High oxidative stress favors oxidative modification of low density lipoprotein (LDL) . The oxidation of LDL in the artery wall is belived to be primary event leading to the initiation and progression of atherosclerosis. Noninvasive ultrasound techniques are used to evaluate vascular system and cardiovascular condition. One such technique, pulse wave velocity (PWV) is defined as arterial pulse’s velocity of moving along the vessel wall, as an indicator of arterial elasticity. Oxidized LDL may impair arterial function and lead to an increase in arterial PWV. This study aims to investigate arterial distensibility using carotid-femoral (aortic) PWV measurements in patient with sarcoidosis. We recruited 19 patients (12 women, 7 men) with sarcoidosis, and 19 sex-matched healthy controls. In all groups carotid-femoral PWV was measured. PWV was determined by using an automatic device, the Complior Colson which allowed on-line pulse wave recording and automatic calculation of PWV. Triglyseride, total cholesterol, low density lipoprotein (LDL) cholesterol, very low density lipoprotein (VLDL) cholesterol, high density lipoprotein (HDL) cholesterol, oxidized LDL, homocysteine, high-sensitivity C-reactive protein (hs-CRP) levels determined. The association with carotid-femoral PWV and current biochemical parameters had been searched. All the values were expressed as means ± S.D. The obtained results were assesed by independent samples test. Correlations were calculated with the Pearson test. Carotid-femoral PWV, LDL cholesterol and hs-CRP were higher in patient with sarcoidosis than in control subjects (p=0.04, p=0.02, p=0.04 respectively) . There was no significantly change in triglyceride, total, VLDL, HDL cholesterol, oxidized LDL and homocysteine levels. There was a significant correlation between PWV and both total cholesterol (p=0.002, r=0.47) and LDL cholesterol (P=0.001, r=0.51). PWV is influenced by total cholesterol, LDL cholesterol. Patient with sarcoidosis must be followed closely for arterial stiffness.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA353

Increased permeability of pulmonary arterioles after cardiopulmonary bypass

T. Beleznai[1], L. Walker[2], R. Ascione[2] and K.A. Dora[1]

[1]Pharmacology, University of Oxford, Oxford, UK and [2]Bristol Heart Institue, University of Bristol, Bristol, UK

Pulmonary injury is a common complication after cardiopulmonary bypass (CPB) in patients undergoing cardiac surgery. The major causes of tissue damage arise from systemic inflammatory responses, and/or factors released by the ischaemic collapsed lungs. To date, there is no evidence to demonstrate whether this CPB-related pulmonary injury can influence both the permeability and function of the pulmonary arterioles.
We developed a method to isolate, cannulate and pressurize porcine pulmonary arterioles to study their vasomotor function, the leak of fluorescent dyes through the arterial wall, and the expression of key proteins. All arterioles were imaged using linescan confocal microscopy. The fluorescent indicators carboxyfluorescein (CF, 0.1 μM, mw 376.3) or FITC-dextran (1 μM, mw 59,000 – 77,000) were perfused into the lumen of arterioles, and increases in fluorescence immediately outside the arteriolar wall (permeability) measured. Tight junction (Zo-1) and caspase 3 staining was performed on the same arterioles, and imaged while still cannulated, to assess the continuity of cell-cell connections and the onset of apoptosis. Arterioles were studied from pigs which had undergone CPB or sham surgery under anaesthesia and categorized into 4 groups: control (lungs collapsed to air with no ventilation during CPB, equivalent to the current method in patients); IPP-ILFV (intermittent pulmonary perfusion with intermittent low frequency ventilation during CPB); IPP-CLFV (intermittent pulmonary perfusion with continuous low frequency ventilation during CPB); and sham (chest opened only). From each group two samples were obtained, one soon after median sternotomy (baseline) and one at 1 hour of recovery after surgery (reperfusion). All baseline and sham pulmonary arterioles had low permeability to CF and FITC-dextran. When studying reperfused arterioles, the arterioles studied following IPP-ILFV and IPP-CLFV were less permeable to CF when compared to control arterioles. The permeability to FITC-dextran was not increased in any group studied, although a TRPV4 agonist did increase permeability to dextran. Furthermore, tight junction staining showed continuous, uniform cell-cell connections in the endothelium of all baseline arterioles. Interestingly, and consistent with the CF leak data, reperfused lung arterioles from the control group did appear to have gaps in tight junction staining and some caspase 3 staining was evident.
These data suggest that cardiopulmonary bypass and concomitant lung collapse leads to increased permeability of pulmonary arterioles due to damaged cell-cell adhesions, which can be prevented by intermittent pulmonary perfusion with low frequency ventilation of the lungs during CPB.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA354

Peripheral circulatory changes during Valsalva maneuver using DC component of Photoplethysmographic signal

D.S. Chandran, A.J. Kattoor, A.K. Jaryal and K.K. Deepak

Physiology, All India Institute of Medical Sciences, New Delhi, Delhi, India

Introduction: Circulatory changes during Valsalva Maneuver (VM) include venous congestion in the extra-thoracic regions with an associated rise in peripheral venous pressures (1). There is a scarcity of techniques available for non-invasively monitoring the circulatory changes in peripheral veins during VM. The magnitude of the DC component of Photoplethysmographic (PPG) signal which is dependent on the average blood volume in tissues (2) has been shown to correlate with the peripheral venous pressure measured invasively (3). We measured the shift in DC component of PPG at different expiratory pressures of VM with the hypothesis that increasing venous congestion associated with the graded increase in Valsalva pressure would produce a proportional shift in PPG DC component.
Methods: Eleven healthy male volunteers (age range; 17 – 30 years) participated in the study. PPG signal was acquired from right middle finger using a reflection mode transducer at a sampling rate of 1 KHz along with air way pressure while the subject performed VM sequentially at different airway expiratory pressures of 10, 20, 30 and 40 mm Hg. DC component of PPG was extracted from the raw signal using a low pass filter of 0.5 Hz (3). The shift in the DC component was calculated as the difference between maximum signal level during VM at each pressure and the average signal level during the preceding baseline period corresponding to the duration of one respiratory cycle. Repeated measures ANOVA with post hoc Bonferroni's test and Pearson univariate correlation analysis was done to statistically analyze the data.
Results: A proportional rise was obtained in the PPG DC component shift with increase in Valsalva pressure (0.085 ± 0.063 Volts (V), 0.177 ± 0.112 V, 0.264 ± 0.139 V and 0.323 ± 0.152 V for VM conducted at 10, 20, 30 and 40 mm Hg pressure respectively). There was a statistically significant ($p<0.05$) increase in DC component shift with the increase in expiratory pressure from 10 to 20 and 20 to 30 mm Hg but not for the increment from 30 to 40 mm Hg. There was a significant positive correlation between the shifts in DC component and the corresponding Valsalva pressures ($r = 0.99$; $p = 0.004$).
Conclusion: The results indicate that shift in PPG DC component during VM may be utilized as a tool to monitor the peripheral circulatory changes during VM. It may also be utilized as a parameter to check the correct performance of the maneuver by the subject as peripheral venous congestion would only accompany a properly conducted VM. The flattening of the response at higher pressures (30 to 40 mm Hg) probably indicates venous congestion approaching the capacitance limit of vessels.

Aliskiren associate with L-Arginine improves vascular reactivity of renovascular hypertension rats

C. Santuzzi, R.V. Tiraddentes, V. Mengal, H. Mauad, P. Matos, S.A. Gouvea, M.H. Cunha and G.R. Abreu

Ciencias Fisiologicas, UFES, Vitoria, ES, Brazil

The antihypertensive therapy with blocked of renin isolated or associate to others drugs is still underexplored in two-kidney one-clip hypertension (2K1C). We investigate the aorta vascular reactivity with aliskiren and its association with L-arginine. Seven days after renal artery clipped, male rats (140-160g, n=8) was divided: 2K1C, 2K1C treated with aliskiren (ALSK) (50 mg/kg /day for 21 days) and 2K1C treated with aliskiren+ L-arginine (L-arg+ALSK). After treatments, rats were anesthetized with pentobarbital (35 mg/kg,i.p.) and killed by exsanguination. The vascular reactivity was analyzed by concentration-response curves to phenylephrine (phen,1 nM-100 μM) and acetylcholine (ach,0.1 nM-300 μM). Were performed blocks (N (G)-nitro-L-argininemethy Ester - L-NAME (100 μM), losartan (10 μM),enalapril (10 μM), incubation with superoxide dismutase(SOD,150 U/ml) and apocynin (0.3 μM). Systolic blood pressure (SBP) was measure before and after treatments by plethysmography and was weighing the left ventricle (LV). In addition, we evaluated the expression of endothelial nitric oxide synthase (eNOS) by the method of Western blotting. Values are means ± S.E.M., compared by ANOVA. (CEUA: 04/2010).The treatments had the following effects: SBP reduced only in the group ALSK + L-Arg (138 ± 4.3 mmHg, P<0.05) compared 2K1C and ALSK groups (204 ± 12.7 and 202 ± 17.7 mmHg, respectively). Was demonstrated that treatment L-arg + ALSK was able to reduce ventricular hypertrophy promoted by hypertension (2K1C:3.32±0.17 mg/g ALSK:2.74±0.14 mg/g ALSK+L- arg:2.58±0.26 mg, P<0.05). 2K1C showed an increase in the concentration response curve to phen and in ALSK and ALSK+L- arg groups this response was reduce. The vasodilator response to ach showed a loss in 2K1C group compared to group ALSK+L-arg. The endothelium removal or incubation with L-NAME increased the vasoconstrictor response to phen in all groups. Apocynin was able to reduce the constrictor response to phen in 2K1C and ALSK+L-arg, however showed no differences in group ALSK. Incubation with SOD showed a decrease in the contractile response to phen in the 2K1C, but no difference in the treated groups. Losartan decrease in contraction to phen in 2K1C and ALSK + L-arg, but not in ALSK group and Enalapril reduce the contractile response only in 2K1C group. In aortic tissue the 2K1C group showed an increase in eNOS protein expression when compared to treatments. The 2K1C showed increase in vascular reactivity to phen, impaired relaxation to acetylcholine and increased expression of eNOS, which seems to be a compensatory mechanism. The ALSK decreased the hyperactivity to phen and expression of eNOS. ALSK+L-arg reduced SBP, vascular reactivity, LV hypertrophy and eNOS expression.These data suggest an important modulation of the renin-angiotensin system and reactive oxygen species in aorta of renovascular hypertension.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Pharmacological analysis of sympathetically-mediated constriction in wild type and α_1-AR knock out mouse tail artery

C. Stevenson[1], C. Daly[1], E. McLachlan[2] and I. McGrath[1]

[1]University of Glasgow, Glasgow, UK and [2]Neuroscience Research Australia, Randwick, NSW, Australia

We have developed transgenic mice lacking the three α1-adrenoceptor (AR) subtypes. Here we report a pharmacological analysis of neurovascular transmission in segments of proximal and distal tail artery of C57/Bl (Wild type), α1AD-AR knock out (ADKO) and α1ABD-AR knock out (ABDKO) mice. In rat proximal tail artery, perivascular stimulation evokes depolarisations mediated by ATP and noradrenaline (1) but contraction is mediated largely by α1- and α2-ARs (2). α2-AR-mediated effects predominate distally (3). The ADKO enables isolation of the α1B-AR which is believed to play a minor role in the vasculature (4) whereas the ABDKO allows study of the remaining receptors to determine the compensatory mechanisms.

Male Wild Type (WT), ADKO and ABDKO mice (4-6 months) were killed by CO2 asphyxiation. Ring segments (2mm) of the tail artery were prepared from proximal (2cm) and distal (5cm) sites. Vessels were mounted on wire myographs under 200mg tension. Contractions were evoked by supramaximal perivascular stimuli (20 V; 0.3 ms pulse width; 20 pulses at 0.5– 8 Hz). Tension was recorded using 'Chart'. The effects of 100nM rauwolscine (α2-AR antagonist), 1mM suramin (P2X receptor antagonist) and 100nM prazosin (α1-AR antagonist) were tested. Data are expressed as mean ± S.E.M. Un-paired t-tests were carried out, with P<0.05 taken as significant.

Proximally, at 0.5 and 8 Hz, the response to nerve stimulation was lower in KO animals compared to WT (P<0.05; WT–n=41; ADKO–n=8; ABDKO–n=14). Distally, the response to nerve stimulation was similar across the strains; except at 8 Hz where the ABDKO response was smaller than the WT response (P<0.05; WT–n=41; ADKO–n=10; ABDKO–n=11). The inhibition of response following rauwolscine incubation at 0.5 Hz was similar in each strain and location (70 % ± 10). However, proximally, at 8 Hz, the reduction was greater in the ABDKO strain compared with the WT and ADKO strain (P<0.05; WT–n=14; ADKO–n=6; ABDKO–n=6). Distally, the reduction was greater in both KO strains compared with the WT response at 8 Hz (P<0.05; WT–n=7; ADKO–n=7; ABDKO–n=6). At both locations following rauwolscine and suramin incubations, a response was detected in the WT and ADKO strains. This response was removed following further incubation with prazosin.

The removal of all α1-ARs or isolation of the α1B-AR has a greater effect proximally. In the WT vessels at 0.5 Hz, the receptor mainly responsible for producing the nerve-mediated response appears to be the α2-AR and this role switches to the α1-ARs at 8 Hz. The residual response following incubation with α2-AR and P2X receptor antagonists in the ADKO indicates a role for the α1B-AR. Even with loss of all of the α1-AR subtypes, the α2-ARs and P2X receptors can support the contraction at both frequencies.

Mathematical modelling of capillary O_2 supply capacity in cardiac and skeletal muscle

A.A. Al-Shammari[1], E.A. Gaffney[1] and S. Egginton[2,3]

[1]Centre for Mathematical Biology, University of Oxford, Oxford, UK, [2]Centre for Cardiovascular Sciences, University of Birmingham, Birmingham, UK and [3]School of Biomedical Sciences, University of Leeds, Leeds, UK

The ability to quantify capillary supply plays a key role in developing effective therapeutic interventions for numerous pathological conditions, e.g. chronic ischaemia in striated muscle, but is fraught with difficulties. Averaged measures – such as mean capillary density (CD) or mean intercapillary distance (ICD) – may characterise global tissue ischaemia [1], but cannot account for local dysfunction associated with the underlying capillary distribution. Detailed tissue geometry including muscle fibre size has been incorporated into indices of capillary supply, e.g. local capillary-to-fibre ratio (LCFR) and local capillary density (LCD), by considering the distribution of *capillary domains*. By identifying vessel locations in a plane perpendicular to muscle fibre orientation, each capillary domain represents the area of supply of its enclosed capillary [2]. Although such geometrical constructs have proven useful in describing oxygenation for homogeneous muscle tissue such as the myocardium [3], it is unclear how well they may capture capillary supply areas in the presence of structural and metabolic heterogeneities.

Using a mathematical framework to assess the maximal capacity of capillary supply in uniform and mixed muscles [4], we theoretically demonstrate that under normal physiological conditions capillary domains can provide an accurate representation of the tissue region supplied by each capillary, or trapping region, based on oxygen flux lines. In contrast, reduced accuracy is found with increasing levels of pathological heterogeneities such as (a) local capillary rarefaction, (b) pathological variations in PO_2 of neighbouring capillaries, and (c) substantial differences in O_2 extraction capacities among different fibre types. For aerobic muscle, the correlation between capillary domain and diffusive supply areas suggests a sensitive local control of angiogenesis on the length scale of fibre diameter.

In contrast, the effect of capillary loss becomes insignificant when localised to glycolytic fibres, suggesting that such rarefaction may be mitigated by reducing the oxygen extraction capacity per fibre volume. Moreover, in the presence of hypoxia, the decay and desaturation of mitochondrial oxygen extraction and myoglobin-O_2 complex, respectively, is predicted to significantly improve the utility of capillary domains. Given that capillary domains are based solely on the spatial distribution of capillaries, this suggests that in chronically hypoxic tissues the oxygen supply of each capillary is predicted to be essentially determined by, and most sensitive to, the distribution of capillaries rather than fibre oxygen demand.

PCA358

The effects of Insulin-like Growth Factor Binding Protein-1 on endothelial repair in the insulin resistant setting

A. Aziz, N. Yuldasheva, J. Smith, N. Haywood, P. Cordell, R. Cubbon, K.E. Porter, M.T. Kearney and S.B. Wheatcroft

University of Leeds, Leeds, UK

Introduction: Insulin resistance predisposes to cardiovascular disease by inducing endothelial dysfunction. Our laboratory has shown that insulin resistance impairs endothelial repair.[1] Additionally, we have discovered that a circulating protein, insulin-like growth factor binding protein-1 (IGFBP-1), is potentially protective in the vasculature by stimulating nitric oxide production and enhancing insulin sensitivity.[2] In cross-sectional studies, low IGFBP-1 levels are associated with diabetes and cardiovascular disease. In this project, we investigated whether IGFBP-1 can enhance vascular endothelial repair in insulin resistant mice in vivo and examined potential mechanisms in human endothelial cells and endothelial progenitor cells in vitro.

Methods: To assess endothelial regeneration, insulin receptor (IR)+/- mice with or without transgenic over-expression of IGFBP-1 (IGFBP1tg) underwent femoral artery endothelial denuding wire-injury. under anaesthesia. Mice were anaesthetised with isoflurane 2-3% before an incision was made. After the operation, the mouse was then placed in an incubator with thermal support until they fully recovered. Mice received post-operative analgesia (buprenorphine 0.25mg/kg s.c.) and were monitored for signs of distress. After five days, the area of regenerated endothelium was quantified in en face sections of injured artery. Endothelial regeneration was also assessed ex-vivo in human tissues by seeding segments of endothelium-denuded human saphenous vein with a sub-confluent density of human coronary artery endothelial cells, which were pre-incubated with or without IGFBP-1. Adherent cells were quantified using con-focal microscopy. The effects of IGFBP-1 on the functional properties of endothelial cells in vitro were examined using cell migration assays.

Results: Endothelial regeneration following wire injury was blunted in IR+/- mice, however regeneration was significantly improved in this model of insulin resistance by IGFBP-1 overexpression (n=5-10 per group). In human umbilical vein endothelial cells (HUVEC), insulin resistance was mimicked by the pro-inflammatory cytokine tumour necrosis factor-alpha, which significantly inhibited migration in a scratch wound assay (n=9). Co-incubation with IGFBP-1 restored the migratory capacity of HUVEC to control levels. There was a trend to enhanced migration of Human Coronary Artery Endothelial Cells (HCAEC) in response to IGFBP-1 in a Boyden chamber assay (P=0.07). IGFBP-1 significantly enhanced

endothelial cell adhesion on a human saphenous vein matrix (n=5, p<0.001).
Conclusions: IGFBP-1 over-expression enhances endothelial repair in the insulin resistant setting. In endothelial cells, IGFBP-1 restores cell migration in a pro-inflammatory setting and improves cell adhesion. Ongoing studies are in progress to examine the underlying mechanisms. Collectively, these data raise the possibility that manipulating IGFBP-1 could be a strategy to enhance endothelial repair in patients with insulin resistance.

PCA359

Tissue- and agonist-specific isolated murine arterial responses to ageing

C. Nicholson, M. Sweeney, S.C. Robson and M.J. Taggart

Newcastle University, Newcastle Upon-Tyne, UK

Cardiovascular diseases (CVDs) account for almost 191,000 deaths per year in the UK – one in three of all deaths [1]. Age-related functional and structural changes in the resistance vasculature, with consequent alterations in arterial tone, contribute to the overall risk of CVD. There appears to be a marked difference in the prevalence of CVD in men and women, with the risk being smaller in women than men aged 30-50. After the menopause, however, the incidence of CVD increases in women and approaches the incidence rate of men [2] indicating a potential beneficial effect of oestrogen although this has resisted absolute confirmation. Therefore, a clearer understanding of vascular functional changes with ageing, and the influence of oestrogens therein, would be informative for assessing effective cardio-protective treatment options in older women. The aims of this study were to investigate the effects of relaxing agents, including 17-β oestradiol (17-β) and oestrogen receptor (ER)-specific agonists, on small arteries from young (3 month) and aged (24 month) female C57BL mice.
Uterine, mesenteric and tail arteries (<250μm) were dissected and mounted on a wire myograph for isometric force measurement. Endothelium-dependent relaxations were assessed in each by the addition of increasing concentrations of acetylcholine (Ach) (0.1nm - 10μM) to maximally constricted arteries. In addition, arteries were maximally pre-constricted with the thromboxane agonist U46619 (1μM) then exposed to increasing concentrations of one of two ER specific agonists, PPT (ER-α) and DPN (ER-β) or 17-β. Changes in tension were measured and responses between groups were compared using 2-way ANOVA (p<0.05 was significant).
Ach-induced relaxations were significantly reduced in all artery types (maximal relaxations (%): UA Young: 57.2±4.0, UA Aged: 43.0±2.6, TA Young: 61.8±5.1, TA Aged: 43.6±2.2, MA Young: 34.1±1.9, MA Aged: 14.6±2.0). In arteries of young and aged mice, concentration-dependent relaxations of all three artery types were induced by 17-β and PPT. For example, maximal relaxations (%) for UA (n=7), TA (n=9) and MA (n=9), to 17-β from young mice were 54.4±3.5, 52.0±5.4, and 63.3±5.1 and from old mice were 58.8±4.9, 36.6±5.1, and 72.0±7.3. However, in contrast, DPN significantly relaxed arteries of young mice (maximal relaxations for UA, TA and MA, respectively: 38.1±2.5, 21.6±1.5, and 42.2±4.6) but failed to do so in UA or TA from old mice.
In summary, age-dependent alterations in endothelial-dependent function are shared across several arteries from distinct vascular beds. In contrast, tissue-specific effects of ageing are evident in arterial vasodilation by the putative ERβ-specific agonist DPN. The data alerts one to the need to consider tissue-specific responses when exploring age-related changes in vascular function.

PCA360

Curcumin could ameliorate diabetic vascular inflammation by decreasing ROS overproduction, leukocyte-endothelium interaction, and NOX2 expression

N. Wongeakin[1], P. Bhattarakosol[2] and S. Patumraj[1]

[1]Department of Physiology, Center of Excellence for Microcirculation, Faculty of Medicine, Chulalongkorn university, Bangkok, 10330, Thailand and [2]Department of Microbiology, Faculty of Medicine, Chulalongkorn university, Bangkok, 10330, Thailand

The number of patients with diabetes is expected to increase more than three-hundred million within ten years. Moreover, in chronic diabetes the overproduction of reactive oxygen species (ROS) involves and mediates many cells damaged. Recently, thioredoxin-interacting protein (Txnip) expression and the activated NADPH oxidase enzyme (NOX2) are reported for developing ROS overproduction and causing vascular inflammation in diabetes. The study aimed to investigate the effects of curcumin, a potent antioxidant with anti-inflammatory property, on preventing diabetes-induced vascular inflammation in association with its actions on Txnip expressions and NOX2 enzyme. Male Wistar rats were divided into three groups: control (CON, n=5), diabetic (DM; streptozotocin (STZ), i.v. 55 mg/kg BW, n=5), and diabetes-treated with curcumin (DMCUR; curcumin 300mg/kgBW in corn oil, n=5). The guideline for experiment animals was suggested by the National Research Council of Thailand. The supplementation of curcumin was started at 10 days after STZ-injection. 12th week after STZ injection, iris blood perfusion and leukocyte adhesion of each rat was measured by using laser Doppler and intravital fluorescent microscopy, respectively. Plasma glucose (BG) and HbA1c were determined using enzymatic and turbidimetric immunoinhibition methods, respectively. Txnip expression, P47phox expression (marker of NOX2), and malondialdehyde (MDA) level at eye fundus were determined by Western Blot analysis and TBAR assay, respectively. Values are means±S.E.M., compared by ANOVA. The body weight and iris blood perfusion of DM (271.67±13.22 g, 246±26.99 AU) and DMCUR (258.00±17.64 g, 311.28±31.13 AU) were decreased significantly as compared to CON (424.00±28.28 g, 870.27±39.61 AU) (P < 0.001). BG and HbA1c of DM (410.33±16.77 dL, 9.47±0.47 %) and DMCUR (390.33±11.59 dL, 9.30±0.21 %) were increased significantly as compared to

CON (172.83±11.08 dL, 4.00±0.06 %, P < 0.001). Interestingly, the leukocyte adhesion, p47phox expression, and MDA level in DM (33.71±0.68 cells/frame, 0.87±0.14, and 11.69±0.22 nmole/protein100μg) were increased significantly when compared to CON (3.64±0.68 cells/frame, 0.39±0.03, and 5.17±1.05 nmole/protein100μg, P < 0.05), and DMCUR (14.94±3.85 cells/frame, 0.51±0.05, and 8.36±0.63 nmole/protein100μg, P < 0.05). Txnip expression in DM (0.83±0.14) and DMCUR (0.71±0.1) were significantly higher than CON (0.45±0.06, P < 0.05). It suggested that curcumin could ameliorate diabetic vascular inflammation by decreasing ROS overproduction, reducing leukocyte-endothelium interaction, and also inhibiting NOX2 activation. Moreover the results also showed a linear correlation between the inhibitory effects of curcumin on leukocyte-endothelium interaction and NOX2 inhibition (y=0.0143x+0.3666, r=0.952, P < 0.05).

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA361

Apocynin prevents vascular effects caused by chronic exposition to low concentrations of mercury

J.T. Dini, D. Rizzetti, F. Maciel Peçanha, D. Valentim Vassalo and G. Wiggers

Universidade Federal do Pampa, Uruguaiana, Rio Grande do Sul, Brazil

Mercury increases the risk of cardiovascular disease, oxidative stress and alters vascular reactivity. This metal elicits endothelial dysfunction as a result of the decreased NO bioavailability by increased oxidative stress and contractile prostanoids production. NADPH oxidase is the major source of reactive oxygen species (ROS) in the vasculature. Our aim was to investigate whether treatment with apocynin, a NADPH oxidase inhibitor, prevents the vascular effects caused by chronic intoxication by low concentrations of mercury. Three-month-old male Wistar rats were treated for 30 days with: a) intramuscular injections - i.m. - of saline; b) HgCl2 (i.m. 1st dose 4.6 μg/kg, subsequent doses 0.07 μg/kg/day); c) Apocynin (1.5 mM in drink water plus saline i.m.); d) Apocynin plus HgCl2. Mercury treatment: 1) increased aortic vasoconstrictor response to phenylephrine and reduced endothelium-dependent responses to acetylcholine; 2) increased the involvement of ROS and vasoconstrictor prostanoids in phenylephrine response whereas reduced the endothelial NO modulation of such responses, 3) reduced aortic activity of superoxide dismutase (SOD) and glutathione peroxidase (GPx) and increased plasma malondialdehyde (MDA) levels. Treatment with apocynin partially prevented the increased phenylephrine responses and reduced the endothelial dysfunction elicited by mercury treatment. In addition, apocynin treatment increased NO modulation of vasoconstrictor responses and aortic SOD activity and reduced plasma MDA levels, without affecting the increased participation of vasoconstrictor prostanoids observed in aortic segment from mercury treated rats. Conclusions: Mercury increases the vasoconstrictor response to phenylephrine by reducing NO bioavailability and increasing the involvement of ROS and constrictor prostanoids. Apocynin protects the vessel from the deleterious effects caused by NADPH oxidase, but not from those caused by prostanoids, demonstrating a two-way action.

PCA362

Sulforaphane pre-treatment reduces Nrf2 content in core and peri-infarct brain regions in rats subjected to ischaemia-reperfusion injury

S. Srivastava, A. Alfieri, R.C. Siow, P.A. Fraser and G.E. Mann

BHF Center of Research Excellence, Cardiovascular Division, King's College London, London, UK

Cerebral stroke is one of the leading causes of adult morbidity within the UK. Oxidative stress is a major consequence of reperfusion injury, resulting in disruption of the blood-brain barrier and neuronal cell death. Activation of the redox-sensitive transcription factor NF-E2 related factor 2 (Nrf2) affords increased protection against stroke via the upregulation of antioxidant defence enzymes such as heme oxygenase-1 (HO-1) and NADPH:quinone oxidoreductase 1 (NQO1). Quantitative immunohistochemistry was employed to examine temporal and spatial distribution of Nrf2 content in contralateral and stroke-affected regions in ex vivo brain sections from male Sprague-Dawley rats (250–300g) subjected to 70 min middle cerebral artery occlusion (MCAo) and reperfusion injury (4, 24 and 72h). Rats were also pre-treated with the Nrf2 inducer sulforaphane (SFN, 5mg/kg i.p.) 1h prior to MCAo followed by 24h reperfusion injury. Coronal brain sections (10μm) were obtained from perfusion-fixed brains and incubated with an anti-Nrf2 primary and horseradish peroxidase conjugated secondary antibody. Core and peri-infarct regions were identified based on glial fibrillary acidic protein (GFAP) expression. Sections were reacted with 3,3'-diaminobenzedine (DAB) and H2O2, and initial rates of DAB polymer formation ((sx103)-1, mean ± S.E.M., n=3-5 animals per group) were measured as an index of Nrf2 concentration. Image processing was used to determine Nrf2 content in nuclear and cytoplasmic compartments. Moreover, murine bEnd.3 brain endothelial cells were treated with SFN (2.5μM) and time dependent expression of HO-1 and NQO1 assessed by immunoblotting. Nrf2 content was greater in cytoplasm compared to nucleus after 4h reperfusion, but was increased in nuclear compartments following 24h reperfusion injury. After 72h, nuclear levels of Nrf2 returned to levels observed at 4h. Total cellular Nrf2 content was greater after 24h reperfusion, with increased levels noted in peri-infarct (1.35±0.016) compared to stroke core (0.72±0.016, P<0.001) regions. Cellular Nrf2 content was also elevated in contralateral regions (0.38±0.005) of stroke versus naïve (0.27±0.004, P<0.001) animals. After 72h, cellular Nrf2 content decreased in stroke-affected regions, but remained elevated in peri-infarct cells. Notably, SFN pre-treatment significantly reduced cellular Nrf2 content in contralateral regions (0.18±0.002) and in peri-infarct (0.049±0.008) and core (0.23±0.005) regions of the stroke hemisphere after 24h reperfusion compared to untreated animals subjected to reperfusion injury (P<0.001). Furthermore, SFN induced a time dependent increase in HO-1 and NQO1 expression in bEnd.3 cells. We conclude that SFN pre-treatment activates the Nrf2

defence pathway, affording protection of the brain against oxidative injury in stroke.

PCA363

Interaction of Sequestosome1/p62 with voltage-activated potassium channels in arterial smooth muscle cells in injury-induced arterial remodeling

T. Ishii[1], E. Warabi[1], R.C. Siow[2] and G.E. Mann[2]

[1]School of Medicine, University of Tsukuba, Tsukuba, Ibaraki Prefecture, Japan and [2]School of Medicine, King's College London, London, UK

Sequestosome1/p62/A170 (SQSTM1) is a multifunctional regulator of cell signaling and metabolism with an ability to modulate targeted degradation of proteins through autophagy. SQSTM1 implements its functions through physical interactions with different types of proteins including atypical PKCs, non-receptor type tyrosine kinase p56Lck (Lck), polyubiquitin and autophagosomal factor LC3. One of the notable physiological functions of SQSTM1 is the regulation of redox sensitive voltage-gated potassium (Kv) channels which modulate membrane potential, signal integration and neurotransmitter release. Kv channels are composed of α and β subunits, (Kvα)4 and (Kvβ)4. Previous studies have established that SQSTM1 scaffolds PKCζ, enhancing phosphorylation of Kvβ. Both PKCζ and SQSTM1 play key roles in acute hypoxia-induced Kv channel inactivation in pulmonary artery.

SQSTM1 is an oxidative stress inducible protein regulated by transcription factor Nrf2, a master regulator of antioxidant system (1). The expression levels of SQSTM1 in vascular cells are up-regulated by atherogenic stimuli, such as oxidized low density lipoprotein and 4-hydroxynonenal, suggesting SQSTM1 has a protective role against oxidative stress (2). We have examined the role of SQSTM1 in neointimal hyperplasia and vascular remodeling in vivo following carotid artery ligation. Neointimal hyperplasia was markedly enhanced near the ligation sites after 3 weeks in SQSTM1-/- compared with wild-type (SQSTM1+/+) mice. The intimal area and stenotic ratio were, respectively, 2.1- and 1.7-fold higher in SQSTM1-/- mice, indicating enhanced proliferation of vascular smooth muscle cells (SMCs). We found that migration of aortic SQSTM1-/- SMCs was enhanced compared to wild type SMCs and that they proliferated more rapidly in response to fetal calf serum and attained 2-3-fold higher cell densities compared to wild type SMCs. The enhanced proliferation of SQSTM1-/- aortic SMCs in vitro highlights a novel role for SQSTM1 in suppressing smooth muscle migration and proliferation following vascular injury (3).

Recent studies have revealed the role of Kv1.3 channels in enhancing migration and proliferation of arterial SMCs (4). As Kv1.3 channels provide a signaling platform and may thereby modulate the migration and proliferation of arterial SMCs and are recognized as a therapeutic target for treatment of restenosis. Based on these studies, we highlight the molecular mechanisms by which SQSTM1 suppresses proliferation of arterial smooth muscle cells and neointimal hyperplasia following carotid artery ligation.

Inhibitory Effects of Sprouty4 on proliferation and migration of vascular smooth muscle cells involving in suppression of MAPK and Akt double signal pathways

H. Li[1,2], X. Yang[2], R. Liaw[2], Y. Shi[3], S. Ma[4] and B. Friesel[2]

[11]1Department of Physiology, College of Basic Medicine, Lanzhou University, Lanzhou, Gansu, China, [2]The Center for Molecular Medicine, Maine Medical Center Research Institute, Scarborough, ME, USA, [3]Guangzhou Baiyunshan Pharmaceutical Factory, Guangzhou, China and [4]Northwest Normal University, Lanzhou, China

Sproutys (Sprys) are novel negative modulators of mitogen-activated protein kinase (MAPK) involving in growth factor-mediated tyrosine kinase receptor signaling, and have been suggested to be an anti-oncogene as reduced expressions of Sprys have been shown in several cancers. Among four of Spry orthologs the expression of Spry1, 2, and 4 is widespread in embryos and adults, while that of Spry3 is believed to be more restricted, and most of researches are focused on Spry1, 2. Spry4 can inhibit angiogenesis, however, molecular mechanism of the suppression has not yet been clarified completely, and so far no evidences have been reported in vascular smooth muscle cells (SMCs). In the present study, primary cultured aortic SMCs from Spry4 transgenic mice (produced in the Maine Medical Center Research Institute (MMCRI)) or from wild-type mice were plated in 6-well plates at subconfluent density, and transduced with LacZ (Control), Cre or Myc-tagged mouse Spry4 adenoviruses (provided by MMCRI) at a concentration of 400 virus particles per cell. After overnight incubation with virus, medium was replaced with fresh SmGM-2 and cells were incubated for an additional 24 to 48 hr, then the over-expression of Spry4 in mouse SMCs was determined by RT-PCR and immunoblotting. Cultured mouse SMCs were used from passage 4 to 6 for all experiments. Over-expression of Spry4 could obviously inhibit the resting and ET-1 or PDGF-BB activated Raf-ERK ½ and p38 MAPK signal, down-regulate phosphorylated ERK ½ and p38 levels, decrease phosphorylated CyclinD1 expression and MMP13 mRNA level in primary cultured SMCs. Further, we showed that PI3K/Akt signaling and its down-stream target Foxo1/Foxo3 proteins were negatively regulated by Spry4 over-expression. A scratch wound assay to monitor SMC migration showed that the percent closure of wounds in Spry4 conditional over-expression group was obvious lower than control group after wounding 24 (22.25±4.40% vs. 36.18±5.16%, $p<0.05$) or 48hr (38.44±5.53% vs. 57.83±9.72%, $p<0.05$). For proliferation studies, SMCs were incubated with 5-bromo-2-deoxyuridine (BrdU) for 24hr, and then were immunostained with a monoclonal anti-BrdU antibody and counterstained with DAPI to label all nucleated cells, and significantly more BrdU positive stained cells were observed in fields of Spry4 conditional over-expression SMCs than control group, and the data clearly showed a lower proliferation rate for Spry4 conditional over-expression SMCs (23.43±3.9%) than for control group (38.03±5.8%) ($p<0.05$). The above results demonstrate that Spry4 can inhibit MAPK and Akt double signal transduction pathways and suppress

proliferation and migration of SMCs, which probably contribute to modulate angiogenesis and vascular remodeling, and are also very important mechanisms in prevention of oncogenesis.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA365

TRPV1 and autocrine serotonin signalling elicit Ca^{2+} release from the acidic organelles of ADP-stimulated human platelets

S. Sage[1] and A. Harper[2]

[1]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK and [2]Institute for Science and Technology in Medicine, Keele University, Stoke-on-Trent, UK

Introduction: We have previously reported that TRPV1 activation is required for a secondary plateau phase of adenosine diphosphate (ADP)-evoked Ca^{2+} release in human platelets, through its ability to control serotonin release from these cells[1]. Here we have further examined the link between TRPV1 activation and serotonin secretion in ADP-stimulated platelets.
Methods: Platelets were isolated from blood obtained by venepuncture of healthy volunteers under informed consent and with local ethical committee approval in accordance with the Declaration of Helsinki. Changes in cytosolic pH (pH_{cyt}), cytosolic Ca^{2+} concentration ($[Ca^{2+}]_{cyt}$), intracellular Ca^{2+} store concentration ($[Ca^{2+}]_{st}$) and acidic organelle pH (pH_{ao}) were measured in BCECF-, Fura-2-, Fluo-5N- and lysosensor green-loaded human platelets respectively. Platelets were stimulated with either 100 μM capsaicin or 50 μM ADP in the absence of extracellular Ca^{2+} at 37°C. Data are presented as mean ± S.E.M. of the number of samples (n) indicated. Statistical significance was tested by Student's t-test.
Results: Stimulation of platelets with capsaicin in the absence of extracellular Ca^{2+} elicited a small rise in $[Ca^{2+}]_{cyt}$, as we have previously reported[1]. Under the same conditions capsaicin also elicited an acidification of the cytosol, an alkalinisation of the acidic organelles and a small decrease in $[Ca^{2+}]_{st}$ (n=3). Stimulation of platelets with ADP elicited the same effects, which could be partially prevented by treatment of platelets with the TRPV1 inhibitor, 5'-Iodo-resiniferatoxin (20 μM, n= 7-14; $p<0.05$). Conversely, concurrent stimulation of platelets with ADP and capsaicin potentiated the changes in $[Ca^{2+}]_{cyt}$ (131.2 ± 8.7 % of control; n = 6; $p < 0.05$), $[Ca^{2+}]_{st}$ (175.0 ± 19.1% of control; n = 6; $p < 0.05$), pH_{ao} (296.4 ± 75.3% of control; n = 6; $p < 0.05$) and pH_{cyt} (291.3 ± 52.5 % of control; n = 6; $p < 0.05$). Previously we have demonstrated that pretreatment of platelets with ketanserin (a 5-HT_{2A} receptor antagonist that inhibits autocrine serotonin signalling) significantly inhibited ADP-evoked rises in $[Ca^{2+}]_{cyt}$[1]. We therefore investigated whether this might be due to an effect on the ADP-evoked alkalinsation of the acidic organelles. Pretreatment for 2 minutes at 37°C with 25 μM ketanserin inhibited the ADP-evoked changes in $[Ca^{2+}]_{st}$ (31.1 ± 6.2% of control; n = 5; $p < 0.05$), pH_{ao} (56.9 ± 14.3% of control; n = 7; $p < 0.05$) and pH_{cyt} (59.4 ± 7.3% of control; n = 6; $p < 0.05$).
Conclusions: These data suggest that TRPV1 regulates ADP-evoked serotonin secretion from human platelets. Autocrine serotonin signalling then elicits Ca^{2+} release from the acidic organelles, potentiating the initial ADP-evoked Ca^{2+} signal.

Exchange protein activated by cAMP (Epac) induces vascular relaxation by activating Ca^{2+}-sensitive K^+ channels in rat mesenteric artery

O. Roberts[1], T. Kamishima[2], R. Barrett-Jolley[3], J.M. Quayle[2] and C. Dart[1]

[1]Institute of Integrative Biology, University of Liverpool, Liverpool, UK, [2]Institute of Translational Medicine, University of Liverpool, Liverpool, UK and [3]Institute of Aging and Chronic Disease, University of Liverpool, Liverpool, UK

Vasodilator-induced elevation of intracellular cyclic AMP (cAMP) is a central mechanism governing arterial relaxation [1]. The vasculature expresses three distinct cAMP effectors: cAMP-dependent protein kinase (PKA), cyclic nucleotide-gated ion channels and the more recently discovered exchange protein directly activated by cAMP (Epac) [2]. The mechanisms by which cAMP induces vasorelaxation are thus likely to be complex and diverse. Here we investigate the role of Epac in mediating vasorelaxation in rat mesenteric arteries.
In myography experiments, the Epac-selective cAMP analogue 8-pCPT-2'-*O*-Me-cAMP-AM (5μM, subsequently referred to as 8-pCPT-AM) elicited a 77.6 ± 7.1% relaxation of phenylephrine-contracted arteries over a 5 minute period (mean ± SEM; n=6). 8-pCPT-AM induced only a 16.7 ± 2.4% relaxation in arteries pre-contracted with high extracellular K^+ over the same time period (n=10), suggesting that Epac's relaxant effect relies upon vascular cell hyperpolarization. This involves Ca^{2+}-sensitive, large-conductance K^+ (BK_{Ca}) channel opening since iberiotoxin (100nM) significantly reduced the ability of 8-pCPT-AM to reverse phenylephrine-induced contraction (arteries relaxed by only 35.0 ± 8.5% over a 5 minute exposure to 8-pCPT-AM, n=5; $p<0.05$ Student's t-test). 8-pCPT-AM increased Ca^{2+} spark frequency in Fluo-4-AM-loaded mesenteric myocytes from 0.045 ± 0.008 to 0.103 ± 0.022 sparks/s/μm ($p<0.05$) and reversibly increased both the frequency (0.94 ± 0.25 to 2.30 ± 0.72s^{-1}) and amplitude (23.9 ± 3.3 to 35.8 ± 7.7pA) of spontaneous transient outward currents (STOCs) recorded in isolated mesenteric myocytes (n=7; $p<0.05$). 8-pCPT-AM-activated STOCs were sensitive to iberiotoxin (100nM) and to ryanodine (30μM). Current clamp recordings of isolated myocytes showed a 7.4 ± 0.9mV (n=4) hyperpolarization in response to 8-pCPT-AM.
Endothelial disruption suppressed 8-pCPT-AM-mediated relaxation in phenylephrine-contracted arteries (24.8 ± 4.9% relaxation after 5 minutes exposure, n=5; $p<0.05$), as did apamin and TRAM-34, blockers of Ca^{2+}-sensitive, small- and intermediate-conductance K^+ (SK_{Ca} and IK_{Ca}) channels, respectively, and N^G-nitro-L-arginine methyl ester (L-NAME), an inhibitor of nitric oxide synthase (NOS). In Fluo-4-AM-loaded mesenteric endothelial cells, 8-pCPT-AM induced a sustained increase in cytosolic Ca^{2+} in 22 out of 47 cells.
Our data suggest that Epac hyperpolarizes smooth muscle by 1) increasing localized Ca^{2+} release from ryanodine receptors (Ca^{2+} sparks) to activate BK_{Ca} channels, and 2) endothelial-dependent mechanisms involving the activation of SK_{Ca}/IK_{Ca} channels and NOS. Epac-mediated smooth muscle hyperpolarization will limit Ca^{2+} entry via voltage-sensitive Ca^{2+} channels and represents a novel mechanism of arterial relaxation.

PCA367

Role of Nitric Oxide in the control of the SR Ca^{2+} release in myocytes of arteriolar networks *in situ*

L. Borysova[1], S. Wray[1], D.A. Eisner[2] and T. Burdyga[1]

[1]Department of Cellular and Molecular Physiology, University of Liverpool, Liverpool, UK and [2]Unit of Cardiac Physiology, University of Manchester, Manchester, UK

NO/cGMP signalling pathway represents one of the possible cross-talk mechanisms between myocytes and endothelial cells in macro- and microvessels. Recent data suggest that NO plays a key role in control of Ca^{2+} release from ryanodine- and IP_3-sensitive Ca^{2+} stores. The functional link between Ca^{2+} release and IP_3R phosphorylation has been established. These data suggest that Ca^{2+} oscillations mediated by IP_3 and/or RyR channels could be potential targets of NO/cGMP pathway. In our recent work we have established that in myocytes of arcade arterioles there are two independent Ca^{2+} stores: one is sensitive to caffeine/ryanodine and the other to agonist/2-APB. In the present work we used 2-and 3-dimensional live confocal imaging of ureteric microvascular networks *in situ* to investigate interaction between endothelium Ca^{2+} signalling and Ca^{2+} signalling in myocytes induced by [Arg^8]-Vasopressin (AVP, 5nM) and caffeine (0.5-2mM) of all sections of arteriolar networks. Caffeine induced irregular Ca^{2+} oscillations exclusively in myocytes of arcade arterioles, which appeared as propagating Ca^{2+} waves with variable spatial spread, selectively blocked by ryanodine (50μM). AVP induced Ca^{2+} oscillations in all sections of arteriolar network, which appeared as fully propagating recurrent Ca^{2+} waves. Ryanodine had no effect on AVP-induced Ca^{2+} oscillations in myocytes of all sections of arteriolar network, selectively inhibited by 2-APB (50 μM). Activation of endothelial Ca^{2+} signalling by 1μM CCh produced complete termination of the AVP-induced Ca^{2+} oscillations in myocytes of all sections of arteriolar network but had no effects on Ca^{2+} sparks and caffeine-induced Ca^{2+} oscillations in myocytes of arcade arterioles. L-NAME but not indomethacin prevented the inhibitory effect of endothelial Ca^{2+} signalling on AVP-induced Ca^{2+} oscillations in myocytes, suggesting that NO was involved. NO donor SNAP (20 μM) or SNP (20μM) produced quick and reversible inhibition of AVP-induced Ca^{2+} oscillations in myocytes of all sections of arteriolar network but had no effect on Ca^{2+} sparks and caffeine-induced Ca^{2+} oscillations in myocytes of arcade arterioles. The data obtained suggest that L-Arginine/NO pathway controls agonist induced Ca^{2+} oscillations in myocytes of arteriolar networks by selective inhibition of Ca^{2+} release via IP_3R channels.

PCA368

Asthmatic cytokines IL-13 and TGFβ alter TRPC6 expression and calcium handling via SMAD2/3 in human airway smooth muscle

Y. Shaifta, D.B. Wright, V. Snetkov and J.P. Ward

Asthma, Allergy and Lung Biology, King's College London, London, UK

Asthma associated cytokines IL-13 and TGF-β affect expression of calcium handling proteins in human airway smooth muscle (hASM) cells. We have previously shown an increase in TRPC6 expression and have now investigated the pathways involved and any change in calcium influx using Flufenamic acid (FFA).
The hASM cells were derived from endobronchial biopsies of healthy volunteers, as approved by the local ethical committee and with informed consent. These were grown and then serum starved for 72h before treatment with cytokines. Sequence specific SMAD2 and SMAD3 siRNAs were cloned and transfected using the AmaxaTM nucleofector device (Lonza). Protein expression was measured via western blots. Intracellular calcium was measured as a ratio of 340/380nm excitation after loading with Fura3-PE/AM.
Stimulating hASM cells with TGF-β alone and in combination with IL-13 caused a significant increase in TRPC6 protein (n=9 $p<0.001$ and n=17 $p<0.001$). TRPC6 splice variants were non-uniformly affected by the combination of IL-13 and TGF-β at one week; 75kDa variant increased by 720 ± 196 % compared to control ($p=0.02$) whereas the ≈100kDa variants increased by 185 ± 20 % ($p=0.003$). SMAD2/3 regulates this increase (see figure 1). The increase in TRPC6 expression by TGFβ is not altered by a scramble siRNA, but both SMAD2 and SMAD3 siRNAs, alone and in combination, inhibit this affect. It has also been found that the combination of IL-13 and TGF-β and TGF-β alone also reduced SMAD3 protein expression significantly ($p<0.001$, n =7).
Flufenamic acid (FFA) has been shown to act as a TRPC6 agonist (Foster et al., 2009). Stimulating hASM cells treated with IL-13 and TGF-β with FFA decreased the peak calcium response at 72 hours ($p=0.02$, n=7-8) and 1 week ($p=0.002$, n=4-5). This decrease in peak calcium may be due to the high increase in expression of the 75kDa TRPC6 variant, which could be displacing the functional ≈100kDa variants.
TGF-β but not IL-13 results in a non-uniform increase in TRPC6 splice variants in hASM cells which is regulated partly by SMAD2 and significantly by SMAD3. An alteration in the calcium handling properties of the hASM results, which as previously described in the literature, could play a key role in the pathophysiology of asthma.

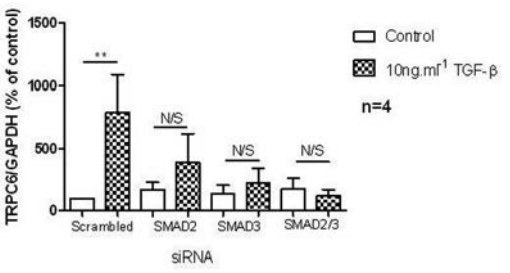

Figure1 SMAD2 and SMAD3 siRNAs inhibit increased expression of TRPC6 in ASM cells by TGFβ.

PCA369

Mechanisms regulating localized and global calcium responses in vascular cells

N. Tsoukias, A. Kapela and J. Parikh

Biomedical Engineering, Florida International University, Miami, FL, USA

The multiplicity of mechanisms involved in regulation calcium (Ca2+) dynamics, the non-homogenous spatial distribution of cellular components and the presence of microdomains in vascular cells (smooth muscle (SMC) and endothelial cells (EC)) result in both intra- and intercellular heterogeneities in Ca2+ levels inside the cells. Experimentation has revealed variety of these intricate intra- and inter-cellular Ca2+ spatiotemporal patterns. The mechanisms behind them remain unresolved. Different variants of deterministic and stochastic models have been proposed to explain global events like Ca2+ oscillations, waves and local events such as Ca2+ sparks and puffs. However, these models are rarely tissue specific and have not been integrated with other important intra- and inter-cellular signaling pathways. Here, we describe the development of detailed computational models that investigate vascular signaling and microcirculatory function. We have previously developed and validated "well-mixed" models of Ca2+ and plasma membrane Vm dynamics in EC and SMC from rat mesenteric arterioles. Models are integrated into multicellular arrangements and adapted to incorporate intra-cellular spatial heterogeneities of cellular components and microdomains like myoendothelial projections. Localized EC Ca2+ mobilization is induced in EC during SM stimulation in the presence of myoendothelial projections which enables an endothelial feedback response that moderates SMC constriction. Myoendotheial IP3 ¬ diffusion is more likely than Ca2+ to mediate this response. Spatial distribution of store or membrane receptor distribution was essential for reproducing intracellular Ca2+ waves in both EC and SMC. Ca2+ diffusion synchronized localized oscillators to form an oscillatory Ca2+ wave. Voltage operated Ca2+ channels modulate Vm oscillations and regulate Ca2+ wave velocity and transition to whole cell oscillations. Electrical current through gap junctions (carried predominantly by K+ ions) is the primary signal that enables conducted responses. Intercellular Ca2+ and IP3 fluxes are small and thus, their passive diffusion is predicted to have a limited effect on Ca2+ mobilization at distant cells. These weak fluxes may be adequate, however, to amplify local current in conducted responses and to promote synchronization of whole cell oscillations of neighboring SMCs in vasomotion. Mathematical models of Ca2+ and Vm dynamics in endothelial and smooth muscle cells allow a more comprehensive investigation of intra and inter-cellular Ca2+ signaling and the elucidation of mechanisms behind localized and global Ca2+ events in the vascular cells.

PCA370

Is platelet mediated leukocyte recruitment a potential therapeutic target in atherosclerosis?

M. Harrison, G.B. Nash, S.P. Watson and E. Rainger

Clinical and Experimental Medicine, University of Birmingham, Birmingham, Other, UK

The role of platelets in the formation of arterial thrombus on atherosclerotic plaque are well documented. However in early disease, platelets also appear to play a role in promoting the recruitment of inflammatory leukocytes. We have recently described a paradigm in which the recruitment of monocytes to TGF-β1 stimulated endothelial cells (EC) is mediated by platelet bridges. TGF-β1 promotes the expression of a matrix of Von Willebrand factor (VWF) on the EC surface which recruits platelets from flowing blood. Upon platelet activation at the EC surface by ADP, monocytes are in turn recruited by platelet P-selectin. The Src family kinases (SFKs) play an important role in platelet activation during haemostasis and we propose that these signalling molecules could represent targets for intervention in platelet mediated monocyte recruitment during atherogenesis. Dasatinib, a broad spectrum SFK inhibitor, ablated ADP dependent aggregation of both human and murine platelets and inhibited the activation of platelets and the secondary recruitment of monocytes on substrates of immobilised VWF or on TGF-β1 stimulated EC. In addition, platelets from the Lyn-/- but not the Fgr-/- mouse, showed deficiencies in aggregation in response to ADP. These data strongly imply that targeting specific SFK members could inhibit platelet dependent recruitment of monocytes in atherogenesis, and these may represent drugable targets for intervening in the chronic inflammatory processes that support atheroma formation.

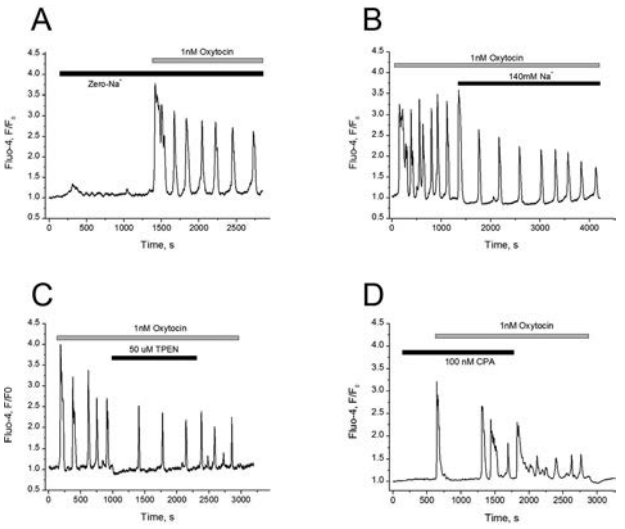
PCA371

The role of Na^+/Ca^{2+} exchange and ER Ca^{2+} buffering in the regulation of oxytocin-induced $[Ca^{2+}]_i$ oscillations

B. Hamilton[1], Y. Timofeeva[2] and A. Shmygol[3]

[1]Warwick Systems Biology Centre, University of Warwick, Coventry, UK, [2]Department of Computer Science, University of Warwick, Coventry, UK and [3]Warwick Medical School, University of Warwick, Coventry, UK

Oxytocin (OT) is involved in all aspects of human reproduction. It often triggers an oscillatory $[Ca^{2+}]_i$ response which depends on Ca^{2+} release from the endoplasmic reticulum (ER) and Ca^{2+} entry from extracellular space. The latter process is vital for replenishment of the ER Ca^{2+} store necessary for maintaining $[Ca^{2+}]_i$ oscillations over time. Both, store-operated and receptor-operated Ca^{2+} entry pathways have been implicated in the OT-induced $[Ca^{2+}]_i$ oscillations [1]. The contribution of the Na^+/Ca^{2+} exchange and the role of intraluminal ER Ca^{2+} buffering in OT-induced $[Ca^{2+}]_i$ oscillations have not been described. We used experimental and theoretical approaches to investigate the role of the above two processes in OT-induced $[Ca^{2+}]_i$ oscillations. **Methods:** Mathematical modelling of the OT oscillator was performed using a modified luminal calcium-sensitive DeYoung-Keiser IP3-receptor model implemented in Matlab and XPPAUT. The experiments were performed on Chinese Hamster Ovary cells stably transfected with human oxytocin receptor (CHO-OT1) using Fluo-4 and wide-field fluorescence microscopy. The following experimental manoeuvres were designed to affect the filling state of the ER: (i) manipulation of $[Ca^{2+}]_i$ removal on the Na^+/Ca^{2+} exchanger by removing and re-introducing extracellular Na^+ (isosmotic substitution with sucrose), (ii) manipulation of ER Ca2+ level using membrane permeable low-affinity Ca^{2+} buffer TPEN, (iii) low dose of reversible SERCA pump inhibitor cyclopiazonic acid to slow down the rate of ER Ca^{2+} uptake. **Results:** Application of 1nM OT induced sustained $[Ca^{2+}]_i$ oscillations in the majority of cells. Na+ removal from the extracellular space caused moderate increase in basal $[Ca^{2+}]_i$ and substantially potentiated OT-induced oscillations (typical trace illustrated in Fig.1A). Activation of Na^+/Ca^{2+} exchange by re-introducing the sodium ions into extracellular medium markedly decreased the amplitude and frequency of the OT induced $[Ca^{2+}]_i$ oscillations (Fig1B). TPEN (50 μM) substantially reduced the frequency and amplitude of oscillations (Fig 1C). Higher concentrations of TPEN abolished the oscillations. Application of 100nM CPA did not change basal $[Ca^{2+}]_i$ but dramatically increased the time delay between initial peak and the onset of oscillations. The frequency of subsequent peaks was not different from that in control (Fig. 1D). Higher concentrations of CPA (0.5 – 10 μM) abolished the oscillations and substantially increased base-line $[Ca^{2+}]_i$. Mathematical model captured these observations when sensitivity of the IP3 receptor to intraluminal Ca^{2+} and variable Ca^{2+} flux from outside the cell were introduced. **Conclusion:** The Na^+/Ca^{2+} exchanger plays important role in establishing the sustained $[Ca^{2+}]_i$ oscillations in response to OT. Parameters of these oscillations are extremely sensitive to Ca^{2+} buffering in the ER.



Effects of CPA, TPEN and Na^+ manipulation on the OT-induced $[Ca^{2+}]_i$ oscillations.

PCA372

Restoring Akt1 activity in endothelial progenitors from insulin resistant humans rescues vascular reparative capacity

R. Cubbon, N. Yuldasheva, H. Viswambharan, B. Mercer, V. Baliga, S. Stephen, J. Askham, P. Sukumar, A. Skromna, R. Mughal, H. Imrie, M. Gage, M. Rakobowchuk, J. Li, K. Porter, S. Ponnambalam, S. Wheatcroft, D. Beech and M. Kearney

Multidisciplinary Cardiovascular Research Centre, The University of Leeds, Leeds, UK

Background: Late-outgrowth endothelial progenitor cells (LEPC) are a potential autologous cell source for cardiovascular therapeutics; however, progenitor function is impaired in potential target groups. We aimed to assess if LEPC dysfunction can be reversed by normalising molecular differences relevant to angiogenesis.
Methods: Analysis of in vitro LEPC function (migration, angiogenesis) was performed in 12 South Asian (SA) men and 12 matched white European (WE) controls. Western blotting was used to assess Akt and eNOS abundance. LEPC were transfused into CD1 immunodeficient mice subsequent to angioplasty wire induced femoral artery luminal injury, or femoral artery ligation induced limb ischaemia, to assess in vivo reparative function. In vitro and in vivo studies were repeated after lentiviral gene delivery of constitutively active Akt1 (E17K) or control (EGFP) to SA LEPC. Data are expressed as mean [standard error of mean]; $p<0.05$ by t-test is denoted by *.
Results: Age and cardiovascular risk factors were comparable in the 2 groups, although the SA group was relatively insulin resistant (HOMA-IR 1.2[0.2] vs. 0.5[0.1] au*). SA LEPC exhibited impaired VEGF induced migration (5[0.7] vs. 10[1.7] LEPC/microscope field*) and in vitro angiogenesis (1.9[0.6] vs. 3.8[0.5] tubular structures/microscope field*), associated with decreased abundance of the phosphorylated forms of S473-Akt1 (0.14[0.05] vs. 0.81[0.2] au*) and S1177-eNOS (0.05[0.02] vs. 0.15[0.01] au*). Transfusion of WE LEPC into

immunodeficient mice after femoral artery injury augmented re-endothelialisation; however, neither SA LEPC, nor vehicle, augmented re-endothelialisation (WE: 54.2 [6.4], SA: 36.9 [3.4], vehicle: 31.1 [2.4] % re-endothelialised [absent Evans blue stain]; WE vs. SA*). Whilst control LEPC promoted perfusion recovery after induction of hind limb ischemia, neither SA LEPC nor vehicle did (WE: 66.4 [4.7], SA: 49.3 [5.6], vehicle: 50.6 [2.8] % ischaemic/non-ischaemic limb flux [Laser Doppler]; WE vs. SA*). Lentiviral gene delivery of E17KAkt, but not EGFP control, to SA LEPC was associated with augmented Akt1 activity. Expression of E17KAkt in SA LEPC rescued in vivo re-endothelialisation capacity (E17K: 55.2 [4.4] vs. EGFP 24.1 [1.3] % re-endothelialised; E17K vs. EGFP*; E17K vs. WE non-transduced cells p=0.9). Furthermore, E17KAkt expressing SA LEPC exhibited markedly augmented limb perfusion after femoral artery ligation, in contrast with EGFP control (E17K: 63.4 [2.4] vs. EGFP 48.0 [1.6] % ischaemic/non-ischaemic limb flux; E17K vs. EGFP*; E17K vs. WE non-transduced cells p=0.9). **Conclusions:** These data provide proof of principle for human LEPC based vascular repair therapy, and provide a mechanism by which function of LEPC from insulin resistant humans can be restored.

The effect of IL-6 -174 G/C polymorphism on adiponectin and IL-6 Levels in peripheral vascular disease

N. Salmayenli[2,3], E. Özkök[1,2] and Y. Basar[3,2]

[1]Clinical Biochemistry, Istanbul University Medical Faculty, Istanbul, Turkey, [2]Clinical Biochemistry, Istanbul University Medical Faculty, Istanbul, Turkey and [3]Department of general Surgery, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey

Peripheral vascular disease (PVD) is a chronic disease and is also an atherosclerotic process. It causes occlusion and stenosis of the lower extremity arteries. Inflammation plays a role in pathogenesis and complications of atherosclerosis. It is known that elevated levels of high sensitivity C-reactive protein (hs-CRP) is related with systemic inflammation. hs-CRP is an acute phase reactant and is stimulated by cytokines. It is known that the elevated levels of hs-CRP are correlated with myocardial infarction (MI), stroke and PVD. Interleukin-6 (IL-6) is one of the proinflammatory cytokines which plays an important role in the pathogenesis of coronary artery disease. A polymorphic variant of IL-6 has also a role in inflammation. It has been shown that IL-6 gene polymorphism is related to atherosclerosis of carotid, coronary and peripheral arteries. Adiponectin is an adipocytokine released from adipose tissue. Adiponectin has protective effects on cardiovascular system through its antiinflammatory properties. It has been suggested that decreased of adiponectin levels is an early cardiovascular risk factor. In the light of these knowledges, we aimed to research the relationship among genetic variant of IL-6 -174 G/C and serum levels of IL-6, hs-CRP and, adiponectin in patients with PAD.

The study consisted of 106 patients with PVD. The control group consisted of 65 healthy adults matched for age and gender with patients. Blood samples were collected in vacuum tubes containing disodium EDTA. Genomic DNA was isolated from these samples by using salting –out method. DNA was amplified using designed primers with polymerase chain reaction (PCR) for IL-6 174 G/C genotyping. For the statistical analyses Pearsons's Chi-Squared ($\chi 2$), Kruskal-Wallis tests were used where appropriate.

The levels of IL-6 and hs-CRP were significantly higher in patients with PVD compared to those of the controls ($p<0.001$). However, adiponectin levels were found significantly lower in patients with PVD than healthy controls ($p<0.001$). They were seen that the distributions of IL-6 -174 G/C genotype were not statistically significant between groups ($p>0.05$). The high levels of IL-6 and hs-CRP were statistically significant among carriers of each three genotypes of IL-6 -174 G/C and in patient with PVD compared to controls. Moreover, it was also found the relation between the decreased levels of adiponectin and IL-6 -174 genotypes between the same groups ($p<0.001$) .

In conclusion, we may suggest that there was an important relationship among genotype distributions of IL-6 -174 variants and hs-CRP, IL-6 and, adiponectin levels in patients with PVD and healthy control groups although there were not statistically significancy in the distrubition of IL-6 -174 G/C genotype between groups

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA374

Applications of pulse-driven magnetoimpedance sensors to biological magnetic fields

S. Nakayama[1], S. Atsuta[3], M. Kondo[1] and T. Uchiyama[2]

[1]Department of Cell Physiology, Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Department of Electronics, Nagoya University of, Nagoya, Japan and [3]Division of Technology Development, Fujidenolo, Komaki, Japan

Any living systems that are electrically excitable simultaneously induce a magnetic field. The superconducting quantum interference device (SQUID), has so far been employed to detect biomagnetic activity. However, this sensor system is too large and expensive for personal and single laboratory use.

In order to enable to measure biomagnetic fields in many research labs and clinics, we have improved the sensitivity of a pulse-driven magnetoimpedance (PMI) sensor toward toward a pico-Tesla (pT) level. Since the sensor head is a product of only small electromagnetic parts such as a pickup coil with a small CoFeSiB amorphous wire, it is operated at body temperature and is made as a small electric chip, which can be mounted in a mobile phone and used as a motion sensor of the operation handle in computer games. The excitation pulse (5V, 50-100 ns) is applied to the magnetic amorphous wire at ~1-2 μs intervals. Thus, this sensor enables quasi real time measurements.

Here, we show examples of applications of PMI sensors to physiological and medical studies. All animal experiments were carried out in accordance with the Animal Experimental Guides of Nagoya University. Animals (guinea-pigs) were sacrificed by cervical dislocation after anaesthetising with diethyl ether. Also, in human study, procedures were approved by the Institutional Ethics Committee. Written informed consent was obtained from all participants. This study complies with the Declaration of Helsinki. First, we applied this magnetic sensor to measure biomagnetic fields in small tissues isolated from the stomach, taenia caeci, portal vein, and urinary bladder of guinea-pigs. Spontaneous electric activities were recorded by the sensor head mounted ~1 mm below the samples across a cover glass. In gastric musculatures, spontaneous magnetic activity was simultaneously measured with extracellular elec-

tric activity, indicating that the biomagnetic field measurements reflected pacemaker electric activity. In addition, spike-like magnetic activities were observed in the presence of K+ channels blockers. Next, we measured magnetic fields on the surface of human chest. Spontaneous magnetic activity was simultaneously measured with electric cardiogram. The magnetic activity was maximal in the 4th intercostals near the center of the sterna. Furthermore, averaging the magnetic activity demonstrated magnetic waves mimicking the P wave and QRS complex. Lastly, we introduce new pulse-driven MI systems. Instead of a sample-hold circuit, fast AD/DA converters were used to sample the whole induction decay in the detector coil. Thus, this system can be used as a DC amplifier of magnetic sensor. Possible numerous applications are suggested.

Renal transplantation improves baroreflex sensitivity and arterial stiffness in end stage renal disease patients

M. Kaur[1], D.S. Chandran[1], C. Lal[2], D. Bhowmik[2], A.K. Jaryal[1], K.K. Deepak[1] and S.K. Agarwal[2]

[1]Physiology, All India Institute of Medical Sciences, New Delhi, Delhi, India and [2]Nephrology, All India Institute of Medical Sciences, New Delhi, Delhi, India

Introduction. Cardiovascular events are a major cause of mortality and morbidity in end stage renal disease (ESRD) patients. This could be attributed to the impaired baroreflex function observed in them (1). The effect of renal transplantation on the baroreflex sensitivity (BRS) in ESRD patients has been poorly addressed. Therefore, we investigated BRS and its relation to arterial stiffness indices and cardiovascular variability parameters (heart rate and blood pressure variability – HRV and BPV) in ESRD patients before and after transplantation.
Methods. We studied 23 ESRD patients (mean age; 35.9 ± 9.3 yrs) prospectively before and at 3 and 6 months after renal transplantation. BRS was determined by spontaneous method [sequence and spectral] (2). Short term HRV and BPV were assessed using frequency domain analysis of RR intervals and systolic blood pressure values recorded beat to beat over a duration of 5 minutes (3, 4). Arterial stiffness indices were measured by carotid femoral pulse wave velocity (PWV), augmentation index (AI) and central pulse pressure (5) using Sphygmocor Vx device (Atcor medical, Australia). Data which followed normal distribution are expressed as mean± SD and analysed using Repeated measures ANOVA with Tukey's post hoc multiple comparison test. Data with non-normal distribution are expressed as median with inter-quartile range (1st quartile – 3rd quartile) and analysed using Kruskal Wallis test with Dunns post hoc multiple comparison test.
Results. Renal transplantation was associated with the normalisation of BRS [11.4±7.9 ms/mmHg at 6 months vs. 6.7±3.1 ms/mmHg at baseline; $p<0.05$] only by 6 months. Arterial stiffness indices - AI [27.7±11.3 % vs. 17.1±9.0 %; $p<0.05$] and central pulse pressure [41.7±13.9 mmHg vs. 33.0±11.1 mmHg; $p<0.05$] showed a significant reduction as early as 3 months after renal transplantation. PWV and frequency domain measures of heart rate variability after renal transplantation did not show statistically significant changes except LF/HF ratio which had significant increase only at 6 months as compared to baseline. Systolic BPV total power [134.0 (118.7–149.5) mmHg2 /Hz vs. 100.4 (78.6–127.1) mmHg2 /Hz] showed a significant reduction as early as 3 months after renal transplantation and showed similar reduction in comparison to baseline at 6 months also.
Conclusions. Our data suggests that renal transplantation normalises BRS in end stage renal disease patients by 6 months which follows the improvement in the arterial stiffness indices observed as early as 3 months post renal transplantation. This improvement in BRS at 6 months reduces the blood pressure variability in renal transplant patients.

Sympathetic Vascular reactivity to cold pressor test in Parkinson's disease and Parkinsonian variant of Multiple System Atrophy with orthostatic hypotension

S. Roy[1], A.K. Jaryal[1], A.K. Srivastava[2] and K.K. Deepak[1]

[1]Physiology, All India Institute of Medical Sciences, New Delhi, New Delhi, India and [2]Neurology, All India Institute of Medical Sciences, New Delhi, New Delhi, India

Objective:
The two neurodegenerative disorders namely Parkinson's disease (PD) and Multiple System Atrophy of the Parkinsonian type (MSA-P) tend to show similar clinical features of Parkinsonism. These disorders also present with autonomic dysfunctions, frequently manifesting as orthostatic hypotension (OH), (42-58% in PD [1] and 80% in MSA-P show OH [2]). The mechanism of OH in PD is proposed to be due to baroreflex failure (central or peripheral lesions) while in MSA-P it is only due to central lesions [3]. We hypothesized that the baroreflex independent vascular reactivity may also be different in them. To evaluate this we assessed sympathetic vascular reactivity to standard cold pressor test in these patients.
Methods:
The diagnosis of PD was done according to the UK Parkinson's disease Society Brain Bank Clinical Diagnostic Criteria and MSA-P was based on the Second Consensus Statement for diagnosis of MSA-P. Data was recorded in 8 patients of PD and 9 patients of MSA-P, both with documented OH. ECG and PPG (photoplethysmography) signals were continuously acquired during a baseline period (1 min) and during 10 degree C cold

exposure (1 min) of the contralateral hand. The vascular response was evaluated by measuring the pulse transit time and amplitude of the finger-photoplethysmography (PPG) waveform [4]. Analysis was done by an unpaired t test.
Results:
The Pulse Transit Time (PTT) decreased in patients of both PD (192.7±3.225 ms vs 199.4±1.639 ms, p = 0.09) and MSA-P (195.23±6.4ms vs. 198.00±6.08 ms, p = 0.7). The patients of PD showed significantly larger decrease in PTT as compared to MSA-P (-7.78±2.06 ms vs -2.81±0.98, p=0.03). During the cold pressor test the amplitude of PPG decreased in both patient groups but the percentage decrease was greater in patients of PD than in MSA-P (51% vs. 46% respectively).
Conclusion:
The vascular reactivity to cold pressor test in patients of MSA-P is lesser than that of PD. The increase in vascular tone (decrease in PTT) during CPT is preserved in PD but significantly lost in MSA-P. Thus the preliminary study shows that baroreflex independent vascular reactivity is significantly different in the patients of PD and MSA-P with documented OH.

PCA378

Pericytes derived from the human foetal kidney are progenitors for renin-producing cells

A. Stefanska[1], J. Mullins[1] and B. Péault[1,2]

[1]University/BHF Centre for Cardiovascular Science, Edinburgh, UK and [2]MRC Centre for Regenerative Medicine, Edinburgh, UK

Renin is a proteolytic enzyme released by the kidneys in response to a decrease in blood pressure or extracellular volume. The lineage identity, origin and possible turnover of renin-producing cells remains poorly understood. Recent reports suggest that renin-producing cells are precursors for multiple cell types in the kidney (1). We hypothesized that renin cells are related to pericytes, progenitor cells embedded in the microvascular wall (2). Since renal diseases are often associated with microvascular complications, studies of renal pericytes may identify a new potential target for therapeutic treatment of kidney disease. We have shown that during normal human development pericyte surface markers CD146 and NG2 label multiple kidney cells including interstitial capillaries, afferent arterioles, mesangial cells. We demonstrated that renin producing cells co-express pericyte markers in the juxtaglomerular region and along renal arterioles between 8-20 weeks of gestation. For the first time we have obtained primary cultures of renal pericytes from the developing human kidney. CD146+CD34-CD45-CD56- pericyte populations were isolated from the foetal human kidney via fluorescence-activated cell sorting (FACS). Cells maintained the selected phenotype through culture; they remained positive for pericyte markers and negative for haematopoietic and endothelial cell markers. Primary cultures of foetal renal pericytes showed tri-lineage mesodermal differentiation. Renin expression was induced by cAMP pathway stimulation (10 μm forskolin and 100 μm 3-isobutyl-1-methylxanthine [IBMX] 24h treatment) on the gene and protein level. In conclusion, a subset of pericytes co-express renin suggesting that renin cells have a perivascular origin. Renal pericytes are a widespread and abundant population in the human foetal kidney that can be isolated and propagated in vitro. Primary cultures of renal pericytes can be a model for renin cell recruitment. Future studies will investigate the mechanism through which pericytes switch into renin-producing cells and possible ways of manipulating the renin-angiotensin system by targeting pericytes.

Intravital investigations of lymphocyte and platelet recruitment to murine liver following ischemia-reperfusion injury

J. Robinson, D.H. Adams and N. Kalia

College of Medical and Dental Sciences, University of BIrmingham, Birmingham, UK

Introduction: Although a contributory role for neutrophils is well established, recent evidence suggests lymphocytes, in particular T-cells, can also directly mediate IR injury. We have previously demonstrated in vitro that lymphocyte adhesion can be increased following incubation with activated platelets. This study further investigated lymphocyte and platelet recruitment in vivo in a model of mouse hepatic IR injury using intravital microscopy (IVM). Most intravital studies visualise trafficking of ex vivo labelled donor cells. Since this may underestimate actual numbers of cells recruited, we compared adhesion of exogenously injected platelets and lymphocytes with a 'novel' method of labelling these cells endogenously.
Methods: Experiments were conducted in anaesthetised mice undergoing hepatic IR injury or sham surgery. To monitor exogenous cells, donor spleen derived T- and B-cells were labelled with CFSE and cell tracker orange respectively and injected via the carotid artery into mice undergoing IVM. To quantitate donor platelet adhesion, CFSE-labelled whole blood platelets were injected in separate mice. To investigate endogenous cell recruitment, T-cells, B-cells and platelets were fluorescently labelled in vivo with anti-CD3/Alexa 647, anti-CD19/Alexa 488 and anti-CD41/Alexa 555 conjugated antibodies respectively.
Results: Adhesion of ex vivo labelled T-cells, but not B-cells, was significantly ($p<0.001$) increased in IR mice compared to shams, albeit numbers were small (1-2 cells/ 20x field). Although donor platelet numbers were similar in IR and sham mice, they were surprisingly high. A significant ($p<0.001$) decrease in free flowing platelets was observed indicative of poor hepatic blood flow in IR mice. Endogenous T-cell adhesion also significantly ($p<0.001$) increased in IR mice but no difference in B-cell or platelet adhesion was observed. However, we found that the fluorescent intravital images of endogenously labelled cells did not differ from those obtained when fluorescently conjugated IgG antibodies were injected. This could be due to hepatic 'trapping' of the antibodies.
Conclusions: Monitoring donor cells labelled ex vivo with cytoplasmic dyes, rather than conjugated antibody labelled endoge-

nous cells, was a more reliable method for quantitating hepatic cell trafficking. This method demonstrated increased recruitment of T-cells, but not B-cells, following IR injury. Adherent T-cell numbers were small, possibly due to their immediate uptake by the spleen post-infusion. We are currently comparing carotid artery cell infusion to intraportal infusion. Since numerous adherent platelets were observed in the liver, further in vivo studies will be conducted in thrombocytopenic mice to determine whether they mediate T-cell recruitment.

PCA380

The effect of L-arginine on the function of the microvascular endothelium in healthy trained and sedentary subjects

K. Cankar, T. Virtic, P. Zaletel and Z. Melik

Institute of Physiology, University of Ljubljana, Faculty of medicine, Ljubljana, Slovenia

BACKGROUND Endothelial dysfunction plays a key role in the aging process and in the development of cardiovascular diseases. Endothelial function is associated with the availability of nitric oxide, produced in endothelial cells from L-arginine. We aimed to study the effect of L-arginine on the function of the cardiovascular system, and to determine whether its use can improve endothelial function, which could be beneficial in preventing the formation and development of cardiovascular diseases in trained and sedentary subjects.
METHODS Measurement were performed in healthy normotensive men, divided into four groups, according to age and physical activity: 12 young sedentary (YS), mean age 23,5 ± 2,4) and age matched trained (YT) (N=18); 11 elder sedentary (ES) (mean age 45,7 ± 7,5) and age matched trained subjects (ET) (N=12). Cardiovascular parameters were measured at rest with the Task Force Monitor device. Laser Doppler (LD) fluxmetry was used to measure skin LD flux on the forearm, before and after administration of 0.9 g L-arginine. Endothelium-dependent vasodilation was assessed by ACh iontophoresis and endothelium-independent vasodilatation with NaNP iontophoresis.
RESULTS After ingestion of L-arginine the heart rate in all four groups statistically significantly decreased (YS 70.4 ± 4.2 vs. 66.3 ± 3.3; YT 62.1 ± 2.7 vs. 58.3 ± 2.0; ES 69.6 ± 3.2 vs. 62.7 ± 2.7; ET 58.0 ± 1.8 vs. 53.6 ± 1.2 beats/min) (paired t-test, $p<0.05$). The cardiac output decreased in three groups except in YS subjects (YT 7.04 ± 0.4 vs. 6.32 ± 0.3; ES 6.95 ± 0.5 vs. 5.9 ± 0.4; ET 7.08 ± 0.6 vs. 6.58 ± 0.4 L/min (paired t-test, $p<0.05$). The systolic (126.3 ± 4.1 vs. 120.0 ± 3.2 mmHg) and diastolic pressure (77.6 ± 2.5 vs. 74.3 ± 1.9mmHg) (paired t-test, $p<0.05$) decreased and LD flux at rest (9.3 ± 2.5 vs. 12.5 ± 1.3 PU) (paired t-test, $p<0.05$) increased in the ES group. After ingestion of L-arginine the endothelium-dependent vasodilation (73.4 ± 4.2 vs. 96.0 ± 9.5 PU) (Dunnett's, $p<0.05$) improved only in the group of YT subjects. Endothelium-independent vasodilation was not altered in any of the groups.
CONCLUSIONS The systemic effect of L-arginine was observed. In contrast, the expected improvement of endothelium-dependent vasodilation in elderly subjects was not found. Improved endothelium-dependent vasodilation in response to L-arginine in young trained subjects could justify the use of dietary L-arginine supplementation in athletes. Unresponsive endothelium-independent vasodilation in all groups confirms that the normal function of endothelial cells is necessary for the synthesis of nitric oxide from L-arginine. Additional studies are required for the final assessment of the impact of L-arginine on the formation and development of cardiovascular diseases.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA381

Molecular and functional changes of Cav1.2 channels in vascular smooth muscles after hypoxia

P. Liao

National Institute of Singapore, Singapore, Singapore

Calcium channel blockers are widely used to treat hypertension by reducing vascular contraction. However, numerous animal experiments and clinical trials failed to demonstrate a beneficial effect on outcome of using calcium channel blockers to treat stroke (1,2). Severe side effect of systemic hypotension often occurred during treatment. Voltage-gated Cav1.2 channels are expressed in cardiovascular system and are the main targets for calcium blocker, dihydropyridine. The aim of the study was to investigate the molecular and functional changes of Cav1.2 channels in cerebral vascular smooth muscle cells under hypoxia conditions. Both primary cultured cerebral vascular smooth muscle cells from Wistar rats and A7r5 cell line were used for the study. After chronic hypoxia and glucose deprivation treatment for one day or three days, Cav1.2 channel expression was reduced gradually in both types of cells. Increase of intracelluar calcium concentration in response to membrane depolarization by application of 145 mM K+ into the bath solution was reduced in hypoxic cells as compared with normoxic cells. Interestingly, hypoxic cells also exhibited enhanced sensitivity to calcium channel blocker isradipine (10nM in A7r5 cells and 5nM in primary cultured cells). After scanning the transcript of Cav1.2 channels, we identified the expression of two alternatively spliced exons were altered both in A7r5 cells and primary cultured cells. More Exon 33 was deleted and exon 9* included after chronic hypoxia treatment. Such changes could lead to more dihydropiridine sensitivity and a similar trend was identified in rat hearts of myocardial infarction with altered electrophysiological properties in our previous reports (3,4). We thus postulate that the splicing profile changes of Cav1.2 channels could contribute at least partially to the altered dihydrapiridine sensitivities after hypoxia. These isoforms of Cav1.2 channels are a novel target for designing therapeutic drugs targeting cerebral blood vessels after stroke with minimal side effect on systemic blood vessels.

PCA382

Bilobalide enhances coronary artery endothelial potassium currents

W.B. Watanapa, T. Wongsatan and K. Ruamyod

Department of Physiology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

A hallmark of coronary heart disease (CHD) is impaired coronary vasodilation. Bilobalide, a main constituent of the terpenoids found in *Ginkgo biloba* leaves, has been found to induce vasorelaxation in some vascular beds. However, little information exists about bilobalide effects on endothelial cells and the involved mechanisms, and there has been no bilobalide study on human coronary artery endothelial cells (HCAECs). To better understand the electrophysiological profile of bilobalide effects in human coronary artery, we aimed to elucidate the effects of bilobalide on K^+ currents in HCAECs.

Standard whole-cell voltage-clamp technique was employed to record HCAEC ionic currents elicited from a holding potential of -40 mV to voltage steps (-100 to +80 mV; 20 mV increments) for 600 ms. Bilobalide powder was dissolved in DMSO (maximum 0.33 %, v/v) which did not alter HCACE currents. Currents in 1 to 100 μM bilobalide were compared to control. Values are mean ± SEM. Bilobalide, at 10, 30 and 100 μM, dose-dependently and reversibly increased HCAEC currents; mean current density at +60 mV was enhanced by 33.2 ± 7.5% (n=6), 42.4 ± 5.0% (n=6) and 47.3 ± 6.7% (n=5), respectively, when compared with controls ($p<0.01$; ANOVA with post hoc Dunnett's test). The EC_{50} and maximum increase, obtained from a non-linear fit of the data to the dose-response equation, were 6.71 ± 1.28 μM and 45.5 ± 4.4 %.

The effect of bilobalide on small-, intermediate- and large-conductance calcium-activated potassium channels (SK_{Ca}, IK_{Ca} and BK_{Ca} channel, respectively), were investigated using specific blockers: 0.5 μM apamin, 10 μM clotrimazole and 1 mM TEA, respectively. Bilobalide-induced HCAEC currents were significantly reduced when exposed to apamin and TEA by 23.3 ± 2.2 % (n=6) and 18.7 ± 4.6 % (n=6, $p<0.01$; *t*-test), but no significant alteration was observed in clotrimazole, suggesting that bilobalide may increase HCAEC currents via SK_{Ca} and BK_{Ca}, but not IK_{Ca} channels. In addition, exposure of bilobalide-induced HCAEC currents to 10 μM La^{3+}, a specific blocker of nonselective cation (NSC) channel, yielded no statistical difference from control currents. Evidently, NSC channel may not be involved in bilobalide-enhanced HCAEC current.

Bilobalide increases HCAEC currents dose-dependently through SK_{Ca} and BK_{Ca} channels. These finding may provide a basis for the mechanism of bilobalide-induced vasodilator release, involving endothelial ion channels, and suggest that bilobalide may be therapeutically effective in cardiovascular disease.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA383

Bronchoconstrictor signal transduction involves protein kinase C-mediated phosphorylation of Kv7.5 potassium channels in human airway smooth muscle cells

J.M. Haick, L.I. Brueggemann, J.R. Prochot, D.S. Randhawa, C. Wigfield and K.L. Byron

Loyola University Chicago, Maywood, IL, USA

In the bronchioles of the asthmatic lung, hypersensitivity of airway smooth muscle cells (ASMCs) to bronchoconstrictor agonists contributes to airway obstruction, though the mechanisms underlying this pathology remain obscure. Our laboratory recently found that Kv7 potassium channels are expressed in ASMCs. These channels maintain an outward flux of potassium ions (K+) to promote a negative resting membrane voltage in smooth muscle cells, thereby opposing their electrical excitability. In the bronchioles, electrical excitation (membrane depolarization) of ASMCs results in activation of voltage sensitive calcium channels, an increase in cytosolic calcium concentration, ASMC contraction, and bronchoconstriction. We previously found that the selective Kv7 channel blocker, XE991, induced robust bronchiolar constriction in human precision cut lung slices (PCLS). Bronchoconstrictor agonists histamine (Hist) and methacholine (MeCh) were found to inhibit Kv7 K+ currents in guinea pig bronchiolar ASMCs, but the mechanisms by which these agonists regulate Kv7 channels in ASMCs are unknown. In preliminary studies, we found that knocking down Kv7.5 in rat ASMCs resulted in elimination of Hist-sensitive Kv7 currents. In the present study, we tested the hypothesis that protein kinase C (PKC), a downstream effector in Hist and MeCh signaling, phosphorylates and consequently inhibits Kv7.5 channels. To detect phosphorylation of Kv7.5 channels, FLAG-tagged human Kv7.5 (FLAG-hKv7.5) channels were overexpressed in primary cultured human ASMCs derived from trachealis muscle (hASMCs). Following treatment with Hist (1 μM, 10 minutes) or the PKC activator phorbol 12-myristate 13-acetate (PMA) (1 nM, 30 min), channel phosphorylation was monitored using immunoprecipitation with anti-FLAG (n=6) or anti-phosphoserine PKC substrate (n=7) antibodies followed by western blot analyses. Both treatments induced an increase in Kv7.5 phosphorylation. Similar results were obtained using fresh human trachealis strips, in which native Kv7.5 channels were increased in anti-phosphoserine immunoprecipitates following MeCh, Hist or PMA treatment. Hist-induced phosphorylation of FLAG-hKv7.5 was blocked by the PKC inhibitor Ro 31-8220 (1 μM, 1 hour, n=3). hASMCs infected with FLAG-hKv7.5 were also subjected to patch-clamp electrophysiology to monitor the Kv7.5 K+ currents. Treatment with either Hist (1 μM, n=4/6) or PMA (1 nM, n=2) inhibited Kv7.5 currents. Hist-induced inhibition was attenuated upon pretreatment with the PKC inhibitor Calphostin C (250nM, 30 min). PMA (100 nM) also induced profound bronchoconstriction in human PCLS (n=2). These findings suggest that PKC induces phosphorylation of Kv7.5 potassium channels in ASM, resulting in channel inhibition and contributing to agonist induced bronchoconstriction.

Heteromultimerization with TRPC1 affects TRPC5 channel function by regulating its plasma membrane residence and cholesterol-triggered retraction

S. Tumova[1,2], B. Hou[1,2], M.S. Amer[1,3], L. McKeown[1,2], N.K. Moss[1,2], Y.M. Bahnasi[1,4], J. Li[1,2], K.E. Porter[2,3], A. Sivaprasadarao[1,2] and D.J. Beech[1,2]

[1]Faculty of Biological Sciences, University of Leeds, Leeds, UK, [2]Multidisciplinary Cardiovascular Research Centre, University of Leeds, Leeds, UK, [3]Clinical Physiology Department, Menoufiya University, Menoufiya, Egypt and [4]Faculty of Medicine and Health, University of Leeds, Leeds, UK

The channels from the Transient Receptor Potential Canonical (TRPC) family are highly relevant in physiological or pathophysiological calcium signalling, especially in cardiovascular, neural or adipose tissue. TRPC5 channel is one of the family members which can function as a homotetramer or in a heteromultimeric assembly with other TRPC channels including TRPC1 (Sukumar et al, 2012). We studied the channels in human vascular smooth muscle cells obtained with ethical approval and in human embryonic kidney cell line exogeneously expressing TRPC5 alone or in combination with TRPC1. We find that cholesterol causes TRPC5 homomer internalization via caveolin-1-dependent retraction, as evidenced by immunostaining, cell surface TRPC5 quantification and calcium influx measurement. On the other hand, lipid raft analysis and GM1 co-localization indicate that heteromultimerization with TRPC1 changes TRPC5 localization in plasma membrane microdomains and this prevents the cholesterol-triggered retraction. Thus, besides affecting the selectivity or gating mechanism of the channel assembly, introduction of TRPC1 has additional functional impact by modifying the membrane localization of the channel. Our study suggests this would be especially pronounced in the face of increased, pathophysiological cholesterol levels.

PCA385

Overload of cholesterol inhibits L-type Ca2+ channel current and augments its voltage-dependent inactivation in A7r5 cells

R. Ochi, S. Chettimada and S.A. Gupte

Biochemistry and Molecular Biology, University of South Alabama, Mobile, AL, USA

Cholesterol (Chol) localizes predominantly in the lipid rafts and caveolae in the membrane and regulates functions of ion channels. In the aortic smooth muscle cells, Ca2+ influx to initiate contraction is supplied mainly by window ICa,L that is determined by the steady-state activation and inactivation of the channel. We clarified the effect of overload and depletion of Chol on both the activation and the inactivation of ICa,L. Previous studies have reported that the overload of Chol utilizing methyl-β-cyclodextrin (CD): cholesterol complex or Chol dissolved by ethanol induces strong inhibition of ICa,L. We applied water-soluble PEG600: cholesterol (PC) to overload Chol and used CD to deplete Chol. Cultured A7r5, a cell line from fetal rat aorta, cells were dissociated and incubated with normal Tyrode solution containing PC or CD in micro-tubes for longer than 90 min at room temperature. In some experiments CD was added after the pretreatment by PC to examine its reversibility. ICa,L was recorded as whole-cell current with 10 mM Ba2+ as the charge carriers and small T-type Ca2+ channel currents were inactivated by 50 ms pre-pulse to -40 mV. The maximal ICa,L density (ICa,L,max) was obtained at 0 mV and was 6.8±0.8 pA/pF (mean±s.e.m., n=18) in the time-matched control. The pretreatment with PC inhibited ICa,L in a dose-dependent manner without any voltage-shift of the I-V relationship. The ICa,L,max after the incubation with PC was: 0.1 mM, 4.9±0.7 (n=10, $p<0.05$ compared with control), 1 mM, 3.1±0.6 (11, $p<0.001$) and 10 mM, 2.8±0.2 pA/pF (14, $p<0.001$). It was significantly increased by the pretreatment with CD: 10 mM, 8.7±1.2 (n=14, $p<0.05$) and 30 mM, 9.5±1.2 pA/pF (n=13, $p<0.001$). We found that loading of Chol by PC augments the voltage-dependent inactivation of ICa,L. V0.5 for the steady-state inactivation (f-V) curve was: control, -30.1±0.5 mV (n=24); 0.1 mM-PC, -32.6±0.5 mV (n=10); 1 mM, -38.0±0.3 mV (n=15); 10 mM, -42.1±0.3 mV (n=14). On the other hand, the depletion of Chol by CD shifted V0.5 to a depolarizing direction: 10 mM, -26.0±0.6 mV (n=19) and 30 mM, -21.7±0.8 mV (n=20). The addition of 30 mM CD to 1 mM PC-pretreated cells in the tube hardly reversed the PC-induced leftward shift of f-V relationship: V0.5, -35.6±0.4 mV (n=11). It implicates that PC could not be removed by CD from the membrane. However, the addition of 30 mM CD after the overload of Chol by 1 mM-PC augmented ICa,L,max to -12.7±1.6 pA/pF (n=11, $p<0.001$ compared with 30 mM CD alone at -10 mV) and shifted the I-V curve to the left. We conclude that Chol is involved in the regulation of basal window ICa,L by decreasing the current density and by augmenting the voltage-dependent inactivation. Chol may be also involved in the regulation of cellular signaling to modulate ICa,L.

PCA386

PDGF maintains stored calcium through a non-clustering Orai1 mechanism but evokes clustering if the ER is stressed by store depletion

L. McKeown[1,2], N.K. Moss[1,2], P. Turner[1,3], J. Li[1,2], N. Heath[1], D. Burke[3], O. David[3], M.S. Gilthorpe[4], P.E. Karen[1,2] and D.J. Beech[1,2]

[1]School of Biomedical Sciences, University of Leeds, Leeds, UK, [2]Multidisciplinary Cardiovascular Research Centre, University of Leeds, Leeds, UK, [3]Leeds Teaching Hospitals, Leeds General Infirmary, Leeds, UK and [4]Faculty of Medicine & Health, University of Leeds, Leeds, UK

Rationale: Calcium entry through Orai1 channels drives vascular smooth muscle cell migration and neointimal hyperplasia. The channels are activated by the important growth factor PDGF. Channel activation is suggested to depend on store-depletion which redistributes and clusters STIM1 which then co-clusters and activates Orai1.

Objective: To determine the relevance of STIM1 and Orai1 redistribution in PDGF responses.
Methods and Results: Vascular smooth muscle cells were cultured from human saphenous vein. STIM1 and Orai1 were tagged with green and red fluorescent proteins to track them in live cells. Under basal conditions the proteins were mobile but mostly independent of each other. Inhibition of sarco-endoplasmic reticulum calcium ATPase led to store-depletion and dramatic redistribution of STIM1 and Orai1 into co-clusters. PDGF did not evoke redistribution, even though it caused calcium-release and Orai1-mediated calcium entry in the same time period. After chemical blockade of Orai1-mediated calcium entry, however, PDGF caused redistribution. Similarly, mutagenic disruption of calcium flux through Orai1 caused PDGF to evoke redistribution, showing that calcium flux through the wild-type channels had been filling the stores. Acidification of the extracellular medium to pH 6.4 caused inhibition of Orai1-mediated calcium entry and conferred capability for PDGF to evoke complete redistribution and coclustering.
Conclusions: The data suggest that PDGF has a non-clustering mechanism to activate Orai1 channels and maintain calcium stores replete. Redistribution and clustering become important, however, when the ER stress signal of store-depletion arises, for example when acidosis inhibits Orai1 channels.

Kv1.3 channel modulates human vascular smooth muscle cells proliferation acting on ERK1/2 signaling pathway

T. Perez-Garcia[1,2], P. Cidad[1,2], E. Miguel-Velado[1,2], C. Ruiz-McDavitt[1,2], E. Alonso[1,2], J. Lopez[3], M. Fernández[3], Y. Marroquín[4] and J.R. López-López[1,2]

[1]Biochemistry and Physiology, University of Valladolid, Valladolid, Spain, [2]Instituto de Biología y Genética Molecular, IBGM, Consejo Superior de Investigaciones Científicas, Valladolid, Spain, [3]Servicio de Cardiología, Hospital Clinico Universitario, Valladolid, Spain and [4]Servicio de Nefrología, Hospital Clinico Universitario, Valladolid, Spain

The cellular responses to vascular injury lead to clinical events such as atherosclerosis, hypertension and restenosis. One common feature of these lesions is the proliferation of vascular smooth muscle cells (VSMCs), that undergo a dedifferentiation process (phenotypic switch). The gold standard treatment of this unwanted vascular remodelling is represented by mTOR inhibitors such as rapamycin and everolimus. However, their numerous side effects had advanced the search for novel, more specific targets.
We have previously found that functional expression of Kv1.3 channels contributes to the phenotypic switch of VSMCs, as selective Kv1.3 blockers inhibit VSMCs migration and proliferation. Moreover, proliferation of mouse VSMCs from several vascular beds associates with a Kv1.5 to Kv1.3 channel switch, so that Kv1.3/Kv1.5 ratio can be considered as a landmark of the phenotype. Here, we determined whether this Kv1.5 to Kv1.3 switch is conserved in VSMCs from human vessels, and we investigated the mechanisms involved in this pro-proliferative role of Kv1.3 channels.
Human uterine, renal and coronary arteries and saphenous veins were obtained from donors at the Clinic Hospitals of Barcelona and Valladolid, with protocols approved by their respective Human Investigation Ethics Committees. Either freshly dissociated, (contractile) VSMCs or cultured (proliferating) VSMCs obtained from explants were used for expression experiments (to quantify mRNA and protein) and for functional studies (electrophysiology of K+ currents and proliferation experiments).
We found that changes in Kv1.3:Kv1.5 mRNA ratio represent an early step during the phenotypic switch of VSMCs. This change is due to the decrease of Kv1.5 expression, as Kv1.3 expression was independent of proliferating stimuli. Functional expression of Kv1.3 and Kv1.5 proteins in contractile and proliferating VSMCs shows a good correlation with mRNA expression data.
Selective blockade of Kv1.3 inhibits VSMCs proliferation in all vascular beds. The anti-proliferative effect of PAP-1 (a selective Kv1.3 blocker), was occluded in the presence of ERK1/2 blockers, and PAP-1 treatment decreased PDGF-induced pERK expression in VSMCs. However, PAP-1 effect on proliferation was additive with those of mTOR inhibitors.
Altogether, our data indicate that Kv1.3 channels could represent a novel therapeutical target to prevent human VSMCs proliferation. Additionally the specific blockade of Kv1.3 could be used to potentiate the therapeutic effect of the currently used drugs in the treatment of restenosis as they inhibit VSMCs proliferation acting on different mechanisms.

Study on mRNA and protein expression levels of small conductance calcium-activated potassium channel in human mesenteric artery from patients with hypertension

L. Mao, T. Li, H. Lan, W. Huang, R. Zhou, C. Li, P. Li, Y. Yang and X. Zeng

Institute of Cardiovascular Research, Luzhou medical college, Luzhou, Sichuan, China

Small conductance calcium-activated potassium channel (SKCa) is the key factor in the regulation of endothelium-dependent vasodilatation. The aim of this study was to measure the expression levels of SK2 mRNA and protein in hypertension (HT) and normotensive (NT) patients. Mesenteric arterial tissues were collected from the removed tissues by abdominal operations in Han Chinese normotensive and primary hypertensive patients. The human tissue collection protocol was approved by the Ethics Committee of Luzhou medical College. In the present study, informed consent was obtained from the patients for the use of vascular tissue (which is usually discarded). Hypertension was defined as systolic blood pressure ≥140 mm Hg and diastolic pressure ≥90 mm Hg according to the Chinese and international diagnostic criteria of hypertension guidelines. mRNA and protein of mesentery artery were obtained from 8 NT and 8 HT patients. The expression of mRNA was detected using quantitative Real-time PCR and analyzed with 2(-ΔΔCT) method. The artery protein

extractions were detected using western blot with SK2 antibody. The statistical analysis was done using independent-samples T test by SPSS 17.0. The average age of HT was 59.2500±1.2256, while the age of NT was 56.6250±8.7331. Real-time PCR and western blot experiments of each sample were repeated for 3 times and the average of the data was for analysis. The expression level of SK2 mRNA in HT was reduced by 38.3%, compared with normal arterial pressure patients. The relative expression of SK2 protein in HT was 1.0387±0.4535, while it was 1.7269±0.5825 in NT, P<0.05. There was significant difference in these two groups. Expression levels of SK2 mRNA and protein were significant down-regulation in essential hypertension patients. It may be another important factor in regulating SKCa channel activity. That may lead to the abnormal of vascular smooth muscle hyperpolarization and the occurrence of hypertension.

PCA389

Changes in the expression, the composition and the function of vascular L-type Ca2+ channels in a mouse model of essential hypertension

J.R. Lopez-Lopez[1,2], S. Tajada[1,2], P. Cidad[1,2], O. Colinas[1,2], E. Alonso[1,2], R. de Pedro[1,2], L.F. Santana[3] and T. Perez-Garcia[1,2]

[1]Physiology, University of Valladolid, Valladolid, Spain, [2]Instituto de Biología y Genética Molecular (IBGM), CSIC, Valladolid, Spain and [3]Physiology and Biophysics, University of Washington, Seatle, WA, USA

The contraction of vascular smooth muscle cells (VSMCs) is critically dependent on the intracellular calcium concentration [Ca2+]i. Relevant mechanisms contributing to tight control of [Ca2+]i include L-type calcium channels (LTCCs), ryanodine receptor channels (RyR), resting membrane potential (Em) and large-conductance Ca2+-activated K+ channels (BK). The increased vascular tone that defines essential hypertension associates to depolarisation of VSMCs. In hypertensive rat models, it has been postulated that depolarization-induced increased expression of α1C subunit of LTCCs leads to elevated basal [Ca2+]i. However, it is unclear whether this mechanism contributes to the genesis and maintenance of essential hypertension, as these models show blood pressure values closed to hypertensive crisis. We have use a genetic mouse model of essential hypertension with moderate blood pressure increase (BPH mice) and its normotensive controls (BPN) to study the functional expression of LTCCs in mesenteric arteries VSMCs. Animal protocols were approved by the Institutional Care and Use Committee of our Institution. Mice were killed by decapitation after isofluorane anaesthesia (5% at 2.5 l min-1 O2), and mesenteric VSMCs were obtained by enzymatic dissociation. Expression and function of LTCCs in VSMCs form BPN and BPH VSMCs were explored with real-time PCR, electrophysiological recordings and observation of calcium influx "sparklets" with total internal reflection fluorescence (TIRF) microscopy . qPCR showed a decreased expression of α1C and β2 mRNA and a significant increase in the $\alpha 2\delta$ subunit in BPH VSMCs. Moreover, LTCCs currents recorded in BPH had a significantly reduced density. Also LTCCs from BPH cells were more sensitive to 5μM BayK 8644 and were differentially modulated by 100 μM gabapentin (GBP), a ligand of $\alpha 2\delta$ subunits, suggesting a different molecular composition of LTCCs. To test this hypothesis, the effect of GBP was explored in HEK cells transfected with different LTCCs subunits. GBP dose-response relationship indicated similarities between α1C+$\alpha 2\delta$+β2 transfected HEK and BPH and between α1C+$\alpha 2\delta$ and BPN. Organization of the LTCCs was studied by TIRF. LTCCs clusters operating in the high open probability mode were significant larger in BPH mice, and sparklets amplitude histograms indicates that LTCCs clusters in BPH are composed of a larger number of channels. In conclusion, we found a decreased mRNA expression and a lower LTCCs current density in BPH. However, LTCCs cluster from BPH were larger and showed higher activity at rest. We postulated that changes in the subunit composition of LTCCs in BPH VSMCs could account for these differences.

PCA390

Myristoylated alanine-rich C kinase substrate (MARCKS) mediates activation of canonical transient receptor potential 1 (TRPC1) channels in vascular myocytes

J. Shi[1], L. Birnbaumer[2], W. Large[1] and A. Albert[1]

[1]St. George's, University of London, London, UK and [2]National Institute of Environmental Health Sciences, North Carolina, NC, USA

TRPC1 Ca2+-permeable cation channels regulate contraction and remodelling of vascular myocytes; phenotypes associated with cardiovascular disease (CVD, Abramowitz & Birnbaumer, 2009). It is apparent that phosphatidylinositol 4,5-bisphosphate (PIP2) and protein kinase C (PKC) are obligatory for TRPC1 channel activation in vascular myocytes (Albert, 2011). Moreover, calmodulin (CaM) is also important for activation of TRPC1 channels (Albert et al, 2006). The present work investigates how interactions between PIP2, PKC and CaM induce TRPC1 channel opening, and reveals a novel role for MARCKS, a membrane-associated phospholipid-binding protein (McLaughlin et al, 2005).
Rabbits were sacrificed using i.v. sodium pentobarbitone (120 mgkg-1), and wild-type (WT) or TRPC1-/- mice were killed by cervical dislocation; both protocols carried out in accordance with the UK Animals Scientific Procedures Act, 1986. Portal vein myocytes were enzymatically dispersed for immunocytochemical staining and patch clamp recording, and tissue lysates were used for immunoprecipiation, Western blot and dot-blot analysis (n=at least 3 replicates or n=at least 6 patches per test condition). Mean data were ± S.E.M, and statistical significance was determined using Students t-test (p<0.05).
MARCKS protein was expressed, and predominantly distributed at the plasma membrane of portal vein myocytes. In rabbit and WT murine portal vein myocytes, a MARCKS inhibitory peptide (MANS) activated whole-cell and single cation channel activities; these channel activities were absence in TRPC1-/- myocytes. MANS-activated TRPC1 channel activity was prevented by lowering PIP2 levels and PKC inhibitors but was

unaffected by CaM inhibitors. These results suggest that constitutive MARCKS activity prevents TRPC1 channel opening, and that TRPC1 channel activation by PIP2/PKC and CaM occur downstream and upstream of MARCKS respectively.
In un-stimulated tissue lysates, TRPC1 associated with MARCKS, and PIP2 primarily interacted with MARCKS. Following stimulation with noradrenaline or MANS, TRPC1 dissociated from MARCKS, and PIP2 was released from MARCKS and interacted with TRPC1. Importantly, noradrenaline stimulated PKC-dependent phosphorylation of TRPC1 but not MARCKS.
We propose that noradrenaline induces TRPC1 channel activity through PKC-dependent phosphorylation of channel proteins, which increases binding of PIP2 to TRPC1 subunits that opens the channels; these levels of PIP2 are provided by MARCKS, which acts as a PIP2 buffer. It is likely that CaM activates TRPC1 by causing MARCKS to release PIP2.
Our conclusions raise the idea that MARCKS is a novel Ca2+ signalling molecule, through modulating TRPC1 and possibly other ion channels, and is a potential therapeutic target for CVD.

GoSlo-SR-5-69: a novel, potent, efficacious BK channel activator

S. Roy[2], T. Webb[2], A. Akande[1], A. Kshatri[1], R. Large[2], K. Thornbury[1,2], N. McHale[1,2], G. Sergeant[1,2] and M.A. Hollywood[1,2]

[1]Smooth Muscle Research Centre, Dundalk Institute of Technology, Dundalk, Louth, Ireland and [2]Ion Channel Biotechnology Centre, Dundalk Institute of Technology, Dundalk, Louth, Ireland

We previously synthesized a novel library of anilinoanthraquinone derivatives termed the GoSlo-SR family, that shifted the half maximal activation voltage (V1/2) of BK channels by ~ –100 mV with an EC50 of ~ 2 μM (Roy et al., 2012). In the current study we hypothesised that the replacement of the phenylamino ring of the anthraquinone moiety by hydrophobic naphthylamino could enhance their potency and efficacy on BK channels.
All experiments were approved by DKIT Animal Care and Use Committee. Rabbits were humanely killed with pentobarbitone (I.V.), their bladders removed and smooth muscle strips cut into 1 mm 3 pieces. Rabbit Bladder SMC (RBSMC) were isolated by enzymatic digestion and plated in 35 mm Petri dishes. Experiments were performed at 37oC using excised inside/out patch configuration with symmetrical K+ solutions (pH 7.2) containing 140 mM KCl, 10 mM Glucose, 10 mM HEPES and either 1 mM EGTA (for [Ca2+] 100 nM) or 1 mM HEDTA (for [Ca2+] > 300 nM).
Excised patches of RBSMC were held at –60 mV and BK channel currents were evoked using voltage ramps (100 mV sec-1). The single channels had a large conductance (~330 pS), reversed at the K+ equilibrium potential (0 mV), were blocked in the presence of penitrem A (100 nM, n=6) and were sensitive to [Ca2+] such that a 10 fold increase in [Ca2+] to 1 μM shifted the activation V1/2 from 142±4 mV to 13±3 mV (ΔV1/2 = –129±5 mV, n=18). The compounds shown in Figure 1 were synthesized by microwave irradiation using copper catalyzed Ullmann coupling reaction (Baqi & Müller, 2007). Their structures were assigned by 1H NMR and HRMS and purity was determined by HPLC.
The addition of naphthylamino or tetrahydro-naphthylamino rings to anthraquinone moiety (Fig. 1) produced variable effects. For example,10 μM GoSlo-SR-5-103 (Fig. 1B) was significantly less effective than GoSlo-SR-5-6 and only shifted the the ΔV1/2 by –44±4 mV (n=18). Application of 10 μM GoSlo-SR-5-65 (Fig. 1C) produced effects very similar to those of GoSlo-SR-5-6 and the ΔV1/2 was –116±10 mV (n=6). We then synthesized the compounds shown in Figures 1D & 1E to examine if the addition of 2-naphthylamino or tetrahydro-2-naphthylamino ring altered the potency. We found the application of 1 μM GoSlo-SR-5-95 (Fig. 1E) produced a ΔV1/2 of –94±9 mV (n=6), suggesting that it was more efficacious than GoSlo-SR-5-6 at this concentration. Similarly, application of 1 μM GoSlo-SR-5-69 (Fig. 1D) produced a ΔV1/2 of –113±10 mV (n=10) and the mean EC50 was 189 nM (confidence intervals 65 nM to 546 nM, n=3-8 patches).
In conclusion, the results of this study suggest that the addition of a tetrahydro-2-naphthylamino ring to the anthraquinone moiety significantly enhances its ability to activate the BK channels in the rabbit bladder.

PCA392

Using BK channel chimaeras to identify the molecular site of action of the BK channel opener GoSlo-SR-5-6

T. Webb[2], R. Large[2], A. Kshatri[1], S. Roy[2], A. Akande[1], G. Sergeant[1,2], N. McHale[1,2], K. Thornbury[1,2] and M.A. Hollywood[1,2]

[1]Smooth Muscle Research Centre, Dundalk Institute of Technology, Dundalk, Louth, Ireland and [2]Ion Channel Biotechnology Centre, Dundalk Institute of Technology, Dundalk, Ireland

GoSlo-SR-5-6 is a novel, potent BK channel activator [1] that does not require functional Ca2+ sensors to mediate its effect [2]. A recent study [3] has shown that the BK channel opener Cym04 was less effective in the Slo1_9a splice variant, which is expressed in the brain. The purpose of this study was to examine if the effects of GoSlo-SR-5-6 were reduced in the Slo1_9a variant.

All experiments were carried out on BK channel α subunits cloned from rabbit bladder or human brain and expressed in human embryonic kidney cells (HEK293). Site-directed mutagenesis on the resulting cDNA was carried out [4]) and confirmed by sequencing. HEK cells were grown in DMEM medium supplemented with 10% FCS, penicillin and streptomycin. HEK cells were dissociated with trypsin (1%), plated onto 35 mm Petri dishes and maintained in culture at 37oC in 5% CO2 prior to use. All experiments were performed at 37oC using the excised inside/out patch configuration with symmetrical 140 K+ solutions containing either 1mM EGTA or 1 mM HEDTA. Excised patches were held at –60 mV and BK channel currents were evoked using voltage steps from -100 mV up to 200 mV before repolarising back to -80 mV. Peak currents were measured during the voltage steps, corrected for driving force and activation curves constructed.

In cells expressing the BKα subunit and exposed to 100 nM Ca2+ at the cytosolic face of the patch, the half maximal activation voltage (V1/2) was 171±2 mV and this was shifted to 57±3 mV (n=12) in the presence of 1 μM Ca2+. Application of GoSlo-SR-5-6 (10 μM) shifted the mean activation voltage (ΔV1/2) by -121±3 mV (n=12). When we examined the effect of GoSlo-SR-5-6 on the Slo1_9a splice variant we found that although a tenfold increase in Ca2+ (from 100 nM to 1 μM) shifted V1/2 from 158±2 mV to 63±3 mV, GoSlo-SR-5-6 application (10 μM) only changed ΔV1/2 by -38 ± 8 mV compared to normal BK channel, ($p<0.001$ unpaired t test, n=10). To assess the contribution of the proximal linker, we generated a 9A9 chimaera, which contained the alternative proximal linker and found that GoSlo-SR-5-6 shifted the V1/2 by -106 ± 5 mV (n=5). The ΔV1/2 of the 9AA chimaera was -88 ± 7 mV (n=6), but this was not significantly different from the 9A9 chimaera, suggesting that the distal linker contributed little to the response. When we investigated the contribution of the S6 segment using the A99 chimaera, the ΔV1/2 was -53 ± 11 mV (n=6, $p<0.05$), but was not further reduced in the A9A chimaera, (-51 ± 9 mV, n=7).

These data suggest the effect of GoSlo SR5-6 is reduced in the Slo1_9a variant and that the majority of this effect appears to be mediated via differences in the S6 segment of this channel.

PCA393

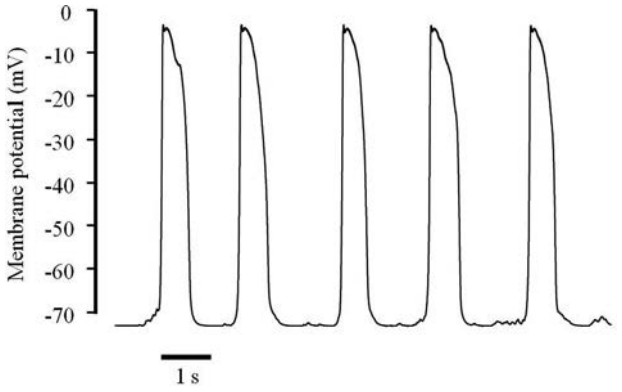
A mathematical model of pacemaking activity in interstitial cells of Cajal

J. Youm[1,2], H. Kim[2], H. Heo[2], N. Kim[1,2], B. Kim[4], C. Leem[3] and J. Han[1,2]

[1]Department of Physiology, Inje University, Busan, Republic of Korea, [2]Cardiovascular and Metabolic Disease Center, Inje University, Busan, Republic of Korea, [3]Department of Physiology, University of Ulsan College of Medicine, Seoul, Republic of Korea and [4]Division of Longevity and Biofunctional Medicine, Pusan National University School of Korean Medicine, Yangsan, Republic of Korea

It is widely accepted that interstitial cells of Cajal generate pacemaker potentials to propagate slow waves along the whole gastrointestinal tract. Previously, we constructed a biophysically based model of interstitial cells of Cajal in mouse small intestine to explain pacemaking mechanism [1]. Since a significant amount of valuable data characterizing ion channels related with pacemaker activity were then accumulated, we tried to improve our mathematical model by including those ion channels and updating pre-existing components. We incorporated 5 more ion channels in the model. They are voltage-gated Na^+ channel (Nav 1.5), Ca^{2+}-activated Cl^- channel, ERG K^+ channel, Ca^{2+}-activated K^+ (BK) channels, and Na^+-leak channel (NALCN). Most of modeling of ion channels were carried out by data fitting to curves for time course of each current, steady-state activation or inactivation, and voltage-dependence of time constants. The IP_3-mediated Ca^{2+} release is a key event to drive the cycle of pacemaker potential and was updated to reproduce its stochastic behavior. The stochastic currents were reproduced by simulating the random openings and closing of an individual ion channel. The updated model was able to reproduce stochastic feature of pacemaker potentials in interstitial cells of Cajal. Pacemaker potential was not uniform in the size, duration, and frequency. The resting and overshoot potential were -72.42±0.51 (mean±S.D., n=10) and -3.45±0.27 (n=10), respectively.The frequency was about 32 min^{-1} and the duration at 50% repolarization was 614.3±40.6 (n=10). The model suggests that the Na^+-leak channel contributes to depolarization about 10 mV in resting membrane potential. The model also suggests that Ca^{2+}-activated Cl^- chan-

nel is more likely to stabilize membrane potential rather than to excite under the physiological condition. We conclude that this improved mathematical model could explain a stochastic nature of pacemaker activity of interstitial cells of Cajal.



Simulated pacemaker potentials of interstitial cells of Cajal in mouse small intestine

Theregulatorymechanismunderlyingthe enhanced expression of large conductance Ca2+ activated K+channelbytestosterone

R. Azizieh[1], A. Ohno[1], S. Ohya[1,2], Y. Suzuki[1], H. Yamamura[1] and Y. Imaizumi[1]

[1]Nagoya city university, Nagoya, Japan and [2]Department of Pharmacology, Division of Pathological Sciences, Kyoto Pharmaceutical University, Kyoto, Japan

The regulatory mechanisms in ion channel expression by sexual hormones are urgent issues in the understandings of cardiovascular diseases after menopause, gender difference in occurrence of psychiatric diseases, side effects of hormonal therapy of genital organ cancers.
Large conductance Ca2+-activated K+ (BK) channels are activated by changes in membrane potential and/or by increases in concentration of intracellular calcium ion (Ca2+) and substantially contribute to outward K+ currents, modulation of action potential duration and theCa2+-dependent regulation of electrical behaviour in many types of cells including central nervous system and smooth muscles.
The activity and/or expression of BK channels can be modulated by steroid hormones as both long-term genomic and acutenon-genomic effects. Female sexual hormones, progesterone and estrogen, regulate BK channel expression andtheir membrane surface clustering in uterine smooth muscles, particularly during pregnancy.We have shown that the expression of BK channels in the amygdala complex is higher in adult (8-10 week old) male rats than in female. Castration at 4-6 weeks old significantly reduces BK channels expression inthe amygdala to a similar level observed in female.
Effects of testosterone on the BK channel expression and their functional significance were then investigated in vas deferens smooth muscles (VDSM) of male rats.Western blot analysis showed that castration caused the marked decrease in the expression of BK channel α (BK-α) and β1 (BK-β1) subunits in VDSMC membrane proteins. In contrast, castration did not significantly change expression levels for BK-a and BK-b1 transcripts in VDSMs.
We hypothesized that the up-regulation of BK channels expressionin VDSM may be due to the inhibitionof ubiquitin-mediated protein degradation by activation of Androgen Receptors (AR). According to this, we speculated that the down-regulation of BK channel expression, observed in castrated rats, is due the AMPK-activated Ubiquitination of these channels secondary to a decrease of AR activation by testosterone. Therefore we tested the ability of BK channel subunits to bind ubiquitin by co-immunoprecipitation, as well as its ability to bind different Ubiquitin ligase such as Nedd 4, Nedd 4-2 and Cullin 1. Our data suggest that BK-α is indeed able to bind Ubiquitin as well as Nedd 4.
In conclusion, AR activation by testosterone critically up-regulates the functional expression of BK channels in VDSMCs, presumably due to inhibition of proteolysis, and thereby substantially modualtes membrane excitability in VDSMs in male rats.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Identification of functional P2X receptors in rat middle cerebral arteries

O. Povstyan, C. Nichols and M. Harhun

Division of Biomedical Sciences, St George's University of London, London, UK

During sympathetic nerve activity ATP is co-released with noradrenaline leading to constriction in muscular arteries. Current views support the notion that physiological contractile responses to ATP are mainly mediated through activation of homomeric P2X1 receptors of the membrane of vascular smooth muscle cells (VSMCs), while the role of other P2X receptors (P2XRs) remains unclear. In this work we studied P2XRs in rat middle cerebral arteries (RMCA). RT-PCR gene expression analysis was performed using preparations from isolated VSMCs. The expression of proteins was confirmed by immunocytochemistry. Agonist-induced $[Ca^{2+}]_i$ changes were monitored using *x-y* confocal imaging in fluo-3 loaded VSMCs. Electrical recordings were performed using patch-clamp technique. Isometric tension recordings were performed using wire myograph. Our results show that RMCA VSMCs express genes encoding only P2X1 and P2X4 receptor subunits and corresponding proteins in their plasma membrane. Both ATP and a potent P2XR agonist, α,β-meATP, evoked dose-dependent increase in $[Ca^{2+}]_i$ of similar amplitude for each concentration with an EC_{50}=0.38±0.29 μmol/l (n=7-17) and EC_{50}=0.59±0.24 μmol/l (n=7-12) for ATP and α,β-meATP respectively. Sub-maximal concentration of noradrenaline (100 μmol/l) produced less than 10% of amplitude of $[Ca^{2+}]_i$ increase evoked by 100 μmol/l ATP in RMCA VSMCs. Under current-clamp recordings 10 μmol/l ATP evoked either fast transient depolarisation or transient response followed by a sustained depolarisation or only sustained depolarisation of the membrane of different

VSMCs. Similarly, under voltage-clamp both10 μmol/l ATP and 10 μmol/l α,β-meATP evoked either transient rapidly desensitising current (I_{fp2x}) or biphasic current consisting of transient and sustained component or only slowly desensitising current (I_{sp2x}) in different VSMCs. I_{fp2x} rapidly desensitised within 3 s of α,β-meATP application, and completely recovered within 8 min after first application of the agonist. Selective P2XR blocker NF279 inhibited I_{fp2x} in dose dependent manner with an IC_{50}=17±2 nmol/l (n=5-6) and complete inhibited the current at 10 μmol/l. NF279 inhibited I_{sp2x} in dose dependent manner with IC_{50}=25±6 μmol/l (n=4-5). These data suggest that monomeric P2X1R predominantly contribute to I_{fp2x} while heteromeric P2X1/4R predominantly contribute to I_{sp2x}. Isometric tension recordings showed that both 10 μmol/l ATP and 10 μmol/l α,β-meATP produced biphasic contractions of RMCA preparations. Incubation of arterial segments with 10 μmol/l NF279 inhibited α,β-meATP (10 μmol/l) evoked contraction by 75±3% (n=6). 100 μmol/l noradrenaline produced only 8±2% (n=7) of contraction evoked by 10 μmol/l α,β-meATP. Our data suggest that in RMCA ATP may play role of the predominant neurotransmitter and that both homomeric P2X1R and heteromeric P2X1/4R contribute to ATP evoked constriction of these blood vessels.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA396

Hydrogen sulfide inhibits recombinant T-type Ca2+ channels

J. Elies[1], M.L. Dallas[2], J.L. Scragg[1], J.P. Boyle[1] and C. Peers[1]

[1]University of Leeds, Leeds, UK and [2]School of Pharmacy, University of Reading, Reading, UK

Awareness of H2S as an important, widespread signalling molecule is growing rapidly. It is known to influence, for example, proliferation of vascular smooth muscle cells and pain sensation (1). Interestingly, both of these processes involve T-type Ca2+ channel activity (2;3). We have therefore investigated whether H2S modulates T-type Ca2+ channels, using whole-cell patch clamp recordings from HEK293 cells over-expressing, separately, T-type Ca2+ channels Cav3.1, 3.2 and 3.3 (4). Bath application of NaHS, which produces H2S in solution, caused a concentration-dependent inhibition of currents in Cav3.2-expressing cells. Inhibition was observed at all activating test potentials, and all subsequent values are of currents recorded at a test potential of -20mV (holding potential -80mV). Maximal inhibition of 35.3±2.2%, n=6, P<0.0001, student's paired t-test) was observed at the NaHS concentration of 1mM. By contrast, current carried by Cav3.1 channels were unaffected over the same concentration range, and those carried by Cav3.3 were only modestly inhibited (13.2±3.6%, n=5, P=0.022) by 1mM NaHS. Thus, H2S appeared to inhibit Cav3.2 channels selectively. Inhibition of Cav3.2 was only poorly reversible, but could be reversed by dithiothreitol (2mM; n=7), suggesting H2S acts via channel redox modulation. Given the high selectivity of H2S for Cav3.2, we examined its effects in H191Q mutant Cav3.2-expressing cells, since this extracellular histidine residue is known to be essential for redox-sensitive binding of divalent metals (3). These mutant channels were insensitive to H2S (1mM NaHS, n=6). In agreement with previous studies (e.g. (5)), the zinc chelator TPEN (10μM) augmented Cav3.2 currents, by 150±9.0% (n=6), and in its presence NaHS was without significant effect on currents carried by Cav3.2 channels.

Our data indicate that H2S selectively inhibits Cav3.2 T-type Ca2+ channels heterologously expressed in HEK293 cells. Inhibition requires the extracellular histidine residue H191. Our results do not, however, support the previous suggestion that H2S might augment T-type Ca2+ channel activity by acting as a zinc chelator (reviewed in (3)).

PCA397

Deletion of the ion channel TRPV4 increases detrusor contractility in the mouse

A.C. Ramos-Filho[2], F. Johnson[1], E. Antunes[2] and A. Grant[1]

[1]Wolfson Centre for Age-Related Diseases, King's College London, King's College London, UK and [2]Dept. of Pharmacology, University of Campinas, Campinas, Brazil

The mechanosensitive Ca^{2+} permeable cation channel TRPV4 is expressed in the urothelium and detrusor smooth muscle (DSM) of rodent bladders (Thorneloe *et al*., 2008). Urothelial stretch during bladder filling activates TRPV4 and produces a Ca^{2+}-dependent release of ATP (Mochizuki *et al*., 2009). This ATP release activates $P2X_3$ receptors on sensory nerves to produce a sensation of bladder filling (Vlaskovska *et al*., 2001). Activation of TRPV4 in the DSM by the selective agonist GSK1016790A (10-100nM) produces a slow and sustained contraction, which can be inhibited by nifedipine (Thorneloe *et al*., 2008). We hypothesised that deletion of the TRPV4 channel would reduce the contractility of isolated DSM strips by reducing the intracellular [Ca^{2+}].

Male C57BL/6 wild type (+/+) and TRPV4 knockout (-/-) mice (22-30g) were used in this study. Bladders were collected, sectioned above the level of the ureters, then cut into 2 longitudinal strips. These were suspended under 0.5g tension in a 10ml organ bath containing Krebs' solution (pH7.4) at 37C and bubbled with a mixture of 95% O_2 and 5% CO_2. Changes in isometric force were recorded using a Power Lab v.4 system (AD Instruments, UK). Concentration-response curves to the muscarinic agonist carbachol (cumulative) and the P2X receptor agonist α,β-methylene ATP (non-cumulative) were constructed. Following pre-contraction of the tissue strips with 80mM KCl, a concentration-response curve was obtained for relaxation to the β-adrenergic agonist isoprenaline. Frequency-response curves to electrical field stimulation (EFS: 10s; 80V; pulse width 1ms) were also obtained. Emax and pEC_{50} values (stated as mean±S.E.M) were compared by unpaired t-tests.

Maximal contractions to carbachol were significantly increased in TRPV4 -/- strips (1nM-30μM; +/+ = 0.029±0.004 vs -/- = 0.077±0.011g/mg, p<0.05, n=5) with no effect on pEC_{50} values. Contractions to EFS (4,8,16,32Hz) were also increased in TRPV4 -/- strips compared to +/+ strips. Contractions to α,β-methylene ATP (1-10μM, n=4) were unaltered by loss of TRPV4. Maximal relaxation to isoprenaline was significantly decreased in TRPV4 -/- strips (1nM-30μM; +/+ = 61.6±8.3 vs -/- = 41.8±3.8

% of KCl contraction, p<0.05, n=5) with no effect on pEC_{50} values. Pretreatment with the P2 receptor antagonist suramin (100μM) had no effect on the maximal contraction to carbachol or the pEC_{50} of the response.
These data suggest that muscarinic and β-adrenergic receptors activate a TRPV4-dependent mechanism, probably via urothelial TRPV4, that inhibits DSM contraction. This inhibitory mechanism is not P2 receptor dependent. Activation of P2X receptors is sufficient to cause DSM contraction without the contribution of TRPV4.

PCA398

Rapid androgen effects on potassium channels in human coronary artery endothelial cells

K. Ruamyod[1], W.B. Watanapa[1] and C. Shayakul[2]

[1]Department of Physiology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand and [2]Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

The mechanisms of testosterone(T)-induced, endothelium-dependent vasodilation are not fully understood. Studies showed that endothelial NO partly mediated this effect (1, 2). The production of endothelial vasodilators, e.g. NO and prostacyclin, are modulated by endothelial ion channels which influence the resting membrane potential, Ca^{2+} electrochemical driving force, the magnitude of Ca^{2+} influx and ultimately $[Ca^{2+}]_i$ (3, 4). This study investigated the effect of T on ion channels of human coronary endothelial cells (HCAECs) and its molecular mechanism using whole-cell patch clamp technique. Values are mean ± SEM (no.) of %increase from control currents. T at 100-1000nM induced a rapid (2-5 minutes), dose-dependent increase in total current [100nM T: 31.9±8.6% (18), 200nM T: 38.8±10.9% (8), 300nM T: 59.7±15.8% (18), and 1μM T: 58.7±7.1% (37)]. The EC_{50} of T, obtained by curve-fitting to the Hill equation was 83.7±1.9nM. 1μMT, after pretreatment with DIDS and La^{3+} (to block Cl^- and transient receptor potential channels, respectively) increased the residual currents (primarily carried by K^+) by 45.2±9.0% (n=13, p<0.05, *t*-test). In contrast, 1μMT did not change currents after pretreatment with K^+ channel blockers TEA + $BaCl_2$ and DIDS or La^{3+} (15.8±8.7% and -0.1±14.1%, n=7 and 7, respectively, n.s., *t*-test). Non-permeant form of T, bovine serum albumin-conjugated T (T-BSA, 1μM), increased HCAEC currents by 93.1±10.2% (n=17, p<0.05; *t*-test). Pretreating with an androgen receptor antagonist flutamide reduced T effect, from 84.8±22.9% (n=7) without to 1.7±4.3% (n=8) with flutamide pretreatment, respectively (p<0.05; *t*-test). The effect of T-BSA was also inhibited by flutamide. However, pretreating with estrogen receptor blocker fulvestrant did not prevent T effects; 101.5±22.0% (n=3) in T vs. 75.2±11.7% (n=8) in T + fulvestrant pretreatment (n.s.; *t*-test). Dihydrotestosterone (DHT), a nonaromatizable androgen, also stimulated HCAEC currents, which was attenuated by flutamide pretreatment; 195.7±45.1% (n=7) without vs. 2.6±19.5% (n=4) with flutamide pretreatment (p<0.05; *t*-test). Incubating HCAECs with pertussis toxin (PTX) partly inhibited the HCAEC current increase by T; 63.1±16.2% (n=6) in T *vs.* 15.2±7.5% (n=6) in PTX pretreatment + T (p<0.05, *t*-test), while pre-incubation with a PLC inhibitor U-73122 did not significantly prevent the T effect. These data suggested that androgens may non-genomicly increase HCAEC K^+ currents via surface androgen receptors. This effect may be partly mediated by $G_{o/i}$-protein but not PLC.

PCA399

Endogenously-generated lipid peroxidation products dilate rat cerebral arteries by activating transient receptor potential channel ankyrin 1 in the endothelium

M.N. Sullivan, A. Bruhl and S. Earley

Vascular Physiology Research Group, Biomedical Science, Colorado State University, Fort Collins, CO, USA

The sole member of the ankyrin (A) subfamily of transient receptor potential (TRP) channels, TRPA1, is Ca^{2+}-permeable and present in the cerebral vascular endothelium.[1, 2] TRPA1 is localized to sites of endothelial cell-smooth muscle communication called myoendothelial junctions.[2] Upon activation with exogenous electrophilic compounds, TRPA1 evokes endothelium-dependent vasodilation,[2] but endogenous agonists of the channel in this tissue remain elusive. TRPA1 channels have been shown to be activated by lipid peroxidation products (LPP)[3, 4] formed from the oxidative degradation of membrane lipids by reactive oxygen species (ROS). Rat cerebral artery immunolabeling revealed the presence of NADPH oxidase isoform 2 (NOX2), a ROS-generating enzyme, in the endothelium within myoendothelial junctions (n = 3). In addition, a proximity ligation assay demonstrated localization of TRPA1 within 40 nm of NOX2, but not NOX4, in intact cerebral arteries (n = 5). We therefore tested the hypothesis that TRPA1 is activated by endogenous LPP generated from local production of ROS by NOX in cerebral arteries. To examine the effect of NOX activation on TRPA1 activity, unitary TRPA1 Ca^{2+} influx events (TRPA1 Ca^{2+} sparklets) were recorded from primary cerebral artery endothelial cells loaded with Ca^{2+} indicator Fluo-4 AM using total internal reflection fluorescence (TIRF) microscopy. TIRF recordings of cells were analyzed using custom software, LC_Pro, where TRPA1 Ca^{2+} sparklets were autodetected, and parameters such as whole-cell frequency (Ca^{2+} sparklets/cell/s) were calculated. Addition of NADPH, a substrate of NOX, to the extracellular solution increased TRPA1 Ca^{2+} sparklet frequency in endothelial cells (0.04 ± 0.02 Hz before vs. 0.28 ± 0.08 Hz after, n = 20-30). This increase in TRPA1 Ca^{2+} sparklet frequency was attenuated by pretreatment with the selective TRPA1 antagonist HC-030031 (HC) (0.03 ± 0.02 Hz, n = 14), indicating that activation of NOX stimulates TRPA1 Ca^{2+} influx in endothelial cells. We then examined the effect of NOX activation in isolated, pressurized (80 mmHg) rat cerebral arteries. Superfusion of NADPH in the bathing solution induced vasodilation in a concentration-

dependent manner (EC_{50} = 1.2 μM). This response was diminished by pre-treatment with HC (61.3 ± 21.6% dilation (NADPH) vs. 8.7 ± 16.2% dilation (HC + NADPH), n = 3). The LPP 4-hydroxy-nonenal (4-HNE) also caused cerebral artery dilation (EC_{50} = 8.4 μM) that was abolished by pre-treatment with HC (51.4 ± 7.8% dilation (4-HNE) vs. 0.0 ± 11.6 % (HC + 4-HNE), n = 5). Together, our findings suggest that NOX-derived LPP generation dilates cerebral arteries through TRPA1 activation. All data are mean ± SE; values of n refer to the number of cells/vessels used per each experiment.

PCA400

NO stimulates BKCa channels in smooth muscle cells of human mesenteric artery

Y. Yang, J. Cheng, J. Wen, P. Li, C. Li, Z. Liu and X. Zeng**

Department of Electrophysiology, Institute of cardiovasology,Luzhou Medical College, Luzhou, Sichuan, China

Nitric Oxide (NO) is an endothelium-independent relaxant agent and its effect is attributed to its direct action on the vascular smooth muscle cells (VSMCs). However, the role of NO in the electrophysiology of human artery SMCs is rarely studied. The aim of this study was to characterize the role of NO on BKCa channels in SMCs freshly isolated from human mesenteric arteries. The use of sodium nitroprusside (SNP) as NO donor in solutions was utilized. The freshly isolated SMCs were used to record BKCa currents using the whole-cell, amphotericin-perforated configuration of patch-clamp technique. Our data show that BKCa currents are often recorded as current spikes (STOCs) and macroscopic currents (MC) under whole-cell voltage clamp conditions. Human mesentery artery SMCs have an average current density of 2.92±0.355 pF/pA (at 0 mV), 16.02±1.15 (at +60 mV) (n=90). In human mesentery artery SMCs, STOCs existed random nature and varied widely from cell to cell and with time, as well as membrane potential. At -30 mV membrane potential, the amplitude was 6-60 pA and frequency 0.03-8 Hz, and at 0 mV, the amplitude (10-120 pA) and frequency (0.5-13 Hz). Extracellular application of SNP enhanced both MC and STOCs. 50 μM SNP increased MC by (8.3±2.3)% (at 0 mV), (29.5% ±16.8)% (at +60mV) (n=3). 100 μM SNP increased MC by (34.6±30.)% (at 0 mV), (41.7±21.1)% (at +60 mV) (n=9), and 200 μM increased MC by (30.9±26.7)% (at 0 mV), (45.5±16.0)% (at +60mV) (n=5). At -30 mV membrane potential, 100 μM SNP increased the frequency of STOCs from 3.32±0.85 (Hz) to 5.43 ±0.75 (Hz) (n=6, $p<0.05$) and amplitude of STOCs from 16.84±1.84 to 18.40±2.61 (pA) (n=6). 200 μM NO induced the frequency to 4.70±1.03 (Hz) (n=4) and amplitude to 16.81±3.15 (pA) (n=4). NO existed short-term effect on BKCa and its action often lasted no more than 10 min after each administration of SNP. The reversibility of NO on BKCa channels was investigated and was determined. Our results suggested that NO could stimulate BKCa channels of human mesenteric artery SMCs in a time dependent and reversible manner.

PCA401

Voltage dependent potassium channels remodeled in hypertrophic intestinal smooth muscle cells induced by partial obstruction in murine

D. Liu, X. Huang, X. Guo, X. Meng, Y. Wu, H. Lu, C. Zhang and W. Xu

School of Medicine, Shanghai Jiaotong University, Shanghai, China

Background: Partial obstruction of the small intestine causes obviously hypertrophy of smooth muscle cells which is a physiological response to the increased pressure in the lumen accompanied by motility disorder.
Aims: To identify electric remodeling of hypertrophic smooth muscle cells in partial obstructed small intestine of mice.
Methods: Partial intestinal obstruction was induced by surgically placing a ring of silicon tube on the distal portion of the ileum in male imprinting control region (ICR) mice. Patch-clamp and intracellular microelectrode recordings methods were used to identify the possible electric remodeling in hypertrophic smooth muscle. Alterations of channel protein expression and phosphorylation level were examined by westernblot, immunofluorescence and immunoprecipitation methods.
Results: Partial obstruction induced smooth muscle hypertrophy in the proximally located intestine after obstruction 14 days and slow waves of intestinal smooth muscles in the dilated region were significantly suppressed, for example, their amplitude and frequency were reduced, whilst the resting membrane potentials were depolarized compared with normal and sham animals. The current density of voltage dependent potassium channel (Kv) was significantly decreased in the hypertrophic smooth muscle cells and changed voltage sensitivity of Kv activation. The sensitivity of Kv currents (IKv) to 4-AP, a Kv blocker, increased significantly but not to TEA, a nonselective potassium channel blocker. However, the Kv4.3 and Kv2.2 expressions were up-regulated in the hypertrophic cell membrane as well as serine and threonine phosphorylation levels of Kv4.3 and Kv2.2 were significantly increased in the hypertrophic smooth muscle cells.
Conclusions: Partial intestinal obstruction-induced smooth muscle hypertrophy accompanyed electric remodeling. The enhanced phosphorylations of serine and threonine in Kv4.3 and Kv2.2 may contribute to membrane potential depolarization of hypertrophic smooth muscle cells.

TRPM2 mediated zinc redistribution mediates H2O2 induced endothelial cell death

N.K. Abuarab, M. Ludlow, J. Ayub, L. Jiang and A. Sivaprasadarao

Multidisciplinary Cardiovascular Research Centre, School of Biomedical Sciences, University of Leeds, Leeds, UK

Oxidative stress plays a central role in the pathogenesis of atherosclerosis. By increasing the production of reactive oxygen species, such as H2O2, oxidative stress causes apoptosis of endothelial cells. Mechanisms by which H2O2 leads to apoptosis, however, are controversial. One study reported that Zn2+ released from H2O2 oxidation of metallothioneins is the cause of cell death [1], while the other suggests that H2O2 activates the TRPM2 channel, resulting in Ca2+ influx and cell death [2].

To address the controversy, we have examined the effect of H2O2 (1 mM, 6h) on human umbilical vascular endothelial cells using live cell imaging. We monitored changes in the intracellular distribution of free Ca2+ and Zn2+ using Fluo-4 and FluoZin-3 respectively. We stained lysosomes and mitochondria with LysoTracker and MitoTracker respectively, and dead cells with propidium iodide. Data recorded from N number of cells and n number of independent experiments are expressed as mean±SEM. P value of <0.05 (Student's t-test) was considered statistically significant.

We found that both Ca2+ and Zn2+ are highly enriched in lysosomes. Mitochondria showed little stain for either ion. H2O2 treatment increased the cytosolic levels of both ions in most cells. In some cells, however, we found striking redistribution of Zn2+ from lysosomes to mitochondria: There was a decrease in the number of lysosomes with Zn2+ (untreated: 61±6%, n/N=3/75; H2O2 treated: 21±1%, n/N=3/49; P<0.01), with a concomitant rise in mitochondria with Zn2+ (untreated: 11±1%, n/N=3/49; H2O2 treated: 41±4%, n/N=3/34; P<0.01). These effects were found in the absence of extracellular Zn2+, indicating redistribution of intracellular Zn2+.

Inhibition of TRPM2 with PJ34 and 2-aminoethoxydiphenyl borate (2-APB) reduced the H2O2 induced release of Zn2+ into the cytoplasm (PJ34: 45±2%, n/N=3/43, P<0.01; 2-APB: 76±1 %, n/N=3/38, P<0.05), as well as its translocation from lysosomes to mitochondria (PJ34: 11±3%, n/N=3/46, P<0.05; 2-APB: 13±2%, n/N=3/35, P<0.05). Transfected HA-tagged TRPM2 channels showed co-localisation with the lysosomal markers, LysoTracker and CD63, suggesting TRPM2 mediates release of Zn2+ from lysosomes.

We next determined the relevance of TRPM2 and Zn2+ redistribution to H2O2-induced endothelial cell death. Blockers of TRPM2 (PJ34 and 2-APB), as well as chelation of Zn2+ with TPEN (N,N,N',N'-tetrakis(2-pyridinylmethyl)-1,2-ethanediamine), completely inhibited H2O2-induced cell death, indicating TRPM2 mediated changes in the redistribution of Zn2+ contribute to endothelial cell death.

In conclusion, we discovered a novel mechanism where H2O2 activation of TRPM2 causes a redistribution of Zn2+ from lysosomes to mitochondria and cytoplasm, resulting in endothelial cell death.

Mutation of R317 in the BK channel splice variant Slo1_9a partially restores the effect of the GoSlo-SR-5-6

A. Kshatri[1], T. Webb[2], R. Large[2], S. Roy[2], G. Sergeant[1,2], N. McHale[1,2], K. Thornbury[1,2] and M.A. Hollywood[1,2]

[1]Smooth Muscle Research Centre, Dundalk Institute of Technology, Dundalk, Louth, Ireland and [2]Ion Channel Biotechnology Centre, Dundalk Institute of Technology, Dundalk, Louth, Ireland

The BK channel opener GoSlo-SR-5-6 shifts the half maximal activation voltage (V1/2) of BKα subunits by >100 mV at 10 μM[1]. To investigate how it activates BK channels, we examined if its effects were altered in the Slo1_9a splice variant[3]. Experiments were carried out on either BK Slo1_9a α subunits cloned from the human brain or BK α subunits cloned from the rabbit bladder and transiently expressed in human embryonic kidney cells (HEK293). Site-directed mutagenesis on the resulting cDNA was carried out as previously described[2] and confirmed by sequencing. HEK cells were grown in DMEM medium supplemented with 10% FCS, penicillin and streptomycin. HEK cells were dissociated with trypsin (1%), plated onto 35 mm Petri dishes and maintained in culture at 37oC in 5% CO2 prior to use. All experiments were performed at 37oC using excised inside/out patch configuration with symmetrical 140 mM K+ solutions containing either 1mM EGTA or 1 mM HEDTA. Excised patches were held at –60mV and BK channel currents were evoked using voltage steps from -100mV to 200mV before repolarising back to -80 mV. Peak currents were measured during the voltage steps, corrected for driving force and activation curves constructed.

Slo1_9a is expressed exclusively in the brain and differs from the normal BK channel in 13 residues between the end of the S6 domain and the RCK1 linker. Application of GoSlo-SR-5-6 to A99 chimaera (which contains the Slo1_9a S6 sequence but normal BK channel proximal and distal linkers) shifted V1/2 by only -53±11 mV (n=6). We hypothesised that the majority of the reduction in the response to GoSlo-SR-5-6 was mediated by the amino acids in the S6 domain of Slo1_9a and used a combination of mutagenesis and electrophysiology to test this. The V1/2 of Slo1_9a currents in 100 nM Ca2+ was 158 ± 2 mV and was shifted to 63±3mV (n=10) in 1 μM Ca2+. Application of GoSlo-SR-5-6 (10 μM) changed activation voltage (ΔV1/2) by -38± 8mV in the Slo1_9a variant compared to -121±4 mV (n=12) in the normal BK channels. When A323I was mutated in Slo1_9a, application of GoSlo-SR-5-6 (10 μM) significantly changed ΔV1/2 to –61±4 mV compared to the Slo1_9a variant (n=6, p<0.05, unpaired t-test). When we mutated R317S in Slo1_9a, application of GoSlo-SR-5-6 to the this mutant increased ΔV1/2 to -90±6 mV (n=7, p<0.001). GoSlo-SR-5-6 also significantly increased ΔV1/2 in the R317I mutant to -69±9 mV. The effect of GoSlo-SR-5-6 was significantly reduced in the when the S317R mutation was performed, with a ΔV1/2 of -80±8 mV compared to -121±4 mV (p<0.001) in normal BK channels. These results suggest that R317 contributes significantly to the reduced response to GoSlo-SR-5-6 in the BK Slo1_9a variant.

Identification and characterization of the functional role of calcium-activated chloride channel anoctamin-1 (ANO1) in rat urinary bladder

D.A. Bijos[2,3], M.J. Drake[2,3] and B. Vahabi[1,2]

[1]Applied Sciences, University of the West of England, Bristol, UK, [2]Bristol Urological Institute, Bristol, UK and [3]School of Clinical Sciences, University of Bristol, Bristol, UK

Interstitial cells (ICs), analogous to the interstitial cells of Cajal in the gut, may generate phasic activity (PA) in smooth muscle tissues including the bladder (1). An established marker of the ICs is c-kit. However, recent studies have shown that anoctamin-1 (ANO1, encoded by Tmem16a), a calcium-activated chloride channel (CaCC), has a fundamental role in generation of pacemaker activity in the ICs of the gut and therefore could be used as a novel marker for these cells (2). CaCC blocking drugs such as niflumic acid (NFA) and 5-nitro-2-(3-phenylpropylamino)-benzoic acid (NPPB) were able to alter the pacemaker activity of the ICs in the gut (3) and thus may be important modulators of these cells in other tissues. Thus, the aim of this study was to investigate whether ANO1 is expressed in the rat urinary bladder and to explore the role of NFA and NPPB in modulating the PA of the bladder tissue.

Male Wistar rats (p19-p23) were killed according to UK Home Office regulations using schedule 1. PCR was carried out on the c-DNA synthesized from total RNA isolated from the whole bladder. Primers were designed for the *Rattus norvegicus* ANO1 mRNA (Accession number: NM_001107564.1). PCR products were separated by electrophoresis and sequenced. Longitudinal strips (5-8mm) of intact detrusor were mounted in perspex microbaths, superfused with Krebs' solution and maintained at 37°C. Isometric tension was measured via UF1 force transducers connected to a Powerlab system using LabChart software. After 90 min of equilibration, the effect of 10μM NFA or NPPB (30min exposure) or the drug vehicle (DMSO) on basal PA was investigated by measuring the amplitude and frequency of PA. Percentage change in the amplitude and frequency of PA was calculated in presence of CaCC blockers relative to that in the absence of the blockers. All data are expressed as the mean±SEM. Statistical analysis was carried out using Student's paired *t*-test.

ANO1 mRNA expression was found in the mucosa of the rat urinary bladder. NFA (n=12) significantly ($p<0.001$) reduced the amplitude and the frequency of basal PA by 68.4±8.8% and 78.8±8.9% respectively. Although NPPB (n=6) significantly reduced the amplitude of PA by 45.4±5.5% ($p<0.001$), it did not have a significant effect on the frequency of PA.

We confirm for the first time that ANO1 is expressed in mucosal layer of the rat urinary bladder. CaCC channel blockers were able to modulate the basal PA of rat bladder strips which may suggest a role of ANO1 channels in mediating the PA of ICs found in rat urinary bladder. However, the exact location and function of these channels in rat bladder requires further investigation.

Cholesterol depletion reveals an inhibitory role of PIP_2 on Ca^{2+}-activated Cl^- Channel activity in rat pulmonary arteries

H.T. Pritchard, A.A. Albert and I.A. Greenwood

BMS, St Georges, University Of London, London, UK

Background: Ca^{2+}-activated Cl^- channels (CaCCs) are thought to be encoded for by the gene TMEM16A, and are functionally present in vascular and non-vascular smooth muscle cells (Davis *et al*., 2010, Davis *et al.*, 2013). Our lab recently showed that the amplitude and pharmacology of CaCC currents (I_{CaCC}) in portal vein myocytes was influenced by cholesterol depletion (Sones *et al.*, 2010). The aim of this study was to investigate the mechanism by which CaCCs were regulated by cholesterol depletion and the possible role of phosphatidylinositol 4, 5-bisphosphate (PIP_2) levels.

Methods and Results: Whole-cell configuration of the patch clamp technique was used to measure I_{CaCC} currents in myocytes dispersed from first and secondary-order branches of pulmonary arteries (PA), from male Wistar rats (200-225g), killed by cervical dislocation in accordance with Schedule 1 of the United Kingdom Animals Act (1986). The pipette solution contained a known amount of free Ca^{2+} (500 nM) which immediately induced an I_{CaCC} upon rupture of the cell membrane, which displayed the distinct voltage-dependent kinetics shown in previous studies. Upon stabilisation of the I_{CaCC}, current voltage (IV) relationships were constructed by stepping from a holding potential (-50mV) to test potentials between -100 mV and 100 mV for 1s. I_{CaCC} was augmented rapidly by the cholesterol depleting agent methyl-β-cyclodextrin (mβcd) (3mg/ml), which was prevented by the application of the TMEM16A inhibitor $T16A_{inh}$-A01. Cells pre-treated with the phosphatidylinositol 4-kinase inhibitor wortmannin (20 μM), thereby inhibiting PIP_2 synthesis, augmented I_{CaCC} and subsequently showed an attenuated response to mβcd application. As wortmannin is also a myosin light chain kinase (MLCK) inhibitor we tested ML-9 (10 μM) to establish if MLCK played a role in CaCC activity, but this had no effect on the current. Enrichment of the pipette solution with diC-8 PIP_2 (1 μM) attenuated I_{CaCC}, and attenuated the stimulatory effect of mβcd.

Conclusions: This study suggests that cholesterol depletion of the cell membrane increases TMEM16A activity, partly through the removal on the inhibitory effect of PIP_2.

Segregated calcium stores are important for stretch-induced calcium signaling in smooth muscle cells: implication in pulmonary hypertension

G. Guillaume, T. Ducret, R. Marthan, J. Savineau and J. Quignard

Université Bordeaux Segalen, INSERM U1045, Bordeaux Cedex, France

Introduction: In pulmonary hypertension (PH) the increased pulmonary blood pressure exerts a stretching force on pulmonary arterial wall that leads to contraction of pulmonary arterial smooth muscle cells (PASMC), a mechanism called myogenic tone. PASMC can transduce the mechanical stretch signal into a biological response by increasing the intracellular calcium concentration via membrane stretch-activated channels (SAC). Here, we investigate how the subcellular organization of calcium stores in PASMC (sarcoplasmic reticulum (SR), lysosomes and mitochondria) is important for the calcium response to stretch during PH.
Methods: PASMC were freshly isolated from normoxic rats (Nx rats) and rats with a pulmonary hypertension induced by an injection of monocrotaline (MCT rats). Inward currents from SAC were recorded after a negative pressure applied by a patch-clamp pipette and calcium variations were recorded with the fluorescent probe indo-1, simultaneously. Cytosolic calcium was also measured with the fluo-4 probe and mitochondrial calcium with the rhod-2 probe by a confocal microscope after an osmotic shock. A pharmacological approach coupled with different coimmunolabelings of ryanodine receptors (RyR) and SERCA2 pumps was used to investigate which RyR subtype is involved in calcium response to stretch. The cellular distribution of lysosomes, mitochondria and sarcoplasmic reticulum was investigated with live cellular probes.
Results: PASMC exhibit different segregated calcium stores: a subplasmalemnal SR store with RyR1 and SERCA2b, associated to mitochondria and a perinuclear SR store with RyR3 and SERCA2a. We showed that a stretch of PASMC induces an inward calcium influx through SAC that is amplified by a calcium release by RyR1. This calcium rise is then buffered by mitochondria. In MCT rats, the subcellular organization of RyR subtypes is modified: RyR3 and SERCA2a are not only expressed in a perinuclear area but also in a subplasmalemnal level. This is correlated with a different organization of mitochondria. In MCT rats, this new organisation leads to a greater amplification by all RyR subtypes and to a higher calcium increase induced by stretch. Furthermore, the calcium response to stretch is enhanced by a mechanism independent on extracellular calcium, involving caveolae.
Conclusion: This study highlights how the spatial organization of calcium stores in PASMC is important for calcium signaling to stretch and that a modification of this segregation leads to PH in rats. Such a study is relevant for a better understanding of cellular mechanisms underlying PH.

PCA407

Molecular identification of P2X receptors in human arteries

C. Nichols[1], O.V. Povstyan[1], O. Khan[2], G. Vasilikostas[2], T.K. Khong[1], A. Wan[2], M. Reddy[2] and M.I. Harhun[1]

[1]Division of Biomedical Sciences, St George's, University of London, London, UK and [2]Department of Surgery, St. George's Hospital, London, UK

In blood vessels vascular tone is controlled by sympathetic nervous activity, during which noradrenaline and ATP are released from perivascular nerves and contribute to sympathetically regulated vasoconstriction. In muscular arteries the contractile physiological responses to ATP are mediated through activation of P2X receptors, which are non-selective ligand-gated cation channels in the plasma membrane of vascular smooth muscle cells (VSMCs). Data about functional P2X receptors in human blood vessels are very limited; therefore the role of P2X receptors in VSMCs from human omental arteries (HOA) was studied in this work. This study conforms to the principles outlined in the Declaration of Helsinki and was approved by the local Research Ethics Committee (09/H0803/103) for retrieval of human tissue. Prior to surgery consent was obtained from patients undergoing elective abdominal surgery (n=7, 4 females, 3 females). Isolated VSMCs were obtained by enzymatic dispersion of small HOA blood vessels. The agonist-induced responses in $[Ca^{2+}]_i$ were investigated in fluo-3 loaded HOA VSMCs using x-y laser scanning confocal imaging. The genes encoding P2X receptor subunits were identified in preparations obtained from manually collected isolated HOA VSMCs using RT-PCR analysis and the expression of corresponding proteins was confirmed by immunocytochemical and Western blot techniques. Application of 10 μmol/l ATP evoked a robust increase in $[Ca^{2+}]_i$ in fluo-3 loaded VSMCs. 10 μmol/l of selective P2X receptor agonist α,βme-ATP evoked increase in $[Ca^{2+}]_i$ with similar amplitude and kinetic of the fluorescent signal (101.7±4.8% of ATP response, n=7, $p>0.05$) suggesting that stimulatory action of ATP on $[Ca^{2+}]_i$ is most likely mediated via activation of P2X receptors of the VSMC membrane. The exposure to 1 μmol/l selective P2X receptor antagonist NF279 significantly (by 32.3±5.5% of the control response, n=6, $p<0.05$) reduced the amplitude of $[Ca^{2+}]_i$ increase evoked by 10 μmol/l α,βme-ATP. The RT-PCR analysis revealed that HOA VSMCs express genes for P2X1 and P2X4 receptor subunits. The expression of corresponding proteins was confirmed by fluorescent immunocytochemical visualisation of VSMCs labelled with antibody detecting P2X1 and P2X4 receptors. These experiments revealed the presence of P2X1 and P2X4 receptors subunit proteins in the plasma membrane but not in the deeper cytoplasm of VSMCs. The Western blot analysis of the fragments of the HOA showed the presence of monomeric and dimeric byproducts of P2X1 (60 and 120 kDA) and P2X4 (43 and 100 kDa) receptor subunits. These data suggest that VSMCs from HOA express P2X1 and P2X4 receptors subunits with homomeric P2X1 channel receptors serving as a predominant functional target for stimulatory action of extracellular ATP in these blood vessels.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA408

Methanol extract of Poncirus fructus modulates pacemaker activity in interstitial cells of Cajal from the murine small intestine

B. Kim[1], H. Kim[1], S. Choi[2], J. Jun[2], I. So[3] and S. Kim[4]

[1]School of Korean Medicine, Pusan National University, Yangsan, Gyeongsangnamdo, Republic of Korea, [2]College of Medicine, Chosun University, Gwangju, Republic of Korea, [3]College of Medicine, Seoul National University University, Seoul, Republic of Korea and [4]Center for Bio-Artificial Muscle and Department of Biomedical Engineering, Hanyang University University, Seoul, Republic of Korea

Poncirus fructus (PF) has been widely used as a traditional medicine in Eastern Asia, especially to ameliorate the symptoms of gastrointestinal (GI) disorders related to abnormal GI motility. Poncirus fructus (PF), also known as Poncirus trifoliata (L.) Raf. (Rutaceae), is widely used as a traditional medicine in Eastern Asia mainly to ameliorate the symptoms of gastrointestinal (GI) disorders related to abnormal GI motility. In a previous study, a methanol extract of PF was found to have particularly potent gastroprokinetic effects. Interstitial cells of Cajal (ICCs) are pacemaker cells in the gastrointestinal tract, but the action mechanisms of PF extract in mouse small intestinal ICCs have not been investigated. Therefore, in the present study, we investigated the effects of a methanol extract of PF (MPF) in mouse small intestinal ICCs. In addition, we sought to identify the receptors involved. Enzymatic digestions were used to dissociate ICCs from small intestines. The whole-cell patch-clamp configuration was used to record potentials (current clamp) from cultured ICCs. In addition, we analyzed intracellular Ca2+ concentrations ([Ca2+]i). MPF decreased the amplitudes of pacemaker potentials in ICCs, and depolarized resting membrane potentials in a concentration dependent manner. Y25130 (a 5-HT3 receptor antagonist) and RS39604 (a 5-HT4 receptor antagonist) blocked MPF-induced membrane depolarizations, whereas SB269970 (a 5-HT7 receptor antagonist) did not. Pretreatment with Na+ or Ca2+-free solution or thapsigargin (a Ca2+-ATPase inhibitor in endoplasmic reticulum) abolished the generation of pacemaker potentials and suppressed MPF-induced activity. [Ca2+]i analysis showed that MPF increased [Ca2+]i. Furthermore, treatments with PD 98059, SB203580, or JNK II inhibitor blocked MPF-induced membrane depolarizations in ICCs. These results suggest that MPF modulates pacemaker potentials through 5-HT3 and 5-HT4 receptor-mediated pathways via external Na+ and Ca2+ influx, and via Ca2+ release from internal stores in a mitogen-activated protein kinase dependent manner. The study shows MPF is a good candidate for the development of a gastroprokinetic agent. In view of the effects of MPF on ICCs, further research is required, particularly to identify the active compound(s) involved and to determine their action mechanisms.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA409

Different regulatory effects of H2S and NO on gastric motility in mice

X. Huang, X. Meng, D. Liu, Y. Wu, X. Guo, H. Lu and W. Xu

School of Medicine, Shanghai Jiaotong University, Shanghai, China

Background NO and H2S are gaseous signaling molecules that modulate smooth muscle motility. NO has been proved to be an important non-adrenergic non-cholinergic (NANC) inhibitory neurotransmitter which is released in response to nerve stimulation and relaxes smooth muscles. And our previous studies showed smooth muscle tonic contraction to be increased significantly by low-concentration NaHS in the gastric antrum. But few studies have been performed in the GI tract to demonstrate the interaction between NO and H2S. We aimed to identify expressions of enzymes that catalyze H2S and NO generation in mouse gastric smooth muscle, and determine relationships between endogenous H2S and NO in regulating smooth muscle motility. Methods Adult male ICR mice were used in the present study. Western blotting and immunohistochemistry methods were used to track expressions of neuronal nitric oxide synthase (nNOS), endothelial nitric oxide synthase (eNOS), cystathionine β-synthase (CBS) and cystathionine γ-lyase (CSE) in gastric smooth muscle. Smooth muscle motility was recorded by isometric force transducers; cGMP production was measured by a specific radioimmunoassay. Key Results CBS, CSE, eNOS, and nNOS were all expressed in mice gastric antrial smooth muscle tissues, but only CBS and eNOS were detected in gastric antrial smooth muscle cells. Aminooxyacetic acid (AOAA), a blocker of CBS, significantly inhibited smooth muscle contractions in the gastric antrum, which was significantly recovered by NaHS, while DL-propargylglycine (PAG), a blocker of CSE, had no significant effect; Nω-nitro-L-arginine methyl ester (L-NAME), a non-selective inhibitor of NOS, enhanced contractions. NaHS at low concentrations increased basal tension but decreased it at high concentrations; SNP significantly inhibited the contractions, which could be significantly recovered by NaHS both in the absence and presence of CuSO4. 1H-[1, 2, 4]Oxadiazolo[4, 3-α]quinoxalin-1-one (ODQ), an inhibitor of soluble guanylate cyclase, did not block NaHS-induced excitatory effect; 3-Isobutyl-1-methylxanthine (IBMX), a non-selective phosphodiesterase inhibitor, partially blocked this effect; cGMP production in smooth muscle was significantly increased by SNP but not affected by NaHS. Conclusion & inferences Endogenous H2S and NO appear to play opposite roles in regulating gastric motility; their effects may be via separate signal pathways. Intracellular H2S/NO levels may be maintained in a state of balance to warrant normal smooth muscle motility.

Keywords: endogenous H2S, endogenous NO, gastric antrial smooth muscle, motility

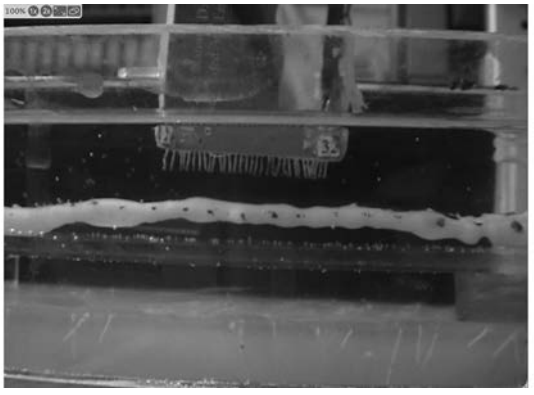
PCA410

Effect of ethanol exposure on slow wave activity and smooth muscle contraction in the small intestine

W. Lammers[1], S.B. Subramanya[2], B. Stephen[1] and H. Schäfer[3]

[1]Physiology, United Arab Emirates University, Al Ain, United Arab Emirates, [2]Dept of Physiology, RAK Medical & Health Sciences University, Ras Al Khaima, United Arab Emirates and [3]University of Applied Sciences, Kaiserlautern, Germany

Background: Ethanol ingestion causes a variety of gastrointestinal disturbances including motility disturbances. Slow waves coordinate gastrointestinal motility and abnormal slow-wave activity is thought to contribute to motility disorders. To date however, little is known about the effect of acute ethanol on motility disturbances associated with slow wave activity.
Method: 7-10 cm duodenum, jejunum and ileal loops from adult male Wistar rats were isolated and mounted in a 300-ml organ bath superfused with a Tyrode solution (100ml/min). The intestinal loops were connected to an inlet and an outlet and intra-luminally perfused with Tyrode (0.5ml/min). Soot markers were applied onto the serosal surface of the segments. After a 15 min equilibration period, the loops were superfused with 1, 3 and 5% ethanol. Motility recordings were performed with a digital video camera and electrical activities were recorded using a single longitudinal row of 32 extracellular unipolar silver electrodes.
Results: In all duodenal, jejunal and ileal segments (n=7), ethanol inhibits motility fully at 3% and 5%. The slow wave activity was also were altered at all the concentration in terms of velocity, frequency and amplitude ethanol. All effects were reversible upon superfusing with normal Tyrode.
Summary: Acute application of ethanol caused widespread but reversible inhibition of slow wave propagation with concurrent inhibition of small intestinal motility.



Video shot of a preparation (ileum of a rat) with soot markers applied and a 32-electrode row approaching the preparation for recording the electrical activities.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

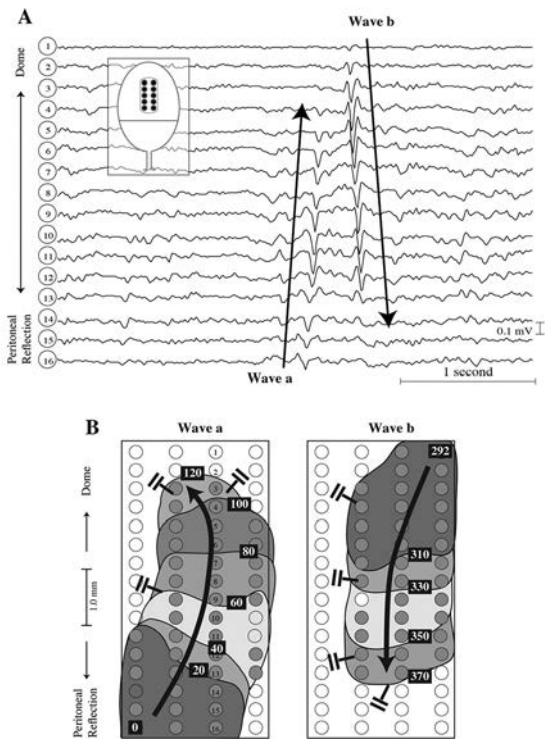
PCA411

Electrical propagation in the guinea pig urinary bladder

W. Lammers[1], J.F. Morrison[1], L. Lubbad[2], B. Stephen[1] and F.T. Hammad[2]

[1]Physiology, United Arab Emirates University, Al Ain, United Arab Emirates and [2]Surgery, United Arab Emirates University, Al Ain, United Arab Emirates

Aim: There is not much knowledge about the patterns of macroscopic electrical propagations in the wall of the urinary bladder. Recording from a large number of extracellular electrodes simultaneously is one technology that could be used to study the patterns of electrical propagations.
Method: The urinary bladders from 6 guinea-pigs were isolated and placed in a Tyrode filled organ bath. A 16x4 electrode array was positioned at various sites on the serosal bladder surface and recordings were performed at different intravesical volumes. At the end of 4 experiments, carbachol (CCH; 10-6 M) was added to the superfusing fluid and electrical activities recorded. After the experiments, the extracellular signals were analysed and propagation maps constructed.
Results: Propagation of electrical waves was detected in all experiments and at all sites on the bladder surface. Waves could originate from any site and propagate for a finite distance before terminating spontaneously. The vast majority of waves propagated preferentially in the axial direction and only a few propagated transversely. Increase in vesical volume decreased significantly conduction velocity (from 4.9±1.5 to 2.7±0.7 cm/sec; $p < 0.05$) whereas CCH did not have any major effect on patterns and speed of propagation
Conclusions: Large electrical waves do propagate across the bladder wall, both in the dome, across the peritoneal reflection and in the base. The preferential propagation in the axial direction may have practical implications during surgical interventions. The electrical waves could form the basis for local spontaneous contractions in the bladder.



Recording from the dome (location of the electrodes indicated in the inset) showing two waves propagating in opposite directions (bladder volume 4 ml). Both waves originated from outside but stopped within the mapped area. Note the block symbols indicating where the propagating waves had stopped spontaneously.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Inhibition of duodenal movement in vitro of rat by Bisphenol A through nitric oxide mediated guanylyl cyclase and α-adrenergic pathways

K. Sarkar, P. Tarafder, M. Ghosh, A. Ghati and G. Paul

Department of Physiology, University of Kalyani, Kalyani, West Bengal, India

Bisphenol A (BPA), an endocrine disrupting compound, has received much attention for its other probable health effects. It is a monomer of polycarbonate plastics, epoxy and polystyrene resins that are extensively used in the interior coating of cans in the food packaging industry and in dentistry. Human exposure to BPA occurs mainly through the ingestion of food and water from such containers and dental materials that leach BPA. Even though BPA is reported to produce reproductive and behavioural toxicity in experimental animals in various doses, the effect of BPA on the intestinal motility is not known till to date. The present study was designed to examine the effect of BPA on the movement of duodenum in vitro of rat. In this study, the movement of isolated duodenum of adult Sprague-Dawley rats (120-150gm, n=7) were recorded by isotonic transducer coupled to a RMS Polyrite-D machine (RMS Pvt. Ltd., India). The concentration-response of BPA on duodenal contraction was obtained in absence and presence of agonists and antagonists. Values are means±S.E.M. compared by Student's t-test, $p<0.05$ vs. control and the treated preparations were expressed as percent change of the basal (or control) values. It was observed that BPA (10, 20, 40, 80, 160, 320μM) decreases the frequency (90.80±9.2, 84.80±4.9, 76.80±3.3, 55.20±2.2, 20.80±1, 2.4±0.4) and amplitude (66.66±3.2, 41.05±1.5, 39.3± 2.3, 35.84±2.2, 20.12±1.2, 9.3±1.3) of duodenal contraction in a dose-dependent manner. At last two doses (160μM and 320μM) the movement of duodenum were fully inhibited. Besides, BPA induced changes in duodenal movement was not blocked by atropine, the muscarinic receptor blocker. Further, BPA potentiated the inhibitory effect of the duodenal movement pre-treated with sodium nitroprusside (SNP, nitric oxide donor, 3.3 μM and 6.6μM). But the BPA induced inhibition of duodenal movement was blocked when the segment was pre-treated with L-NAME (nitric oxide synthase inhibitor, 90μM and 180μM) or methylene blue (MB, guanylyl cyclase inhibitor, 100 μM and 200 μM) (figure 1), and the blocking action of BPA was found to be fully reversed after 25,20,20 and 15 minutes respectively. It was also observed that phentolamine (3μM and 6μM), an α-adrenergic blocker, blocks the action of BPA upto the dose of 80μM (figure 2). But the BPA induced changes in the movement was not reversed by the propranolol, a β-adrenergic blocker. In other sets of experiments, equivalent doses of DMSO (solvent used for BPA) did not produce any change in the movement of isolated duodenum. From the results, it may be concluded that BPA inhibits the duodenal movement presumably by inducing nitric oxide mediated guanylyl cyclase and α-adrenergic signal pathways in duodenal smooth muscle cells.

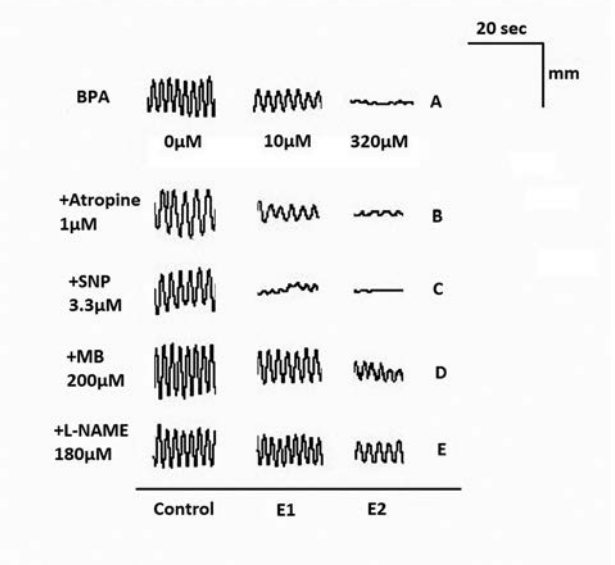

Figure 1: Recordings of the effects of two representative doses of BPA on the movement of isolated duodenal segment pre-treated with atropine (panel B), SNP (panel C), MB (panel D) and L-NAME (panel E). Panel A shows the recordings of effects of representative doses of BPA on the movement of duodenum. E1= Drug+10 μM BPA, E2=Drug+ 320μM BPA.

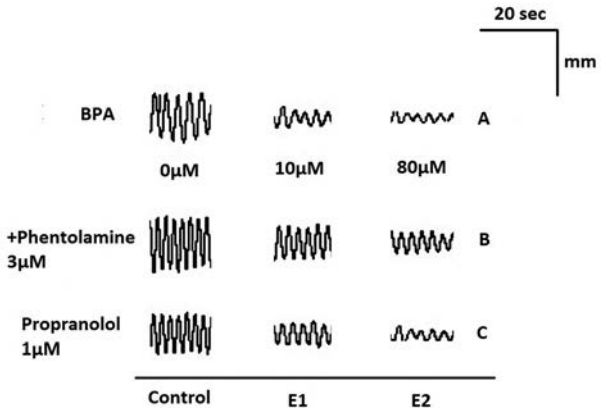

Figure 2: Recordings of the effects of two representative doses of BPA on the movement of isolated duodenal segment pre-treated with phentolamine (panel B) and propranolol (panel C). Panel A shows the recordings of effects of the representative doses of BPA on the movement of duodenum. E1= Drug+10 μM BPA, E2=Drug+ 80μM BPA.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCA414

Gender differences in the response to salt stress in uninephrectomised Sprague-Dawley rats

A.K. Oloyo, O.V. Oyeniyi, Y.A. Oduneye, O. Salau and O.A. Sofola

Physiology, University of Lagos, Surulere, Lagos, Nigeria

From puberty onwards, blood pressure (BP) is consistently higher in males when compared with females. The kidney plays a central role in the regulation of BP by regulating salt excretion. High salt diet (HSD) is implicated in the onset of hypertension. Generation of reactive oxygen species (ROS) is one of the mechanisms by which a HSD induces hypertension1, as HSD has been shown to drive production of ROS in the renal tissues2. Both oxidative stress3 and BP elevating effect of a HSD4 have been shown to exhibit sexual differences. Therefore, experiments were designed to assess the effect of gender on oxidative stress in uninephrectomised rats fed a HSD. Weanling Sprague-Dawley rats (90 – 100g) of both sexes were divided into 4 groups (n = 6) each. They were either sham operated or uninepherectomised under (90mg/kg bodyweight ketamine and 10mg/kg bodyweight xylazine i.p) anaesthesia and fed a normal 0.3% or high 4% NaCl salt diet for 10 weeks. Renal weight index and fluid balance were determined. BP was measured via carotid artery canulation under 25% Urethane and 1% alpha chloralose (5ml/kg bodyweight i.p) anaesthesia. Plasma concentration of nitrates was measured, lipid peroxidation (LP) and superoxide dismutase (SOD) activity was determined in the kidney homogenate. H&E histological staining of the kidney was also carried out. HSD increased fluid retention (ml) in sham male (16.83±2.07vs.11.34±1.91) and female (20.5±2.35vs.10.57±2.04) as well as in uninephrectomised male (22.17± 2.39vs.12.43± 1.84) and female (24.17±2.36vs.11.90±1.50) rats. However, gender has no effect on fluid balance. HSD elevated BP (mmHg) in sham male (121±2vs.101±4) and female (117±3vs.95±3) and also in uninephrectomised male (141±5vs.105±3) and female (131±5vs.104±3) rats. BP elevating effect of a HSD and uninephrectomy was higher in the males when compared with females (141±5vs.131±5). Reduction in the weight index of the remnant kidney was more in high salt fed males (0.27±0.015vs.0.30±0.013) and female (0.23±0.023vs.0.30±0.023) as well as in the females when compared with males (0.23±0.023vs.0.27±0.015). Plasma concentration of nitrates was reduced in uninephrectomised plus high salt diet groups: male (0.32±0.08vs.1.24±0.14) and female (0.75±0.07vs.1.60±0.23), and this reduction is more in the male (0.32±0.08vs.0.75±0.07). HSD increased LP (0.11±0.017vs.0.05±0.008) but reduced the SOD activity (2.04±0.26vs.4.02±0.24) in the kidney and this effect was higher in the males: LP (0.11±0.017vs.0.03±0.005). HSD aggravated to a greater extent Bowman's capsule vacuolation and tubular atrophy observed in uninepherectomised groups in male when compared with female rats. Thus reduced NO production, increased oxidative stress and distortion of renal cytoarchitecture can contribute to the gender differences in the response to a HSD in uninephrectomised Sprague-Dawley rats.

PCA415

Quantification of urinary exosomes by nanoparticle tracking analysis

W. Oosthuyzen, E. Turtle, J.M. Street, J. Pound, D.J. Webb, C.D. Gregory, M.A. Bailey and J.W. Dear

University of Edinburgh, Edinburgh, Edinburgh, City of, UK

Exosomes are cell-derived vesicles that are released from the kidney into urine. They contain protein and RNA from the glomerulus and all sections of the nephron and represent a non-invasive reservoir for biomarker discovery. Current methods for identifying and quantifying human urinary exosomes are time-consuming and only semi-quantitative. Nanoparticle tracking analysis (NTA) is a technology that can size and count nanoparticles, such as those released from cultured cells and in human plasma. NTA is based on the principle that at any particular temperature, the rate of Brownian motion of nanoparticles in solution is determined solely by their size. Published studies demonstrate that NTA can count and size specific subgroups of particles using fluorescent antibodies against surface proteins, but this has not yet been applied to urine.
In the current study we applied NTA to human urine (n=5) and identified a range of nanoparticles, including exosomes. Using antibodies against the exosomal marker proteins CD24 and aquaporin 2 (AQP2), conjugated to a fluorophore, we could identify a sub-population of CD24 and AQP2 positive particles of characteristic exosomal size (figure 1). Extensive pre-NTA processing of urine was not necessary; however, the intra-assay variability in the measurement of exosome concentration was significantly reduced when an ultra-centrifugation step preceded NTA. Building upon previous work in our group in investigating exosomal signalling between cells, we were also able to track exosomal AQP2 upregulation induced by desmopressin stimulation of murine collecting duct cells by using

NTA. Finally, when urine was stored at room temperature, 4C or frozen, nanoparticle concentration was reduced; freezing at -80C produced the least reduction. This reduction was substantially reduced by addition of protease inhibitors to urine before storage (figure 2). In conclusion, with appropriate sample storage, NTA has potential as a tool for rapidly characterising and quantifying exosome concentration in human urine and for further understanding the mechanism of intra-cellular signalling mediated by exosomes.

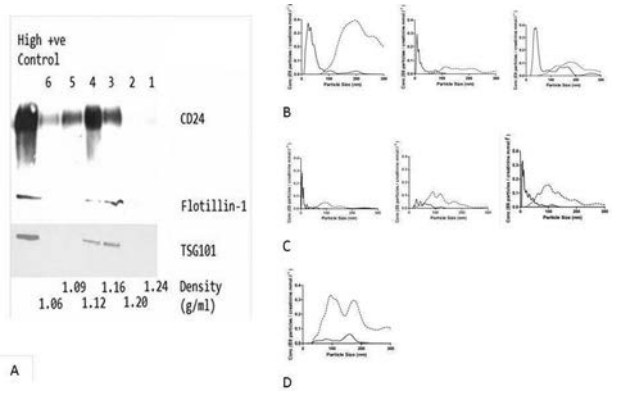

Figure 1. Exosome marker specific fluorescent labelling. A) CD24, flotillin 1 and TSG101 on a sucrose density gradient. B) Human urine samples labelled with CD24-Qdots in light scatter mode (dashed line – all particles) and fluorescent filter in place (solid line – CD24 labelled particles). (n=3). C) Human urine samples labelled with AQP2-Qdots in light scatter mode (dashed line – all particles) and fluorescent filter in place (solid line – AQP2 labelled particles). (n=3). D) Human urine labelled with mouse IgG conjugated to Qdot as isotope control in light scatter mode (dashed line) and with the fluorescent filter in place (solid line).

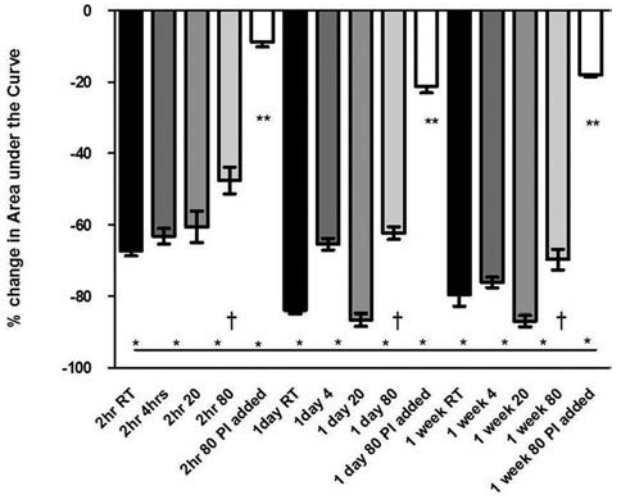

Figure 2. Different storage protocols and urine particle concentration. NTA was used to measure the particle concentration between 20 – 100 nm in diameter (AUC20-100).

PCA416

Comparison of the phasic activity of upper, middle and lower segments of pig ureter

M.M. ElMahdy[1], M. Drake[1,2] and B. Vahabi[1,2]

[1]Urology, Bristol Urological Institute, Bristol, UK and [2]University of the West of England, Bristol, UK

The propagation of urine from the kidney is initiated by the pacemaker activity in the renal pelvis (1-2). The density of cholinergic nerve fibers in the ureter increases from renal pelvis to the bladder with the ureterovesical junction being the most densely innervated region. The difference in contractile behavior between the upper, middle & lower ureteric segments is not well understood in response to cholinergic modulators. This study investigates the contractile behavior of the different ureteric segments of the pig and the effect of cholinergic-receptor modulators.

Ureters were isolated from freshly slaughtered pigs (6 to 8 months old). Three centimeter longitudinal strips of upper (UU), middle (MU) and lower ureter (LU) were suspended in 25 ML organ baths containing Krebs bicarbonate solution, maintained at 37°C & gassed with 95% O2 & 5% CO2. Tissue tension was measured using isometric force transducers connected to a PowerLab data acquisition system using 'Chart' software. Tissue segments were equilibrated under 2g of tension for 60 min and assessed for basal spontaneous activity (BSA). Tissues without BSA were discarded. Amplitude and frequency of BSA were compared between different ureteric segments. The effect of cholinergic-receptor modulators, carbachol (CCh, 10 μM) and atropine (AT) (1μM) (10-15 min exposure to each drug), on BSA of UU, MU & LU was then investigated. All data is expressed as the mean ± SEM. Statistical analysis was performed using one-way ANOVA and Student's paired t-tests.

Results

100% of UU (n=23), 65% of MU (n=24) & 65% of LU (n=24) segments demonstrated BSA. The amplitude of BSA in the LU (0.028±0.003 g tension/mg tissue) was significantly ($p<0.001$) higher than MU (0.015±0.002 g tension/mg tissue) & UU (0.009±0.002 g tension/mg tissue). However, the frequency of BSA was significantly ($p<0.001$) higher in UU (25.09±2.07 events in 5min) vs. MU (3.08±0.68 events in 5 min) and LU (3.63±0.78 events in 5min) segments. 10μM CCh significantly ($p<0.01$-0.001) enhanced the amplitude and the frequency of BSA in MU (n=13) & LU (n=17) segments, however it did not affect the BSA of UU (n=16). 1μM AT reduced the amplitude of BSA in MU (n=13) & LU (n=14), (although not statistically significant), with no effect on the UU (n=12) segments.

The pattern of BSA was significantly different in UU, LU and MU segments. The frequency of BSA was significantly higher in UU compared to LU and MU strips. In contrast, the amplitude of BSA was significantly higher in the LU compared to MU and UU segments, demonstrating that each segment plays a different role in mediating the peristaltic movement of the ureter. The differences in the sensitivity of different ureteric segments to cholinergic-receptor manipulation can provide a better understanding of ureteric pharmacology and aid devel-

opment of a targeted approach in the management of ureteric conditions.

PCA417

The effects of cannabinoid receptor 1 on capsaicin/bradykinin-induced activity of afferent nerve in an ex vivo rat ectopic endometrium preparation

G. Zhang, B. Sun and W. Rong

Physiology, Shanghai Jiaotong University School of Medicine, Shanghai, China

Endometriosis (ENDO) is a disease common in women that is defined by abnormal extra uteral growths of uterine endometrial tissue and associated with severe pain. Recent studies in a rat model and women showed that sensory and sympathetic nerve fibers sprout branches to innervate the abnormal growths. Furthermore, the endocannabinoid system is involved in both endometriosis and its associated pain. It is not clear whether cannabinoid receptor 1 (CB1R) is involved in the sensitivity of afferent nerve innervating ectopic endometrium to capsaicin (Cap)/bradykinin (BK) Herein, using an ex vivo ectopic endometrium preparation from rat model of endometriosis, we examined the sensitivity of afferent nerve innervating ectopic endometium to Cap/BK, and the effects of CB1R agonist ACPA on Cap/BK-evoked activity of afferent nerve. ENDO model: female Sprague-Dawley rats (200-225g, n=9) in diestrus were anesthetized with sodium pentobarbital (50 mg/Kg, i.p.), four pieces of uterine horn (2×2 mm) were sewn around alternate cascade mesenteric arteries starting from the caecum, which will form ectopic uterine cysts. Recording of afferent nerve innervating ectopic cyst was performed in an ex vivo preparation 10 weeks after ENDO. The preparation was superfused continuously at a rate of approximately 15 ml/min with oxygenated (95%O2/5%CO2) Krebs solution at 37 °C. ACPA (300 nM) diluted in Krebs superfused the preparation 10 min before either Cap (300 nM) or BK (300 nM) superfusion. Spike 2 software was used to calculate the change of afferent activity. Values are means ± S.E.M., compared by ANOVA. The response of afferent nerve innervating ectopic cyst either to Cap or BK was changed compared to that in ex vivo naïve ileum preparation. The peak increase of afferent activity was occurred at 90 sec after Cap in ex vivo either ectopic cyst or naïve ileum preparation, while the Cap-induced afferent activity was decreased followed by increase in ex vivo ectopic cyst preparation. The BK-induced increase in afferent activity was occurred at 90 sec and 3 min after BK in ex vivo naïve ileum and ectopic cyst preparations, respectively. The peak increase in afferent activity induced by either Cap or BK was inhibited by ACPA (8.33 ± 0.89 vs. 4.35 ± 0.36 imp/30s, Cap alone vs. Cap + ACPA, $p < 0.05$; 12.37 ± 0.85 vs. 7.33 ± 0.34 imp/30s, BK alone vs. BK + ACPA, $p < 0.05$). However, ACPA did not affect the response of afferent nerve to either Cap or BK in ex vivo naïve ileum preparation. These findings indicate that peripheral CB1R affects the sensitivity of afferent nerve innervating ectopic endometrium to capsaicin or bradykinin.

PCA418

Combined endothelial progenitor cells (EPCs) and mesenchymal stem cells (MSCs) can enhance wound healing in diabetic mice model associated with increased VEGF and decreased neutrophil infiltration

S. Sukpat[1], N. Israsena[3] and S. Patumraj[2]

[1]Physiology, Chulalongkorn university, Bangkok, Thailand, [2]Pharmacology, Chulalongkorn University, Bangkok, Thailand and [3]Physiology, Chulalongkorn University, Bangkok, Thailand

Non-healing diabetic ulcer causes the patient at much higher risk for lower extremity amputation. Several studies showed that both MSCs and EPCs can promote wound healing, increase angiogenesis and release of proangiogenic factors into the wound. Therefore, the objective of this study is to investigate whether the combination of EPCs and MSCs can enhance angiogenesis and wound healing in diabetic mice. Balb/c nude mice were divided into five groups. Group 1 was control group (Con; n=6). Group 2 was diabetic group treated with fibrin gel (DM; n=6). Group 3 was diabetic group injected with 1X106 cells MSCs (DM+MSCs; n=6). Group 4 was diabetic group injected with 1X106 cells EPCs (DM+EPCs; n=6). Group 5 was diabetic group injected with combined 0.5X106 cells MSCs and 0.5X106 cells EPCs (DM+MSCs+EPCs; n=6). Diabetic groups were induced by injection of streptozotocin (45 mg/kg i.p. daily for 5 days). At 7 weeks after, mice were anesthetized with sodium pentobarbital (55 mg/kg i.p.) and created bilateral full-thickness excisional skin wounds on the dorso-rostral back (0.6x0.6 cm2). On day 7 and 14 post-wound, the percentage of wound closure (%WC), the percentage of capillary vascularity (%CV), the neutrophil infiltrations and tissue vascular endothelial growth factor (VEGF) level were determined by using image analysis software, intravital fluorescence microscopy, H&E staining and ELISA, respectively. Values are means ± S.E.M., compared by ANOVA. The %WC in DM+EPCs, DM+MSCs, DM+MSCs+EPCs and Con increased significantly than DM group at day 7 (78.66 ± 2.29, 78.28 ± 4.16, 72.04 ± 4.12, 72.47 ± 4.52 vs. 55.65± 3.92; $p<0.05$) and day 14 (89.65 ± 1.07, 85.43 ± 1.58, 85.42 ± 0.64, 86.36 ± 0.84 vs. 80.42 ± 1.37; $p<0.05$). On day 7, the %CV in DM+EPCs, DM+MSCs, DM+MSCs+EPCs and Con were significantly increased than DM (22.86 ± 1.20, 21.42 ± 0.61, 27.44 ± 1.07, 19.95 ± 0.82 vs. 14.72 ± 1.49; $p<0.05$). The %CV of DM+EPCs+MSCs was increased significantly than DM+MSCs and DM+EPCs ($p<0.05$). On day 14, the %CV of DM+EPCs+MSCs was significantly higher than DM (24.92 ± 1.81 vs. 16.72 ± 1.39; $p<0.05$). Number of neutrophil infiltration in DM+EPCs, DM+MSCs, DM+MSCs+EPCs and Con increased significantly than DM at day 14 (12.40 ± 2.40, 11.60 ± 3.14, 14.60 ± 1.63, 13.00 ± 2.16 cells/field vs. 34.25 ± 4.59 cells/field; $p<0.05$). The VEGF levels in DM+EPCs, DM+MSCs, DM+MSCs+EPCs and Con were significantly higher than DM on day 7 (188.43 ± 28.09, 218.84 ± 27.50, 216.45 ± 53.01, 232.30 ± 44.09 pg/mg protein vs. 44.06 ± 10.70 pg/mg protein; $p<0.05$). In conclusion, the present study has demon-

strated that the combined EPCs and MSCs can increase VEGF level and increased angiogenesis which lead to reduce number of neutrophil infiltration and enhanced wound healing in diabetic mice model.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB001

Inhibition of the ventricular function of rat by Bisphenol A

P. Tarafder, K. Sarkar and G. Paul

Department of Physiology, University of Kalyani, Kalyani, West Bengal, India

Bisphenol A (BPA) is a controversial chemical. The possible toxic effect of BPA on the function of the heart has not been studied in detail till to date. So, the aim of the present study was to examine the effect of BPA on the ventricular function of heart at the molecular physiological level in rat. Studies were performed on adult male rats of Sprague- Dawley strain (150-200gm, n=7). BPA was administered at a dose of 50mg/kg body weight/day for 20 and 30 days by oral gavage. The rats were sacrificed by cervical dislocation on the 24th hour after the last treatment. Paraffin embedded ventricular tissue sections were stained with hematoxylin and eosin (H&E); and Von-Kossa's technique after Bancroft et al, 2008. The activities of superoxide dismutase (SOD)(Marklund and Marklund,1974), catalase (CAT)(Sinha,1972), glutathione reductase (GR)(Staal et al,1969), glutathione peroxidase (GPX)(Rotruck et al, 1973) were determined and the amount of malondialdehyde (MDA)(Devasagayam and Tarachand,1987) was estimated in microsomal fraction of ventricular myocytes (VMs). Acetylcholinesterase (AChE) activity was measured after Ellman et al,1961. Values are means±S.E.M., compared by Student's t-test. We found significant changes in the size and shape of the nucleus of VMs in H&E stained tissue sections of test rats in a duration dependent manner. Moreover, many lacunae were seen in the matrix of the VMs. We also observed significant deposition of Ca2+-salt at all durations in Von-Kossa's stained ventricular tissue section. These findings suggest that BPA damages the VMs and hampers calcium homeostasis by causing Ca2+-salt deposition in VMs. The activities of antioxidant enzymes were seen to be decreased in both 20 and 30 days durations compared to the control groups [(SOD-6.51±0.2 vs. 7.08±0.3 and 6.47±0.2 vs. 6.58±0.3 U/mg protein)(CAT-25.18±0.4 vs. 27.06±0.5 and 24.42±0.5 vs. 26.59±0.6 U/mg protein, p<0.05)(GPX-3.61±0.3 vs. 4.78±0.3 and 3.77±0.2 vs. 4.87±0.4 nmoleGSH/mg protein, p<0.05)(GR-16.23±0.6 vs. 24.28±0.9 and 11.48±0.5 vs. 23.94±0.8 nmoleNADPH oxidized/min/mg protein, p<0.001) respectively]. While, the MDA production was increased in test groups than control groups in both durations [(16.66±0.5 vs. 14.96±0.5 and 19.74±0.2 vs. 13.98±0.7 nmole MDA/mg protein-p<0.001) respectively]. These results suggest that BPA induces oxidative stress in rat VMs by depleting antioxidant defense system and increasing lipid peroxidation. Further, the activity of AChE was decreased significantly in treated rats in both durations [(4.43±0.4 vs. 10.19±0.6 and 3.91±0.3 vs. 10.19±0.6 μmole/min/mg protein, p<0.001) respectively]. This suggests that BPA inhibits ventricular functions by inhibiting AChE at the ventricular synapse. In conclusion, BPA inhibits ventricular function in rat presumably by hampering Ca2+-homeostasis and causing oxidative stress in VMs; and inhibiting AChE activity in ventricular synapse.

PCB002

Relationship between chronic kidney disease and left ventricular mass independent of haemodynamic factors in an African community sample

F. Maunganidze, N.R. Gavin and A.J. Woodiwiss

Physiology, University of The Witwatersrand, Johannesburg, South Africa

Chronic kidney disease (CKD) preceding the development of renal failure, is independently associated with cardiovascular outcomes as explained by a number of mechanisms including haemodynamic and non-haemodynamic factors.[1-3] Our aim was to evaluate whether the relationship between CKD and left ventricular mass (LVM) occurs in a community sample and the extent to which this relationship depends on haemodynamic factors. In 418 randomly selected, non-diabetic participants from a community sample, 236 of whom were normotensive (NT), glomerular filtration rate was estimated (eGFR), [3] LVM and dimensions determined using echocardiography, and aortic BP assessed from applanation tonometry and SphygmoCor software.[4] Unadjusted means and proportions were compared by the large-sample z test and the χ2-statistic, respectively. Relationships were determined using multivariate regression analysis with adjustments for clinic BP (or alternative haemodynamic factors), age, sex, waist circumference, HbA1c, regular tobacco intake, regular alcohol intake, pulse rate and treatment for hypertension in the models. Aortic pulse wave velocity and high quality 24-hour BP values were available from 362 and 304 participants respectively. With adjustments for confounders (including clinic systolic BP), eGFR was associated with LVM index (LVMI) and LVM in excess of that predicted from stroke work (inappropriate LVM, LVMinappr) in the whole sample (LVMI: partial r = - 0.24, p<0.005; LVMinappr: partial r = - 0.33, p<0.0001) and in NT only (LVMI: partial r = - 0.30, p<0.01; LVMinappr: partial r = - 0.37, p<0.0001). Differences in LVMI and LVMinappr were noted in the eGFR range above 105 mls/min/1.73 m2) (p<0.0001 for differences in LVMinappr between upper two quartiles of eGFR). When replacing clinic BP with either aortic systolic BP, 24-hour BP, PWV, stroke work (for LVMI), LV end diastolic volume, or circumferential wall stress in the regression models, eGFR retained the strong association with LVMI (p<0.05 to <0.0005) and LVMinappr (p<0.0001 for all) and these effects were replicated in NT only. Therefore, strong relationships between early renal dysfunction and LVM occur at a community level irrespective of the presence of hypertension and independent of 24-hour and aortic BP, PWV, LV end diastolic volume, stroke work and wall stress. Non-haemodynamic factors appear to explain a considerable proportion of the relationship between early CKD and LV hypertrophy.[5]

Signal Transducer and Activator of Transcription 3 (STAT3) and heart failure with age: A position-dependent gene knock out model in mice

A. Imamdin[1], J. McCarthy[1,2], S. Lecour[1], K. Sliwa-Hanle[1] and N. Davies[3]

[1]Medicine, Hatter Institute for Cardiovascular Research in Africa, University of Cape Town, Cape Town, South Africa, [2]Chemical Pathology, Division of Lipidology, University of Cape Town / Groote Schuur Hospital, Cape Town, South Africa and [3]Cardiovascular Research Unit, Chris Barnard Division of Cardiothoracic Surgery, University of Cape Town, Cape Town, South Africa

Introduction: Heart failure (HF) is the inability of the left ventricle to fill with or eject blood. It often occurs as a side-effect of cardiovascular complications such as ischemia. At the molecular level, Signal Transducer and Activator of Transcription 3 (STAT3) is linked to HF, as STAT3 deficient (STAT3 KO) mouse models have shown development of HF with age.
Hypothesis: In a mouse model, induction of heart failure consecutive to a deletion in the STAT3 gene depends on the locus of the splice-site in the gene.
Material and methods: STAT3 KO and wildtype (WT) mice were aged to provoke heart failure. Mice were anesthetised for all aspects of this experiment by intraperitoneal injection of Sodium Pentobarbitone (50mg/kg body weight) . A sufficient degree of anaesthesia was considered to be obtained in the absence of the pedal reflex, after which the chest cavity was opened, and hearts were excised. Mitochondrial respiration was measured in aged hearts using permeabilized heart fibres and an oxygen-sensing Clarke-type electrode, with fatty acids (FA) as a substrate (n=4 per group). Inability to respire with FA is a typical metabolic state of a failing heart. Histology staining (picrosirius stain) was also performed on these aged mouse hearts to quantify fibrosis, a marker for heart failure (n=6 KO, n=4 WT).
Results: No significant differences detected in mitochondrial respiration using a FA substrate, indicating similar metabolic profiles in both groups (see Figure 1, $p>0.05$). Failing hearts exposed to FA should have shown impaired mitochondrial respiration. Histology staining for fibrosis in the aged STAT3 KO hearts showed minimal fibrosis, similar to WT hearts (KO 0.83±0.203% and WT 0.57±0.104%, $p> 0.05$), demonstrating no overt heart failure. All data was expressed as mean ± SEM. An unpaired student's t-test was used for all statistical analysis.
Conclusion: The STAT3 KO mouse model in our laboratory presents a different phenotype with aging compared to other published STAT 3 KO mouse models. This may be due to the location of the splicing in the STAT3 gene and the possibility of aberrant STAT3 proteins which contribute to HF in certain models, but not in others. It would therefore appear that the tendency to heart failure in STAT3 KO mice is dependent on the position of the deletion or the duration of aging.

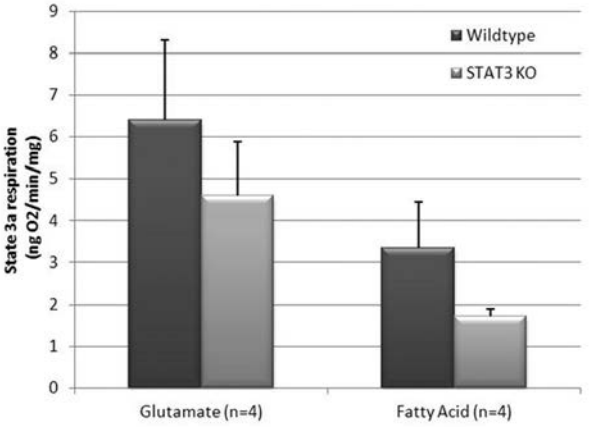

Figure 1: Measurement of state3a respiration (indicating the ability of mitochondria to convert ADP to ATP) is shown in the graph. Glutamate serves as a control substrate to which to compare fatty acid oxidation. There was no significant difference in respiration between wildtype and KO hearts within or between treatment groups (p>0.05).

Novel interventions to ameliorate hyperglycemia-induced cardiac dysfunction following ischemia-reperfusion

R.F. Mapanga and M.F. Essop

Physiological Sciences, Stellenbosch University, Stellenbosch, Western Cape, South Africa

Stress-induced, acute hyperglycemia co-presenting with myocardial infarctions is associated with poor prognosis. Hyperglycemia-induced oxidative stress result in DNA damage and subsequent activation of poly-ADP-ribose polymerase (PARP) as a restorative mechanism. However, PARP attenuates glyceraldehyde–3-phosphate dehydrogenase (GAPDH) activity, thereby diverting upstream glycolytic metabolites into damaging non-oxidative glucose pathways (NOGP). For example, hyperglycemia-induced stimulation of four NOGP, i.e. the polyol pathway, hexosamine biosynthetic pathway (HBP), advanced glycation end products (AGE), and PKC activation elicit cardiovascular complications. We therefore hypothesized that NOGP inhibition blunts hyperglycemia-induced oxidative stress and cardiac contractile dysfunction following ischemia-reperfusion. We employed several experimental systems: 1) Isolated rat hearts were perfused ex vivo with Krebs-Henseleit buffer containing 33 mM glucose vs. controls (11 mM glucose) for 90 min, followed by 30 min global ischemia and 60 min reperfusion ± respective NOGP inhibitors added during the first 20 min of reperfusion. The following inhibitors were individually employed: AGE pathway (100 μM aminoguanidine); PKC (5 μM chelerythrine chloride); HBP (40 μM 6-diazo-5-oxo-L-norleucine); and polyol pathway (1 μM zopolrestat); 2) Infarct size determination as in #1) but with 30 min regional ischemia and 120 min reperfusion ± similar treatments. Our data shows that acute administration of each inhibitor attenuated superoxide levels and concomitantly increased superoxide dismutase activity. In parallel, we found that it decreased PARP and enhanced GAPDH activities while diminishing myocardial apoptosis. Each inhibitor employed blunted activation of the other three pathways here examined. Hearts treated with NOGP inhibitors also displayed improved functional recovery and smaller infarct sizes following ischemia-reperfusion. Interestingly, NOGP inhibitors resulted in the same degree of change (for all above-mentioned parameters evaluated) when compared to each other. The current study demonstrates that acute NOGP inhibition initiated after ischemia offers significant potential as therapeutic agent(s) for myocardial infarction under acute hyperglycemia. Moreover, our findings establish for the first time that there is a convergence of downstream NOGP effects in our model, i.e. increased myocardial oxidative stress, further pathway activation, apoptosis, and impaired contractile function. Thus a vicious metabolic cycle is established whereby hyperglycemia-induced NOGP further fuels its own activation by generating even more oxidative stress, thereby exacerbating damaging effects on the heart under these conditions.

Effect of oral administration of levonogestrel with or without ethinyl estradiol on glucose tolerance and plasma lipid parameters in female Wistar rats

O.S. Michael and L.A. Olatunji

Deparment of Physiology, University of Ilorin, Ilorin, Kwara, Nigeria

Combined oral contraceptives (COCs) have become the most common or popularly used method of reversible contraception worldwide (1). The impact of oral contraceptives (OC) on cardiovascular health remains an important issue due to the popularity of this contraceptive choice combined with the knowledge that OC usage has been linked to adverse cardiometabolic effects (2). Estrogen is believed to have cardiometabolic protection effect; but its beneficial effects have recently been queried. The aim of the present study was to determine whether or not the altered glucose tolerance and plasma lipid profile was associated with OC and due to the estrogenic or progestogenic-component in 120-180g female rats. Rats (8 per group) were divided into control, combined

ethinyl estradiol-levonogestrel OC-treated (LEE) (receiving 0.75μg ethinyl estradiol/7.5μg levonorgestrel, p.o.), and low dose levonogestrel only OC-treated (LOC) (receiving 3.75 μg levonorgestrel, p.o.) groups. Rats were given distilled water (0.3ml, p.o), LEE and LOC daily for 6 weeks. Values are means± S.E.M. Glucose challenge test was performed 48- hours prior to the end of the experiment. The animals had 12-hour overnight fast and glucose tolerance was expressed as a function of the area under the tolerance curve (3,4).The results showed that treatment with a combination of levonogestrel and ethinyl estradiol led to significant decrease in glucose tolerance (370.6±14.9 vs. 280.6±10.1mmol/l) and increase in plasma triglyceride (TG) levels (105.6±9.2 vs. 63.2±1.2mg/dl) while treatment with levonogestrel only did not lead to any alteration in glucose tolerance and TG levels when compared with the control. However, treatment with a combined levonogestrel and ethinyl estradiol or levonogestrel only did not cause significant changes in total cholesterol (TC), high-density lipoprotein-cholesterol (HDL-C), low-density lipoprotein-cholesterol (LDL-C), total cholesterol/high-density lipoprotein-cholesterol (TC/HDL-C) ratio, and fasting blood glucose. In conclusion, the present study demonstrated that the use of OC containing levonogestrel in combination with ethinyl estradiol but not levonogestrel-only OC use caused impaired of glucose tolerance associated with increased triglyceride. This indicates that estrogenic but not progestogenic component of OC may be responsible for the altered glucose tolerance and lipid metabolism in this animal model.

Benfotiamine: a novel therapeutic agent for the treatment of hyperglycemia-mediated cardiac contractile dysfunction

R.F. Mapanga, B. Adams and M.F. Essop

Physiological Sciences, Stellenbosch University, Stellenbosch, Western Cape, South Africa

Acute hyperglycemia co-presenting with myocardial infarctions is associated with poor prognosis. Higher oxidative stress and subsequent activation of non-oxidative glucose utilizing pathways (NOGP), i.e. hexosamine biosynthetic pathway (HBP), polyol pathway, advanced glycation end products (AGEs) and PKC have been implicated as potential mediators of this process. Hyperglycemia-induced oxidative stress can also result in dysregulation of the ubiquitin-proteasome system (UPS) that removes misfolded proteins. There are conflicting data whether increased/decreased UPS is detrimental with hyperglycemia and/or in response to ischemia-reperfusion. For example, we found cardioprotection with attenuated UPS activation following ischemia-reperfusion under hyperglycemic conditions, suggesting that increased UPS activity elicits damaging effects on the heart. We recently established that benfotiamine (BFT)-vitamin B1 analog- improved cardiac function under similar experimental conditions by shunting flux away from the NOGP and lowering myocardial oxidative stress. In light of this, we hypothesized that BFT acts as a novel cardioprotective agent by diminishing myocardial oxidative stress and UPS activity in response to ischemia-reperfusion under acute hyperglycemic conditions. Hearts were excised from male Wistar rats and perfused ex vivo with Krebs-Henseleit buffer containing 33 mM glucose vs. controls (11 mM glucose) for 60 min, followed by 20 min global ischemia and 60 min reperfusion ± 100 μM BFT or 5 μM/L lactacystin (a specific UPS inhibitor) added during the first 20 min of the 60 min of reperfusion. In parallel experiments with similar treatments, we determined infarct sizes following 20 min regional ischemia and 120 min reperfusion. The data reveal that BFT enhanced functional recovery of LVDP at baseline (11 mM glucose) and hyperglycemia (33 mM) conditions with the highest dose (100 μM) triggering a robust effect early during the reperfusion period, reaching ~71.1 ± 5.9% ($p<0.01$ vs. respective control) under hyperglycemic perfusion conditions. BFT also reduced infarct sizes to 39.0 ± 2.5% and 49.7 ± 7.4% versus 52.3 ± 2.8% and 74.5 ± 4.9% at baseline and hyperglycemic perfusions, respectively. Likewise, lactacystin administration improved LVDP recovery and decreased infarct sizes following ischemia-reperfusion under hyperglycemic perfusion conditions. BFT treatment also attenuated myocardial oxidative stress and protein carbonylation, and blunted UPS activity. This study demonstrates that BFT may exert its cardioprotective effects by diminishing myocardial oxidative stress and UPS activity following ischemia-reperfusion under acute hyperglycemic conditions. Our findings suggest that the UPS may be a unique therapeutic target to treat ischemic heart disease in individuals that present with stress-induced, acute hyperglycemia.

Congenital Heart Diseases (CHD) and role of NKx 2.5 in Pakistani population

A. Arif, S. Qamarunissa, S. Zehra and A. Azhar

Biomedical Division, Karachi Institute of Biotechnology and Genetic Engineering (KIBGE), Karachi, Sindh, Pakistan

Congenital heart disease (CHD) is worldwide a major threat for children below the age of five, it has high mortality and morbidity ratio. The number is increasing 5% every year in USA, where figures are scanty in our population.

Introduction:

In Pakistan, the adult population with congenital heart diseases is increasing and consanguineous marriages, a custom in region in also playing a role in increasing CHDs. In our study we look social and genetic aspects for these diseases. Nkx 2.5, a transcription factor and first progenitor in cardiac formation. (Olson E. and Srivastava D., 1996) to date, no data is available about the mutations in this gene responsible for CHD in Pakistani population. Nkx 2.5 gene encodes 324 aa. contains a homeodomain (142-200aa) which is highly conserved among vertebrates.

Materials and Methods:

A cohort of 225, CHD patients who were registered at National Institute of Cardiovascular Diseases (NICVD) from 2005-2008 were included in the study; these are non syndromic and sporadic cases. Informed consents and detail family history was obtained. The cohort contains Atrial Septal Defect (ASD), Ventricular Septal Defects (VSD), Tetralogy of Fallot (TOF), Patent Ductus Arteriosus (PDA) and Dextro transposition of Great Arteries (DTGA). Control group (n= 120) is healthy unrelated individuals with mean age 4± 2.0. DNA was extracted and NKx 2.5 gene was amplified and sequenced to check mutations. (McElhinney, D. B., 2003)

Results:

CHD patients (n=225, 57% male and 43% female). Age ranges 0.001-17 yrs. mean age is 4.45 ± 3.5. More than 40 mutations are reported till date (Liu XY., et al, 2011). Our findings were five SNPs in our population. Out of these two are missense, two are in 5'UTR region and one is inframe deletion. These mutations are potent in damaging protein structure predicted by SIFT, mutation taster and polyphen.

Discussion:

CHD is a major cause of child death in the first year of life. Our study concludes a few aspects and will broaden it to other genes as it is a need to find aetiology of these diseases and to combat it with the modern genetic therapeutics.

Comparative effect of ciprofloxacin and levofloxacin on systolic, diastolic and mean arterial blood pressure values of dogs

O. Omobowale, O.A. Oridupa, B.O. Fabiyi, J.O. Abiola, T.O. Ajibade and T.E. Adeyeoluwa

University of Ibadan, Ibadan, Nigeria

Antibacterials are among the most commonly used drugs in veterinary medical practice. Among this class of therapeutic agents are the fluoroquinolones which have been widely employed both in veterinary and medical practices because of their excellent antibacterial activities and wide antibacterial spectrum. Despite these known beneficial effects of the fluoroquinolones, adverse reactions affecting several systems including the cardiovascular system have been reported. This study was designed to investigate the possible effect of two commonly used fluoroquinolone drugs, Ciprofloxacin and Levofloxacin on cardiac function in dogs using arterial blood pressure as clinical index

Eight apparently healthy male dogs were equally and randomly divided into 2 groups. Ciprofloxacin and Levofloxacin were orally administered respectively to each group at the dosage of 25mg/kg twice daily for 14 days.Noninvasive blood pressure measurements were taken 30 minutes before administration and thereafter on days 2, 5, 7, 10 and 14 of treatment. Data were analysed using ANOVA at a confidence level of 95%. Following the administration of ciprofloxacin, there was a drop in pre-treatment mean systolic blood pressure from 149.8±20.7 mm Hg to 132.0±8.2 mmHg on day two and further to 122.0±20.9 mmHg on day five. After day five, a gradual increase in the mean systolic blood pressure was observed on days 7 and 10 to 129.3±14.7 mmHg and 133.0±19.5 mmHg respectively. A further decrease in the mean systolic blood pressure was recorded on day 14 to 123.5±12.4mmHg. In the Levofloxacin group, a similar pattern was observed in dogs treated with an initial reduction of the pre-administration mean systolic blood pressure from 133.8±8.7 mmHg to 123.8±24.2 mmHg by day two of treatment and a rise to a peak of 145.8±10.0mmHg by day five of treatment. For these two treatment groups however, there were no statistically significant ($p>0.05$) differences between pre-administration and post-administration values recorded.

Mean diastolic blood pressure decreased in the ciprofloxacin group from 82.5±8.5 mmHg to 62.5±10.7 mmHg by day two of treatment but increased to 77.8±12.1 mmHg and 83.8±10.2 mmHg by days 5 and 7 respectively. Levofloxacin also caused a decrease in the mean diastolic blood pressure from 81.3±12.1 mmHg to79.8±9.3 mmHg on day 2 of treatment. These values increased to 98.5±11.3 mmHg by day five of treatment. There were no statistically significant ($p>0.05$) differences between pre-administration and post-administration Mean Arterial Pressure values for both groups.

From this study ciprofloxacin and levofloxacin did not appear to have any adverse effects on arterial blood pressure values in dogs at the dosage administered. Further work is however required to evaluate the possible effect of longer periods of treatment and higher dosages on blood pressure.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB009

Improvement of the anabolic-to-androgenic ratio of nandrolone decanoate by 5α-reductase inhibition worsen its cardiac effects

G.A. Brasil[1], E.F. Mata[1], A.M. Nascimento[1,3], E.M. Lima[1,3], I.C. Kalil[1], D.C. Endringer[1], G.A. Boechat[1], N.S. Bissoli[3] and T.U. Andrade[1,2]

[1]Pharmacy, UVV, Vila Velha, Espirito Santo, Brazil, [2]Pharmaceutical Sciences, Federal Uniersity of Espírito Santo, Vitoria, Espírito Santo, Brazil and [3]Physiological Sciences, Federal Uniersity of Espírito Santo, Vitoria, Espírito Santo, Brazil

Androgens can act directly on its receptors or via its dehydro metabolite. Its well determined that dehydrotestosterone is more potent than testosterone. Androgenic Anabolic Steroids (AAS) were developed to obtain a drug with its anabolic effect potentialized. Nandrolone decanoate (ND) is one of the most used AAS worldwide, mainly as drug of abuse to improve exercise performance and for aesthetic purposes. Dehydronandrolone (DHN) is less potent in acting on androgen receptor than ND itself. AAS has been implicated in cardiac side effects, such as cardiac hypertrophy, cytokine imbalance, and sudden cardiac death. But if ND or DHN are implicated remain to be evaluated. We investigated if the increase of the anabolic-to-

androgenic ratio of the ND by the inhibition of the 5α-reductase improves the cardiac side effects of ND on heart, especially on cardiac hypertrophy and cytokine imbalance. Male Wistar rats were divided into 3 experimental groups: control animals receiving the vehicle (CONT; n=8; peanut oil, I.M., wekly; 0.9% saline; i.p., daily), animals receiving ND (DECA; n=8; 10 mg.Kg-1, twice a week, I.M.; 0.9% saline; i.p., daily), and animals receiving ND (DECAF; n=8; DN 10 mg.Kg-1, twice a week, I.M.) plus finasteride (100 μg.kg-1, i.p., daily), for four weeks. Surgical procedures were performed under sodium pentobarbital anesthesia (50mg.kg-1, intra-peritoneal, Crystal, Brazil). The experiments were performed in accordance with the ethical principles for animal experimentation by the Brazilian College of Animal Experimentation and were approved by our Institutional Ethics, Bioethics and Animal Welfare Committee (Protocol 68/2009). After the treatment period, animals were euthanized, the hearts were removed for morphometric analyzes, and determination of the cardiac pro- (TNF-α) and anti-inflammatory (IL-10) cytokines. Values are expressed as the mean ± S.E.M, compared with ANOVA using Tukey s post hoc test. Figure 1 shows that animals from DECA group present myocyte hypertrophy. Increasing the anabolic-to-androgenic ratio by finastride action, worsen all the morphometric parameters. Figure 2 presents the results of the cardiac cytokine evaluation. ND treatment increase TNF-α level while reduce the cardiac IL-10 content, indicating that ND determines cytokine embalance. Finasteride co-treatment with ND worsens the imbalance on cardiac cytokine elevating the pro-inflammatory cytokine and reducing the level of IL-10, when compared with the isolated ND treatment. In conclusion, increasing the anabolic-to-androgenic ratio of ND, by 5-α-reductase inhibitions worsen the side effects of ND on cardiac myocyte and cytokine balance, indicating that ND itself, not the DHN, is more important to determine these effects.

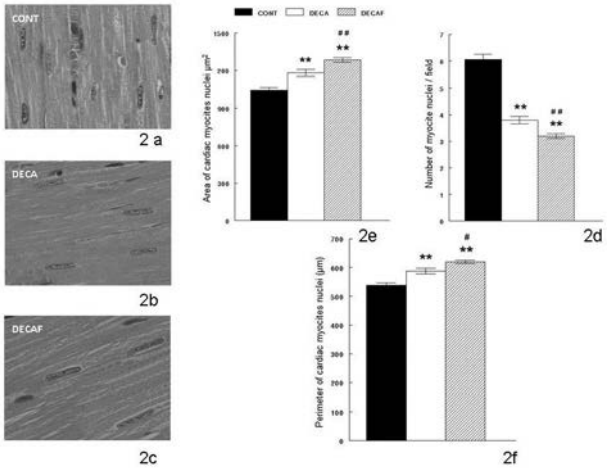

Figure 1: Hystological and morphometric analysis of hearts of CONT (2A), DECA (2B) and DECAF (2C) groups. The samples were stained with hematoxylin and eosin (H&E): 40x. 2D: number myocyte nuclei / high resolution field. 2E: myocytes nuclei area. 2F: myocyte nuclei perimeter. The values are expressed as the mean ± S.E.M, compared with ANOVA using Tukey s post hoc test. **p<0.01 compared with CONT group. #p<0.05 and ##p<0.01 compared with DECA group.

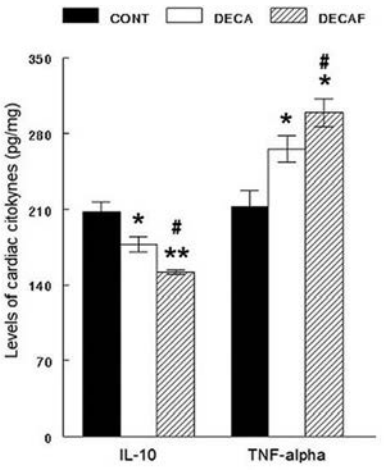

Figure 2: Effect of Nandrolone Decanoate plus Finasteride Treatment on cardiac inflammatory citokynes. There is an increase in pro-inflammatory (TNF-α) and reduced levels of anti-inflammatory (IL-10) cytokine on DECAF group compared with DECA and CONT. The values are expressed as the mean ± S.E.M, compared with ANOVA using Tukey s post hoc test. **p<0.01; *p<0.05 compared with CONT group. #p<0.05 compared with DECA group.

[1]Pharmacy, University Vila velha - UVV, Vila Velha, ES, Brazil, [2]Pharmaceutical Sciences, Federal University of Espírito Santo, Vitória, Espírtio Santo, UK and [3]Physiological Sciences, Federal University of Espírito Santo, Vitória, Espírtio Santo, UK

Anabolic androgenic steroids (AAS) lead to cardiac complications, and relationship among AAS, tumor necrosis factor alpha (TNF-α), and renin-angiotensin system (RAS) has been reported. Apoptosis is implicated in the shifting of the hypertrophic heart to the heart failure. The testosterone (T) in anabolic concentration induces apoptosis in cardiac myocytes. However, little is known about the relationship among testosterone, TNF-α, and RAS in this process. We investigated whether the apoptosis and the caspase-3 activity induced by testosterone in anabolic concentration involves the participation of the angiotensin converting enzyme (ACE) and TNF-α in cardiac myocyte cell culture (H9c2, ATCC). Cardiomyocytes were treated with testosterone (100 μM), doxorubicin (DOX; 5 μg/mL), T + etanercept (Eta; 100 μg/mL), T+losartan (Los; 10-7 M), and T+ Ac-DEVD-CHO (200 μM). The treatment time with testosterone alone or in combination in culture wells was 72 h. Cell viability was evaluated by the MTT assay in different concentrations of T (0,5-200 μM). Apoptosis was determined by flow cytometry, proteolytic activity of caspase-3, TNF-α quantification and ACE activity by ELISA method. Values are expressed as the mean ± S.E.M, compared by ANOVA, followed by the post-hoc Tukey test. T elicit a concentration-dependent decrease in cell viability (0.5 μM: 12.49±1.54%, 5 μM: 21.36±0.94%, 50 μM: 30.06±1.38%, 100 μM: 64.74±1.16%,

200 μM: 74.85±1.97%), and co-treatments with Eta (5.3±1.7%), Los (6.4±1.8%) or Ac-DEVD-CHO (12.9±3.5), reduced the effect of T in anabolic concentration (100 μM; 64.7±1.2%). T also induces apoptosis (concentration-dependent)(Figure 1) and increase in the proteolytic activity of caspase-3, which were reduced by the co-treatments (Figure 2). TNF-α and ACE activity were elevated by T treatment, and co-treatment with Los and Eta were able to reduce these effects (Figure 2). It is concluded that there is an interaction between testosterone, Ang II and TNF-α in inducting apoptosis and caspase-3 activity in cultured cardiac myocytes, which contributes to reducing the viability of these cells (cytotoxic effect) induced by testosterone in anabolic concentration.

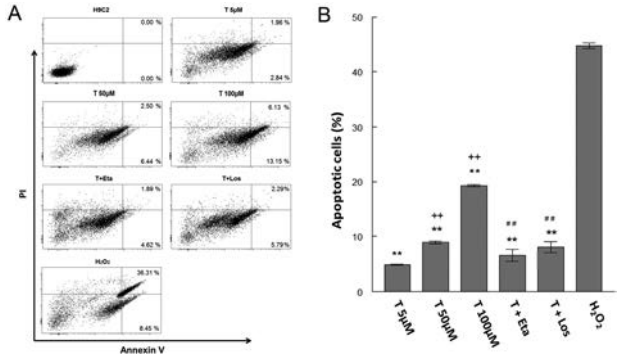

Fig. 1. Concentration-dependent apoptosis (5, 50, 100 μM) induced by testosterone (T) in H9c2 cells. After the treatment period of 72 h cells were stained with Annexin V-FITC and propidium iodide (PI) followed by analysis in the flow cytometer. Cells in the initial stage of apoptosis were defined as annexin-V(+)/PI(-), while late apoptotic cells were defined as double positive. Co-treatment with etanercept H9c2 cells (Eta, 100 μg/mL) or losartan (Los, 10-7M) reduced apoptosis induced by T. A, Data representative of three independent experiments. B, Percentage of apoptotic cells (sum of Annexin-V (+)/ PI(-) and double positive). Eta: etanercept; Los: losartan. Values are expressed as the mean ± S.E.M, compared by ANOVA, followed by the post-hoc Tukey test.; **p<0.01 compared to positive control (H2O2); ++p < 0.01 relative concentrations previous T; ##p < 0.01 compared to T 100 μM.

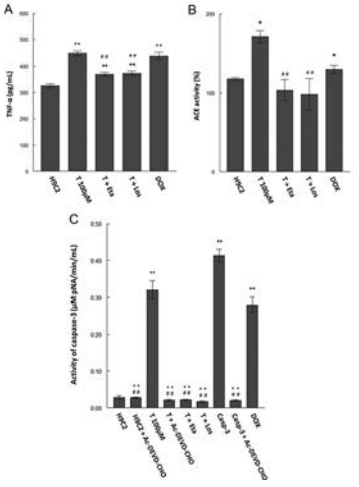

Fig. 2. Testosterone induces increased TNF-α, activity of ACE and caspase-3 activity in cardiomyocytes cells. Cells (H9c2) were treated with Testosterone (T) 100μM with or without co-treatment with etanercept (Eta, 100μg/mL) or losartan (Los, 10-7M); and Doxorubicin (DOX, 5μg/mL) or Ac-DEVD-CHO (200μM) for 72 h. A, Quantification of TNF-α. B, Evaluation of ACE activity. C, Evaluation of caspase-3 activity. Values are expressed as the mean ± S.E.M, compared by ANOVA, followed by the post-hoc Tukey test; *p<0.05 or **p<0.01 compared to control (H9c2). ++p<0.01 and +p<0.05 relative to caspase-3 (casp-3). # #p<0.01 compared to T 100 μM.

Enrichment of metabolic substrates diminish nitric oxide synthase-mediated anti-adrenergic effect of insulin in LV myocytes from normal and hypertensive rats

Z. Zhao, C. Jin, S. Kim and Y. Zhang

Physiology, Seoul National University College of Medicine, Seoul, Republic of Korea

Background & Aim: Metabolic syndrome (MetS) triggers abnormal insulin signaling and insulin resistance, which is associated with impaired nitric oxide (NO) availability. Endothelial NO synthase (eNOS) has been link to insulin signaling but the role of neuronal NOS (nNOS) remains unknown. Recently, nNOS is shown to be up-regulated in hypertensive left ventricular (LV) myocardium (HP). Here, we tested whether enriching metabolic substrates in vitro affects insulin regulation of LV myocyte contraction and the functional contribution of nNOS in normal and in HP rat LV myocytes.

Materials & Methods: LV myocytes were isolated using enzymatic dispersion technique from normal and angiotension II-induced hypertensive rats (*via* osmotic minipump, 125 ng/min/kg, 10-12 weeks, males). Myocyte contraction was assessed by using a video-sarcomere detection system (IonOptix Corp, field stimulation at 2 Hz, 36 ± 1˚C). Metabolic substrates (oleic acid 200 μM, palmitic acid 100μM, linolic acid 100μM, lactate 1mM, pyruvate 100μM and carnitine 50μM) were supplemented (termed nutrition full, NF solution) to the normal tyrode (NT) solution. Insulin (1-10 nM), isoprenaline (ISO, 10-50 nM), S-methyl-L-thiocitrulline (SMTC, 100 nM), L-NG-nitroarginine methyl ester (L-NAME, 1 mM) and n-acetyl cysteine (NAC, 1 mM) were used in the study.

Results: Our results demonstrated that sarcomere shortenings were greater with NF in both normal and HP under basal conditions (P<0.0001, n=19 in normal and P<0.0001, n=8 in HP) and after ISO treatment (P=0.0003, n=14, n=24 in normal and P<0.0001 n=15, n=8 in HP). NAC did not affect NF increases in myocyte contraction in normal (P=0.003, n=6) and in HP (P=0.02, n=5). In normal rats, insulin pre-treatment abolished ISO-stimulation of LV myocyte contraction with NT (P=0.8, n=27) but not with NF (P<0.001, n=20), suggesting impaired insulin response in NF. L-NAME, but not SMTC, prevented the anti-adrenergic effect of insulin in these rats (L-NAME: P=0.004, n=6; SMTC: P=0.16, n=9). In contrast, ISO failed to increase LV myocyte contraction with NT in HP (P=0.1, n=15); SMTC restored the positive inotropic effect of ISO (P=0.004, n=6). The inotropic response of ISO in HP was not affected by insulin (P=0.3, n=11 in NT; P<0.0001, n=11 in NF). SMTC or L-NAME did not affect myocyte contraction the effect of ISO with NF in HP (P=0.8, n=11, n=7 with SMTC; P=0.3, n=11, n=5 with L-NAME).

Conclusion: Our results show that eNOS mediates anti-adrenergic effect of insulin in normal rat LV myocytes and nNOS exerts such an effect in HP. *In vitro* enrichment of metabolic substrates diminished insulin responsiveness in LV myocytes by attenuating the role of NOS. Downstream mechanisms mediating impaired insulin signaling in cardiac myocytes in metabolic syndrome and in HP warrant further study.

Coronary perfuse pressure is associated with angiotensin-converting enzyme (ACE) in female and with ACE2 activity in male SHR

N. Bissoli[1], P.L. Dalpiaz[1], S.G. Figueiredo[1], A. Lamas[1], I.F. Caliman[1], A. Medeiros[2], T. Andrade[3], M. Alves[4], A.K. Carmona[4], W. Gonçalves[5] and M. Moysés[1]

[1]UFES, Vitória, Brazil, [2]Federal Institute of Espirito Santo, Vila Velha, Brazil, [3]Department of Pharmacy, University Vila Velha, Vila Velha, Brazil, [4]Department of Biophysics, Escola Paulista de Medicina, Federal University of São Paulo, São Paulo, Brazil and [5]UNESC, Colatina, Brazil

The renin-angiotensin system (RAS) plays an important role in the pathophysiology of cardiovascular disease (CVD). ACE (angiotensin-converting enzyme) 2 degrades Ang (angiotensin) II, the main effector of the classic RAS, and generates Ang-(1-7). Thus, ACE2 plays a crucial role in the RAS because it opposes the actions of Ang II. However, the activity of ACE and ACE2 and the relationship between theses enzymes with coronary perfusion pressure (CPP) in male and female spontaneously hypertensive rats (SHR) remain unclear and were our objectives. The procedures were approved by the Ethical Committee of the Federal University of Espírito Santo (023/2009). Female and male SHR rats were divided into 4 experimental groups: sham and castrated. After 51 days of the castration, the rats were anesthetized with ketamine (70 mg/kg i.p.) and xylazine (10 mg/kg i.p.) and their hearts were immediately excised. Studies on the coronary vascular bed were performed on whole hearts using a Langendorff preparation for perfused isolated hearts and were perfused with modified Krebs solution, equilibrated with 95% oxygen and 5% carbon dioxide at a controlled pressure of 100 mmHg to give a pH of 7.4. Langendorff preparations were perfused at a rate of 10 mL/min with a peristaltic pump. After the CPP were measured, the coronary were isolated and the ACE and ACE2 activity were evaluated by fluorimetry. Female rats exhibited a higher CPP (125±5 mmHg, $p<0.05$), ACE (110±15 AFU, $p<0.05$) and ACE2 (0.1±0.02 AFU, $p<0.05$) activity than the male rats (CPP: 85±3 mmHg; ACE 60±3 AFU and ACE2 0.06±0.002 AFU). Castration reduced the ACE (32±3 AFU) and CPP (90±5 mmHg) in the female rats but did not affect ACE2 (0.09±0.002), while in the male rats the CPP (145±6 mmHg) and ACE2 (0.03±0.001 AFU) were increased and ACE (46±5 AFU) activity was reduced. One of the main findings of this study was the observation of sex dimorphisms among CPP, ACE and ACE2 activity and the different relationship of RAS on CPP in SHR, dependent of the sex. In female SHR the CPP is associated with ACE, while in male rats is with ACE2 activity. The present results may contribute to understand the sex differences in the regulation of cardiovascular system and the incidence of cardiovascular disease in women.

Elevated myocardial oxygen consumption during cutaneous cold stress in young adult overweight and obese Africans

T.A. Olaniyan[1,2] and L.A. Olatunji[1]

[1]Physiology, University of Ilorin, Ilorin, Nigeria and [2]Public Health, The University of Northampton, Northampton, UK

Increased adiposity has been associated with high risk of developing hypertension and cardiovascular disease (1,2). Exaggerated sympathetic-mediated cardiovascular responses to stressful stimuli (such as exposure to cold) has been linked to the development of hypertension and cardiovascular disease (3,4), which in turn has been demonstrated to predict the development of future hypertension (5). The rate-pressure product (RPP) is considered as the best indirect method to evaluate myocardial oxygen consumption (MVO_2) as well as an indicator of myocardial stress. The aim of the present study was to test the hypothesis that enhanced change in RPP to cutaneous cold stress may be one potential mechanism that predisposes overweight/obese individuals to developing hypertension. We determined heart rate (HR), blood pressure (BP), and RPP in 40 normotensive young individuals aged between 18 – 25 years at baseline and during sympathetic activation elicited by cutaneous cold stimulation (CCS). Following CCS, a change in RPP was also estimated. The median body weight of 59.50kg of the study population was used for classification. This was further standardized by also classifying the participants based on their body mass indices (BMI). There was no significant differences in the baseline RPP between the groups classified by body weight ($P=0.629$) or among the groups classified by BMI ($P=0.415$). However, following CCS, there was a significant enhanced RPP change in overweight individuals ($P=0.019$). Furthermore, multivariate regression analysis showed that BMI, but not body weight had a significant influence on RPP variation following CCS. Thus, it can be concluded that normotensive overweight or obese individuals have an exaggerated RPP response to the CCS. However, exposure to cold may augment sympathetic reactivity in overweight/obese individuals, which may contribute to increased risk of developing myocardial dysfunction, even in young normotensive individuals. Furthermore, RPP changes to CCS could be a useful simple measure for early detection of cardiac complications, particularly in low/middle income countries.

Diurnal variation in sympathetic control of excitation-contraction coupling: the role of β3 adrenoceptors and nitric oxide

H.E. Crumbie, G.C. Rodrigo and I. Squire

Department of Cardiovascular Sciences, University of Leicester, Leicester, UK

We have previously shown a time-of-day variation in the response of systolic $[Ca^{2+}]_i$ to the non-specific β-adrenergic (β-ADR) agonist isoproterenol (ISO), linked to a variation in Nitric Oxide (NO) signalling [1]. This may reflect stimulation of β3-ADRs, which induces a NO-dependent negative inotropic response [2]. As the action potential duration (APD) regulates systolic $[Ca^{2+}]_i$, and a time-of-day variation exists in the cardiac action potential [3], we set out to investigate the effect of β3-ADR stimulation and NO-signalling on the APD and systolic $[Ca^{2+}]_i$.

Ventricular myocytes were isolated by enzymatic digestion at time points corresponding to 3 hours into the male Wistar rats rest (ZT3) and active-period (ZT15). Measurement of systolic $[Ca^{2+}]_i$ was made in myocytes loaded with Fura-2 and APD using the whole-cell patch clamp technique.

A significant time-of-day variation was found in systolic $[Ca^{2+}]_i$ following stimulation with ISO (10nM), a non-specific β-ADR agonist, which was higher in ZT3 (1040.0 ± 116.9nM) compared to ZT15 myocytes (428.0 ± 63.1nM) (n=3, S.E.M., 2-way ANOVA, $P<0.001$). The difference in systolic $[Ca^{2+}]_i$ during ISO stimulation was abolished following inhibition of NOS with L-NNA (500μM) (2-way ANOVA, *ns*). To determine whether this time-of-day variation in response to ISO can be explained by a variation in AP configuration in response to β-ADR stimulation, APD at 30% (APD_{30}) and 50% (APD_{50}) were recorded. ISO stimulation increased APD_{30} and APD_{50} significantly more in ZT15 than ZT3 myocytes, with % increase in APD_{30} of 120.3 ± 14.9% in ZT15 compared to 10.6 ± 8.2% in ZT3 myocytes (n=3, S.E.M., students t-test, $P<0.001$), and APD_{50} of 95.9 ± 13.2% in ZT15 compared to 11.6 ± 7.4% in ZT3 myocytes (n=3, S.EM., students t-test, $P<0.001$). We also investigated systolic $[Ca^{2+}]_i$ and APD in ZT3 and ZT15 myocytes in response to the specific β3-ADR agonist BRL37344 (200nM), to determine if time-of-day variation in systolic $[Ca^{2+}]_i$ following ISO-stimulation could be explained by variation in β3-ADR signalling. A significant reduction in systolic $[Ca^{2+}]_i$ in ZT3 myocytes was found following BRL37344 stimulation, from 458.5 ± 41.2nM to 361.2 ± 18.0nM (n=4, 2-way ANOVA, $P<0.001$) but no effect on ZT15 myocytes. BRL37344 also significantly reduced APD_{30}, (18.3 ± 2.2ms to 14.4 ± 1.6ms) (n=5, 2-way ANOVA, $P<0.001$), and APD_{50} (32.9 ± 4.3ms to 26.5 ± 3.1ms) (n=5, 2-way ANOVA, $P<0.001$) in ZT3 myocytes with no significant change in ZT15 myocytes.

Our data shows a reduction in systolic $[Ca^{2+}]_i$ in rest-period myocytes (ZT3) in response to β3-ADR stimulation, which may reflect the reduction in APD. This suggests that the reduced response of systolic $[Ca^{2+}]_i$ to ISO-stimulation in active-period myocytes (ZT15) is not due to a strong negative inotropic action of β3-ADR activation during the active period.

PCB015

Acute pre- or –post, ischaemic treatment with elevated extracellular glucose imparts a cardioprotection to isolated cardiomyocytes

C.E. Poile, I.B. Squire and R.D. Rainbow

Cardiovascular Sciences, University of Leicester, Leicester, UK

Reperfusion of the myocardium after an ischaemic insult can cause marked and irreversible damage. Minimizing infarct size is important for improving prognosis after a prolonged ischaemia. A number of cardioprotective interventions have been demonstrated to improve the outcome after myocardial infarction, including ischaemic pre-and post-conditioning and pharmacological pre-treatment (1, 2, and 3). Here we present data demonstrating that perfusing isolated cardiomyocytes for a short period of time with elevated extracellular glucose prior to, or following, the ischaemic insult, gives a marked cardioprotection. Adult male Wistar rats were culled humanely in accordance with Home Office guidelines and cardiomyocytes were enzymatically isolated. Contractile function of the isolated cardiomyocytes was assessed using a simulated ischaemia/reperfusion injury protocol, where cardiomyocytes were stimulated to contract at 1Hz by electrical field stimulation and perfused with Normal Tyrode (NT) solution at 32±2°C. Ischaemia was simulated using a metabolic inhibition (MI) solution of Substrate-Free Tyrode solution containing cyanide (2mM) and iodoacetic acid (1mM) for 7 minutes, followed by 10 minutes of 'reperfusion' with NT. Our data shows that supplying cardiomyocytes with a 5 minute pre-treatment of an elevated extracellular glucose concentration (20mM) prior to simulated ischaemia significantly increases the percentage of cardiomyocytes able to regain contractile function from 29.5±2.4% (control) to 61.8±2.4%*** (Results presented as mean ±S.E.M; N= 6 experiments, ≥116 cardiomyocytes for each experiment, ***P<0.001 Bonferroni's post-hoc test). Additionally, supplying 20mM glucose for only the first 5 minutes of the 10 minute reperfusion stage significantly increases contractile recovery to 62.8±4.8%*** (Results presented as mean ±S.E.M; N= 6 experiments, ≥115 cardiomyocytes for each experiment, ***P<0.001 Bonferroni's post-hoc test). These data show that both pre- and post-treatment of isolated cardiomyocytes with an acute elevated glucose concentration imparts a degree of cardioprotection. We hypothesise that there is increased glycolytic substrate availability during ischaemia after pre-treatment with 20mM glucose. For cardiomyocytes treated with elevated glucose on reperfusion it is hypothesised to give a more gradual ATP delivery therefore reducing reperfusion injury.

Induced automaticity in the ventricular myocytes of transgenic mouse overexpressing HCN2

K. Oshita[1,2], S. Igata[1], Y. Kuwabara[3], K. Kuwahara[3], K. Ushijima[2] and M. Takano[1]

[1]Department of Physiology, Kurume University School of Medicine, Kurume, Japan, [2]Department of Anesthesiology, Kurume University School of Medicine, Kurume, Japan and [3]Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan

Hyperpolarization-activated cyclic nucleotide-gated channels (HCNs) are expressed in the ventricle of fetal hearts, and are silenced during the development. These channels are up-regulated in the hypertrophied heart, and have been suggested to underlie arrhythmogenesis. To test this hypothesis, we generated a transgenic mice overexpressing HCN2 in the heart (HCN2-Tg) using alpha-MHC promoter, and analyzed the electrophysiological properties of ventricular myocytes.
Mice (8-12 weeks old) were deeply anesthetized with 3% sevoflurane. Ventricular myocytes were isolated with collagenase digestion. Action potential and membrane currents were recorded with ruptured whole-cell patch clamp method using standard high K^+ pipette solution. Values are means ± S.D. Statistical analysis was carried out using Student`s T-test. We first confirmed that amounts of mRNA and protein of HCN2 were significantly higher in HCN2-Tg than wild type (WT). However, contrary to our expectation, HCN2-Tg was not vulnerable to arrhythmia. In physiological bathing solution, the resting potential (RMP) of ventricular myocyte was not significantly different between WT (-81.5±1.0 mV) and HCN2-Tg (-81.6±1.6 mV, n=8, p=0.42). No spontaneous action potential (SAP) was recorded in HCN2-Tg myocytes, although robust HCN current (I_h) was recorded in the presence of 1 mM Ba2+. However, application of 0.3 μM isoproterenol (iso) to HCN2-Tg myocytes depolarized their RMP and subsequently induced SAP in 71%, coincident with the shifting of voltage-dependent activation curve of I_h; the voltage for the half maximal activation was -118.5±2.9 mV (control), and -90.2±1.5 mV (iso), respectively (n=4, p <0.01). In HCN2-Tg myocytes without SAP, RMP was significantly more depolarized (-77.2±2.1 mV) than that of WT (-82.1±1.0 mV, n=8, P<0.01). 3 μM ivabradine (iva), a specific HCN channel blocker, reversed iso-induced depolarization to the control level. We further compared the AP waveform elicited by electrical stimulation in WT and HCN2-Tg myocytes without SAP. In HCN2-Tg, action potential duration (APD) at -60 mV was significantly prolonged, and the rates of repolarization at -60 mV were significantly slower, both in the presence and absence of 0.3 μM iso. On the other hand, APD at 0 mV was significantly shorter in HCN2-Tg, most probably due to the outward tail current of I_h. When the myocytes were perfused with 3 mM K^+ bathing solution, RMP was -95.6±1.5 mV in WT, and -91.2±3.3 mV in HCN2-Tg (n=6, p<0.01). Under this condition, SAP was induced in 57% of HCN2-Tg myocytes. Application of 3 μM iva hyperpolarized RMP in HCN2-Tg.
These findings suggested overexpression of HCN2 potentially increased the vulnerability to arrhythmia, particularly in pathological conditions such as excessive β adrenergic stimulation or hypokalemia.

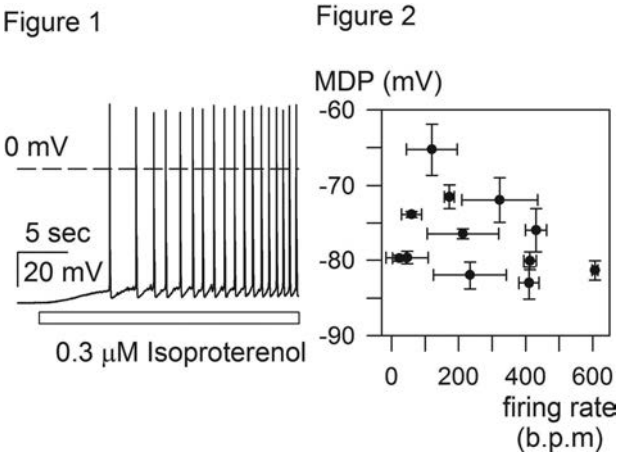

Figure1. Induced automaticity of HCN2-Tg ventricular myocytes. The white bar indicates the application of 0.3 μM iso. Depolarization of RMP is followed by SAP. Figure 2. The scatter plot of maximal diastolic potential (MDP) and firing rate of iso-induced SAP in HCN2-Tg myocytes.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Arrhythmogenic profile of the atrium and atrioventricular node in pulmonary arterial hypertension

I.P. Temple[1], G.M. Quigley[1], O. Monfredi[1], T.T. Yamanushi[2], M. Zi[1], E.J. Cartwright[1], V.S. Mahadevan[1], M.R. Boyett[1] and G. Hart[1]

[1]Medicine, University of Manchester, Manchester, greater manchester, UK and [2]Kagawa Prefectural College of Health Sciences, Kagawa, Japan

Introduction:
Arrhythmias are common in pulmonary arterial hypertension (PAH) causing severe symptoms and sudden death. Current treatments are often ineffective and have considerable side effects and therefore new therapies are required.
Methods:
Male Wistar rats (200 g) were injected with either monocrotaline (MCT) (60 mg/kg) or saline (control). They were sacrificed if they showed clinical deterioration or on day 28. *In vivo* echocardiography and ECG were performed under isofluorane anaesthesia. For whole heart experiments, the heart was excised and mounted on a Langendorff perfusion column at 37°C. For right atrial (RA)/atrioventricular (AV) node experiments, a tissue preparation was superfused at 37°C. Baseline ECG and atrio-His (AH) interval were recorded. Stimulation protocols were used to measure conduction velocity (CV) along the crista terminalis, AV effective refractory period (AVERP) and AV functional refractory period (AVFRP). Optical mapping was used to record the activation sequence across the right atrium.
Results:

Echocardiography demonstrated PAH (decrease in pulmonary artery acceleration time and increase in pulmonary artery deceleration) and right ventricular (RV) hypertrophy (increase in RV wall thickness) in the MCT rats. The whole heart experiments demonstrated an increase in AVERP and AVFRP in the MCT rats. The isolated RA/AV node preparation demonstrated a reduction in CV along the crista terminalis and a high incidence of complete heart block in the MCT rats (Table 1). The decrease in CV was supported by the optical activation sequences.

Conclusions:

Our data demonstrate slow atrial conduction and impaired AV node function in PAH which may serve as a basis for supraventricular arrhythmias. Reversing these changes is a potential theraputic target.

The effects of gastric afferent autonomic activity on cardiac efferent autonomic balance in healthy human volunteers

L.C. Kazadi, J. Fletcher and P. Barrow

Biomedical Science and Physiology, University of Wolverhampton, Wolverhampton, UK

Cardiovascular responses induced by drinking water are blood hypo-osmolality dependent, mediated by TRPV4 receptors in the periphery and osmoreceptors in the CNS acting through sympathetic autonomic efferents1,2, rather than being related to either blood volume loading, or gastric distension1. We investigated the effects of the temperature and hypoosmolality of ingested drinks on cardiovascular parameters in healthy human volunteers who ingested 300ml of either isotonic saline solution or water at either 37 or 6 0C (n=9, aged 24±3 years). Written informed consent was obtained, and the studies were approved by the University of Wolverhampton Life Science Ethics Committee. Factors known to alter autonomic balance were controlled. Following an acclimatisation period (≥20 min.), heart rate (HR) and blood pressure (BP) were continuously monitored using a Finapres device (Ohmeda Ltd). Lead 2 of 3-lead ECG and pneumotrace respiratory strap were used to record ECG and respiratory movements. Subjects' ventilation was paced at 0.2 Hz, to standardise ventilatory function. Recordings lasted for 2 hours and were separated by at least one week. Five minutes of baseline recording were made prior to drink ingestion, followed by 5 minute recordings as various intervals. Cardiac vagal and sympathetic tone were assessed offline using time and frequency domain analysis of R-R interval variability and analysis of corrected QT interval (QTc).Cold saline decreased HR for 110 minutes (mean 2.035±0.26 beats/min reduction, p<0.01, paired t-test), with an increase in parasympathetic tone (mean 14.68±3.67 msec increase in RMSSD, p<0.01, paired t-test), with a concomitant reduction in systolic BP up to 20 minutes after ingestion (mean 11.5423±3.53 mmHg reduction in SBP, p<0.1, paired t-test). Conversely the combined hypo-osmolarity and cold effects of drinking cold water decreased HR for only 40 minutes (mean 3.15±0.86 beats/min reduction, p<0.01, paired t-test), with an increase in parasympathetic tone (mean 25.68±3.63 msec increase in RMSSD, p<0.05, paired t-test) and a fall in systolic BP up to 20 minutes after the drink (mean 5.8±0.45 mmHg reduction in SBP, p<0.1, paired t-test). Analysis of QTc following cold water ingestion indicated a shortening of QTc up to 80 minutes (mean 9.71±0.94 msec reduction in Qtc, p<0.01, paired t-test)3 after which it lengthened (mean 1.38±0.67 msec increase in Qtc, p>0.05, paired t-test) indicating a possible cardiac sympathetic withdrawal in the short term, but sympathetic reintroduction over the longer term. We conclude that the ingestion of the cold saline drink caused an increase in cardiac parasympathetic autonomic tone up to 110 minutes, but this was truncated with cold water drinking due to sympathetically mediated hypo-osmolarity effects leading to CVS parameters returning to near-resting levels.

The transmembrane proteoglycan syndecan-4 regulates cardiac myofibroblast differentiation in response to pressure overload, affecting extracellular matrix composition and myocardial stiffness

K.M. Herum[1,2], I.G. Lunde[1,2], B. Skrbic[1,3], W.E. Louch[1,2], A. Hasic[1,2], I. Sjaastad[1,2], A. Unger[4], W.A. Linke[4], M.F. Gomez[5] and G. Christensen[1,2]

[1]Institute for Experimental Medical Research, Oslo University Hospital and University of Oslo, Oslo, Norway, [2]KG Jebsen Cardiac Research Centre and Center for Heart Failure Research, University of Oslo, Oslo, Norway, [3]Department of Cardiothoracic Surgery, Oslo University Hospital Ullevål, Oslo, Norway, [4]Department of Cardiovascular Physiology, Ruhr University Bochum, Bochum, Germany and [5]Department of Clinical Sciences, Lund University, Malmö, Sweden

Pressure overload of the heart leads to remodeling of the left ventricle involving hypertrophic remodeling of cardiomyocytes and excessive production of extracellular matrix by activated cardiac fibroblasts that differentiate into contractile myofibroblasts. This compromises heart function by increasing the myocardial stiffness. The molecular mechanisms underlying stress-induced myofibroblast differentiation and the role of this process in regulating cardiac stiffness are poorly defined. We recently identified the focal adhesion proteoglycan syndecan-4 as important for myofibroblast differentiation in response to mechanical stress. Here we investigate the role of syndecan-4 in regulating myocardial stiffness and left ventricular remodeling of the extracellular matrix in response to pressure overload.

Aortic banding, performed under anaesthesia, caused a ~6-fold increase in collagen I and III mRNA in the left ventricle of wild-type (WT) mice. Remarkably, this response was completely absent in mice lacking syndecan-4. mRNA levels of the collagen cross-linking enzyme lysyl oxidase (LOX) were also dramatically increased in WT left ventricles, whereas this response was blunted in syndecan-4 knock-out (KO) mice, suggesting a potentially impaired collagen cross-linking following mechanical stress in mice lacking syndecan-4. Supporting these findings, cardiac fibroblasts from syndecan-4 KO mice had lower expression of collagen I and III and LOX when plated on fibronectin in vitro, a model previously shown to induce myofibroblast differentiation. To assess the effect of syndecan-4 deletion on mechanical properties, we measured passive tension of muscle fiber bundles from left ventricular tissue of syndecan-4 KO mice. Passive tension was reduced in cardiac tissue from syndecan-4 KO mice compared to WT and increased in both genotypes following aortic banding, albeit to a lower degree in mice lacking syndecan-4. Salt extraction of myosin and actin filaments was performed to eliminate the effect of titin, a cardiomyocyte protein which is central in determining passive tension. Passive tension after salt extraction was affected equally in muscle fiber bundles from WT and syndecan-4 KO mice, indicating that the reduced passive tension in mice lacking syndecan-4 was due to alterations in the extracellular matrix and not changes in cardiomyocyte titin. Supporting this, no isoform shift of titin was detected in left ventricles of WT and syndecan-4 KO mice.

In conclusion, we demonstrate reduced passive tension in hearts of mice lacking syndecan-4, possibly due to inhibited differentiation of fibroblasts into myofibroblasts, reduced extracellular matrix production and attenuated collagen cross-linking.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

AmphiphysinII controls t-tubule formation in cardiac muscle

J.L. Caldwell, D.A. Eisner, K.M. Dibb and A.W. Trafford

University of Manchester, Manchester, UK

Regular invaginations in the surface membrane of ventricular myocytes, known as transverse tubules (t-tubules), enable synchronous intracellular Ca release, facilitating contraction. Evidence shows t-tubules are remodelled in several models of heart failure (HF), leading to delayed asynchronous Ca release. It remains unclear how t-tubule structure and function change during cardiac disease. Previous data indicates a role for Amphiphysin (AMPII) where KO models of AMPII lead to t-tubule disruption, similar to observed in HF (1). We aim to investigate if a) t-tubules and AMPII are reduced in a sheep model of HF; b) t-tubule biogenesis depends on the presence of AMPII; c) loss of AMPII leads to asynchronous Ca release.

Under isoflurane anaesthesia (2-4% v/v oxygen) sheep were instrumented with a pacemaker and pacing lead. Post-operative analgesia (meloxicam 0.5mg/kg) and antibiosis (enrofloxacin 2.5mg/kg) were provided for 24hrs. HF was induced by right ventricular tachypacing at 210bpm for 4-5wks (2). Upon sacrifice, left ventricular (LV) and atrial (LA) myocytes were isolated and tissue samples were snap frozen. T-tubule density was assessed using di4ANEPPS and confocal microscopy (3). Data presented as mean±SEM statistical significance $p<0.05$ (t-test). The distance at which 50% of pixels in sheep HF cells are from a membrane compared with control increases (18±3.3% $p<0.05$ n=7). Western blotting on samples obtained from LV and LA showed a reduction in AMPII protein in HF (LV 24±7.5%, LA 35±12.3% n=7 $p<0.05$). Western blotting shows a reduction in AMPII in atria compared to ventricle in; rat, 58±6.7%, ferret, 55±9.8%, sheep, 27±9.6%, n=7.

Transfecting rat ventricular myocytes with siRNA against AMPII causes t-tubule loss. The distance at which 50% of pixels in target cells are from a membrane compared with scrambled cells increases 50±6.6% $p<0.05$ n=20. Western blotting on transfected cells shows AMPII reduces 14±3.2% $p<0.05$ n=18 in target cells, compared with scrambled. Pearson's coefficient performed on paired data shows the distance at which 50% pixels in target cells are from a membrane increases as AMPII decreases $p<0.05$ n=18. Immunocytochemistry was used to confirm loss of AMPII in transfected cells. Transfected cells, loaded with Fluo-3 AM and field stimulated, showed asynchronous Ca release. The STDEV of time to reach 50% peak fluorescence for each pixel of the line scan increases 159±43.8% $p<0.05$ n=9 in cells transfected with AMPII siRNA compared with cells transfected with scrambled siRNA.

AMPII protein expression is reduced in a sheep model of tachypacing induced HF in both atria and ventricle and in the atria of species that lack t-tubules. There is also a loss of t-tubules in cells transfected with siRNA against AMPII, suggesting AMPII plays a role in the maintenance of t-tubules. This reduction results in asynchrous Ca release, likely to cause reduced contractility and HF.

Does the crista terminalis possess a key role in the elevated risk of arrhythmogenic episodes in the elderly population?

F.S. Hatch[1], M.K. Lancaster[2] and S.A. Jones[1]

[1]University of Hull, Hull, UK and [2]University of Leeds, Leeds, UK

We have previously reported changes in intracellular calcium handling and associated protein expression within the sinoatrial node (SAN) during ageing (Hatch et al, 2012; Jones et al, 2007). It is however unknown whether other parts of the conduction pathway within the atria, specifically the crista terminalis (CT) and right atrial (RA) muscle itself undergo similar changes. Implicated in atrial arrhythmia generation, changes in the properties of the CT may predispose to ectopic activity and arrhythmias such as atrial fibrillation. Therefore, our study examined the expression of calcium handling proteins across the right atria including the SAN and CT.
Male Wistar rats at the ages of 6 months (young) and 24 months (old) (n=5) were sacrificed by intraperitoneal anaesthetic overdose of pentobarbital. The right atrium was removed and dissected to isolate the CT, SAN and RA muscle. Western blot and immunocytochemistry were used to examine the protein expression of sarcoendoplasmic reticulum Ca2+ ATPase pump (SERCA2a), phospholamban (PLB), ryanodine receptors (RYR2), L-type calcium channels (Cav1.2) and the sodium-calcium exchanger (NCX1). Data are presented as mean±SEM, assessed by t-test or two-way ANOVA as appropriate. Ethical approval was given by the University of Hull.
When compared with the RA in the young animal; the CT consistently exhibited reduced expression of all calcium-regulatory proteins studied, whilst the SAN possessed reduced protein levels of RYR2 and NCX1. Ageing significantly decreased Cav1.2 protein expression by 40.3±2.6% in the SAN from old animals (p=0.009), but conversely in the CT ageing increased of Cav1.2 expression (64.4±3.9%; p=0.011). Similarly with age RYR2 protein levels fell by 32.0±0.2% within the SAN (p=0.03), but rose by 63.8±5.0% (p<0.001) in the CT from old animals. By contrast NCX1 expression remained the same for both ages in the CT, but was up-regulated by 72±13.5% in the aged SAN (p=0.009). SERCA2a regulation was assessed by the ratio of SERCA2a to monomeric PLB. In young animals there was no significant difference in the ratio across the SAN, CT or RA. Ageing evoked a significant decline in the ratio, 29±8.5% within the SAN and a larger reduction of 40±8.5% in the CT (p<0.001). In contrast, there was a non-significant drop of 12±4.5% in the RA.
In conclusion ageing had heterogeneous effects on the expression of calcium regulatory proteins across the right atria. The loss of calcium influx and release channels in the SAN is likely to lead to a reduction in the ability of the pacemaker to operate, despite a potential counter-effect of increasing NCX. In contrast the changes in the CT may increase the likelihood to form an ectopic pacemaker, destabilising the atria and increasing susceptibility to arrhythmias in old age.

Ageing further increases the diversification between the atria in the expression of cellular calcium regulators: a substrate for increased arrhythmia risk?

F.S. Hatch[1], J.S. Waby[1], M.K. Lancaster[2] and S.A. Jones[1]

[1]University of Hull, Hull, UK and [2]University of Leeds, Leeds, UK

At present ~20% of the Western population are over 65 years of age, and by 2050 this is predicted to increase to 25% [Cracknell, 2010]. The risk of atrial arrhythmias progressively increases in an age-dependent manner presumably due to structural and functional remodelling however the full details of this remains unknown. Our study has examined the effect of age on the protein expression of key calcium regulators and their mRNA expression across the atria.
Male Wistar rats at the age of 6 months (young) and 24 months (old) (n=5) were sacrificed by an intraperitoneal anaesthetic overdose of pentobarbital. The right atrium (RA) and left atrium (LA) of each heart were assessed for changes in sarcoendoplasmic reticulum Ca^{2+} ATPase pump (SERCA2a), phospholamban (PLB), ryanodine receptors (RYR2), L-type calcium channels (Cav1.2) and sodium-calcium exchanger (NCX1). Western blot and immunocytochemistry were used to identify changes in protein expression and quantitative PCR changes in mRNA levels. Data are presented as mean±SEM, assessed by t-test or two-way ANOVA as appropriate (p<0.05). Ethical approval was given by the University of Hull.
A comparison of atria in the young rat identified in the LA significantly higher protein levels of SERCA2a by 65.7±7.89% (p<0.001) and RYR2 60.7±8.09% (p<0.001), which correlated with elevated levels of mRNA in the LA for SERCA2a (92.2±7.8%; p=0.001) and RYR2 (27.5±4.8%; P=0.007). Ageing instigated a significant decline in all the investigated proteins within the RA; Cav1.2 fell by 46.4±6.2% (p=0.005), RYR2 by 25.7±4.11% (p=0.012), SERCA2a by 51.2±10.7% (p=0.009) and NCX1 by 57.1±3.63% (p=0.001), however there were no significant changes in their mRNA levels. In contrast the LA exhibited an increase of protein levels for Cav1.2 (52.5±2.5%, p=0.022) and NCX1 (27.5±2.9%, p=0.034), but in terms of mRNA levels only NCX1 significantly increased by 33.5±5.3% (p=0.005) with age. Data from immunocytochemistry reflected the data from western blot analysis. Comparing atria from the young animals, the ratio of SERCA2a to PLB monomer was significantly greater in the RA by 35.5±0.7% (p<0.001). Conversely considering each atrium and the effect of increased age, the ratio increased in the LA by 46±1.2% (p=0.001), but declined in the RA by 22±4.4% (p=0.01).
In conclusion, existing inter-atrial heterogeneity of cellular calcium regulation increases in old age. The fall in RA proteins might be expected to reduce potential systolic function in old age whilst the LA changes, which have some parallels with changes seen in heart failure, may predispose to arrhythmias

and calcium dysregulation. Combined these changes are a possible substrate for atrial fibrillation.

Characterization of small-conductance Ca2+-activated K+ channels in patients with chronic atrial fibrillation

M. Li, T. Li, H. Lan, L. Mao, X. Ou, C. Li, Y. Yang and X. Zeng

Key laboratory of medical electrophysiology, LuZhou, China

In 2003, Small-Conductance of Ca2+-activated K+ channels(SK) are first reported to present in Cardiac myocytes, which is expressed more abundant in the atria compared with the ventricles. Genetic knockout of the SK channels results in the delay in cardiac repolarization and showed inducible atrial fibrillation(AF). The purpose of this study was to confirm whether SK channels are involved in electrical remodeling of human chronic atrial fibrillation (CAF).The ionic currents were recorded using whole-cell Conventional patch clamp techniques(35 appendages from patients with SR and 18 appendages from patients with CAF). SK2 channel protein expressions were assayed by western blot technique(12 appendages from patients with SR and 24 preparations from patients with CAF). Our result indicate that SK channels present in patients atrial with SR Group and CAF Group,identified it with SK channel blocker apamin (100nmol/L) . SK channels are voltage-independent and inwardly rectifying . The SK channel current densities were significantly increased in CAF(n=24,[Ca2+]i=500nmol/L,p<0.05) compare to SR (n=49, [Ca2+]i=500nmol/L). The increased proportion of SK channel current densities in CAF(n=8,[Ca2+]i=1000nmol/L,p<0.05) were larger than in SR (n=10,[Ca2+]i=1000nmol/L). it manifested that SK is more sensitive to intracellular Ca2+ in CAF than in SR.Western bloting result demonstrated that SK2 protein level is significant decrease in CAF than in SR.Our results showed SK channels present in patients atrial with SR and CAF ;SK channel density in CAF were significantly increase than in SR.In patients with CAF, the SK channels are more sensitive to [Ca2+]i. Compared with SR,the protein level of SK2 was down-regulation in Patients atrial with CAF.these results indicated the increase densities of SK channel in CAF maybe depend on the more sensitive to [Ca2+]i and higher intracellular Calcium level,which lead to increase channels activity,not by the numbers of channels.It might be one of the treatment targets of patients with Atrial Fibrillation,involving in human atrial electric remodeling in CAF.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB024

Investigation of the interaction between flecainide and hERG potassium channels, through the use of flecainide analogues

D. Melgari[1], A. El Harchi[1], C.E. Dempsey[2] and J.C. Hancox[1]

[1]School of Physiology and Pharmacology and Cardiovascular Research Laboratories, University of Bristol, Bristol, UK and [2]School of Biochemistry, University of Bristol, Bristol, UK

Flecainide is a Class Ic (Na+ channel blocking) antiarrhythmic drug widely use in clinical treatment of atrial fibrillation that has been associated with an increased risk of arrhythmic events in post-myocardial infarction patients (Echt et al., 1991). In addition to its Na+ channel blocking activity, flecainide can inhibit hERG K+ channels at clinically relevant concentrations (Paul et al., 2002; Du et al., 2011; Breindahl et al., 2000). Flecainide's potency against hERG is reduced both by extracellular acidosis (as occurs in myocardial ischaemia) and when the drug is applied directly from the intracellular side of the membrane (Du et al., 2011). This study was conducted to gain greater insight into the interaction between flecainide and hERG, by using charged and uncharged flecainide analogues (Liu et al., 2003). Neutral (NU-Flec; pKa 6.3) and fully charged (QX-Flec) flecainide analogues (ASCENTTM Scientific) were tested in whole cell patch-clamp experiments performed at 37oC on HEK293 cells stably expressing hERG. hERG current (IhERG) tails were measured at -40mV after a 2 sec depolarizing step from -80mV to +20mV (N≥5 at each concentration). Normal flecainide produced concentration-dependent inhibition of IhERG with an IC50 value of 1.69μM (CI:1.44-1.99) and a corresponding Hill coefficient of 0.82 (CI:0.70-0.94). When applied extracellularly both analogues showed a slowed, less extensive blocking action compared with flecainide: 6 minutes of continuous superfusion with 100μM NU-Flec inhibited IhERG by only 49.9±4.3% (n=10); while 100μM QX-Flec produced an IhERG inhibition of 45.5±3.5% (n=10). Differences between the two analogues were observed when they were applied to the cell interior via the patch pipette. 100μM of pipette- applied NU-Flec produced little effect on IhERG density (p>0.5, t-test, unpaired comparison); while 10μM or 100μM of internally applied QX-Flec produced a fast and extensive current density reduction of ~80% and ~97% respectively. One interpretation of these findings is that both charged and uncharged flecainide can cross the membrane, but that the charged form seems to be mainly involved in the physical interaction and block of hERG channels from the cytosolic side of the cell membrane.

Fat tissue remodelling in persistent atrial fibrillation – 3D quantitative analysis using high-resolution magnetic resonance imaging

C.M. Afonso[1,2], B. Maesen[3,4], R.B. Burton[5], S. Zeemering[4], D.J. Stuckey[5], D.J. Tyler[5], U. Schotten[4], P. Kohl[2,6] and V. Grau[1]

[1]Oxford e-Research Centre and Institute of Biomedical Engineering, University of Oxford, Oxford, UK, [2]The Heart Science Centre, National Heart and Lung Institute, Imperial College London, Harefield, UK, [3]Department of Cardiothoracic Surgery, Maastricht University Hospital, Maastricht, Netherlands, [4]Department of Physiology, Maastricht University, Maastricht, Netherlands, [5]Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, UK and [6]Department of Computer Science, University of Oxford, Oxford, UK

MOTIVATION: Atrial fibrillation (AF) is a cardiac arrhythmia characterized by a fast and irregular electrical activity in the atria. Highly prevalent (1–5%) and associated with a doubling of mortality and substantial morbidity, AF represents a high socio-economic burden [1]. The unsatisfactory efficiency of AF treatments demands a better understanding of the disease. AF is a complex disease, usually resulting from the interplay of several factors. One of the main factors is structural remodelling, which contributes to the accommodation and progress (paroxysmal to persistent to permanent) of AF itself [2]. One of the less studied structural changes is the increase in fat tissue. Available studies have only analysed the epicardium at relatively low resolution [3]. In this study, we analyse the accumulation of fat tissue in persistent AF, in the 3D structure of the goat left atrial wall (epicardium to endocardium) at unprecedented resolution. METHODS Tissue samples: In open chest experiments, left atrial wall tissue samples were excised maintaining tissue-pretension using rigid clip-on frames from two goat groups: persistent AF (5 goats) and control (6 goats). Persistent AF goats had been under AF for a period of 7 to 12 months. The collected tissue was stored in Karnovky's fixative solution (2% paraformaldehyde, 2.5% glutaraldehyde in 0.1M sodium cacodylate buffer). Magnetic resonance imaging (MRI): Fixed tissue samples were preconditioned in gadolinium-containing (2mM) cacodylate buffer and then stabilised in an MRI tube using low melting 1% agar (Cambrex, Busieve GTG agarose). MRI scans were performed using a vertical-bore, 11.7 Tesla MR system with a Bruker console, a 40mm quadrature-driven birdcage coil (Rapid Biomedical, Würzburg, Germany), and a 3D fast gradient echo sequence: TE/TR 1.8/15ms, 15° pulse, field of view 40mm×40mm×40mm, matrix size 512×512×512, voxel size 78μm×78μm×78μm, and 10 averages. Image processing: MRI images were aligned in an epi- to endocardium view using a 3D rigid transformation. Thresholding and morphological operations were used to first correct the MRI background inhomogeneities, then segment tissue from the background, and finally segment fat from other tissue types. Validation of the fat segmentation was done using whole-mount pictures of tissue samples after excision and trichrome-stained histological slices (for details of histology see [4]). RESULTS and CONCLUSIONS We developed a method to successfully segment fat tissue in MRI data of atrial tissue samples. We are currently quantifying and comparing the accumulation of fat tissue in persistent AF versus control. Preliminary results suggest a larger volume of fat in AF then in control; and its preferential accumulation in near-epicardial layers. We will present the final analysis at the IUPS 2013 congress.

The β3 agonist BRL37344 mediates a negative inotropic effect in rat atrial cells

C.L. Sam[1,2], T.B. Bolton[2], I.T. Piper[1], M. Al-Jobarah[1] and N.S. Freestone[1]

[1]Faculty of Science, Engineering and Computing, Kingston University, Surrey, UK and [2]Biomedical Division, St George's, University of London, London, UK

A third cardiac β-adrenoceptor (AR) has been reported in ventricular cells from a number of species including humans (Gauthier *et al.*, 1998). This receptor has been shown to mediate negative inotropic effects unlike the other β-ARs of the heart. BRL37344 is a β3 agonist and upon its stimulation of the β3-AR, the Gi sub-unit is activated which leads to production of nitric oxide (NO) by endothelial nitric oxide synthase (eNOS). The production of NO activates guanylate cyclase (GC) which catalyses the production of cGMP. An increase in cGMP levels activates protein kinase G (PKG) and calcium (Ca^{2+}) entry via the L-type Ca^{2+} channel is inhibited hence causing the cardioinhibitory effects. Due to the negative inotropic effect of BRL37344, investigations of its expression during heart failure have been carried out. It has been shown that these receptors are up-regulated in such circumstances to protect the heart from excess catecholamines (Moniotte *et al.*, 2001). In this study we have used BRL37344 in quiescent WKY rat atrial cells to investigate its effect on Ca^{2+} spark frequency. Atrial cells from WKY rats were loaded with fluo-4AM (5μM) and whole cell and line scan mode images of Ca^{2+} events within these cells were obtained every 3ms using an LSM 510M confocal microscope. Cardiomyocytes were perfused with BRL37344 (300nM) in the presence and absence of a β-blocker, propranolol (200nM). It was discovered that the frequency of Ca^{2+}sparks decreased significantly in the presence of BRL37344 (and propranolol) compared to propranolol on its own (15.4 ± 3.3 sparks s^{-1} compared to 29.3 ± 6.4 sparks s^{-1} respectively ($n = 6$, $p = 0.05$). No larger Ca^{2+} events such as non-propagating wavelets or whole cell waves were observed. Furthermore, when the quiescent atrial cells were perfused with only BRL37344 the mean frequency of Ca^{2+} sparks tended to decrease compared to basal conditions (14.5 ± 2.4 spark s^{-1} to 22.0 ± 3.0 sparks s^{-1} respectively ($n = 5$, $p = ns$). Furthermore, atrial cells under basal conditions expressed on average 1.07 ± 0.24 wavelets s^{-1}. The reduction observed in intracellular Ca^{2+} release events with BRL37344 was due to β3-ARs stimulation, mediated by a PKG-dependent pathway. The neg-

ative inotropic effect of BRL37344 observed in rat atrial cells is associated with fewer spontaneous Ca^{2+} release events.

PCB029

Differences in intracellular calcium handling in rabbit atrial and ventricular myocytes

H.C. Gadeberg, C.H. Kong, M.B. Cannell and A.F. James

University of Bristol, Bristol, UK

Atrial myocytes differ from ventricular myocytes in ultrastructure and calcium handling proteins and consequently show subtle differences in calcium signalling. However there is little quantitative information characterising atrial calcium signalling. This study compares atrial and ventricular calcium transport focussing on the removal of calcium from the cytosol by sarcoplasmic Ca-ATPase (SERCA).

All procedures were approved by the University of Bristol ethics committee and conformed to the Animals (Scientific Procedures) Act, 1986. Rabbit atrial and ventricular myocytes were isolated by enzymatic digestion. Isolated cells were loaded with fluo-4, electrically stimulated at 1 Hz and line-scan images acquired using a Zeiss Pascal LSM5 laser-scanning confocal microscope. Rates of decay were obtained by fitting the recovery phase of calcium transients with a single exponential decay. Electrical stimulation of atrial and ventricular cells resulted in calcium transients, which were homogenous across the cell in ventricular myocytes, but were consistent with preferential coupling between calcium entry and release at the edge in atrial cells. However, there was no significant difference in the rate of recovery (k_{twitch}) of the spatially averaged calcium transients in atrial (1.8 ± 1.1 s^{-1}, n=18) and ventricular myocytes (1.5 ± 1.1 s^{-1}, n=11, P=0.21 un-paired t-test). Application of 10 mM caffeine, to release calcium from the sarcoplasmic reticulum and prevent its subsequent re-uptake, significantly slowed the rate of recovery (k_{caff}) in both cell-types. However, whereas k_{caff} was 50.0 ± 5.7% (n=11) of k_{twitch} in ventricular cells, k_{caff} was 14.4 ± 1.2% (n=19) of k_{twitch} in atrial myocytes, indicating that SERCA plays a greater role in the removal of calcium in atrial cells than in ventricular cells. When 10 mM Ni was applied in the presence of caffeine to block Na/Ca exchanger, further slowing of the rate of recovery (k_{Ni}) was observed in both cell types, although to a much larger extent in atrial cells. That k_{Ni} was faster in ventricular cells suggests that other slow pathways contribute more to calcium extrusion in these cells. To confirm the greater role of SERCA in atrial cells, the SERCA inhibitor thapsigargin (TG) was applied during electrically-stimulated calcium transients. Rate constants in the presence of 5 μM TG were significantly reduced in both atrial and ventricular cells, representing 16.8 ± 3.1% of k_{twitch} (n=6) in atrial compared with 49.7 ± 7.2% (n=8) in ventricular cells, consistent with the caffeine data. In summary, the data presented here indicate a greater contribution of SERCA to calcium extrusion in atrial cells compared to ventricular cells and highlights important differences in atrial and ventricular calcium signalling.

PCB030

Alterations to secreted levels of extracellular matrix moderators in young and aged ovine cardiac fibroblasts

M.A. Horn and A.W. Trafford

Unit of Cardiac Physiology, University of Manchester, Manchester, UK

Heart failure is characterised by an increase in circulating catecholamine levels and alterations to the cardiac extracellular matrix (ECM) – the latter of which we have found to be strongly influenced by age (1). Despite this association little is known regarding how β-adrenergic signalling modulates cardiac fibroblast (CF) – dependent remodelling of the ECM. The aims of this study were; i) determine if β-adrenergic stimulation of CFs alters production of matrix metalloproteinases (MMPs) and the tissue inhibitors of MMPs (TIMPs) and, ii) determine whether these secreted levels change with age.

Female Welsh Mountain ewes aged either 18 months (young) or >8 years (aged) were killed by intravenous administration of 200 mg.kg-1 pentobarbitone sodium following 10,000 U of heparin. CFs were isolated from LV samples (~0.5g) by incubation with 1,000 U/ml collagenase type II (Worthington) for 90mins. Primary cultures were maintained at 37oC, 5% CO2. CF proliferation was measured at passage 3 using a CyQUANT Direct Cell Proliferation Assay kit (Life Technologies). Confirmation that isolated cells were CFs and that they expressed the β2-adrenoreceptor (β2-AR) was carried out by immunostaining. At passage 4, 2x10e6 cells were seeded in 225cm2 culture flasks, serum-starved for 24h, and then media replaced with that containing either PBS (control), 0.1, 1 or 10μM isoprenaline (ISO) for 48h. After which, conditioned-media was collected, concentrated with centrifugal filters (Millipore) and assessed for MMP activity (gelatin zymography) and TIMP proteins (immunoblotting). In these experiments, each sample was run in triplicate and data expressed as a mean change ± standard error of the mean and normalised to vimentin protein level in cell pellet extracts. All statistical comparisons were made using a 2-way repeated measures analysis of variance, apart from the proliferation assay where a t-test was performed.

All cells isolated were positive for the fibroblast marker vimentin. CFs also expressed the β2AR. Proliferation was increased in aged CFs compared to young (P<0.05, n=9 young & 6 aged). Overall, MMP-2 activity in the CF conditioned media was less after treatment with 1μM compared to 0.1μM ISO (P<0.01, n=4 young & 4 aged). Although TIMP-1 protein levels were unchanged with either ISO or ageing, TIMP-2 protein was diminished after treatment with both 1 and 10μM ISO in both the young and the aged CFs (all P<0.01, n=4 young & 4 aged).

These initial experiments suggest that β-adrenergic signalling may play a role in ECM remodelling by altering levels of key players in matrix remodelling, but ageing has little effect on these changes.

All procedures accord to The UK Animals (Scientific Procedures) Act, 1986.

PCB031

The influence of estrogen on circadian rhythms of body temperature and heart rates in female rats

S. Marui, M. Matsuda and K. Nagashima

Human Sciences, Waseda University, Saitama, Japan

Purpose We aimed to assess influence of estrogen on circadian rhythms of body temperature, heart rates and physical activity, in addition to expression of β-adrenoceptor of the heart. ***Methods*** Under general anesthesia with isoflurane, female Wistar rats (7 wk of age, n = 14) were bilaterally ovariectomized, and implanted a telemetry device for measurements of body temperature (Tb), physical activity (Act), and electrocardiogram (ECG) in the abdominal cavity. Two silicon tubes (o.d., 1.57; and length 30 mm) containing 17β-estradiol were subcutaneously placed for one group (n=7, E2(+)), empty tubes for the other (n=7, E2(-)). The tubes were removed 10 days after the surgery. On Days 7 and 21 after the removal, the heart was excised, and the cell membrane of the atrium and ventricle of the heart was prepared for the determination ofβ-adrenoceptor (Western blotting). Tb, Act, and ECG were continuously monitored during the period. ***Results*** Before the tube removal, Tb was lower (P<0.05) in the E2 (-) group than that in E2 (+) group, but only at 0:30-1:00 am (37.4 ± 0.1°C and 38.0 ± 0.3°C, respectively), which was not seen on Day 15. Before the tube removal, heart rates (HR) in the E2 (-) group were greater (P<0.05) than those in the E2(+) group (387 ± 14 and 336 ± 13 beats/min (bpm) in the light phase, and 450 ± 11 and 389 ± 11 bpm in the dark phase, respectively). HR in E2(+) group increased (349 ± 11, 375 ± 13, and 377 ± 13 bpm in the light phase; and 422 ± 13, 436 ± 13, and 425 ± 16 bpm in the dark phase on Days 1, 7, and 15, respectively). Difference in HR became unclear on Day 15. The expression of β-adrenoceptor of the heart was changed with plasma estrogen level. ***Conclusion*** Estrogen level may affect circadian rhythms of body temperature and heart rates, in which independent mechanism seems to be involved. Moreover, estrogen may influence expression ofβ-adrenoceptor of the heart and HR change after ovariectomy.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB032

Prevention of β-adrenergic myocardial damage by α-linolenic acid enriched diet

A. Folino[2], A.E. Sprio[2], G.N. Berta[2], G. Losano[1] and R. Rastaldo[2]

[1]Dpt. Neuroscience, University of Turin, Torino, Italy and [2]Dpt. Clinical and Biological Sciences, University of Turin, Orbassano, TO, Italy

An increased sympathetic discharge affects the heart since the early stage of a failure. If initially it compensates the reduced cardiac output, its long term effect results in myocardial fibrosis and hypertrophy with worsening of the failure. The damage can be prevented by ω-3 fatty acids. such as docosahexaenoic (DHA), eicosapenaenoic (EPA) and α-linolenic acid (ALA) (1,2). While DHA and EPA are found in fishes, ALA is present in various vegetables included flaxseeds. A flaxseed enriched diet is reported to prevent the appearance of myocardial fibrosis in δ-sarcoglycan-null cardiomyopatic hamsters (2). We studied whether this diet can prevent myocardial fibrosis and hypertrophy in rats treated with isoproterenol (ISO). Wistar rats were divided in 3 groups: Control group (CTR; n=7) after 7 days of acclimatization rats underwent a daily subcutaneous injection of saline (0.5 ml) for 5 days and were fed with a standard pellet chow; ISO group (n=7+7) rats received 100 mg/kg of ISO instead of saline and were fed as CTR; ISO+ALA group (n=7) rats received ISO, but were fed with an ALA enriched diet before, during and after ISO. For all groups the observation lasted 60 days after the end of ISO treatment. Then surviving rats were anaesthetized with peritoneal injection of ketamine (100 mg/kg) and xylazine (5 mg/kg), heparinised (200 IU) and decapitated. The hearts were excised and weighted. Data are expressed as means±SD. One-way ANOVA was used. Seven rats of ISO group died during treatment. Thus 7 additional rats were added to have the same number of hearts to examine in all groups. ALA enriched diet prevented the ISO-induced death. Heart/body weight ratio was 0.32±0.2% in CTR. It increased in ISO group to 0.41±0.15% (p<0.01), while it was unchanged in ISO+ALA. In ISO group, histology (n=4 each group in triplicate) revealed a remarkable production and deposition of collagen, with an increase in the cross sectional area of myocytes from 199±3 μm^2 in the CTR to 250±10 μm^2 (p<0.001). NO change was observed in ISO+ALA.

Western blot analysis (n= 3 each group in triplicate) showed the following changes in ISO group with respect to CTR: 4 time increase (p<0.001) of Transforming Growth Factor-β (TGF-β) expression; reduction by about 25% (p<0.05) of Tissue inhibitor of metalloproteinase 1 (TIMP1) expression; increase by more than 3 times of β-myosin concentration (p<0.001). The changes were not observed in ISO+ALA. Zymography revealed that the activity of both latent and active forms of Metalloproteinase2 (MMP2) increased by about 50% (p<0.05 and p<0.001 respectively) in ISO group. In conclusion, ALA prevents cardiac fibrosis by abolishing the changes in TGF-β, TIMP1 and MMP2 expression induced by β-adrenergic hyperactivity. Moreover, since hypertrophy is related to the increase of TGF-β, it is likely that its prevention by ALA takes place by limiting the expression of this cytokine.

Cardiac remodeling in obese and non-obese insulin resistant rat models

J. Huang and L. Hung

Chang Gung University, Tao-Yuan, Taiwan

Currently, increasing attention has been paid to insulin resistance as a distinct cause of cardiac dysfunction, cardiomyopathy and heart failure (HF) in diabetic individuals. Therefore, the present study aims to explore the pathogenesis and reciprocal causal relationships between insulin resistance and cardiomyopathy/HF in two obese and non-obese insulin resistant animal models (SD rat). Here, we have created obesogenic diet (45% calorie from fat) induced obese, and atherogenic diet (4% cholesterol) with 10% fructose in drinking water induced non-obese animal models. Both obese and non-obese animals have developed insulin resistance syndrome compared to age-matched controls. Euglycemic-Hyperinsulinemic Clamp technique indicated that the obese animal exhibited insulin resistance (IR). In addition, obese rats accompany with hyperinsulinemia, activation of neurohumoral systems, concentric hypertrophy with slightly impairment of cardiac mechanical performance (Pressure-Volume catheter), fewer changes in both plasma and myocardial metabolites profiling (LC-MS metabolites analysis) compared to non-obese IR rats. In contrast, less insulin resistance, hypoinsulinemia, hyperactivity of neurohumoral systems, eccentric hypertrophy with worse mechanical performance, robust changes in both plasma and myocardial metabolites profiling have been found in non-obese IR rats. In our animal models demonstrate that obese IR heart switched on the physiological adaptation and remodeling in the face of obese and insulin resistant stimuli. Whereas non-obese IR heart seems switched on the pathological adaptation and remodeling, and this adaptive eccentric hypertrophy was consequent detrimental to cardiac function. Our study indicated that insulin resistance but not obesity plays a pivotal role in development of cardiomyopathy. Insulin resistance disturbs systemic metabolic homeostasis may precipitate cardiac maladaptation and remodeling which may consequently lead to evolution of cardiomyopathy.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Unaltered mitochondrial organization and compartmentation in creatine deficient GAMT-/- mouse cardiomyocyte

J. Branovets[1], M. Sepp[1], S. Kotlyarova[1], N. Jepihhina[1], N. Sokolova[1], D. Aksentijevic[2], C.A. Lygate[2], S. Neubauer[2], M. Vendelin[1] and R. Birkedal[1]

[1]Laboratory of Systems Biology, Institute of Cybernetics, Tallinn University of Technology, Tallinn, Estonia and [2]Department of Cardiovascular Medicine, Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, UK

Creatine kinase (CK) is considered an important spatial and temporal energy buffer in the heart. It catalyzes the transfer of a phosphoryl group between creatine and ATP. Previous studies suggest that mice lacking cytosolic and mitochondrial CK exhibit cytoarchitectural modifications and changes in regulation of mitochondrial respiration in the heart. The aim of this study was to asses whether similar changes occurred in creatine-deficient mice lacking the creatine synthesizing enzyme guanidinoacetate methyltransferase (GAMT). More specifically, we wanted to characterize the modifications in cardiomyocyte mitochondrial organization, regulation of respiration and intracellular compartmentation associated with inhibition of the CK system by GAMT-deficiency. Mice received an i.p. injection of 250U heparin, and were anesthetized with ketamine/dexmedetomidine mixture (150 mg/kg and 0.5mg/kg, i.p.respectively). Cardiomyocytes were successfully isolated from 8 GAMT-/- (4 females and 4 males) and 9 WT mice (5 females and 4 males) of similar age (females WT 46.9 ± 4.9 weeks and GAMT-/- 45 ± 4.3 weeks; males WT 45.6 ± 1.5 weeks and GAMT-/- 45.9 ± 1.4 weeks). Three-dimensional mitochondrial organization at whole cell level was assessed by confocal microscopy.Kinetic measurements on permeabilized mouse cardiomyocytes included ADP and ATP-kinetics of respiration, the competition between mitochondria and pyruvate kinase for ADP produced by ATPases, ADP-kinetics of endogenous pyruvate kinase and ATP-kinetics of ATPases. Using fluorescence microscopy, ADP-kinetics of respiration was confirmed on single permeabilized cardiomyocytes by recording autofluorescence response to changes in ADP. The experimental results were analyzed by mathematical models to estimate intracellular compartmentation. Quantitative analysis of the morphologic and kinetic data, as well as derived model fits showed no difference between GAMT-deficient and wildtype littermates. Thus, we conclude that inhibition of the CK-system by GAMT-deficiency does not alter mitochondrial organization, regulation of respiration and intracellular compartmentation in relaxed cardiomyocytes. This raises questions on the importance of the CK system as a spatial energy buffer facilitating the communication between mitochondria and ATPases in cardiomyocytes.

We wish to acknowledge Prof. Dirk Isbrandt (University of Hamburg, Germany) for generating the strain of GAMT-deficient mice. This research was funded by The Wellcome Trust (Fellowship no. WT081755MA), European Union through the European Regional Development Fund, the Estonian Science Foundation (grant no. ETF8041), and by British Heart Foundation grant RG/10/002/28187.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB035

Ivabradine reverses the extracellular matrix changes and affects fibroblast number and phenotype in heart failure

P. Dias, M. Navaratnarajah, P. Sarathchandra, S. Alayoubi, J.E. Cartledge, N. Latif, M.H. Yacoub and C.M. Terracciano

National Heart and Lung Institute, Imperial College London, London, UK

In the failing heart, the extracellular matrix (ECM) undergoes structural remodelling with changes in the accumulation and organisation of ECM proteins. Ivabradine (IVA) an inhibitor of the pacemaker (If) current has been shown to have beneficial effects in the structure and function of the failing heart including the reversal of myocardial fibrosis. However, whether IVA alters the expression of specific ECM proteins during the progression of heart failure (HF) is unknown. In addition, changes in the fibroblast number and phenotype before and after IVA

treatment have not been studied. HF was induced by permanent coronary artery ligation in rats anaesthetized with Isoflurane. Sham-operated animals (S) were used as controls. After 12 weeks, HF (HF-12) animals (ejection fraction<40%) were treated either with oral IVA (HF-IVA) (10mg/kg/day) or saline (HF-S) for a further 4 weeks. Values are presented as means±S.E.M. and compared by an ANOVA. Using immunofluorescence and confocal microscopy, sections were studied for specific ECM proteins and the percentage area fraction was quantified on 8-10 fields per section (3-4 hearts per group) using ImageJ software. IVA significantly reduced the levels of collagen I (S: 0.76±0.07%, n=69; HF-12: 1.12±0.08%, n=57; HF-S: 1.59±0.12%, n=70; HF-IVA: 0.68±0.06%, n=52; $p<0.05$), collagen III (S: 0.88±0.06%, n=78; HF-12: 1.26±0.09%, n=90; HF-S: 1.91±0.13%, n=74; HF-IVA: 0.75±0.65%, n=60; $p<0.05$) and elastin (S: 0.62±0.06%, n=52; HF-12: 1.16±0.06%, n=85; HF-S: 1.93±0.22%, n=68; HF-IVA: 0.52±0.09%, n=29; $p<0.05$) compared with HF-12. Vimentin, a marker for cardiac fibroblasts was measured using western blotting. IVA reduced the vimentin expression observed in HF-S to sham levels (in arbitrary units, S: 0.33±0.04, n=5; HF-S: 0.59±0.05, n=6; HF-IVA: 0.37±0.02, n=5; $p<0.05$). Since vimentin is also expressed in endothelial cells, von Willebrand factor (vWf) was measured. No change in vWf was observed suggesting that endothelial cell number was not affected. α-smooth muscle actin, a marker used to identify myofibroblasts but also present in smooth muscle cells, was also measured. IVA normalised the levels of α-smooth muscle actin to sham levels (S: 0.50±0.13, n=5; HF-S: 1.00±0.13, n=6; HF-IVA: 0.44±0.08, n=4; $p<0.05$). Expression of the hyperpolarisation-activated cyclic nucleotide-gated channel isoform 4 which encodes the If channels was up-regulated during HF but IVA down-regulated this overexpression (S: 0.31±0.05, n=5; HF-S: 0.57±0.05, n=6; HF-IVA: 0.38±0.05, n=5; $p<0.05$). Our results demonstrate that IVA reverses the accumulation of several components of the ECM and reduce fibroblast number and phenotype which may explain the changes observed in the ECM. Thus IVA appears to play a beneficial role in the structural integrity of the ECM which can be important in the reparative process of the failing heart.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB036

Electrophysiological remodelling in response to chronic mechanical load variations: A multicellular study

S. AlAyoubi[1,2], M. Ibrahim[1], J. Cartledge[1], M.H. Yacoub[1], C.M. Terracciano[1] and P. Camelliti[1]

[1]National Heart & Lung Institute, Imperial College, London, UK and [2]King Fahad Cardiac Center, King Saud University, Riyadh, Saudi Arabia

Chronic variations in load are clinically relevant as mechanical overload can result in heart failure and unloading with left ventricular assist devices is used in the management of patients with heart failure. Previous studies have investigated the effect of chronic load variation on the electrophysiological properties of the left ventricle using isolated cardiomyocytes and whole hearts. Here, we study the load-dependent remodeling using myocardial slices, an intact multicellular preparation that allows the investigation of functional and structural regional heterogeneities.

Lewis rats were anaesthetized with isoflurane and pressure overload was induced by transverse aortic constriction (TAC) for 10 and 20 weeks. Sham-operated animals (S) served as control. Mechanical unloading (MU) was obtained by heterotopic abdominal heart-lung transplantation for 8 weeks. The recipient's native heart acted as control. Vibratome-cut myocardial slices (350μm thick) were prepared from the left ventricle, tangentially to the epicardial surface. Slices were electrically stimulated and studied using a multi-electrode array (MEA) system. Extracellular field potentials, recorded from 60 MEA microelectrodes, were analysed to measure field potential duration (FPD) - an index of action potential duration. Conduction velocity (CV) was also measured. Values are mean ± S.E.M., compared by t-test.

The measurement of heart weight/body weight ratio confirmed the presence of hypertrophy in the TAC group (10 weeks: 4.9±0.2, n=5; S: 3.8±0.1, n=5; $p<0.01$, 20 weeks: 4.1±0.2; n=4; S: 3.1±0.1 n=5; $p<0.05$) and atrophy in the unloading group (MU: 1.4±0.1, n=3; control: 3.5±0.1, n=3; $p<0.05$). Myocardial slices prepared from the TAC group showed significantly faster CV compared with the SHAM group at 10 weeks (TAC: 49±4 cm/s, n=25 slices; S: 35±4 cm/s, n=17 slices; $p<0.05$) but no significant change at 20 weeks (TAC: 67±10 cm/s, n=17 slices; S: 56±6 cm/s, n=22 slices; $p>0.05$). FPD did not change at 10 weeks TAC (TAC: 124±3 ms, n=16 slices; S: 122±2 ms; n=13 slices; $p>0.05$), but was significantly prolonged at 20 weeks (TAC: 122±2 ms, n=18 slices; S: 114±3 ms, n=20 slices; $p<0.05$). Slices obtained from the MU group showed significantly prolonged FPD (MU: 116±2 ms, n=11 slices; control: 108±2 ms, n=13 slices; $p<0.05$), but unchanged CV (MU: 30±3 cm/s, n=10 slices; control: 32±5cm/s, n=13 slices; $p>0.05$). Our data show that chronic mechanical overloading temporarily increases CV with delayed repolarisation. The latter is also observed during unloading without effects on CV. Delayed repolarisation may represent a compensatory response to variations in mechanical load and underlie possible arrhythmogenic effects. Future studies will employ myocardial slices to determine the structural alterations responsible for the observed electrophysiological remodeling.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB037

Sarcoplasmic reticulum content is reduced by the RyR2^{R4496C} mutation at a range of frequencies in mouse cardiac myocytes

C. Circelli, L.A. Venetucci, A.W. Trafford and D.A. Eisner

Unit of Cardiac Physiology, University of Manchester, Manchester, UK

Motivation: Patients with catecholaminergic polymorphic ventricular tachycardia (CPVT) have RyR2 mutations and are prone to delayed after depolarisations (DAD), triggered by Ca^{2+} waves during β- adrenergic stimulation. These arrhythmias are often seen during periods where the heart rate increases; therefore, our objective was to study the effects of various stimulation frequencies in the RyR2^{R4496C} knock-in mouse model of CPVT.
Methods: Ventricular cardiac myocytes were isolated from either control or RyR2^{R4496C} knock-in mutant mouse hearts by enzymatic digestion and loaded with Fluo-5F. Cells were then voltage clamped at -50 mV and depolarised to 0 mV using a 50 ms pulse. Cells were paced at frequencies of 1, 3, and 5 Hz in the presence of 1 μM isoproterenol. SR Ca^{2+} content was measured using the application of 5 mM caffeine and 20 mM 2,3-butane-dione-monoxime, with integration of the Na^{+}-Ca^{2+}

exchange current. All animal experimentation was compliant with the 1986 Scientific Procedures Act (UK). **Results:** Our data show that SR Ca^{2+} content is reduced by the $RyR2^{R4496C}$ mutation at 1, 3 and 5 Hz ($P<0.05$). Furthermore, SR Ca^{2+} content also increases with rate in control cells (1 Hz vs. 3 and 5 Hz $P<0.05$). However, this relationship appears to be impaired in $RyR2^{R4496C}$ mutant cells, with only 1 Hz vs. 5 Hz showing an increase in SR Ca^{2+} content. Our work also shows that increasing the stimulation frequency reduces both the L-type Ca^{2+} current and systolic Ca^{2+} transient amplitude. In addition, the $RyR2^{R4496C}$ mutation does not alter other Ca^{2+} cycling parameters, such as, the rate constant of decay for the systolic Ca^{2+} transient. **Conclusion:** These experiments demonstrate the $RyR2^{R4496C}$ mutation lowers SR Ca^{2+} content at all frequencies of stimulation, and modifies the relationship between frequency of stimulation and SR Ca^{2+} content. These observations suggest that the mutated $RyR2^{R4496C}$ responds differently to increases in the pacing frequency. This abnormal response to high frequencies of stimulation could explain why spontaneous Ca^{2+} release occurs at high frequencies of stimulation. This work offers mechanistic insights into the function of RyR2 in health and disease, aiding the development of future therapeutics.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB038

Regulation of the cardiac sodium/calcium exchanger by protein palmitoylation

L. Reilly, M. Ashford and W. Fuller

Division of Cardiovascular and Diabetes Medicine, University of Dundee, Dundee, UK

The cardiac sodium/calcium exchanger (NCX1) plays a vital role in the regulation of intracellular Ca in cardiac muscle, removing Ca that enters the cell during systole. Inappropriate NCX1 function contributes to cardiac contraction abnormalities and heart failure: reduced NCX1 activity reduces Ca removal and therefore impairs relaxation, whereas overactive NCX1 unloads the intracellular Ca stores and impairs systolic function. Although the structure-function relationship of NCX1 is well characterised, the dynamic regulation of NCX1 function is controversial. The reversible attachment of the 16-carbon fatty acid palmitate to cysteine residues in proteins (palmitoylation) is an important and common post-translational modification in a variety of tissues. However, the cardiac palmitoyl proteome remains largely uncharacterised. In general, palmitoylation targets proteins to the lipid bilayer as addition of palmitate increases the hydrophobicity of proteins. With respect to ion transporters, palmitoylation controls cell surface expression, spatial organisation, and voltage-sensitivity as well as cross talk with other signalling pathways (Linder & Deschenes 2007). Given that multiple ion channels and transporters are palmitoylated, palmitoylation of cardiac calcium handling proteins may be as important as phosphorylation in the regulation of excitation-contraction coupling and thus cardiac output. We investigated the palmitoylation of NCX1 from ventricular myocytes (VM) isolated from adult male Wistar rats by retrograde perfusion of collagenase. Using site-specific resin assisted capture (Acyl Rac), palmitoylated proteins were purified from isolated adult rat VM. Data is presented as mean±SEM, with differences analysed by t-test. NCX1 is substoichiometrically palmitoylated in VM (proportion of NCX1 purified by Acyl Rac: 73±5%, n=6) compared to the constitutively palmitoylated protein, caveolin-3. We expressed NCX1 in HEK-293 cells by transient transfection and measured palmitoylation by Acyl Rac, and cell surface localization using membrane impermeable biotinylation reagents. The global palmitoylation inhibitor 2-bromopalmitate (100μM, 18 hours), significantly reduced NCX1 palmitoylation (by 89±4%% compared to untreated cells, n=4, $p<0.001$), and significantly decreased cell surface expression of NCX1 (by 49±11% compared to untreated cells, n=3, $p<0.05$). NCX1 is regulated via a large intracellular loop between transmembrane domains 5 and 6, in which a number of cysteine residues are located. Site-directed mutagenesis of cysteines 383, 387, 485 or 557 did not reduce NCX1 palmitoylation in transiently transfected HEK-293 cells. In conclusion, palmitoylation of NCX1 influences its turnover at the plasma membrane and/or processing in the secretory pathway. The effect of palmitoylation on NCX1 activity is currently under investigation.

Pacemaker phenotype is the basis of tachyarrhythmias originating in the atrioventricular rings and the right ventricular outflow tract

S.R. Logantha, H. Schneider, A.J. Atkinson, G. Hao, M.R. Boyett and H. Dobrzynski

Institute of Cardiovascular Sciences, University of Manchester, Manchester, UK

The atrioventricular (AV) ring tissue (surrounding the atrial orifices of tricuspid and mitral valves) and the right ventricular outflow tract (RVOT) are major sources of ectopic electrical activity causing arrhythmias (1, 2). The aim of this study was to characterise these tissues in structurally normal hearts, identify whether they are predisposed to generate arrhythmias and investigate the mechanisms underlying arrhythmogenicity.
Male Wistar rats (275-375 g) were killed in accordance with the United Kingdom Animals (Scientific Procedures) Act, 1986. Isolated tissue preparations were superfused at 37°C and extracellular electrograms were recorded with a multi-electrode array and intracellular action potentials (APs) were recorded using microelectrodes. Ion channel expression was characterised using qPCR and immunohistochemistry. Data are presented as means±SEMs and 'n' denotes number of animals.
In right atrial preparations, multi-electrode array recordings showed the leading pacemaker site at the level of the sinus node; AV ring APs were atrial-like (n=2), showing a maximum diastolic potential (MDP) of -82±1 mV, a fast upstroke velocity (dV/dt_{max}, 205±17 V/s), a large amplitude (102±2 mV) and the time to 50% (T_{50}) and 90% (T_{90}) repolarization of 22±1 ms and 80±1 ms, respectively. Upon detaching the sinus node, spontaneous activity originated in the AV ring and propagated towards the terminal crest. Intracellular APs recorded at the leading pacemaker site in the AV ring were sinus node-like. Spontaneous APs occurred at a frequency of 2.1±0.3 Hz (n=4) and were characterised by a MDP of -50±3 mV, a slow upstroke (dV/dt_{max}, 7±1 V/s), a small amplitude (49±3 mV) and slow diastolic depolarization. The T_{50} and T_{90} were 46±5 ms and 87±8 ms, respectively. Pacemaking in the AV ring was accel-

erated by treatment with the β-adrenergic agonist isoproterenol (0.05 μM) and could be inhibited by either blocking the pacemaker current I_f with 2 mM Cs^+ or disrupting Ca^{2+} release from the sarcoplasmic reticulum with ryanodine (2 μM).
In RVOT preparations, spontaneous electrical activity was observed in 2 out of 7 cases. The leading pacemaker site was located immediately inferior to the pulmonary valve and again showed sinus node-like APs (MDP, -41±2 mV; dV/dt_{max}, 25±7 V/s; amplitude, 44±12 mV; n=2) with prominent diastolic depolarization. Curiously, both the right AV ring and the RVOT showed bursting activity. Consistent with these observations, qPCR and immunolabelling showed an expression pattern of ion channels, Ca^{2+}-handling proteins and receptors in the right AV ring and RVOT similar to that in the sinus node.
The AV rings and the RVOT of the normal heart are capable of pacemaker activity and this is the likely basis of arrhythmias originating in these tissues.

Increased sarcoplasmic reticulum diastolic calcium leak can produce biphasic decay of the cardiac systolic calcium transient

R. Sankaranarayanan, Y. Li, D. Greensmith, A.W. Trafford, D.A. Eisner and L.A. Venetucci

Cardiac Physiology, University of Manchester, Manchester, UK

Introduction: Cardiac contraction results from a brief increase in cytosolic calcium (Ca) concentration (systolic Ca transient). The majority of this increase is due to release of Ca from the sarcoplasmic reticulum (SR) through the ryanodine receptor (RyR). For relaxation to occur, the RyRs close and Ca is removed from the cytoplasm, largely by pumping Ca back into the SR via the sarco-endoplasmic reticulum Ca ATPase (SERCA). If the RyR becomes leaky then the resulting extra efflux of Ca from the SR will reduce the effects of SERCA-mediated Ca uptake and decrease SR Ca content and thence the amplitude of the Ca transient. Previous work has also shown that increasing RyR leak slows the rate of decay of the Ca transient and this may contribute to impaired relaxation in heart failure [1]. The aim of this study was to characterize the precise details of this slowing of decay of the Ca transient.
Methods: Single rat ventricular myocytes were voltage clamped using the perforated patch clamp technique. 100 ms duration pulses from -40 to 0 mV were applied at 0.5 Hz. Cytosolic Ca concentration was measured using Fluo-4 AM. SR Ca leak was induced using 1 mM caffeine. Statistical analysis was performed using the t-test.
Results: Application of caffeine decreased the amplitude of the Ca transient (to 45% of control) and its rate constant of decay (to 75%). In 3 out of 11 cells the decay of the Ca transient was clearly biphasic with an initial rapid phase of decay followed by a slower one. This biphasic decay was seen much more frequently (12 out of 15 cells) if caffeine was applied in the presence of isoprenaline (1 μM) as shown in Fig. 1 (A-raw trace and B- normalised). In isoprenaline the Ca transient decays as a single exponential with a rate constant of decay of 18.1±1.8 s^{-1}. The addition of caffeine results in bi-exponential decay with the rate constant of the fast phase (16.5±2.4 s^{-1}) being the same (p=0.61) as in the absence of caffeine. Thus, in the normalized traces (B), the initial fast phase superimposes on that in isoprenaline alone. The slow phase has a rate constant of 1.3±0.3 s^{-1}. We hypothesise that the initial rapid phase of decay is a consequence of the SR Ca content and therefore leak being reduced following systolic release. Only when SR Ca content begins to increase does the leak become sufficient to significantly oppose SERCA. In 6 cells showing biphasic decay in caffeine plus isoprenaline we investigated the effect of partial inhibition of SERCA and found that thapsigargin reduced the amplitude and rate constant of decay of the fast component .
Conclusions: We conclude that Ca leak from the SR can lead to biphasic decay of the Ca transient because the effect of leak is greater at later times when the SR Ca content is increased. These results will be relevant to relaxation in heart failure.

PCB041

The modulation of mitochondrial Ca^{2+}-uptake by inorganic phosphate, pH, adenosine phosphates and Mg^{2+} in single permeabilized ventricular myocytes of rat

J. Lee[1], J. Ha[1], J. Youm[2] and C. Leem[1]

[1]Physiology, University of Ulsan College ofMedicine, Seoul, Republic of Korea and [2]Physiology, Inje University, Busan, Republic of Korea

Mitochondrial Ca^{2+} regulation is closely related to cellular function including energy production and cell viability. Intramitochondrial Ca^{2+} overload is eventually destined to cellular death, therefore, the modulation of the mitochondrial Ca^{2+} uptake is important to regulate cellular function. In this study, we would like to see the effect of inorganic phosphate (Pi), pH, adenosine phosphates and Mg^{2+} on mitochondrial Ca^{2+} uptake kinetics with newly developed quantitative method. We enzymatically isolated single ventricular myocytes of rat. All procedures were accorded with national legislation. Buthanedione monoxime was present to prevent contracture. We measured NADH, mitochondrial Ca^{2+} with Fura-2FF and mitochondrial membrane potential (ψm) with tetramethylrhodamine ethyl ester, simultaneously. To maintain mitochondrial membrane potential, 5 mM of pyruvate and malate were present at all times. The Ca^{2+} uptake rate was increased as extramitochon-

drial Ca^{2+} was increased in a dose dependent manner. As intramitochondrial Ca^{2+} increased, NADH and mitochondrial membrane potential was decreased. The half-activating Ca^{2+} concentration (Kh) was about 0.33 μM. In the presence of Pi,Ca^{2+} uptake was not occurred properly and mitochondrial membrane potential was rapidly depolarized. These phenomena were prevented by ATP and the Kh was 1.79 μM in the presence of ATP and Pi. The Kh was shifted to the right, compared to the control Kh. ADP did not shift the Kh. Mg^{2+} markedly shifted the Ca^{2+} sensitivity to the right and the Kh value was about 1.83 μM. In addition, the maximal uptake rate also decreased. Cytosolic acidification to pH 6.0 also shifted Kh to the right and the Kh was about 1.56 μM. From the above results, ATP, Mg^{2+} and acidic pH decreased the cytosolic Ca^{2+} sensitivity of mitochondrial Ca^{2+} influx and those modulations must be important in diverse pathologic conditions.

Pak1 deficiency in cardiomyocytes increases in susceptibility to ventricular arrhythmogenesis in mice

H. Tsui[1], Y. Wang[1], W. Liu[1,2], Y. Shi[3], R. Wang[3], Y. Zhang[1], R. Solaro[4], Y. Ke[4], H. Zhang[5], D. Terrar[6], E. Cartwright[1], X. Wang[2] and M. Lei[1]

[1]Medicine & Human Sciences, University of Manchester, Manchester, UK, [2]Faculty of Life Sciences, University of Manchester, Manchester, UK, [3]Department of Cardiovascular Medicine, Union Hospital, Wuhan, China, [4]Department of Physiology and Biophysics and Centre for Cardiovascular Research, University of Illinois at Chicago, Chicago, IL, USA, [5]School of Physics and Astronomy, University of Manchester, Manchester, UK and [6]Department of Pharmacology, University of Oxford, Oxford, UK

50% of mortalities attributable to cardiac causes are accounted for by ventricular tachyarrhythmias occurring either independently or as a result of other underlying heart diseases. Yet, despite the enormity of this problem, the identification of pathophysiological mechanisms contributing to ventricular tachyarrhythmias as well as the development of safe and effective antiarrhythmic agents remain elusive[1,2]. The aim of the present study is to determine the role and underlying mechanisms for P^{21} activated kinase 1(Pak1) in ventricular arrhythmogenesis under stress conditions in mice carrying a ventricular cardiomyocytes specific deletion of Pak1 mice ($Pak1^{cko}$) and control mice ($Pak1^{f/f}$).

10-12 week old mice were subjected to either acute treatment of isoprenaline (ISO, 5-50nM) or chronic treatment with ISO at concentration 10mg/kg/day for 14-days delivered by mini-osmotic pump. The *in vivo*, *ex vivo* electrocardiography (ECG) and monophasic action potential (MAP) were recorded by Chart5 program. At both *in vivo*, *ex vivo* conditions, $Pak1^{cko}$ mice, but not control $PAK1^{f/f}$ mice, showed high occurrences (4/12 and 8/12 respectively) of ventricular arrhythmias induced by programmed electrical stimulation (PES) protocols, particularly at high stimulation frequencies. At cellular level, action potential (AP) alternans, delayed after-depolarization typed APs and spontaneous APs were frequently observed from $PAK1^{cko}$ myocytes, but not from control $Pak1^{f/f}$ myocytes. The involvement of Pak1 in Ca^{2+} handling was further investigated at cellular level. Dysfunctional Ca^{2+} handling was observed in $Pak1^{cko}$ myocytes in contrast to control $Pak1^{f/f}$ myocytes, in particular, under ISO stress conditions, these include alterations of SR content, the kinetics of NCX, SERCA, SR refilling and the diastolic cytosolic Ca^{2+}. Molecular characterisation demonstrated that SERCA2 protein and mRNA levels were increased in $Pak1^{f/f}$ hearts under ISO stress condition, however, such effect was abrogated in $Pak1^{cko}$ hearts. Further *in vitro* experiments on primary neonatal cardiomyocytes demonstrated that SERCA2 expression is regulated by Pak1 through activation of serum response factor, a transcription factor that has previously been linked to cardiac hypertrophy and development[3].

In conclusion, Pak1 plays a crucial role in regulating cardiac electrical function and Ca^{2+} handling in preventing stress associated ventricular arrhythmogenesis.

PCB044

Remodelling of the caveolar domain in right ventricular failure in rats

R. Norman, M. Hardy, E. Fowler, E. White and S. Calaghan

University of Leeds, Leeds, UK

Heart failure (HF) is a major health problem affecting nearly 1 million people in the UK today. The mechanisms which underlie its progression are not fully understood. A hallmark of remodelling in the failing heart is a desensitisation of the β-adrenoceptor (AR) signalling pathway, associated with aberrant spatial control of cAMP. Caveolae, flask-shaped lipid rafts, are key controllers of β-AR signalling [1]. Many of the proteins involved in the β-AR cascade are present in caveolar domains or interact with caveolin. Here we determine whether caveolar remodelling occurs in a model of right ventricular (RV) HF caused by pulmonary hypertension.

Male Wistar rats (190-230g) received an i.p. injection of 60 mg/kg monocrotaline (MCT) or saline (CON). MCT induces RV hypertrophy which progresses to RV HF by 21-28 days post-injection. When clinical symptoms of HF were apparent, the heart was quickly excised and the coronary circulation cleared of blood on a Langendorff apparatus. The RV was homogenised in detergent-free buffer (500mM Na_2CO_3 with protease inhibitor cocktail) then sonicated. Samples were mixed with Laemmli sample buffer for Western blotting to assess total protein expression, or separated on a discontinuous sucrose gradient [1] to assess protein distribution. Proteins of interest include caveolar proteins caveolin (Cav) 1, Cav3 and cavin 1 which are crucial for caveolar formation, and components of the β-AR cascade (β1-AR, β2-AR and adenyly cyclase (AC) 5/6).

As shown in Fig. 1A, expression of all caveolar proteins and both β1 and β2-ARs was decreased in MCT rats compared with

CON (P<0.01, t-test). AC 5/6 expression was not affected by HF. Cav3 is the major caveolar protein in the cardiac myocyte. Following sucrose density gradient fractionation, caveolae-containing membranes (indexed by enrichment in Cav3) are typically found in fraction 5 and 6 which we designate the buoyant fractions (BF). Fig. 1B shows that the distribution of Cav3 in the membrane is perturbed by RV failure. The ratio of Cav3 in BF to heavy fractions (HFr;9-12) was significantly reduced in MCT rats compared with CON (P<0.05, t-test).
Together the finding of decreased expression of caveolar proteins along with a translocation of Cav3 from caveolar fractions is consistent with a disruption of the caveolar microdomain. These changes are likely to impact on both the basal function and AR responses of the myocyte. We consider that a better understanding of the changes which occur in the caveolar domain could lead to identification of possible pharmacological targets for reverse remodelling of the βAR pathway in HF.

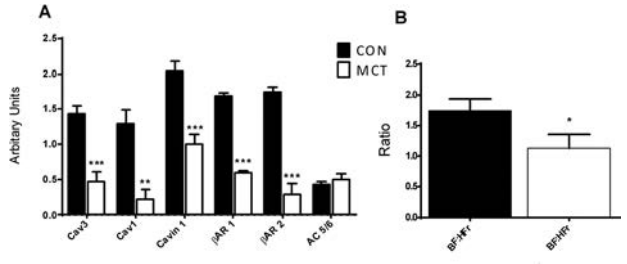

Figure 1. A. Effect of RV failure on caveolar and β-AR cascade protein expression. All values are normalised to β-adaptin. B. Ratio of Cav 3 expression in buoyant fractions (BF;5,6) to heavy fractions (HFr;9-12). All data are mean + S.E.M (n=5-6; *P<0.05; **P<0.01; ***P<0.001).

Regional differences in inflammation and fibrosis in right- and left-sided heart failure

G.M. Quigley[1], I.P. Temple[1], M. Zi[1], E. Cartwright[1], T.T. Yamanushi[2], X. Cai[1], J.F. Yanni[1], H. Dobrzynski[1], G. Hart[1] and M.R. Boyett[1]

[1]Institute for Cardiovascular Research, Univeristy of Manchester, Manchester, UK and [2]Kagawa Prefectural University of Health Sciences, Takamatsu, Japan

Introduction
Left-sided heart failure (HF) is mainly the result of hypertension and coronary disease, whereas isolated right-sided HF results from a different set of conditions, including pulmonary arterial hypertension (PAH) and congenital heart disease. However, pump failure and arrhythmias are common in both types of HF. The aim of this study is to determine if inflammation, fibrosis and apoptosis are involved.
Methods
To induce PAH, monocrotaline (MCT, 60 mg/ml/kg) was injected subcutaneously into 200 g male Wistar rats. Weight-matched saline injected rats were used as controls. The rats were sacrificed ≤ 28 days later. To induce left-sided HF, rabbits underwent two surgical steps. First, volume overload was caused by aortic valve destruction, followed 3 weeks later by pressure overload by partial constriction of the abdominal aorta. Heart samples were frozen for qPCR analysis, histology and immunohistochemistry.
Results
qPCR analysis revealed a significant increase in mRNA levels of inflammatory cytokines, IL1β and TGFβ1, in the sinoatrial node (SAN), right atrium (RA), right ventricle (RV) and right Purkinje fibres (RPF) of the MCT-injected rats. There was an increase in mRNA levels of fibrosis markers, collagen1, elastin, fibronectin, CTGF and TIMP1, in the same tissues. There was an increase in collagen3 mRNA in the RA, RV and RPF. Vimentin mRNA increased in the SAN, RA and RV. In contrast, only modest changes were seen in the left side of the heart and a significant reduction in mRNA levels of collagens1 and 3, elastin, fibronectin and CTGF in the left ventricle (LV). Histology demonstrated proliferation of non-myocyte nuclei in the RV, but not the LV, in the MCT-injected rats. Immunohistochemisty revealed that these cells express vimentin and CD68, demonstrating they are macrophages and possibly fibroblasts. In the rabbit model, the RA demonstrated significant increases in mRNA levels of IL1β, TNF, NFκB and angiotensin II receptor 1 (AT1R). There was an increase in levels of the fibrosis markers MMP2 and TIMPs 1 and 2. The SAN demonstrated a significant increase in collagen3 and fibronectin, and a reduction in AT1R and TIMP3. There was an increase in fibronectin and TIMP1 in the RV, with no change in the LV. Fibronectin mRNA increased in the RPF, while AT1R and TIMP4 were reduced in the left Purkinje fibres (LPF).
Conclusion
In the rat model of right-sided HF, there was increased expression of inflammatory and fibrosis genes in the right side of the heart, including the SAN. This could contribute to dysfunction and predispose to arrhythmias in PAH. Unexpectedly, few changes were found in the LV and LPF in the rabbit left-sided HF model, the majority of changes occuring in the RA. The thin walled chambers of the heart, namely the RA and RV, could possibly be more susceptible to stretch as they mount an inflammatory response to HF triggers.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB047

Ultrastructural evidence of cardiomyocyte apoptosis in acute myocardial infarction and chronic aneurism wall

Y. Kyyak, O. Barnett, H. Kyyak and O. Leshchuk

Lviv National Medical University named by Danylo Halitskyy, Lviv, Ukraine

Acute myocardial infarction (AMI) is characterized by myocardial cell necrosis,inflammatory response and scar formation. The aim was to reveal whether cardiomyocyte (CMC) apoptosis is present in the infarction zone of the left ventricle compared with postinfarction chronic aneurizm wall.
Subject and methods: Myocardial express necropsies from 24 patients (age range 39-71) who suffered mainly from hypertension (HT) and died from STEMI complicated with Heart Failure (HF) or Cardiogenic Shock were examined. Biopsies from postinfarction aneurism wall from five patients (38-61 y.o), suffering from HT and HF were obtained and their ultrastructure was compared with changes in necropcies from infarction zone.
Results. According to electron microscopic investigation in infarction zones of the left ventricle exept necrotic, hibernated and apoptotic myocytes, as well as apoptotic endothelial and

plasmatic cells,macrophages and fibroblasts, with features of pycnosis, nuclear chromatin condensation and cytoplasma vacualization where detected. As the result of prominent interstitial fibrosis, very poor vascularization and moderate matrix edema,CMC usually were dissociated and myocardium loses its synthityal organization. Separately located CMC were hibernated finally resulting in apoptosis. Numerous hibernated and apoptotic CMC were destroyed via secondary necrosis predominantly during short time (three months) after AMI. In aneurism wall 14 years after AMI onset, hibernating and some viable CMC were still present as the result of myocardium neovascularization.
Conclusions: CMC necrosis is the main mechanism of cell death in acute aneurism wall, while apoptosis develops predominantly in subacute periods of AMI. In chronic aneurism wall viable CMC are present, but hibernating and apoptotic CMC prevalent.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Rate-dependency of effective electrical size in healthy and border-zone remodelled myocardium in small mammalian and human ventricular models: implications for modelling scar-related arrhythmias

Y. Hill[1], A. Pavithran[1], G. Plank[2], N. Smith[1] and M. Bishop[1]

[1]Biomedical Engineering, King's College London, London, UK and [2]Institute of Biophysics, Medical University of Graz, Graz, Austria

Sudden cardiac death resulting from cardiac arrhythmia is a significant cause of mortality in Western Society. Effective electrical size (ratio of ventricular size to electrical activation wavelength) plays a significant role in governing reentrant arrhythmia dynamics. Due to similarities in effective size, the rabbit is suggested to be the most useful model for clinical investigations of fibrillatory arrhythmias(1,2). However, how well effective size of the rabbit, or other small mammalians, correlates to the human at slower pacing rates, as commonly seen during scar-related arrhythmias, and how it varies with frequency, is not well understood. In addition, electrophysiological changes in infarct-scar border-zone (BZ) cells(3,4) may cause crucial differences in effective electrical size and restitution between species which may be important in governing reentrant dynamics during infarction. Computational ionic ventricular cell models of human, rabbit, guinea pig and rat were used to investigate interspecies differences in action potential duration (APD), conduction velocity (CV) and wavelength restitution under S1S2 and dynamic restitution protocols. Effective size was calculated to observe how restitution effects combine to induce rate-dependent variations in effective size. Ionic changes were also implemented in rabbit and human models to simulate BZ remodelling and restitution protocols repeated. The human model displayed the steepest restitution curves for all metrics. The rat model displayed negative APD restitution, at single cell and tissue levels due to known limitations with this model. The rabbit model produced the most similar effective electrical size to the human across a range of activation rates (Fig 1), although differences in effective size became more apparent at higher frequencies due to the steeper APD and CV restitution properties of the human model. Similar results were observed between S1S2 and dynamic protocols. Incorporating electrophysiological changes to represent infarct BZ cells demonstrated further differences between rabbit and human models; the human showing more pronounced changes to restitution dynamics than the rabbit in BZ tissue relative to healthy myocardium, although less of an increase in absolute APD. Failure of the rabbit model to produce similar rate-dependent effects in effective size to the human in healthy or BZ tissue suggests potentially important interspecies differences in the initiation and anchoring of reentrant waves around structures, which are currently being investigated in preliminary simulations of reentry in 3D human and rabbit infarct models. This research highlights the need for further investigation into the utility of such models for informing the study of clinical scar-related arrhythmias.

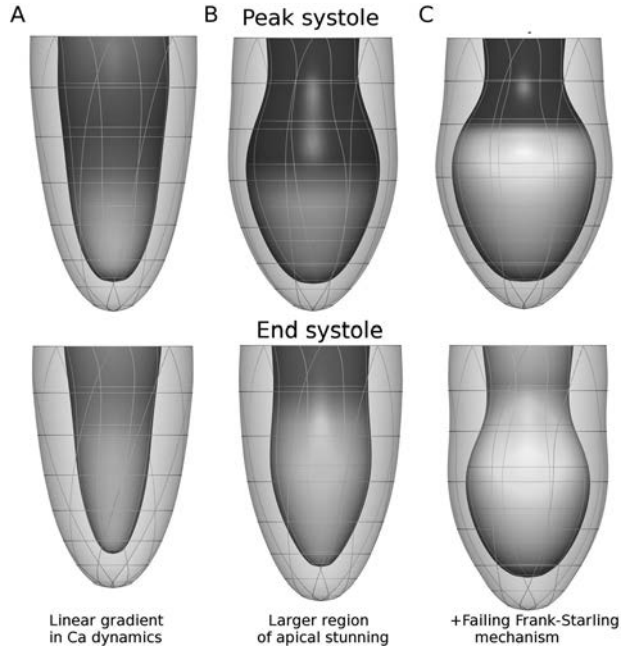
Computational modelling of stress (Takotsubo) cardiomyopathy

S. Land[1], S. Niederer[1], D. Stuckey[2], M. Sikkel[2], S. Harding[2] and N. Smith[1]

[1]Department of Biomedical Engineering, King's College London, London, UK and [2]Faculty of Medicine, Imperial College London, London, UK

Stress cardiomyopathy is a clinical syndrome characterized by acute apical dysfunction, where the shape of the left ventricle resembles the Japanese fisherman's octopus pot (tako tsubo) during systole. Results from a recent animal study have uncovered adrenaline-induced stunning of the myocardium as a potential mechanism (1,2). Exposing cardiac cells with human β_2 receptors to high concentrations of epinephrine cause a decrease in force generated by these cells (3). However, both the quantitative gradients in tension generated by the myocardium, as well as the biophysical mechanisms underpinning this phenomenon remain poorly understood.

In our work we have used biophysically based computational models of the left ventricle to investigate these potential mechanisms. Our first model assumes cellular calcium transients vary from apex to base due to differences in adrenergic stimulation.The properties of this gradient were varied in this model study in combination with the calcium sensitivity of the myofilaments.
Selected results are shown in Figure 1. These show that combination of a gradient in adrenergic effects on the calcium transient, combined with a homogeneous decrease in calcium sensitivity, are potentially sufficient to reproduce apical ballooning at mid-systole. However, by end-systole, apical ballooning is significantly decreased. We hypothesised this to be due to compensation produced by the Frank-Starling mechanism. Further model results confirm that a weakened length-dependent response of cardiac muscle increases apical ballooning at both mid- and end systole. Incorporating this mechanism resulted in a deformation of the ventricle with significant reduction in stroke volume, consistent with reported clinical cases where significant end-systolic ballooning was observed (1).
In conclusion, changes in calcium regulation through adrenergic mechanisms are sufficient to reproduce the magnitude of apical ballooning seen in Takotsubo cardiomyopathy. Significant apical ballooning at end systole may indicate a failure of the Frank-Starling mechanism.



Results of left-ventricular simulations. Darker colours on the endocardium indicate higher active tension.

(A) A linear gradient in calcium transient magnitude from apex to base does not result in significant ballooning at peak systole.

(B) A larger region of apical stunning does show the typical `Takotsubo' shape, though by end-systole this is reduced.

(C) A failure of length-dependent activation increased ballooning during peak systole and end-systole, and decreases stroke volume significantly.

Regional action potential heterogeneity in the sheep left ventricle- changes in heart failure and isolated dyssynchrony

G. Kirkwood, M. Richards and A.W. Trafford

Cardiac Physiology, University of Manchester, Manchester, UK

Background
Recent studies have identified that dyssynchronous ventricular activation can have detrimental effects including hypertrophy, dilatation and ultimately heart failure. The mechanisms are incompletely understood but appear to involve regional heterogeneities in ventricular workload. We investigated cellular remodelling in a model of dyssynchrony induced by right ventricular pacing, with regards to regional heterogeneity and how this relates to an existing model of heart failure.
Methods
Experiments were performed in female Welsh Mountain sheep, with isofluorane anaesthesia (1-4%) used for all surgical procedures. For the dyssynchrony model, transvenous pacemaker leads were implanted at the right ventricular apex and right atrial appendage. These were attached to a dual chamber pacemaker, programmed in VDD mode with a 40ms atrioventricular delay. For the heart failure model, the heart was paced at a rate of 210 bpm via a single lead implanted at the right ventricular apex. Pacing continued for 6-8 weeks in the heart failure model and 3 months in the dyssynchrony model. The animals were then euthanased with Pentobarbitone (200mg/kg IV) and the hearts excised. Ventricular myocytes were isolated by enzymatic digestion from the mid layer of the intraventricular septum (IVS) and left ventricular free wall (FW). After loading with Fura-2, these were studied at 37°C using the perforated patch current clamp technique. Action potentials were recorded at a stimulation frequency of 0.5Hz in normal Tyrode's solution, and the time to 70% repolarisation (APD70) was measured. The magnitude of the calcium transient (Ca-Tran) was calculated, along with its exponential decay rate constant (Ca-RC). Statistical comparison was performed using 2 way ANOVA with significance accepted at $p<0.05$.
Results
Results are shown as mean ± standard deviation. APD70 was longer in the septum than the free wall and in both regions was shortened in heart failure. This was associated with a reduction in the magnitude and rate of decay of the calcium transient. Dyssynchrony was associated with a trend towards APD70 shortening, and no apparent effect on the calcium transient.
Discussion
These preliminary data suggest that this model of dyssynchrony may display similar action potential changes to the heart failure model. Further experiments will explore the underlying mechanisms, and whether dyssynchrony might be considered an intermediate stage in the remodelling seen in heart failure.

Measurements for LV Free Wall (FW) and Intraventricular Septum (IVS)

Measurement	APD70 (FW)	APD70 (IVS)	Ca-tran (FW) (Peak:Baseline ratio)	Ca-tran (IVS)	Ca-RC (FW)	Ca-RC (IVS)
Control (n= 55/16)	369.6 ± 109 ms	448.5 ± 82.4 ms	1.5 ± 0.4	1.5 ± 0.4	3.0 ± 1.1 ms^{-1}	2.9 ± 0.9 ms^{-1}
Failure (n= 23/10)	302.4 ± 69 ms	399.2 ± 94.7 ms	1.2 ± 0.1	1.2 ± 0.	1.8 ± 0.4 ms^{-1}	1.7 ± 0.1 ms^{-1}
Dyssynchrony (n = 9/3)	257.8 ± 45.2 ms	368.6 ± 93.1 ms	1.5 ± 0.1	1.8 ± 0.1	2.4 ± 0.4 ms^{-1}	3.2 ± 1.1 ms^{-1}
P (Mid vs Sep)	< 0.005		n.s.		n.s.	
P (Model vs Control)	Failure < 0.05. Dyssynchrony = 0.06 n.s.		Failure < 0.05. Dyssynchrony = n.s.		Failure < 0.05. Dyssynchrony = n.s.

Freshly isolated adult fibroblasts from normal and overloaded hearts affect viability, cell volume and calcium cycling of cardiac myocytes in co-culture by paracrine TGF-β signalling

J. Cartledge, P. Dias, M. Ibrahim, S. Alayoubi, M.H. Yacoub, P. Camelliti and C.M. Terracciano

Imperial College London, London, UK

The interaction of cardiac fibroblasts (FBs) and myocytes (CMs) is gaining considerable interest due to growing evidence that fibroblasts can affect myocyte structure and function. This interaction can occur through direct cell contact or paracrine communication. Very limited data exists regarding paracrine communication, particularly between adult cells. We examined the effect of fibroblasts from normal and overloaded hearts on adult myocytes. TGF-β is a potential paracrine mediator and was investigated.

Adult Lewis rat CMs were co-cultured with FBs from pressure overloaded (10 week thoracic aortic constriction (TAC)) (T+CM) or sham operated hearts (S+CM) at 1:2 CM/FB ratio in a co-culture system that allows paracrine communication but prevents direct cell contact. CMs co-cultured with CMs (CM+CM) served as control. After 24 hours co-culture, CM viability was measured as the % rod shaped cells. CM volume was measured using di-8-ANEPPS membrane staining. Ca2+ transients were recorded using the Ca2+ sensitive dye Fluo-4. 10 μM SB431542 (SB) was used to block TGF-β type 1 receptors. Data is shown as mean±SEM (n number) and analysed by 1 way ANOVA with Tukeys post hoc analysis.

Co-culture with sham or TAC FBs reduced the viability of co-cultured CMs but this was blocked by SB (in %: CM+CM 70±1.1 (5); CM+CM+SB 72±1.7 (5); S+CM 61±2.3 (6); S+CM+SB 74±2.4 (6); T+CM 52±2.2 (6); T+CM+SB 66±2.8 (6). $p<0.05$: S+CM vs CM+CM, T+CM vs CM+CM, S+CM+SB vs S+CM, T+CM+SB vs T+CM). Both sham and TAC FBs induced CM hypertrophy which was also prevented by SB (in x103μm3: CM+CM 48±1.2 (60); CM+CM+SB 49±1.7 (43); S+CM 53±1.3 (48); S+CM+SB 48±1.4 (47); T+CM 56±1.7 (44); T+CM+SB 50±1.8 (42). $p<0.05$: S+CM vs CM+CM, T+CM vs CM+CM, S+CM+SB vs S+CM, T+CM+SB vs T+CM). Ca2+ transient amplitude was increased after co-culture with sham FBs but reduced after co-culture with TAC FBs. These effects were also prevented by SB (in F/F0: CM+CM 3.4±0.1 (42); CM+CM+SB 3.2±0.1 (33); S+CM 4.6±0.2 (50); S+CM+SB 3.3±0.1 (60); T+CM 2.8±0.1 (36); T+CM+SB 3.3±0.2 (45). $p<0.05$: S+CM vs CM+CM, T+CM vs CM+CM, S+CM+SB vs S+CM, T+CM+SB vs T+CM). Time to 90% decay of the Ca2+ transient was reduced after co-culture with sham or TAC FBs but unaffected by SB (in ms: CM+CM 359±8.5 (42); CM+CM+SB 390±17.2 (33); S+CM 322±6.2 (50); S+CM+SB 339±7.0 (60); T+CM 295±13.5 (36); T+CM+SB 317±9.3 (45). $p<0.05$: S+CM vs CM+CM, T+CM vs CM+CM). Time to peak and time to 50% decay were unaffected.

These results show that FBs affect viability and Ca2+ cycling of CMs by paracrine TGF-β signalling. FBs from overloaded hearts alter Ca2+ cycling of CMs differently from normally loaded FBs, suggesting that this paracrine interaction is sensitive to chronic variations in load and may play a role in the pathophysiology of cardiac disease.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

A chromanol-sensitive outward potassium current contributes to the repolarization of action potential in mouse sino-auricular node cells

M. Gonotkov and V. Golovko

Institute of Physiology, Komi Science Centre, the Ural's Division RAS, Syktyvkar, Russian Federation

The aim of the present study was to verify the hypothesis about the contribution of the slow component of delayed rectified K-current (IKs) in the mouse sino-auricular node (SA) pacemaker cells. Methods. Experiments were performed on albino male mice (30±5 g) two months of age (n=13). Using microelectrode technique we examined the effects of 4-chromanol on spontaneously beating strips of sino-auricular region. Results. Application of 4-chromanol (30 μm) slowed the final phase of repolarization from 0.59±0.09 V/sec to 0.43±0.09 V/sec (- 27%, n=5; $p \leq 0.05$) in the true pacemaker cells (dV/dt max ≤ 5V/sec). The velocity of the diastolic depolarization decreased from 146 mV/sec to 113 mV/sec. The frequency of action potential (AP) generation in strips decreased from 308±34 beats per min to 260±29 beats per min compared with the control. The 4-chromanol (30 μm) did not change the other parameters of AP (for example, the amplitude, dV/dtmax). This made it possible to consider this drug as a specific blocker of the slow component of delayed rectified K-current (IKs). The frequency of AP generation was 286±30 beats per min in the latent pacemaker cells (dV/dt max ≥10 V/sec) (n strips = 10). Application of IKs inhibitor 4-chromanol (30 μm) slowed the phase of the "plateau" from 0.43 V/sec to 0.25 V/sec (n=6; $p \leq 0.05$). The phase of final repolarization velocity was decrease from 0.75±0.13 V/sec to 0.37±0.1 V/sec (- 51%). The velocity of the diastolic depolarization was reduced by 52%. As a result, the frequency of AP generation decreased by an average of 31% compared with the control. Interestingly, that 4-chromanol (30 μm) decreased V0max of AP in four times compared with the control and in twice times compared with 10 μm in latent pacemaker cells.

Conclusion. The data have indicated that the contribution of the current sensitive to 4-chromanol (presumably current IKs) to repolarization and diastolic depolarization phase cells SA node mouse cells is 20-30%.

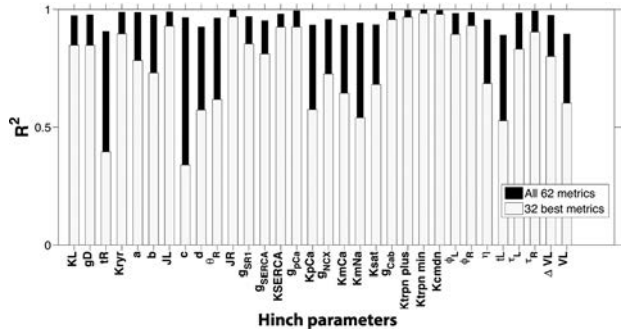
Can we automatically identify parameters from experiments? Modeling calcium dynamics in the rat cardiac myocytes

S. Gattoni, S. Niederer and N. Smith

Biomedical Engineering, King's College London, London, UK

As part of the NIH funded Virtual Physiological Rat project (VPR) [1], we aim to simulate the integrated cardiovascular function of the rat, with the potential of providing new validated computer models that account for genetic variation across rat strains. Within the cardiovascular system we focus in particular on the heart, and the cardiac cell models of the ventricular myocyte. While there is a long history of significant advances in this field, in many cases the existing electrophysiology models have been derived combining different frameworks, resulting in the majority of currently applied models being parametrized from heterogeneous experimental sources. Thus, what is now required to further develop the field and increase the applicability of models to understanding wet lab contexts, is the development of species and temperature consistent models obtained by directly fitting parameters to experimental data. To address this issue we have implemented a rat electromechanical model by combining the electrophysiological framework of the Pandit 2001 [2] model with the Hinch 2004 [3] model of Ca^{2+} dynamics. To customize the coupled Pandit-Hinch model and automatically identify the parameters, we have implemented a linear regression parameter estimation method, following the approach of Sobie 2009 [4]. Synthetic data have been preliminarily used to generate simulated experimental data, physiological phenotypes have been quantified and a reverse regression has been performed to identify the parameter values specifying the previously generated simulations. The accuracy of the predictions is shown in (Fig. 1) in terms of R^2 values for all the parameters used in the Hinch model using this approach. We were able to identify the majority of the parameters involved in the formulation of the sarcoplasmic reticulum Ca^{2+}-ATPase (SERCA), the RyR channel and the L-type channel within tight ranges; predictions of parameters on the Na^+/Ca^{2+} exchanger were less accurate. This approach will be applied to experimental data as part of the VPR project, with the potential of determing the choice of new experimental protocols according to parameterisation needs.



R^2 values showing the level of prediction for 32 parameters in the Hinch [3] model; 100 sets of randomly varied parameters have been collected in an input matrix X. Physiological phenotypes have been quantified from simulations and stored in an output matrix Y for each parameter set. A "reverse regression" has been implemented using 62 phenotypes (black) and the 32 most predictive phenotypes (white) to obtain the displayed regression coefficients.

The direct anti-fibrillatory action of vagus nerve stimulation is mediated by nitric oxide release from neuronal nitric oxide synthase

J. Winter, S.H. Chin, K.E. Brack and G. Ng

Department of Cardiovascular Sciences, University of Leicester, Leicester, UK

Introduction

We have previously shown that vagus nerve stimulation (VNS) flattens electrical restitution (RT) slope and increases ventricular fibrillation threshold (VFT) via a nitric oxide (NO) dependent mechanism [1] that is independent on acetycholine [2]. The aim of this study was to elucidate whether NO release from neuronal nitric oxide synthase (nNOS) mediates this anti-fibrillatory effect.

Methods

Adult New Zealand White rabbits (n=5, 3.0-3.5Kg) were presedated with an i.m mixture of ketamine (10mg/kg), medetomidine hydrochloride (0.2mg/kg) and butorphanol (0.05mg/kg). Following sedation, animals were heparinised (1000IU, i.v.), anaesthetised (propofol, 5mg as required, i.v.) and their hearts isolated with intact autonomic innervation. Animals were humanely killed with an overdose of sodium pentobarbitone (160mg/kg, i.v.). The preparations were perfused in constant flow Langendorff mode and instrumented for the measurement of left ventricular pressure (LVP) and epicardial monophasic action potentials. RT slope and effective refractory period (ERP) was measured using single extrastimulus protocol (300ms cycle length). VFT was the minimum current needed to induce sustained VF with burst pacing (30x30ms). The effects of VNS on baseline (BL) parameters were measured in control conditions, during perfusion of the selective nNOS inhibitor (TRIM,200μM) and following drug washout. Data are mean±SEM. 2-way ANOVA with Bonferroni or paired t-test, *P<0.05 vs. BL, **P<0.01 vs. BL, ***P<0.001 vs. BL.

Results

VNS flattened the maximum RT slope (Fig 1A), prolonged ERP (Fig 1B) and increased VFT (Fig 1C). Perfusion of TRIM abol-

ished the effects of VNS on RT slope and VFT but had no effect on the VNS increase in ERP (Fig 1). TRIM exerted a negative inotropic effect reducing peak LVP (33±3 [TRIM] vs. 41±3 [Control] mmHg, P<0.05) with no effect on baseline heart rate (135 ±5 [TRIM] vs. 135±5 [Control] bpm) or coronary perfusion pressure (30±2 [TRIM] vs. 30±1 [Control] mmHg). The degree of heart rate reduction during VNS was reduced by TRIM perfusion (change in heart rate, -45±6 [TRIM] vs. -63±5 [Control] bpm, P<0.05). All effects of TRIM were reversed on drug washout.

Conclusion

NO release from nNOS mediates the direct anti-fibrillatory action of VNS. Further experimental work is required to investigate the mechanism by which NO exerts this protective effects.

Independent roles for isoforms 1 and 4 of the plasma membrane calcium ATPase in the development of left ventricular hypertrophy and failure

N. Stafford, M. Zi, M. Shaheen, S. Cook, T. Mohamed, L. Neyses and E.J. Cartwright

Institute of Cardiovascular Sciences, University of Manchester, Manchester, UK

Abnormal calcium handling is known to be instrumental in the development of cardiac hypertrophy and failure. Both isoforms 1 and 4 of the diastolic calcium extrusion pump plasma membrane calcium ATPase (PMCA) are downregulated in failing human and rodent hearts, yet their role in the disease process has not been studied.

Methods: We generated cardiomyocyte-specific knockout mice for PMCA1 (PMCA1-/-), PMCA4 (PMCA4-/-) and the two pumps combined (PMCA1:4-/-), closely modelling the situation in human heart failure. Cardiac phenotype and calcium handling in isolated ventricular myocytes were studied in each mouse line under basal conditions, and in response to pressure overload following two weeks transverse aortic constriction (TAC).

Results: Cardiac structure and function was not altered by the absence of PMCA1 or 4, nor their dual deletion under basal conditions. The PMCA contribution to global calcium extrusion was found to be 2%, and for the first time solely dependent upon PMCA1. When challenged with TAC, PMCA1-/- hearts rapidly progressed into decompensated hypertrophy displaying signs of impaired inotropy, lusitropy and heart failure as evidenced by decreased fractional shortening (20.6±1.6 v 32.4±3.3 %), increased relaxation time constant (8.8±0.8 v 6.6±0.3 ms) and greater normalised lung weight (11.5±1.1 v 7.8±0.8 mg/g) compared to controls. This was accompanied by increased apoptosis and extensive interstitial fibrosis. Analysis of intracellular calcium handling prior to the onset of failure (1 week post surgery) revealed impaired extrusion of the systolic transient in PMCA1-/- TAC cells compared to both wild type TAC and sham PMCA1-/- controls. In stark contrast, the deletion of PMCA4 attenuated the hypertrophic response to pressure overload with an 86% reduction in normalised heart weight compared to wild type TAC controls, whilst systolic and diastolic function were preserved. We hypothesised the deletion of PMCA4 may rescue the failing phenotype in PMCA1-/- mice, so PMCA1:4-/- mice also underwent TAC. Hearts displayed reduced heart weight/tibia length compared to wild type controls (7.0±0.4 v 9.2±0.6 mg/mm), accompanied by preserved function and reduced fibrosis.

Conclusions: These results provide novel evidence of isoform-specific roles for PMCA1 and 4 in cardiac muscle, both capable of influencing the pathological progression of cardiac hypertrophy. PMCA1 may be critical in adapting to the increased demands placed on the heart during pressure overload, whilst the inhibition of PMCA4 may negate the need to adapt altogether and could be a potential target for future anti-hypertrophic therapies.

PCB056

Prolonged arsenic trioxide treatment increased action potential duration and increased sensitivity to HERG channel blockade in induced pluripotent stem cells cardiomyocytes

M.P. Hortigon-Vinagre[1], I.A. Ghouri[1], F.L. Burton[1], B.D. Anson[3], R. Wallis[2], M. Craig[2] and G. Smith[1]

[1]Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, UK, [2]Clyde Biosciences, Glasgow, UK and [3]Cellular Dynamics Inc., Madison, WI, USA

Long QT syndrome (LQTS) is a heart rhythm disorder that increases the risk of fatal cardiac arrhythmia known as Torsade de Pointes (TdP). One common cause of LQTS (type 2) is a mutation in HERG gene, which encodes the rapidly activating delayed rectifier potassium channel (IKr) and reduces channel activity by causing defective channel trafficking to the surface membrane. Previous studies in animals have shown that arsenic trioxide (As2O3) treatment can disrupt HERG channel trafficking and induce LQTS. In this study we report the ability of As2O3 to induce a LQT phenotype in commercially available human induced pluripotent stem cells (iPSC) cardiomyocytes.

iPSC (obtained from Cellular Dynamics Incorporated), were maintained in culture for 10 days before exposing to 10 μM As2O3 in serum free medium for 1 or 24 hrs. The cells were then washed in serum free medium and exposed transiently to 3 μM Di-4-ANEPPS and left for 60-90mins before electrical recordings were made. The multi-well plate was placed on a stage incubator of an inverted microscope and the spontaneous electrical activity was recorded from the Di-4-ANEPPS fluorescence signal from areas of iPSCs in individual wells visualized using a 40x (NA0.6) objective. Fluoresence signals were

digitized at 10kHz and the digital records subsequently analysed off-line.
Under basal conditions, the spontaneous activity occurred every 1.98±0.54s (n=14) and the mean action potential duration at 75% repolarization (APD75) was 539±18ms. Treatment with As2O3 for 1 hr had no effect on the action potential duration (control vs. As2O3; 433±51 vs. 425±37), exposure for 22-24hrs prolonged APD75 significantly (P<0.05) to 601±21 ms (n=12) without any change in the rate of spontaneous activity (1.93±0.50s). Addition of the HERG channel inhibitor E4031 (30nM) increased APD75 in both groups (control: 1162±181ms and As2O3:1591±129ms). Early afterdepolarizations (EADs) occurred more frequently in the As2O3 group after treatment with E4031 (3 and 10nM) than in the corresponding control group.
In conclusion, As2O3 treatment pronged APD in iPSCs. Treatment with a HERG channel blocker causes a further prolongation of APD and increased the incidence of arrhythmic events when compared to the control group. Thus As2O3 treatment was able to recapitulate the prolonged action potential duration and increased pro-arrhythmic sensitivity to HERG channel blockade associated with LQTS in human hearts.

This work was financially supported by Clyde Biosciences (Glasgow UK), M.P.H.-V. is recipient of a postdoctoral fellowship from Fundacion Alfonso Martin Escudero (Spain).

PCB057

Reduced expression of creatine kinase and diastolic dysfunction in failing rat ventricular myocytes

E. Fowler, R. Stones, D.S. Steele and E. White

School of Biomedical Sciences, University of Leeds, Leeds, UK

Creatine kinase (CK) catalyses the exchange of inorganic phosphate from phosphocreatine (PCr) to ADP in the myofilament lattice in cardiac myocytes and is essential for normal heart function. CK activity is decreased in heart failure (HF) causing [ADP] to rise, impairing relaxation. We have investigated the role of CK in the diastolic dysfunction of rats with right ventricular (RV) failure.
Male Wistar rats (200 g) were injected with 60 mg.kg^{-1} monocrotaline to induce pulmonary hypertension and RV failure (FAIL; N=14) or an equivalent volume of saline (CON; N=11); FAIL rats were sacrificed upon showing symptoms of HF, CON rats were sacrificed on equivalent days. Homogenates of ventricular tissue were used for Western blotting analysis. Isolated cardiac myocytes were obtained by enzymatic dissociation. Single cell experiments were conducted at 21 or 37 °C. Resting sarcomere length (SL) was measured online by fast Fourier transform of the cell's video image. Data are presented as mean±SEM; 1 or 2-way ANOVA was used to identify differences and p<0.05 was considered significant.
Resting SL was significantly shorter in RV FAIL compared to CON cells (FAIL 1.79±0.01 μm, CON 1.89±0.01 μm; p<0.05, n=79-139). Expression of muscle-isoform CK (normalised to GAPDH) was decreased by 50% in RV FAIL (N=6) compared to RV CON (N=6, p<0.05), there was no difference in CK expression between LV CON and FAIL (N=3) (Fig.1). Compared to Tyrode alone, the CK inhibitor FDNB in Tyrode (20 μM, for 10 min) significantly shortened resting SL in both CON (FDNB 1.78±0.03 μm, Tyrode 1.89±0.01 μm; p<0.05, n=10) and FAIL cells (FDNB 1.67±0.01 μm, Tyrode 1.80±0.01 μm; p<0.05, n=24).
CK binds to the myofilaments of skinned muscle fibres. Saponin-skinned cells were incubated (30 min) in solutions containing or lacking bovine CK (4.4 mg.ml^{-1}) and 10 mM PCr; in their absence the resting SL of FAIL RV was significantly shorter than CON RV (CON 1.95±0.01 μm, FAIL 1.83±0.02 μm, p<0.05, n=24) but not in their presence (CON 1.94±0.01μm, FAIL 1.90±0.01μm; p>0.05, n=24).
The results suggest that in RV failure the shorter SL is caused by reduced CK expression. Reduced CK expression may reduce resting SL by allowing local [ADP] to increase, with consequent effects on cross-bridge cycling. We are currently investigating the functional consequences of this.

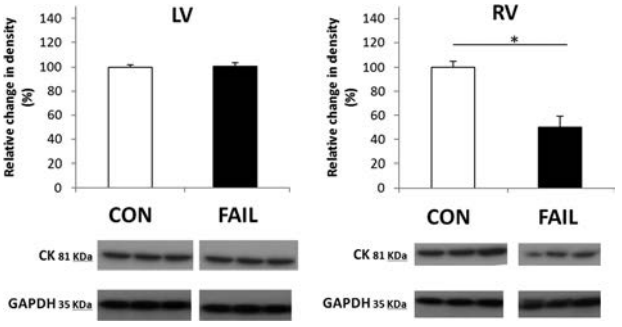

Figure 1. CK expression decreased only in the RV of rats with right heart failure

PCB058

Differential regulation of the slow and rapid delayed rectifier potassium currents by cGMP dependent nitric oxide signalling pathways in isolated adult guinea pig ventricular myocytes

R.E. Caves[1], K. Brack[2], A. Ng[2] and J. Mitcheson[1]

[1]Cell Physiology and Pharmacology, University of Leicester, Leicester, UK and [2]Cardiovascular Sciences, University of Leicester, Leicester, UK

Recently, nitric oxide (NO) signalling pathways have been linked with abnormalities in cardiac repolarisation and cardiac arrhythmias. Studies from isolated heart preparations have demonstrated an antifibrillatory effect following vagus nerve stimulation, which is NO dependent. The cellular and molecular basis for this protective effect is unknown. In this study, cGMP dependent regulation of repolarisation was investigated using BAY 60-2770, a novel NO and haem independent soluble guanylyl cyclase (sGC) activator. Action potentials (APs) and ionic currents were recorded from isolated guinea pig ventricular myocytes at 37ºC using the perforated patch clamp technique. APs were stimulated at 2 Hz and the slow and rapid delayed rectifier potassium currents, I_{Ks} and I_{Kr} were measured as tail currents elicited by a voltage step from +40 mV to -50 mV. Cellular cGMP was quantified by radioimmunoassay and expressed as a fold change relative to basal levels. Values are presented as means ± S.E.M. compared by paired t test. 1 μM BAY 60-2770 increased cellular cGMP by 2.2 ± 0.3 fold (n=8) and by 7.1 ± 0.8 fold (n=7) in the presence of 100 μM IBMX (3-

Isobutyl-1-methylxanthine), a non-selective phosphodiesterase (PDE) inhibitor. In vitro assays on purified sGC have shown that ODQ (1H-[1,2,4]Oxadiazolo[4,3-a]quinoxalin-1-one) potentiates the action of BAY 60-2770. This was corroborated in our experiments, BAY 60-2770 + 10 μM ODQ increased cGMP by 27.9 ± 9.6 fold (n=4). Despite substantial increases in cellular cGMP, changes in times to 90% repolarisation of action potentials (APD_{90}) were modest. BAY 60-2770 modestly, but significantly ($p<0.001$, n=8) shortened APD_{90} by 11.3 ms, subsequent addition of ODQ in the presence of BAY 60-2770 caused no significant further APD_{90} shortening. In contrast, in the presence of IBMX, BAY 60-2770 significantly ($p<0.05$, n=7) lengthened APD_{90} by 15.7 ms, suggesting PDE inhibition permits repolarising currents to be inhibited by cGMP dependent signalling pathways. Further experiments showed that I_{Ks}, but not I_{Kr}, was inhibited by BAY 60-2770, in the presence of IBMX. IBMX enhanced I_{Ks} by 77 ± 9 % ($p<0.001$, n=8). Subsequent addition of BAY 60-2770 reduced the IBMX dependent enhancement of I_{Ks} by 68 ± 2 % ($p<0.001$, n=8). BAY 60-2770 had no significant effect on I_{Kr}, either on its own or in the presence of IBMX. Overall, these findings demonstrate the complex interplay between cGMP and cAMP mediated effects on the ion channels regulating cardiac repolarisation. The modest effect of BAY 60-2770 + ODQ on APD_{90}, despite a substantial increase in cellular cGMP, highlights that PDEs limit cGMP accumulation close to ion channels in the sarcolemma, thus compartmentalising cGMP signalling.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

The mechanisms responsible for atrial fibrillation (AF) are complex. At the tissue and cellular level, Ca2+ currents are downregulated whereas repolarizing K+ currents are maintained, leading to action potential shortening. At the protein level however, Kv1.5 channels, the molecular expression of IKur, the main repolarizing current in human atria, is significantly decreased.

We used a rat model of atrial remodeling induced by myocardial infarction (dilated atria) which reproduces the substrate of AF to investigate the mechanisms responsible for Kv1.5 channel internalization. Kv1.5 protein was decreased by 30% in dilated atria. However, the whole-cell current as measured by patch-clamp was maintained in dilated myocytes. The discrepancy between reduced protein level and maintained current density suggest that in dilated myocytes more Kv1.5 functional channels are inserted into the sarcolemma. We thus studied the internalization of Kv1.5 channels in control and diseased atria.

Firstly, we investigated the endocytosis pathway for Kv1.5 channels in the atria. High resolution 3-Dimensionnal microscopy revealed that Kv1.5 channels are associated with clathrin vesicles in atrial myocytes but not with caveolin. Electron microscopy (EM) showed that vesicles are found both at the lateral sarcolemma and at the intercalated disc. Blockade of the clathrin pathway using hypertonic media or SiRNA induced an increase in IKur, an accumulation of Kv1.5 channels at the sarcolemma as shown by biotinylation assays and an increased fluorescence recovery after photobleaching (FRAP), supporting the idea that Kv1.5 channels are internalized via the clathrin pathway.

Secondly, we studied the internalization activity in the dilated atria. In dilated atria, Western blot experiments showed a 35% reduction in clathrin levels. High resolution 3-Dimensionnal microscopy showed reduced association between Kv1.5 channels and clathrin vesicles in dilated myocytes. However, EM showed no significant difference in the internalization activity between sham and dilated atria.

Therefore, the reduced clathrin protein synthesis observed in dilated atria is not likely to be responsible for the accumulation of Kv1.5 channels at the sarcolemma. Other mechanisms such as increased recycling and/or membrane stabilization must be investigated to understand how IKur is maintained in dilated atria and during chronic AF.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB060

The effect of stimulation frequency on post-rest potentiation and calcium handling in sheep atrial myocytes

D.K. Wrigley, A.W. Trafford and K.M. Dibb

University of Manchester, Manchester, UK

The atria are the site of the most common arrhythmia observed in clinical practice, atrial fibrillation (AF). It is hypothesized that abnormal calcium (Ca) handling in the atrial myocardium is involved in the pathogenesis of AF. As AF is strongly characterised by abnormalities in rate and rhythm, changes in these are frequently used as experimental manoeuvres to evaluate the behaviour, or to disclose abnormalities of Ca kinetics on excitation-contraction-coupling (1). Accordingly, post-rest-potentiation (PRP) allows indirect evaluation of sarcoplasmic reticulum (SR) function (2,3). PRP is a result of Ca accumulation in the SR during a pause, and an increased fractional release (FR) upon resumption of stimulation (3,4). Previous data focus on the length of the rest period, and how this affects PRP. In this study I aim to investigate the role stimulation frequency plays on PRP in sheep atrial myocytes.

Atrial myocytes were isolated from the left auricle of healthy adult sheep, which were killed by an intravenously administered overdose of pentobarbitone (200mg/kg). Experimental protocols were carried out under perforated patch, voltage clamp conditions, at 37°C. Intracellular Ca was measured using fluo-5F at stimulation frequencies of 1, 3, and 5Hz. PRP measurements were taken after rest periods of 5 seconds. Ca changes are expressed as pseudo ratio (F/F0) measurements. An increase in stimulation frequency resulted in a rise in amplitude for the first Ca transient following a period of rest (2.77±0.41, 3.86±0.70, 3.96±0.38 at 1, 3, and 5Hz respectively, $p<0.01$, n=25). This indicates a positive relationship between PRP and stimulation frequency. Conversely at steady state an effect is observed, where Ca transient amplitude decreases with a rise in stimulation frequency (1.56±0.14, 1.14±0.07, 0.86±0.07, at 1, 3, and 5Hz respectively, $p<0.01$, n=39). There were no differences in peak L-type Ca current for the first PRP following rest, with changes in stimulation frequency.

A rise in stimulation frequency results in an increase in the amplitude of the first Ca transient following a period of rest. In contrast, a negative Ca transient amplitude to frequency

relationship is observed during periods of steady state. As there is no difference in peak L-type Ca current within the first transient post rest between each frequency, a greater amount of Ca released from the SR, as a result of increased SR Ca content may play a role, which could impact on the force generation upon the first activation following rest. However, as I have not directly measure SR Ca content after periods of rest further investigation is required. This positive relationship between PRP and stimulation frequency may play an important role in contraction under arrhythmic conditions.

Spontaneously contracting 3D in vitro heart model established from fish for the use in pharmacology

B. Grunow[1], L. Mohamet[2] and H. Shiels[1]

[1]Faculty of Life Science, University of Manchester, Manchester, UK and [2]School of Dentistry, University of Manchester, Manchester, UK

Cellular models are an important tool for studying human heart disease. To date, many research groups focus on mouse models, but murine cardiac physiology is different from human cardiac physiology. Interestingly, recent data suggests the electrophysiology of fish cardiomyocytes largely resembles that of humans (Brette et al. 2008), opening up the possibility of the fish to become a good model system to study heart disease. Recently, a fast and cost-effective in vitro heart model system has been developed (Grunow et al. 2010, 2011, 2012). The model is a 3D cell cluster which beats spontaneously and is generated from fish larvae. Morphological and molecular characterisation of the 3D in vitro heart model revealed high similarities to human heart in terms of beat rate, drug responses and structural morphology (Grunow et al. 2011).The present work uses electrophysiological techniques to characterize underlying ion currents in myocytes acutely isolated from the 3D in vitro heart model. Our results suggest that the 3D in vitro heart model has high potential

The absence of interference sounds present the phase shifting and signal missing on the heart sound spectral

N. Finahari[1,3], S.P. Sakti[2], R. Ratnawaty[3] and M. Indra[3]

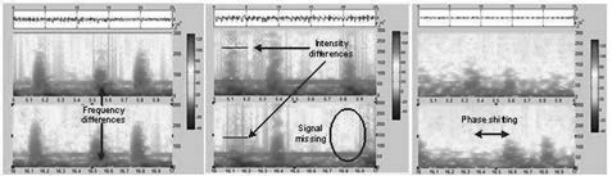
[1]Mechanical Engineering, Widyagama University of Malang of Indonesia, Malang, East Java, Indonesia, [2]FMIPA, Brawijaya University, Malang, East Java, Indonesia and [3]Medical Faculty, Brawijaya University, Malang, East Java, Indonesia

Introduction: The interactions between heart and lungs activities are the manifestation of cardioresipratory synchronization. The harmonization between heart pulse and respiratory rate is a true synchronization phenomenon eventhough not the main variable of cardiorespiratory interaction [1]. From the mechanical physic point of view, the neighboring position of heart and lungs, raising the possibility for the interference sound waves to be occure, so that can be considered as the form of cardiorespiratory synchronization too. So far, the interference sounds just considered as noise that must be minimized or removed [2-4]. This research try to give different ways to understand the interference sounds. In this context, will be proved that the interference sounds bring a unique characteristics to the heart sounds.

Method: The research was done by analyzing the heart sounds spectral obtained from the hold and free breathing condition. These data were recorded simultaneously with the electrocardiograph (ECG) signal and the respiratory rates, from the healthy male/female in sitting position. The free breathing condition was done for 40 seconds, meanwhile the hold breathing was recorded for 15 seconds. All raw data were obtained from Amit et al. [5].

Result: The spectral analysis for the hold breathing heart sounds shows the phenomenon of phase shifting and the signal missing (Fig. 1). The results of correlation analysis prove that the phase shifting correlate with respiratory cycles, meanwhile the signal missing correlate with the ECG signal. These findings seems to be associate to the hold breathing condition that similar with the maximum inspiration condition. It means that the left ventricular filling volume flows constantly so that the heart sounds on the left area just influence by the variation of constraction-relaxation triggered by the heart electricity. The hold breathing condition is seems like permanent inspiration too because of the subject have filled the lungs as much as possible before holding the breathing. This condition makes the minimum filling volume to trigger the heart valve opening to be delayed. It means that the heart sounds generation become delayed also.

Conclusion: The present of phase shifting and signal missing in the recorded heart sounds for the hold breathing condition prove that the interference sounds between heart and lungs do have significant influences to the heart sounds dinamics. Separating the lungs sounds from the heart sounds in the auscultation process will decrease the accuracy of the analysis results.



The results of spectral analysis for free (upper) and hold (lower) breathing condition. The colour represent the magnitude of frequency, the horizontal axis represent time (phase), and the vertical axis represent the sound intensity

Bupranolol blocks the cardiostimulatory effect of CGP12177 in rat atrial myocytes mediated via the low affinity β1-adrenoceptor

C.L. Sam[1,2], T.B. Bolton[2], I.T. Piper[1] and N.S. Freestone[1]

[1]Faculty of Science, Engineering and Computing, Kingston University, Surrey, UK and [2]Biomedical Division, St George's, University of London, London, UK

A number of β-adrenoceptor blockers (eg. pindolol and CGP12177) cause cardiostimulation at high concentrations and have been contraindicated in the treatment of ischemic heart disease due to sympathomimetic effects (Podrid and Lown, 1982). Previously Freestone *et al.* (1999) showed that a non-conventional partial agonist, CGP12177 is pro-arrhythmic in paced mouse ventricular cells. Recently, it has been shown that CGP12177, in quiescent rat atrial cells, provokes an increase in spontaneous calcium (Ca^{2+}) release events from the sarcoplasmic reticulum (SR) even in the presence of propranolol (Sam *et al.,* 2012). These propranolol-insensitive effects have led to the designation of a new receptor subtype - the $\beta1_L$-adrenoceptor (low affinity) distinct from the classical β1-adrenoceptor now called the $\beta1_H$-adrenoceptor (high affinity). A non-selective β-blocker, bupranolol, blocks the $\beta1_L$-adrenoceptor with moderate potency (Kaumann *et al.,* 1998) and thus may inhibit pro-arrhythmic effects caused by CGP12177. In this study we have used bupranolol in quiescent rat atrial cells to investigate its effect on SR Ca^{2+} release stimulated by CGP12177. Atrial cells were isolated from WKY rats (Freestone *et al.,* 2000) and were loaded with the Ca^{2+} fluorescent dye, fluo 4-AM (5μM). Ca^{2+} events within quiescent cells were imaged in whole cell and line scanning mode of the LSM510 M confocal microscope. Cells were perfused with propranolol (200nM) alone, CGP12177 (1μM) in the presence of propranolol (200nM) and CGP12177 (1μM) in the presence and absence of bupranolol (1μM) and the frequency of calcium events recorded. Propranolol produced 0.4 ± 0.1 large but localised Ca^{2+} release events (wavelets) s^{-1}. Co-administration of CGP12177 with propranolol significantly increased the incidence of wavelets to 0.86 ± 0.17 s^{-1} (n=12, $p < 0.005$). Perfusion with bupranolol alone and bupranolol with CGP12177 produced no wavelets. In terms of Ca^{2+} sparks, bupranolol produced an average of 27.4 ± 8.6 sparks s^{-1}. Co-administration of bupranolol with CGP12177, elicited 47.6 ± 12.8 sparks s^{-1} but this difference was not statistically significant. In cells not exhibiting waves or wavelets, CGP12177 increased Ca^{2+} spark frequency (compared to propranolol perfusion alone) from 42 ± 5.3 s^{-1} to 62 ± 6.1 s^{-1} (n=6, $p < 0.01$). As shown previously, CGP12177 (working through $\beta1_L$) isassociated with more potent arrhythmogenic effects in cardiomyocytes than for example, ISO (working through $\beta1_H$). It can also be concluded that bupranolol inhibits spontaneous Ca^{2+} release activity mediated via $\beta1_L$.

Isoprenaline induced changes of action potential configuration, the role of Ca^{2+} and K^+ currents of canine ventricular cells

K. Kistamás, N. Szentandrássy, L. Bárándi, B. Hegyi, F. Ruzsnavszky, K. Váczi, T. Bányász, J. Magyar and P.P. Nánási

Department of Physiology, University of Debrecen, Medical and Health Science Centre, Debrecen, Hungary

It is well known, that a non-selective β-adrenergic receptor agonist, the isoprenaline (ISO) activates several ionic currents in mammalian myocardium, however their relative contribution to the ISO-induced changes in action potential morphology is not well explored. Therefore, our aim was to describe the effects of ISO on action potential configuration, L-type Ca^{2+} current ($I_{Ca,L}$), slow delayed rectifier K^+ current (I_{Ks}) and fast delayed rectifier K^+ current (I_{Kr}) in canine left ventricular myocytes.

Adult beagle dogs (n=39) were anaesthetized with the mixture of ketamine hydrochloride (10 mg/kg) and xylazine hydrochloride (1 mg/kg, both I.M.) according to a protocol approved by the local ethical committee, which conformed to the principles outlined in the Declaration of Helsinki. Single myocytes were obtained by enzymatic dispersion using the segment perfusion technique. Action potentials were recorded with conventional sharp glass microelectrodes, ionic currents were measured using conventional and action potential voltage clamp techniques on isolated ventricular cardiomyocytes (n=157) from dog hearts. Values are expressed as mean ± S.E.M., compared by ANOVA.
ISO (10-100 nM) caused significant and reversible shortening of action potential duration accompanied by elevation of the plateau potential. Similar results were observed when ISO was applied after pretreatment with an IKr blocker (1 μM E-4031). In the presence of an IKs blocker (1 μM HMR1556) action potentials were significantly lengthened by ISO in spite of the pronounced plateau elevation. Both ISO-induced changes were prevented by pretreatment with nisoldipine ($I_{Ca,L}$ blocker, 5 μM). Action potential voltage clamp experiments revealed a prominent slowly inactivating $I_{Ca,L}$ followed by a rise in I_{Ks}. Similar ISO-induced responses were seen in the presence of 1 μM E-4031, while the ISO-induced activation of I_{Ks} was abolished by 1 μM HMR1556. Conventional voltage clamp experiments revealed that ISO increased I_{Ks}, I_{Kr} and $I_{Ca,L}$ to 420±4 (n=5, p<0.05), 133±1 (n=8, p<0.05) and 340±13 % (n=8, p<0.05) of their baseline values, respectively, with the concomitant EC_{50} values of 14.5±1.1, 13.7±2.5 and 15.3±3.5 nM (n=5, n=8, n=8, respectively).
Our results suggest that the ISO-induced activation of I_{Ks} - but not I_{Kr} - may be responsible for the observed shortening of action potentials in the canine myocytes. The similar EC_{50} values estimated for I_{Ks}, I_{Kr} and $I_{Ca,L}$ may indicate a common mechanism responsible for the ISO-induced activation of these currents.

PDE5 inhibition reduces ICa-L and systolic calcium transient in the failing sheep ventricle

M. Lawless, D.A. Eisner and A.W. Trafford

University of Manchester, Manchester, UK

Heart failure (HF) is a major cause of premature mortality and increased morbidity. One of the hallmarks of HF is a decrease in responsiveness to beta-adrenergic (β-AR) stimulation. As HF patients have elevated levels of circulating catecholamines, it is possible that changes to β-AR signalling are caused by desensitisation of the β-adrenoreceptors. The second messengers cAMP and cGMP enable correct β-AR signalling by facilitating phosphorylation of a number of excitation contraction-coupling (ECC) targets. It is believed that remodelling of the cAMP pathway in HF may lead to β-AR desensitisation. In a similar vein to beta-blocker therapy, inhibitory cGMP pathway activation may improve contractility in HF patients through modulation of the remodelled cAMP pathway. Thus, we sought to investigate the effects on ECC parameters in the presence of a selective inhibitor of the main cGMP-hydrolysing phosphodiesterase isoform, PDE5.
Heart failure was induced in sheep using tachypacing. Animals were anaesthetised for pacemaker implantation (isoflurane, 1-3% in oxygen) and perioperative analgesia provided (meloxicam, 0.5 mg/kg). After 7 days recovery, right ventricular pacing (210-220 bpm) was applied until clinical symptoms of HF were evident. Animals were sacrificed by I.V. injection of pentobarbitone (200mg/kg) and collagenase digestion was used to isolate mid-myocardial left ventricular myocytes for whole cell voltage clamp studies. In the presence of the selective PDE5 inhibitor sildenafil (1 μM), systolic transient amplitude and L-type calcium current (ICa-L) were significantly reduced in both control (n=6, P<0.005) and HF (n=5, P<0.05) myocytes. When co-stimulated with the non-selective β-AR agonist isoprenaline (100 nM), PDE5 inhibition attenuated increases in ICa-L (n=5, P<0.05) with no effect on calcium transient amplitude in control myocytes. No effects of PDE5 inhibition were observed on the responses to β-AR stimulation in HF myocytes. In HF sheep chronically treated (~4 weeks) with the selective PDE5 inhibitor tadalafil (20 mg/kg) preliminary analysis of the ICa-L current properties, in comparison to control myocytes, showed a significant rightward shift of current inactivation and decreased window current. Significance assessed using one way repeated measures ANOVA and student's t-test.
The present data shows that PDE5 inhibition, possibly through increased PKG activity, can reduce baseline ICa-L and systolic calcium transient amplitude in ventricular myocytes from both normal and HF sheep. However, under stimulation of an already impaired β-AR pathway in HF myocytes, the suppressive effects of PDE5 inhibition are not observed. This may suggest a role for remodelling of the signalling pathways governing interaction of cAMP and cGMP.
Experiments were carried out in accordance with the UK Home Office Animals (Scientific Procedures) Act 1986.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Chamber-specific expression of sarcoplasmic reticulum Ca^{2+}-ATPase in healthy and diseased rat hearts

C.L. Sam[1,2], T.B. Bolton[2], A. Feldheiser[3], I.T. Piper[1] and N.S. Freestone[1]

[1]Faculty of Science, Engineering and Computing, Kingston University, Surrey, UK, [2]Biomedical Division, St George's, University of London, London, UK and [3]Department of Anaesthesiology and Intensive Care Medicine, Charité-Universitätsmedizin Berlin, Berlin, Germany

Depolarisation of cardiac cells causes calcium (Ca^{2+}) release from an intracellular store known as the sarcoplasmic reticulum (SR). The transient elevation in intracellular Ca^{2+} concentration that results causes cardiac contraction. SERCA2a enables cardiac relaxation when it pumps Ca^{2+} back into the SR hence refilling the Ca^{2+} store for the next contraction. The abundances of SERCA2a differ in atria and ventricles of various species so that relaxation times are shorter in atria under normal conditions (Freestone *et al.*, 1999). We show that SERCA2a has a tendency to be differently expressed in different chambers from healthy and diseased rat hearts. Left and right atria and ventricles from rats experimentally-induced to manifest heart failure (aorto-caval shunt causing volume overload) and sham-operated Wistar rats, as well as spontaneously

hypertensive rats (SHR) and their normotensive controls were snap frozen and homogenised. Western blotting was carried out and the protein abundance was quantitatively determined by densitometry. Sham-operated and normotensive animals had a tendency to have a higher abundance of SERCA2a than animals with heart failure and hypertension in both atrial and ventricular tissues as shown in Table 1. The ventricular tissue expresses less SERCA2a compared to the atria in both normal and hypertensive animal populations. A trend arises where there is a tendency for less SERCA2a protein in the disease state compared to the normal state. SERCA2a has a tendency to be less expressed in heart failure tissues (especially for left ventricular and left atrial shunt and sham-operated tissues, p = 0.1). SERCA2a also has a tendency to be expressed more in WKY compared to SHR for all four heart chambers, which may relate to less Ca^{2+} release in the SHR animals and consequently less forceful contractions of the hypertrophied heart (Li *et al.,* 2005). SERCA2a is therefore expressed in a chamber-specific manner in the cardiac tissue samples of both healthy and diseased heart.

	WKY	SHR	Sham	Shunt
LV	1.26±0.05	1.00±0.05	1.24±0.02	1.08±0.08
RV	1.04±0.03	1.00±0.01	0.96±0.10	0.87±0.08
LA	1.27±0.14	1.18±0.06	1.32±0.18	0.73±0.04
RA	1.20±0.12	0.81±0.02	1.12±0.16	0.98±0.09

Table 1. SERCA2a abundances in left and right atrial and ventricular tissues under normal conditions and diseased states.

(LV, RV, LA and RA depicts left ventricular, right ventricular, left atrial and right atrial tissues respectively).

Dietary fat does not alter mechanical efficiency of the rat heart: an isolated working heart study

S. Goo[1], J. Han[2], A. Taberner[2,3], P. Nielsen[2,3], I. LeGrice[1,2] and D. Loiselle[1,2]

[1]Physiology, University of Auckland, Auckland, New Zealand, [2]Auckland Bioengineering Institute, Auckland, New Zealand and [3]Engineering, University of Auckland, Auckland, New Zealand

It has been previously reported [1] that a two-fold increase in mechanical efficiency of the heart can be achieved following dietary supplementation of fish oil, namely DHA and EPA. In the same study, saturated fat-rich diet caused a significant decrease of efficiency. The objective of our study was to re-examine these two findings. Male Wistar rats, at the age of 6 weeks, were divided into three diet groups: reference (REF, n=15), fish oil-rich (FO, n=14) and saturated fatty acid-rich (SAT, n=16). The REF diet contained 6% fat (by weight), whereas both the high-fat groups (FO and SAT) contained 16% fat. Rats were fed the specified diet for 6-8 weeks, reaching weights of 400-500 g. At the end of this period, they were deeply anaesthetised with 5% isoflurane in oxygen and, after cervical-spinal dislocation, their hearts excised. Isolated working heart experiments were performed, as originally described by Neely et al. (1967) [2], at both 37 °C and 32 °C. The perfusate was a modified Tyrode's solution, gased with 100% O2. Hearts were paced at 5 Hz and 4 Hz at 37 °C and 32 °C, respectively, and subjected to a range of preloads and afterloads. Pressure-volume work of the left ventricle, global myocardial oxygen consumption and mechanical efficiency were calculated. Analysis of Variance revealed no statistically significant effect of temperature on any energetic variable. More importantly, there was no difference (p = 0.96) of mechanical efficiency among the diet groups (9.6 ± 0.3, 7.3 ± 0.3 & 7.9 ± 0.2% at 37 °C and 8.7 ± 0.4, 10.6 ± 0.4 & 10.7 ± 0.2% at 32 °C, mean ± S.E.M., for REF, FO and SAT groups, respectively). We conclude that dietary supplementation with neither Omega-3-enriched fish oils nor saturated fat alters the mechanical efficiency of the myocardium.

The effect of drugs on cardiac electrophysiology is important in commercial screening for human drug development. Isolated tissue from animal models and non-muscle expression-systems are currently used to screen for potential pro-arrhythmic effects. Recently, human cardiomyocytes derived from induced pluri-potent stem cells (iPSCs) with an electrophysiological phenotype similar to the ventricular myocardium have become available commercially. This study investigated the sensitivity of these cells to a series of standard drugs, and compared responses to published effective therapeutic concentrations in humans.

iPSC (obtained from Cellular Dynamics Inc, Madison WI), were maintained in culture for 10 days in a plastic 48 well plate. The cells were washed in serum-free medium and exposed transiently to 3 μM Di-4-ANEPPS. The plate was placed was placed in a stage incubator on an inverted microscope and the spontaneous electrical activity was recorded as the Di-4-ANEPPS fluorescence signal from areas of iPSCs in individual wells using a 40x (NA 0.6) objective. Fluoresence signals were digitized at 10kHz and the records subsequently analyzed off-line. Cells

were exposed to cumulative increases in drug concentrations allowing 30 mins incubation at each concentration. The procedure was repeated up to 9 times and parallel measurements were done on cells with equivalent concentrations of vehicle. Incrementing the drug concentration by 0.5 log units, a threshold was established as the first concentration at which detectable differences between the drug and control group were observed. Action potential parameters were measured, including 10%-90% rise time (Trise) action potential duration at 75% duration (APD75). Drugs used in this study were: E4031, Mexiletine, Nifedipine. Data are expressed as % change from baseline for the drug and vehicle groups.
Significant effects on APD75 were detected at 30nM E4031 vs. the control (40.0% vs. 3.2%, P<0.01 n=9). Mexiletine at 3μM significantly increased Trise (343.5% vs 134.8%, P<0.01 n=9, P<0.01 n=9). Nifedipine decreased APD75 (39.1% vs. 75.5%, P<0.05 n=4 P<0.05 n=4) at 300nM.
The detection threshold for these drug effects co-incides with published values of effective therapeutic plasma levels: (E4031, 3nM, Fujiki et al (1994); Mexiletine 2-4μM, Harner et al (2011); Nifedipine, 4-8nM, Redfern et al (2003). In conclusion, iPS derived cardiomyocytes appear to show drug sensitivities that would make them an appropriate for an invitro screen for electrophysiological effects of compounds invivo.

Long non-coding RNAs are differentially expressed in heart failure

E.L. Robinson[1], S. Haider[2], H. Hei[3], G.M. Formovsky[3], L. Roderick[1] and R. Foo[4]

[1]Epigenetics, Babraham Institute, Cambridge, UK, [2]Bart's Cancer Institute, London, UK, [3]Partners Research Facility, Cambridge, MA, USA and [4]Genome Institute Singapore, Genome, Singapore

Heart failure is the gradual inefficacy of the heart to pump blood around the body and contributes at least 10% of the mortality rate in the UK. Hypertrophic cardiomyopathy (HCM) and dilated cardiomyopathy (DCM) are the two main pathophysiological states, the former often progressing into the latter as the condition increases in severity. Although clinically distinct conditions, changes in myocardium gene expression are similar and it is believed there are common underlying biochemical mechanisms.
The revolution in high throughput sequencing technology has enabled unbiased de novo whole transcriptome profiling. It is now known that at least 70% of the genome is transcribed to RNA, with just around 2% of this made up by the known protein-coding genes. The majority of the mammalian genome is transcribed into long non-coding RNAs (lncRNAs), defined as polyribonucleotides of ≥200 nucleotides.
Mechanically stretching neonatal mouse cardiac myocytes with equibiaxial stretch apparatus mimics pathological hypertrophy in the heart and well established alterations in gene expression in cardiac hypertrophy were confirmed by RT-qPCR. My project aims to discover whether the myocardial transcriptome array of lncRNAs changes in our mouse model of HCM.
Paired end RNA-seq from a 300-400bp library of stretched and non-stretched neonatal mouse cardiomyocyte total RNA was carried to generate 30-40 million 76-mer sequence reads per sample.
Stretching resulted in an upregulation of two lncRNAs, MIAT and MALAT-1. RT-qPCR anlaysis also detected upregulation of MALAT-1 and MIAT in the transverse aortic constriction (TAC) mouse model of pressure-overload induced heart failure, validating our findings in the stretched myocyte model. MIAT and MALAT-1 have previously been associated with increased risk of myocardial infarction and metastatic cancers respectively, but never before with cardiomyopathy. Mice undergoing surgery were anesthetized with an initial concentration of 3% isoflurane carried by medical oxygen, delivered via a nose cone. Mice were followed weekly with echocardiography. Compensated hypertrophy and cardiac dilatation were confirmed by weeks four and eight respectively.
Two additional novel unannotated transcripts were identified that showed differential expression in stretched cardiomyocytes. These are regions of the genome that are currently unannotated and potentially transcribe novel lncRNA and differential expression was validated by RT-qPCR.
LncRNA are increasingly recognised as playing a major role in genomic regulation. We therefore hypothesise that changes in expression of target genes which contribute to the deterioration of the failing heart could be due to the actions of these lncRNAs.
Subsequent in vitro and in vivo experiments will seek to understand the role of these lncRNAs in cardiac biology and how they could contribute to the progression of this complex disease.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

L-arginine and asymmetric dimethyl arginine (ADMA) levels in human pericardial fluid in patients with open cardiac surgery

Z. Nemeth[1], A. Cziraki[3], S. Keki[2], B. Biri[2], S. Szabados[3], I. Horvath[3], A. Parniczky[1], I. Seffer[1], A. Miseta[4] and A. Koller[1]

[1]University of Pécs Medical School, Pécs, Hungary, [2]University of Debrecen, Faculty of Science, Department of Applied Chemistry, Debrecen, Hungary, [3]University of Pécs, Medical School, Heart Institute, Pécs, Hungary and [4]University of Pécs, Medical School, Department of Laboratory Medicine, Pécs, Hungary

Background - Recent studies provide evidence that vasoactive active substances are present in the pericardial fluid (PF), which levels may change in cardiovascular diseases. Increasing evidence suggests that methylated L-arginine derivative, asymmetric dimethylarginine (ADMA) is a risk factor of most cardiovascular diseases. Furthermore, it has been shown that

ADMA inhibits endothelium-dependent vasodilation by interfering with endothelial nitric oxide (eNOS) activity and/or eliciting oxidative stress, both of which interfere with the bioavailability of endothelium derived nitric oxide (NO). We hypothesized that ADMA levels in the PF reflects/contributes the pathological processes in the heart. Methods and patients - Patients were classified into two groups according to the type of surgery: coronary artery bypass graft (CABG, n = 28) and valve replacement (VR, n = 16). Blood and PF were collected during CABG and VR surgery. Levels of L-arginine and ADMA were determined in plasma and PF (with fluorescent detection after liquid chromatographic separation) of patients underwent CABG and VR surgery, compared them and an indicator of eNOS substrate availability, L-arginine/ADMA ratios were calculated. Values are expressed as means ± S.E.M. Comparisons between groups were performed using paired Student's t-test. Results - We found that in CABG group, the L-arginine levels were similar in plasma and PF (75.7±4.6 micromol/L vs. 76.9±4.4 micromol/L). In VR group, the L-arginine levels were significantly ($p<0.05$) lower in plasma compared to the PF (57.7±5.9 micromol/L vs. 71.5±5.7 micromol/L). In CABG group, the ADMA levels were the same in plasma and PF (0.7±0.0 micromol/L vs. 0.7±0.1 micromol/L). In VR group, the ADMA levels were similar in plasma and PF (0.8±0.1 micromol/L vs. 0.9±0.1micromol/L). In CABG group, the L-arginine/ADMA ratios were significantly higher compared to the VR group in both plasma (125.4±10.7 vs. 74.9±8.3) and PF (110.4±7.2 vs. 79.5±5.8). Conclusion – Based on these findings we propose that the lower L-arginine/ADMA ratios suggest increased methylation of L-arginine and limited substrate availability for eNOS and thus impaired nitric oxide signaling and vascular function in patients with heart valve disease. Keywords: pericardial fluid, vasoactive active substances, coronary heart disease, L-arginine, asymmetric dimethyl arginine, nitric oxide.

Cardioprotection from insulin is dependent on ROS signalling at reperfusion and is abrogated when combined with ischemic postconditioning

E. Helgeland, L. Breivik and A.K. Jonassen

Institute of Biomedicine, University of Bergen, Faculty of Medicine and Dentistry, Bergen, Norway

Reactive Oxygen Species (ROS) generated during ischemic and pharmacological pre- and postconditioning are important triggers of cardioprotection.[1,2] We have previously shown that insulin is cardioprotective both as a continuous infusion (Ins 15' rep)[3] and when given in short bursts of 3x30s at the immediate onset of reperfusion (InsPost, unpublished data), and that this protection is mediated via PI3K-Akt-p70s6K. But whether ROS is involved in insulin mediated cardioprotection is largely unknown. In addition, there has been variable success in combining cardioprotective treatments to give additional cardioprotection.[4,5] Our study therefore explores **(1)** the effect of ROS-scavenging on insulin cardioprotection, and **(2)** the effect of combining IPost with insulin therapy.

We used Langendorff-perfused rat hearts subjected to 20 min stabilization, 30 min of regional ischemia and 120 min of reperfusion. The hearts were randomized to either control (Ctr), IPost, InsPost, Ins 15' rep or Ins 15' rep + IPost, with or without the presence of the ROS scavenger N-mercaptopropionylglycine (MPG, 1 mM or 10 mM). Infarct size was determined by tetrazolium staining, and expressed as percent of area at risk. Values are expressed as means ± S.E.M. compared by one-way ANOVA and Fischer's post hoc test. Significance level was set to 0.05 and all groups were n≥6.

Our results show that both IPost and insulin treatment is dependent on ROS signalling (IPost 34.9±3.1 vs. IPost+MPG 57.0±3.7, InsPost 33.1±7.8 vs. InsPost+MPG 56.0±6.8, and Ins 15' rep 36.0±5.9 vs. Ins 15' rep+MPG 63.4±6.2, all $p<0.05$). MPG had no effect on infarct size alone (Ctr 51.8±5.5 vs. MPG 59.7±3.3 ns.). Combining insulin treatment with IPost did not afford any additional cardioprotection but abrogated it instead (IPost+Ins 1' Rep 41.6±7.5, IPost+Ins 5' Rep 57.0±3.6 and IPost+Ins 15' Rep 60.8±3.8 vs. Ctr 51.8±5.5 ns.) Scavenging free radical formation with MPG did not affect the infarct size regardless of dose (Ctr 51.8±5.5, MPG 1mM 59.7±3.3 and MPG 10 mM 66.4±5.2 vs. IPost+Ins 15' Rep + MPG 1 mM 49.7±7.1 and IPost + Ins 15' Rep + MPG 10 mM 52.3±5.3 ns.)

In conclusion, our data suggest that cardioprotection from insulin is dependent on ROS-signalling. Surprisingly, combining IPost and Ins 15' rep did not afford any additional cardioprotection, but abrogated it via blunted Akt-phosphorylation. The protection was not regained by ROS scavenging with MPG regardless of dose.

Estrogen reduced the occurrence of Takotsubo cardiomyopathy via balancing Gs /Gi protein signal pathway

D. Sun, C. Zhou, L. Zhang, X. Cao, L. Fu, L. Sang, J. Chong, S. Kang, Y. Liu and H. Sun

Physiology, Xuzhou Medical College, Xuzhou, China

Some studies show that a high concentration of catecholamines is the triggering factor of Takotsubo cardiomyopathy (TCM), particularly epinephrine (Epi) [1,2]. A high concentration of Epi switches G protein from Gs to Gi protein signal pathway, increasing negative inotropic effect [3,4]. The patients of TCM have a clear gender predilection, most of whom are primarily post-menopausal women [5]. It is unknown whether low estrogen level following menopause is associated with G protein or not in TCM.

Female Sprague–Dawley rats were ovariectomized (OVX). Six weeks later, ventricular cardiomyocytes were isolated. We

found that the shortening amplitude of cardiomyocytes increased in the OVX group, compared with the Sham group (Sham vs. OVX, p<0.05). The decrease of shortening amplitude in cardiomyocytes of Sham group was eliminated by estrogen antagonist (Sham+ ICI182 vs. OVX, p>0.05).
Further, we isolated Sham and OVX rat ventricular cardiomyocytes and subjected to Epi for making TCM model in vitro to explore the relationship between estrogen and G protein in TCM. We found that the percentage of rod-shaped cells and shortening amplitudes of the above cardiomyocytes were all decreased, compared without Epi group (Sham vs. Sham + Epi, OVX vs. OVX + Epi, p<0.05), more seriously in cardiomyocytes from OVX group (Sham + Epi vs. OVX + Epi, P<0.05). But, pertussis toxin, the antagonist of Gi protein, abolished all the differences of the above groups. We also measured the concentration of cAMP, a substance of GS downstream signaling. We found that the concentration of cAMP was increased in the Sham group and decreased in the OVX group, if the cardiomyocytes were pretreated with Epi (Sham vs. Sham + Epi, OVX vs. OVX + Epi, p<0.05). And the concentration of cAMP in Sham group was lower than that in OVX group without Epi state (Sham vs. OVX, p<0.05).
Our results indicated that the estrogen activated Gi protein signal pathway, producing negative inotropic effect at physiological state. And the estrogen activated Gs protein signal pathway rapidly when the concentration of Epi in plasma increased sharply, which limited the negative inotropic effect of Gi protein. Our results suggested that estrogen reduced the occurrence of TCM via balancing Gs /Gi protein signal pathway. In low estrogen levels, such as postmenopausal women, high concentration of Epi doesn't activate the Gs protein signal pathway effectively and the Gi protein signal pathway is strengthened. This may be the reason why TCM usually occurs in postmenopausal women.

PCB075

The role of nitric oxide and Ca^{2+}-regulation in cardioprotection from remote ischaemic preconditioning

C. Thaitirarot, H.E. Crumbie and G.C. Rodrigo

Cardiovascular Science Department, University of Leicester, Leicester, UK

We have previously shown that ischaemic preconditioning (IPC) of the whole heart protects the isolated ventricular myocytes against Ca^{2+}-overload injury during simulated ischaemia [1]. Nitric oxide (NO) signalling is known to modulate Ca^{2+}-regulation in cardiac myocytes [2] and plays a central role in IPC [3]. We have compared the involvement NO-signalling in cardioprotection in IPC versus remote ischaemic preconditioning (rIPC).
We used an isolated ventricular myocyte model of IPC of whole hearts [1] and compared this to rIPC myocytes, where naïve cardiomyocytes are "remotely conditioned" with the superfusate from preconditioned hearts. Two models of ischaemia-reperfusion (I/R) injury were used to determine protection. 1) Ischaemia was simulated in myocytes centrifuged to a dense pellet and layered with mineral oil to prevent gaseous diffusion (37°C, 30 min), and reperfusion by dispersing the myocyte pellet into oxygenated 2mM Ca^{2+} Tyrode [1] and cell death was assessed by Calcein and Propidium Iodide staining. 2) $[Ca^{2+}]_i$ was recorded from field-stimulated myocytes loaded with Fura-2 and subjected to metabolic inhibition (2 mM NaCN and 1 mM Iodoacetic acid) for 8 min followed by re-energization with 2mM Ca^{2+} Tyrode for 12 min. Cell injury was determined as the inability to maintain low diastolic $[Ca^{2+}]_i$ and to contract in response to electrical stimulation. Data are mean ± S.E.M (n = number of experiments, hearts; one-way ANOVA followed by Tukey's multiple comparison post-hoc test).
IPC and rIPC both significantly reduced the degree of necrotic injury compared to control myocytes [IPC 29.7 $\pm$ 2.1% (n = 32, 6; *P*<0.001); rIPC 30.9 $\pm$ 3.7% (n = 17, 12; *P*<0.001); control 55.1 $\pm$ 2.9% (n = 18, 13)]. The protective effect of rIPC was abolished by the non-specific NOS inhibitor L-NAME (100 μM) at 56.5 $\pm$ 3.8% (n = 13, 10; *P*<0.001), when present during the rIPC stimulus and the I/R protocol. Both IPC and rIPC increased the percentage of myocytes that recovered contractile function on re-energization following metabolic inhibition, from 39.8 $\pm$ 3.7% of control myocytes (n = 30, 12), to 63.8 $\pm$ 2.3% (n = 24, 7; *P*<0.001) and 55.7 $\pm$ 3.2% (n = 24, 9; *P*<0.01) respectively. This increased recovery of contractile function was not blocked by L-NAME present during the rIPC stimulus. However, only IPC increased the percentage of cells able to maintain a low diastolic $[Ca^{2+}]_i$ (fura-2 ratio<1) following re-energization, from 19.4 $\pm$ 3.2% of control myocytes (n = 30, 14) to 48.3 $\pm$ 3.8% of IPC myocytes (n = 24, 7; *P*<0.001) and 24.9 $\pm$ 4.5% of rIPC myocytes (n = 23, 9; ns).
Our data show that the protection against necrotic cell death of rIPC involves NOS-signalling, whereas, the improved recovery of contractile function was NOS-independent. Further, rIPC was not associated with maintained Ca^{2+}-regulation, as seen in true IPC.

Oxidation of DHA is responsible for its anti-arrhythmic effects on mouse ventricular myocytes

J. Roy[1], O. Touzet-Mercier[1], J. Roussel[1], C. Oger[2], J. Galano[2], E. Pinot[2], T. Durand[2] and J. Leguennec[1]

[1]Inserm U1046, Physiologie et médecine expérimentale du cœur et des muscles, Montpellier, France and [2]UMR CNRS 5247, Institut des Biomolécules Max Mousseron, Universités Montpellier-1 et Montpellier-2, ENSCM, Montpellier, France

Since forty years, it is known that long-chain polyunsaturated fatty acids of the series n-3 (PUFAs) have cardioprotective effects by preventing cardiac arrhythmias1. The main n-3 PUFAs are eicosapentaenoic acid (C20:5 n-3, EPA) and docosahexaenoic acid (C22:6 n-3, DHA) that are highly peroxidable due to the presence of the skipped dienes2. The effects of n-3 PUFA on cardiac function are still debated, notably because of the lack of information on the mechanisms involved3. For example, it is not really known which the active lipid is: the PUFA or one of its oxygenated metabolites. A diet enriched in n-3 PUFAs (mainly fish-based), leads to enrichment in these fatty acids of cardiac cell membranes. Our hypothesis is that, during an infarct, the oxidative stress and the generation of reactive oxygen species might be responsible for an oxidation of membrane-bound PUFAs and the oxygenated metabolites generated might modulate the activity of ionic channels to exert anti-arrhythmic effects4. We thus decided to investigate the influence of the peroxidation of DHA on its potentially anti-arrhythmic properties. In this study, we applied DHA free acid or DHA methyl ester (OMe) on freshly isolated mouse ventricular myocytes without or with α-tocopherol (Vitamin E, to prevent oxidation) or hydrogen peroxide (to enhance oxidation). We investigated, using a photometric system, calcium transients (using the ratiometric calcium fluorescent dye Indo-1) and cell shortening of electrically stimulated myocytes. By stimulating β-adrenergic pathways with 10 nM isoproterenol, it is possible to observe the occurence of arrhythmic events. We observed that DHA free acid reduced the percentage of arrhythmic cells but do not DHA-OMe. The effects of DHA are correlated with the peroxidation of the fatty acid since α-tocopherol prevented the anti-arrhythmic effects while hydrogen peroxide enhanced them. In resting cells, single RyR channels spontaneously open with a very low frequency. An increased frequency of these events can cause propagating calcium waves that can lead to arrhythmias. The spontaneous calcium released events named sparks, can be observed by confocal microscopy. Here again, we observed that the frequency of calcium sparks is negatively correlated with the oxidative status of the DHA solution. These results suggest thus that rather than DHA itself, it is one or more non-enzymatic oxygenated metabolites derived from DHA that are potentially anti-arrhythmic such as neuroprostanes and/or neurofuranes4.

Regulation of calcium homeostasis by palmitoyl-carnitine in ventricular cardiomyocyte: Role of mitochondria

J. Roussel[1], J. Thireau[1], V. Scheuermann[1], C. Brenner[2], A. Lacampagne[1], J. Le-Guennec[1] and J. Fauconnier[1]

[1]U1046, INSERM, Montpellier, France and [2]U769-LabEx LERMIT, INSERM, Châtenay Malabry, France

In physiological conditions, the energy required for cardiac contraction is provided by the β-oxidation of long chain free fatty acids (i.e. palmitate) in the mitochondrial matrix. To diffuse through the mitochondrial membrane, palmitate formed a complex with carnitine called palmitoyl-carnitine (PC). In order to reach the contractile demand, the rate of ATP synthesis is dynamically regulated through a mechanism called excitation-metabolism coupling (EMC). The EMC depends on the Ca2+ movement between the mitochondria and the sarcoplasmic reticulum (SR). In obesity and type 2 diabetes, patients develops a diabetic cardiomyopathy (DC), characterized by a ventricular dysfunction, with contractile and Ca2+ signaling disturbances, associated with a mitochondrial dysfunction. In the DC, the increase of fatty acid oxidation is associated with a decrease of ATP/Oxygen ratio, indicating a mitochondrial uncoupling. Although long chain fatty acid also alter Ca2+ handling, the cross regulation between mitochondria uncoupling and Ca2+ handling are not fully understood. In this work we aimed to study the effect of an acute application of PC on Ca2+ signaling and mitochondrial function on left ventricles of control C57/BL6 mice. The application of 10μM of PC on isolated mitochondria decreases the Adenine Nucleotide Transporter (ANT) activity and induced a depolarization of mitochondrial membrane. This depolarization is also observed in freshly isolated cardiomyocytes and is associated with a massive increase of mitochondrial ROS production. This PC-induced ROS production increases diastolic SR Ca2+ leak through the oxidation of SR Ca2+ release channels (the ryanodine receptor 2 (RyR2)). This disturbance of Ca2+ handling is associated to an increase of arrhythmia episodic. Inhibition of ANT using bongrekic acid prevents the mitochondrial defects, the RyR2 oxidation, altered Ca2+ handling and arrhythmia leading by an acute application of PC. Altogether, these results suggest that an acute elevation of long chain fatty acids disturbed ANT activity which affects Ca2+ handling. Disturbance of ANT activity and increase ROS production may thus contributes to development of DC.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Regulation of a specific population of Nav1.5 channels by CASK

C.A. Eichel[1], F. Louault[1], G. Dilanian[1], M. Essers[2], H. Abriel[2], A. Coulombe[1], S. Hatem[1] and E. Balse[1]

[1]U956, Inserm, Paris, France and [2]Clinical Research, University of Bern, Bern, Switzerland

MAGUK proteins are a superfamily of proteins implicated in the anchoring and scaffolding of macromolecular complexes at the plasma membrane. The MAGUK protein CASK differs from other MAGUKs as it possesses an N-terminal calcium/calmodulin-dependant protein kinase domain, a single PDZ domain and has the capacity to translocate to the nucleus, where it acts as a co-activator to induce the transcription of T-element containing genes. However, apart from the fact that it is expressed in the heart, little else is known about its function in this organ. We found that CASK was expressed at the protein level in rat and human myocardia. Immunostainings of myocardial cryosections revealed that CASK was located at the lateral membrane of myocytes in sharp-contrast with the other cardiac MAGUKs, SAP97 and ZO1, which are found at the intercalated disc. CASK belongs to the costamere complex at the lateral membrane as it colocalized with syntrophin/dystrophin. Co-immunoprecipitation experiments performed on heart lysates showed that CASK and dystrophin interact. Moreover, in MDX mice which lack dystrophin, CASK was no longer present at the lateral membrane of myocytes, confirming that CASK participates in the syntrophin/dystrophin costameric complex. We have previously demonstrated that cardiomyocytes express two distinct pools of Nav1.5 channels: one at the intercalated discs interacting with SAP97 and a second at the lateral membrane interacting with the syntrophin/dystrophin complex. Due to its particular location, we hypothesized that CASK was involved in the targeting of the subpopulation of Nav1.5 channels to the lateral membrane. GST pull down experiments performed on heart lysates showed that CASK interacts with Nav1.5. In addition, immunostainings revealed that CASK and Nav1.5 colocalize in freshly isolated myocytes. Furthermore, in a HEK293 cell line stably expressing Nav1.5 channels, whole-cell patch clamp recordings showed that CASK silencing enhanced the sodium current (INa) (at -30mV, -95.1 ± 10.9 pA/pF, n=12 vs control -51.4 ± 5.7 pA/pF, n=13; mean ± SEM, p<0.01) while CASK overexpression decreased INa (at -30mV, -58.6 ± 10.2 pA/pF, n=8 vs control 88.6 ± 10.6 pA/pF, n=6; mean ± SEM, p<0.05). Finally, in cultured rat atrial myocytes where CASK was silenced, INa was also enhanced. In conclusion, CASK is a new cardiac MAGUK protein which shows unique cell localization. Our results indicate that CASK is present at the costamere level where it interacts with dystrophin. Interestingly, CASK is able to regulate the Nav1.5-mediated current suggesting that it is a new partner of the Nav1.5 macromolecular complex specifically at the lateral membrane. These results characterize a previously unreported ion channel partner and provide new insight into the regulation and organization of cardiac ion channels.

Osmotic activation of Na^+/H^+ exchanger and Na^+/HCO_3^- cotransporter in isolated rat ventricular myocytes

L. Sottmann, P. Swietach and R.D. Vaughan-Jones

Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, UK

Na^+/H^+ exchanger 1 (NHE1) is a ubiquitous membrane transporter that regulates pH_i, $[Na^+]_i$ and cell volume. In the heart, stretch-activation of NHE1 has been claimed to be a key element of the slow force response to stretch[1]. By raising pH_i and $[Na^+]_i$, NHE1 activation may initiate hypertrophy[2]. We examined osmotic activation of NHE1 and the related Na^+/HCO_3^- cotransporter (NBC) in rat isolated ventricular myocytes.

Adult rat ventricular myocytes were enzymatically isolated. pH_i was imaged using cSNARF-1. 160 mM sucrose was added to increase osmolarity. Data are mean ± SEM, compared with unpaired Student's t-test.

Intrinsic buffering capacity (β_{int}) was measured by ammonium removal. Hyperosmotic shrinkage increased β_{int} 1.6-fold (26.3±1.6mM (n=17) vs. 16.1±1.9mM (n=6) at pH 7.3, P<0.01). pH_i was increased using an ammonium prepulse and the slope of pH_i recovery was used to calculate acid-efflux ($J=dpH/dt^* \beta$). NHE-mediated acid-efflux was greatly increased in hyperosmotic medium (11.0±0.5mM/min (n=25) vs. 2.7±0.3mM/min (n=8) at pH 7.0, P<0.001), producing an alkaline shift of 0.25 pH units in the pH_i-flux relationship.

Upon addition of 160 mM sucrose, myocytes showed gradual NHE-mediated alkalinization of 0.3 pH units over 8 min (n=5). This was abolished by the NHE-inhibitor DMA (5-(N,N-dimethyl)amiloride, 30μM, n=7).

To elucidate the osmotic regulation of NBC, bicarbonate-buffered solutions were used (NHE inhibited with 30μM DMA). NBC-mediated acid-efflux was 1.8-fold increased in hyperosmotic solution (6.3±0.7mM/min (n=17) vs. 3.4±0.3mM/min (n=25) at pH 7.0, P<0.001).

Testing a possible role of carbonic anhydrase (CA) in the osmotic activation of NHE1 and NBC, we found that acid-efflux was not altered by addition of ETZ (100μM) in isosmotic or hyperosmotic bicarbonate-buffered media (isosmotic: 10.5±0.9mM/min (n=21) vs. ETZ 14.1±1.6mM/min (n=6) at pH 6.6, P=0.065; hyperosmotic: 25.9±1.7mM/min (n=15) vs. ETZ 26.7±1.8mM/min (n=5) at pH 6.7, P>0.8). This rules out the necessity of CA activity for the combined osmotic effect on NHE and NBC.

Given the strong osmotic effect on NHE, we examined its role in myocyte volume regulation. Both video-imaging and z-stack techniques[3] showed a rapid shrinkage in hyperosmotic solution within the first minute without subsequent regulatory volume increase (z-stack data as normalized volume: after 1 min, 81.8±0.7%; 5 min, 81.1±1.0%; 10 min, 79.5±1.3%, n=7). The contribution of NHE to cellular volume maintenance during hyperosmotic shock was found to be negligible (30μM DMA added, compared to above data: after 1 min, 86.6±1.2%, P<0.01; 5 min, 83.9±0.7%, P>0.065; 10 min, 81.2±1.0%, P>0.36, n=5).

We conclude that strong activation by hyperosmotic stimuli is a common characteristic of the cardiac acid-extruders NHE1 and NBC, but does not directly involve activation of catalytic activity from native carbonic anhydrase.

Histones induce rat ventricular myocyte arrhythmia and cell necrosis

A. Bleakley, C. Evers, A. Duke, Z. Yang, D. Steele and S.M. Harrison

School of Biomedical Sciences, University of Leeds, Leeds, UK

RATIONALE: Ischaemic heart disease is the leading cause of mortality in the western world. In ischaemic heart disease, the myocardium may be at risk of injury from the products of cell necrosis, such as histones. Histones, which are released into extracellular circulation from the nuclei of necrotic cells, are cytotoxic (Xu et al., 2009). Histone-induced toxicity is mediated through direct cellular membrane interaction and resultant cation influx. The aim of this study was to investigate the effects of histones on Ca^{2+} regulation, contractility and viability in rat ventricular myocytes.
METHODS: Ventricular myocytes were isolated from healthy male adults Wistar rats (200-250 g) that had been killed humanely using an ethically approved Schedule 1 procedure. First, electrically stimulated myocytes (1Hz), loaded with fura-2 AM, were superfused at 30°C with a normal Tyrode solution in the absence and presence of H3 (3.0 μg/ml) or Hmix (H1-H2A-H2B-H3-H4-H5; 3.0 μg/ml) for a maximum of 10 min. Second, this was repeated in the absence or presence of the membrane stabilizing agent pluronic F-68 or foetal calf serum (FCS). Third, quiescent myocytes were incubated at room temp with normal Tyrode solution (with and without FCS) in the absence or presence of H3. Cell viability was measured after 5 and 60 min.
RESULTS: In 33 out of 34 electrically stimulated myocytes, exposure to H3 induced Ca^{2+} overload and spontaneous contractions within 8 min. In 13 out of 22 stimulated myocytes, exposure to Hmix also induced arrhythmogenesis. Pluronic F-68 (100 mg/100 ml) offered no protection on exposure to H3 as 18 out of 18 myocytes were arrhythmic, whereas 5% FCS protected 10 out of 11 myocytes from arrhythmogenesis. For populations of quiescent myocytes, incubation with H3 led to a significant 27% reduction in cell viability ($P<0.05$) from 5 to 60 min, however the presence of 5% FCS protected against necrosis.
CONCLUSION: H3 induced Ca^{2+} overload, arrhythmogenesis and cell death in ventricular myocytes. Pluronic F-68 failed to protect myocytes while FCS protected against cell necrosis, suggesting plasma proteins are potential cytoprotective agents against acute histone-induced cytotoxicity.

PCB082

Phosphodiesterase type 4 inhibition increases delayed afterdepolarizations upon β-adrenergic stimulation in cardiac myocytes: Role of protein kinase A and Ca^{2+}/calmodulin kinase II

P. Bobin, R. Fischmeister, G. Vandecasteele and J. Leroy

Signaling and Cardiac Physiopathology, INSERM UMR-S 769 LabEx LERMIT University Paris-Sud, Châtenay-Malabry, France

β-adrenergic receptor (β-AR) stimulation increases cardiac function by increasing cAMP levels and activating protein kinase A (PKA). PKA enhances Ca^{2+}-induced Ca^{2+}-release by phosphorylating L-type Ca^{2+} channels, ryanodine receptors and phospholamban which are also targets of the Ca^{2+}/calmodulin kinase II (CaMKII). Any disregulation in the β-adrenergic pathway can lead to cardiac arrhythmias. Multiple cyclic nucleotide phosphodiesterases (PDEs) regulate local concentrations of cAMP, among which the PDE4 family plays an important role. The aim of this study is to investigate the proarrythmic effects of PDE4 inhibition and evaluate the relative contribution of PKA and CaMKII in this mechanism. Action potentials (AP) were recorded at a frequency of 1 Hz in isolated adult Wistar rat ventricular myocytes using the patch clamp technique. Application of the non selective β-AR agonist Isoprenaline (Iso 1 nM) induced delayed afterdepolarizations (DADs) recorded during 10 s after the cessation of electrical stimulation which were potentiated by the selective PDE4 inhibitor Ro20-1724 (1.5±0.3 DADs/10s, n=18 with Iso alone, $p<0.01$ versus control; and 2.9±0.5 DADs/10s with Iso+10 μM Ro20-1724, $p<0.01$ versus Iso alone, values are means±S.E.M. compared by one-way ANOVA with Tukey *post hoc* test). These DADs correlated with spontaneous calcium release events (SCRs) recorded with an IonOptix® system in myocytes loaded with Fura-2AM (5 μM). The SCRs appeared upon Iso application (1 nM) and their incidence increased from 1.6±0.4 SCRs/10s (n=21) in Iso alone to 4.3±0.5 SCRs/10s (n=25; $p<0.001$) when PDE4 was concomitantly inhibited. The SCRs observed in the presence of Iso+Ro were abolished in cells preincubated with the PKA inhibitor H-89 (10 μM) (n=6; $p<0.001$) and their occurrence diminished by 40% when CaMKII was inhibited by 10 μM KN-93 (n=23; $p<0.05$). The inactive KN92 (10 μM) compound had no effect on SCRs (n=13). These results show that upon β-AR stimulation, PDE4 inhibition promotes DADs due to SCRs through both PKA and CaMKII activation.

Contribution of active and passive stiffness to diastolic dysfunction in rats following aortic banding

.T. Røe[1,2], J. Aronsen[1,2], M. Frisk[1,2], O.M. Sejersted[1,2], I. Sjaastad[1,2] and W.E. Louch[1,2]

[1]Institute for Experimental Medical Research, Oslo University Hospital and University of Oslo, Oslo, Norway and [2]KG Jebsen Cardiac Research Center and Center for Heart Failure Research, University of Oslo, Oslo, Norway

In approximately half of heart failure patients, systolic function is near normal while diastolic function is impaired. This condition is therefore referred to as diastolic heart failure (DHF)

or heart failure with preserved ejection fraction (HFpEF). The mechanisms underlying the diastolic dysfunction are still unclear, but may be attributed to stiffening of the myocardium. Alterations in the extracellular matrix and cytoskeleton have been reported to contribute to greater passive stiffness in this condition (1). However, the contribution of altered Ca2+ handling to the active process of cardiomyocyte relaxation remains largely uninvestigated. Hypertrophy due to aortic stenosis is one of several etiologies associated with DHF, and with aortic banding (AB) we similarly induced hypertrophy and diastolic dysfunction in Wistar rats. All procedures were performed during inhalation anesthesia (65% N2O, 32% O2, 2.5% isoflurane). Experiments were performed 6 weeks after aortic banding. Rats with detectable systolic heart failure (reduced left ventricular shortening) were excluded. Compared to sham-operated controls, echocardiography revealed hypertrophy and diastolic dysfunction in AB. This was indicated by increased posterior wall thickness and decreased peak early diastolic tissue velocity. The in vivo diastolic dysfunction was confirmed by isometric force measurements in myocardial strips. We observed longer time to peak force and slower relaxation in AB across a range of stimulation frequencies (0.5-6 Hz). Surprisingly, isolated cardiomyocytes exhibited the opposite features. Single cell contractions, measured by edge detection, revealed significantly faster time to peak contraction and faster relaxation in AB. At high frequencies, AB cardiomyocytes also showed less diastolic contracture than sham cells. The mechanism underlying the improved single cell relaxation appeared to be faster cytoplasmic Ca2+ removal, evident as more rapid decay of Ca2+ transients (whole-cell fluorescence, fluo 4-AM) in AB across a range of frequencies. Furthermore, with increasing pacing rate AB cardiomyocytes exhibited a less pronounced increase in diastolic [Ca2+] than sham, and elevated SR Ca2+ content. These observations were consistent with a measured increase in the rates of both sarcoplasmic reticulum Ca2+ reuptake and Ca2+ extrusion in AB. Confocal imaging of cells stained with di-8-ANEPPs indicated maintained t-tubule organization, consistent with an unaltered time to peak of Ca2+ transients. Our results consequently indicate that despite improved Ca2+ handling, AB induces diastolic dysfunction in vivo as well as in intact myocardium ex vivo. We therefore suggest that increased passive stiffness is the major contributor to the impaired diastolic function in this condition.

Smooth Muscle in Turtle Atrial Myocardium: Functional and Histological Evidence

S.N. Saxton[1], J. Stecyk[2], B. Gannon[3], T. Farrell[4] and H. Shiels[5]

[1]Faculty of Life Sciences, University of Manchester, Manchester, UK, [2]Department of Biological Sciences, University of Alaska, Anchorage, AK, USA, [3]Department of Anatomy and Histology, Flinders University, Adelaide, SA, Australia, [4]Faculty of Land and Food Systems and Department of Zoology, University of British Columbia, Vancouver, BC, Canada and [5]Faculty of Life Sciences, University of Manchester, Manchester, UK

In 1887 some unusual characteristics were noted in the contractile properties of tortoise atria that became known as "oscillations of tonus". The oscillations were later found to be present in the turtle atria, and believe to be caused by a layer of endocardial smooth muscle. Since 1925, there has been no further published interest in these oscillations. In this study, histological and immunohistochemical staining techniques were used to confirm the presence of endocardial smooth muscle, and contractile studies were used to further characterise its properties. Atrial tissue was isolated from the red eared slider turtle (Trachemys scripta), and contractile responses to adrenaline, acetylcholine and wortmannin were recorded. Tissue was also embedded in paraffin and stained using haematoxylin & eosin stain, or was labelled using smooth muscle α-actin monoclonal antibodies. Results from these studies will be considered in relation to earlier findings and the significance of the smooth muscle layer in the reptile myocardium will be discussed.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

5-HT2 receptor activation maintains phrenic motor output following chronic cervical spinal cord injury

K. Lee[1], B.J. Dougherty[2], M.S. Sandhu[2] and D.D. Fuller[2]

[1]Biological Sciences, National Sun Yat-sen University, Kaohsiung, Taiwan and [2]Department of Physical Therapy, University of Florida, Gainesville, FL, USA

C2 spinal hemisection (C2Hx) results in inactivation of ipsilateral phrenic bursting due to interruption of bulbospinal respiratory pathways. Plasticity in the spinal phrenic circuitry results in partial recovery of phrenic output over weeks to months and the recovery correlates with time-dependent return of spinal serotonin (5-HT) immunoreactivity. Both the 5-HT type 2A and 2C receptor subtypes are present on phrenic motoneurons, and the 5-HT2A subtype is upregulated after C2Hx compared to spinal-intact tissues. We explored the functional role of these receptors by testing the hypothesis that pharmacologic blockade would attenuate phrenic motor output in rats with chronic (8-10 weeks) C2Hx. In initial experiments, bilateral phrenic activity was recorded in anesthetized, vagotomized and mechanically ventilated rats. The 5-HT2A/C receptor antagonist ketanserin (1 mg/kg, i.v.) had no impact on respiratory burst frequency, but triggered a persistent, bilateral reduction in phrenic burst amplitude in C2Hx but not spinal-intact rats. The relative reduction of phrenic bursting was considerably greater in the nerve ipsilateral to the lesion. In additional experiments, tidal volume and diaphragm EMG activity were measured during spontaneous breathing in vagally-intact anesthetized rats before and after i.v. ketanserin. The ipsilateral diaphragm EMG signal was significantly attenuated following ketanserin in C2Hx but not spinal-intact rats. The ketanserin-triggered reduction of ipsilateral diaphragm EMG was accompanied by a small increase in inspiratory tidal volume. We speculate that the increased tidal volume reflects robust compensatory recruitment of accessory inspiratory muscles. We conclude that activation of 5-HT2A/C receptors facilitates phrenic motoneuron bursting following chronic C2Hx, and that these receptors are likely located in the spinal cord.

Effect of moderate aerobic exercise on cardiovascular autonomic function in type 2 diabetes mellitus

R.K. Goit[1], R. Khadka[2], L. Thapa[3] and B.H. Paudel[2]

[1]Physiology, Nepalgunj Medical College, Banke, Nepal, [2]Physiology, BP Koirala Institute of Health Sciences, Dharan, Nepal and [3]Internal Medicine, College of Medical Sciences, Bharatpur, Nepal

Several studies have reported that regular physical activity is an important component of a healthy lifestyle and low levels of physical fitness are closely related to several chronic diseases, including type 2 diabetes mellitus (T2DM). Many studies have also suggested beneficial effects of regular exercise in preventing sudden cardiac death in healthy individuals and in patients with cardiovascular disease. Despite this, there is widespread tendency to ignore exercise testing in clinical management of patients with diabetes mellitus even when evidence abound showing that exercise improves health status in patients with diabetes mellitus (George & Russell, 2007). A very serious and common complication of T2DM is diabetic autonomic neuropathy (DAN). Cardiac autonomic neuropathy is the most clinical important and well-studied form of DAN, due to its association with a wide spectrum of adverse cardiovascular outcomes (Vinik et al, 2003). It is commonly perceived that a regular heart beat is a sigh of healthy heart. However, the rhythm of a healthy heart is characterized by significant beat to beat variability. This heart rate variability (HRV) has been used as a simple, non-invasive technique to examine cardiovascular autonomic function. HRV of 15 individuals with T2DM were assessed. Resting electrocardiogram (ECG) at spontaneous respiration was recorded for 5 min in supine position. Recording was performed before and after a six month, supervised, progressive, aerobic training program, three times weekly. The data were expressed as median (interquartile range). The p value <0.05 was considered statistically significant. In the time domain variable square root of the mean of the squared R-R intervals (RMSSD) [29.7 (26 - 34.5) vs. 46.4 (29.8 - 52.2) ms, p=0.02] and number of R-R intervals that differ by more than 50 ms (NN50) [35 (18 - 47) vs. 98 (20-114)] count, p=0.03) were significantly increased after exercise. In the frequency domain variables low frequency (LF) [62.4 (59.1 - 79.2) vs. 37 (31.3-43.3) nu, p=0.03) and LF/HF [1.67 (1.44 – 3.8) vs. 0.58 (0.46 - 0.59) p=0.009] were significantly decreased while high frequency (HF) [95 (67-149) vs. 229 (98-427) power, p=0.006] and HF [37.6 (20.8-40.9) vs. 63 (56.7-68.7) nu, p=0.003) were significantly increased after exercise. In Poincare plot standard deviation (SD) 1 [21.3 (18.5-24.8) – 33.1 (21.5 – 37.2), p=0.027] was significantly increased after exercise. These data suggest that three times weekly, six month, moderate aerobic exercise program is associated with significant improvements in cardiovascular autonomic function in person with T2DM by increasing vagal tone and decreasing sympathetic activity.

Comparison of the functional regenerative activity of Human Umbilical Cord Blood MNCs and CD34+ cells in acute myocardial infarction rat model

N.M. Abogresha[1], M.I. Mohamed[1], M.K. Tawfik[2], M.M. Habba[3] and Y.M. El-Wazir[1]

[1]Physiology, Faculty of Medicine, Suez Canal University, Ismaillia, Egypt, [2]Pharmacology, Faculty of Medicine, Suez Canal University, Ismaillia, Egypt and [3]Radiology Department, Faculty of Medicine, Suez Canal University, Ismaillia, Egypt

Myocardial infarction is a leading cause of morbidity and mortality worldwide. Recently, studies have been focused on myocardial regeneration and neovascularization through stem cell therapy. The aim of this study is to compare between the roles of human umbilical cord blood mononuclear cells (MNCs) and CD34+ stem cells in improving functional changes resulting from induced acute myocardial infarction (AMI) in rats. Methods: Forty albino Wistar rats divided into 5 groups were included; group 1 is control untreated group; group 2 received subcutaneous injection of 0.2 ml saline; group 3 is AMI group; group 4 is MNCs treated group and group 5 is CD34+ treated group. AMI was induced in groups 3, 4 and 5 by isoprenaline hydrochloride. One day after AMI induction cardiac enzymes were assessed to ensure occurrence of AMI. After one week groups 3 and 4 were treated by IV injection in the tail vein with a dose of 107 MNCs/rat and 106 CD34+ cells/rat respectively. After 4 weeks, rats were anesthetized by intraperitoneal injection of urethane in a dose of 1.25 mg/Kg (Iwamoto etal., 1987) and subjected to ECG monitoring and Echocardiography, then animals were sacrificed and hearts were removed for assessment of vascular endothelial growth factor (VEGF) mRNA expression. Results: One day after AMI induction, cardiac enzymes were significantly higher in groups 3, 4 and 5 compared to other groups verifying occurrence of AMI induction. ECG showed marked elevation of ST segment and presence of pathological Q wave in G3 compared to the control group. There was significant reduction in ST segment in rats treated with MNCs or CD34+ cells associated with the disappearance of pathological Q wave compared to rats with AMI. Ejection fraction (EF) was statistically lower in G3 when compared to G1, G4 and G5 indicating that the treatment with CD34+ cells and MNCs improve EF. There was no difference between the two treated groups in both ECG and EF indicating that the treatment with MNCs or CD34+ has the same therapeutic effect. VEGF mRNA gene expression in group 3 was slightly higher than control group and its expression increased significantly in both treated groups compared to control and AMI groups; indicating the formation of new vessels. However, there was no significant difference in both treated groups; indicating that both kinds of treatment have the same effect on the gene expression. Conclusion: Treatment with human umbilical cord blood MNCs and CD34+ cells can improve the chemical, electrical and functional alterations in the heart after AMI induction in a rat model. This improvement could be attributed to enhanced new vessel formation. Keywords: AMI, Human Umbilical cord blood, CD34+ cells, MNCs & VEGF.

PCB091

Ghrelin - Is it cardioprotective in type 2 diabetics?

S. Abd El-Fattah[1], G. Nasr[2], D. Abd-Elhalim[1] and Y.M. El-Wazir[1]

[1]Physiology, Suez Canal University, Ismailia, Egypt and [2]Cardiology, Suez Canal University, Ismailia, Egypt

Diabetes is commonly associated with changes in cardiac structure and function, even in the absence of epicardial atherosclerotic disease. The exact cause of these non-atheroscelrotic cardiac changes is not exactly known (1). In view of the recently reported favorable metabolic effects of ghrelin in type 2 diabetes (2), and also the reports of its beneficial effects in several cardiovascular disorders (3), we assessed fasting serum ghrelin concentrations in 26 diabetics of type 2 with asymptomatic left ventricular structural and functional changes (study group) and 26 age and sex matched subjects having type 2 diabetes without left ventricular structural and functional changes (control group). Both groups were assessed for clinical characteristics, metabolic (lipid profile and fasting blood glucose (FBG) and hormonal parameters (serum leptin, ghrelin and insulin levels), ECG was performed and QTc dispersion (QTcd) was calculated for detection of cardiac autonomic neuropathy and the following LV structural and functional parameters were assessed by two-dimensional echocardiography: left ventricular end-systolic diameter (LVESD), left ventricular end-diastolic diameter (LVEDD), left ventricular posterior wall thickness, (PWT), interventricular septal thickness at end-diastole (IVST), left ventricular mass index in gm/m2 (LVMI, E/A ratio, ejection fraction, Comparing the related parameters in the 2 groups was done by t-test.. Results showed that no significant difference was found as regarding clinical and lipid profile parameters. Study group was found to have significantly higher levels of FBG, leptin and insulin, while fasting serum ghrelin levels were significantly lower in this group of patients. Statistically significant correlations were found between both leptin and ghrelin, with FBG, insulin, QTcd, and all echocardiographic LV structural and functional parameters. In conclusion, left ventricular structural and functional changes among type 2 diabetics are associated with decreased serum levels of ghrelin, and higher levels of serum glucose, insulin and leptin. These data infer that ghrelin might have a cardioprotective effect in patients with diabetes type.

Echocardiographic, metabolic and hormonal parameters in the 2 groups

	Study group (n=26)	Study group (n=26)	p-value
LVMI (g/m2)	107.8 + 36.9	69.1 + 7.1	0.001
EF (%)	62.2 + 3.2	71.8 + 4.01	0.001
E/A ratio	0.8 + 0.1	1.3 + 0.1	0.001
QTc dispersion (msec.)	61.9 + 5.2	47.9 + 4.08	0.001
Fasting blood glucose (mg/dl)	269.5 + 36.8	156.4 + 43.9	0.001
Leptin (ng/ml)	25.5 + 11.1	7.2 + 3.4	0.001
Ghrelin (fmol/ml)	2.2 + 0.4	4.3 + 2.4	0.001
Fasting serum insulin (μU/ml)	18.6 + 13.2	5.7 + 1.6	0.001

Assessment of autonomic nerve function in patients with irritable bowel syndrome

M. Nayem, N. Begum and S. Ferdousi

Physiology, Bangabandhu Sheikh Mujib Medical university, Dhaka, Bangladesh

Background: Autonomic nerve function impairment is related to development of Irritable Bowel Syndrome (IBS). Heart rate variability (HRV) is a useful tool to measure autonomic nerve function activity and also sympatho-vagal balance.Objective: To assess autonomic nerve function activity by heart rate variability analysis in patients with Irritable Bowel Syndrome. Methods: This cross sectional study was conducted in the Department of Physiology, Bangabandhu Sheikh Mujib Medical University (BSMMU), Dhaka from 1st July 2010 to 30th June 2011. Ninety patients aged 20-50 years of both sexes with Irritable bowel syndrome were included in the study group. They were enrolled from the OPD of Gastroenterology in BSMMU. For comparison age and sex matched 30 apparently healthy subjects were also studied as control. The power spectral HRV parameters were recorded by a digital Polyrite. For statistical analysis ANOVA, independent sample t-test and Pearson's correlation coefficient test were performed. Results: Mean resting pulse rate, mean HR, SBP, DBP, LF, LF norm and LF/HF were significantly higher and total power, HF, HF norm were significantly lower in IBS group compared to those of control. Again total power, HF, HF (nu) were negatively correlated and LF power, LF (nu), LF/HF were positively correlated with duration of disease .But the correlation of total power was statistically significant. Conclusion: The results suggest markedly lower parasympathetic with concomitant higher sympathetic activity and shifting of sympathovagal balance towards sympathetic predominance in patients of IBS. In addition, decreased vagal modulation may be inversely related to the duration of IBS.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Orchidectomy attenuates cardiopulmonary reflex-mediated bradycardia and hypotension in conscious rats

T.U. Andrade[1,2], A.M. Nascimento[1,2], O.A. Heringer[1], K.O. Cassaro[1], P.L. Cunha[1], I.C. Kalil[1] and N.S. Bissoli[2]

[1]Pharmacy, University of Vila Velha - UVV, Vila Velha, Espírito Santo, Brazil and [2]Pharmaceutical Sciences, Fedral University of Espírito Santo - UFES, Vila Velha, Espírito Santo, Brazil

The influence of male hormones in the reflex control of the cardiovascular system has been investigated lately. Testosterone has been shown to improve the baroreflex-madiated bradycardia, but high doses of anabolic-androgenic steroids (AAS) have the opposite effect. Cardiopulmonary reflex is

blunted under AAS influence, but surprisingly, no study has already investigated the physiological role of testosterone on this reflex (the Bezold-Jarisch Refelx-BJR). We investigated the effect of castration, in different periods after orchidectomy (OVX), in the BJR control of diastolic arterial pressure (DAP) and HR. Male Wistar rats were divided into six experimental groups, as stated in Table 1. OVX was performed under sodium pentobarbital anesthesia (50mg.kg-1, intra-peritoneal, Crystal, Brazil). The experiments were performed in accordance with the ethical principles for animal experimentation by the Brazilian College of Animal Experimentation and were approved by our Institutional Ethics, Bioethics and Animal Welfare Committee (Protocol 118/2010). BJR was analyzed by measuring the bradycardia and hypotension responses elicited by phenyldiguanide administration (1.5–24 μg/kg). Mean arterial pressure (MAP) was assessed and myocyte hypertrophy was determined by morphometric analysis. Testosterone and 17β-estradiol were measured in blood samples. Table 1 shows that the reduction of BJR control of DAP starts after 72h of OVX and after 7 days in the control of HR. After 21 days of castration the BJR reach its lowest capacity to control DAP and HR. The levels of testosterone were reduced in orchidectomized groups (OVX24h:0.26±0.02; OVX72h:0.18±0.01; OVX7D:0.12±0.01; OVX14D:0.08±0.01; OVX21D:0.01±0.00 ng/mL; p<0.01) in comparison with SHAM (0.47±0.12 ng/mL). Blood 17β-estradiol (SHAM:0.022±0.003; OVX24h:0.023±0.002; OVX72h:0.028±0.003; OVX7D:0.025±0.003; OVX14D:0.023±0.001; OVX21D:0.026±0.002 ng/mL), MAP (SHAM:104±3; OVX24h:101±5; OVX72h:108±4; OVX7D:110±4; OVX14D:107±5; OVX21D:105±4 mmHg), and myocyte hypertrophy (SHAM:5.3±0.4; OVX24h:4.9±0.3; OVX72h:4.8±0.3; OVX7D:5.6±0.5; OVX14D:5.1±0.4; OVX21D:5.3±0.4 myocyte nuclei/high power filed) did not change among the experimental groups. We conclude that castration of male animals caused decrease in testosterone levels and reduced sensitivity of BJR, indicating a positive physiological role of testosterone on functioning of this reflex.

PCB095

Combined assessment of capillary microcirculation and arterial stiffness to identify cardiovascular risk in human hypertension

M. Dinkel[1,2], M. Saedon[1,2], J. Lismore[2], P. Ray[2], C.H. Imray[2,1] and D.R. Singer[1,2]

[1]Warwick Medical School, Warwick, UK and [2]UHCW NHS Trust, Coventry, UK

Introduction: Both arterial stiffness (AS) and capillary rarefaction are biomarkers of cardiovascular risk. We assessed whether capillary videomicroscopy may complement measurement of arterial stiffness in clinical assessment of cardiovascular risk.
Subjects & Methods: We studied 94 out-patients with treated hypertension (age 63.9±1.5(SE)yrs, blood pressure (Omron) 147/87+2/1mmHg, 27F; hypercholesterolaemia 59, diabetes mellitus 23, chronic kidney disease 28, ischaemic heart disease 27, stroke syndromes 16, peripheral vascular disease 31). AS was estimated from aortic pulse wave velocity (PWV: Arteriograph, Unimedic); basal (BCD) and maximum skin capillary density (MCD) by videomicroscopy (KK Technology): abnormal AS PWV≥10 m/s, BCD ≤59 per 0.6mm^2 field, MCD <66/field. Written informed consent was obtained for the studies, which were approved by the local research ethics committee.
Results: Results were obtained both for PWV (11.1+0.2m/sec) and capillary density (BCD 53.4+1.5/ field; MCD 62.1+1.7/ field) in 70 patients (74%: 95%CI 65-83); for PWV alone (10.5+0.8 m/sec) in 8 patients (8%: 95% CI 3-13%); for capillary density alone (BCD 47.6+2.6/field; MCD 59.9+3.4/ field) in 10 patients (11%: 95% CI 5-17); and neither measurement in 6 patients (6%: 95%CI 1-11). Both PWV and capillary density were abnormal in 29 patients (41%: 95%CI 29-53). Capillary density was low but PWV normal in 22 (31%: 95%CI 20-42). PWV was raised but capillary density normal in 14 patients (20%: 95%CI 11-30); both readings were normal in 5 patients (7% 95%CI 1-13). PWV correlated positively with systolic (r_s=0.457, p<0.001) and diastolic blood pressure (r_s=0.265, P=0.021). Aortic augmentation index (Aix: 31.9+1.8%) also correlated significantly with systolic (r_s=0.459, p<0.001) and diastolic blood pressure (r_s=0.325, P=0.004). Basal capillary density correlated highly with maximum capillary density (r_s=0.831, p<0.001). There was no significant correlation between PWV and BCD or MCD, before or after adjustment for history of ischaemic heart disease. Waist hip ratio was inversely related to MCD in patients without known ischaemic heart disease (n=57: r_s -0.264, P=0.047).
Conclusions: Large and small vessel readings were only concordant in 2 out of 5 patients in indicating increased cardiovascular risk. Capillary imaging identified a third of patients at increased cardiovascular risk not detected by PWV alone. Our findings support use of diagnostic tests for both micro- and macrocirculation when assessing clinical cardiovascular risk in patients with hypertension with or without cardiovascular co-morbidity.

Characterisation of rebound depolarisation in mice deep dorsal horn neurons i*n vitro*

I. Rivera-Arconada and J.A. Lopez-Garcia

Physiology, University of Alcala, Alcala de Henares, Madrid, Spain

The differential array of ionic conductances expressed by a single neuron determines its intrinsic excitability and how it integrates synaptic inputs to generate adequate responses in accordance with its role. Dorsal horn neurons constitute the first relay of somatosensory information participating in sensory and motor processing. Here we show the presence of rebound depolarisation due to the presence of H and T-like currents in these neurons. Rebound behaviour has been related to neuronal plasticity and coding properties of several neuronal types. Spinal cords were removed from 7-12 day-old c57/CBA mice under urethane anaesthesia (2 g/kg; i.p.), hemisected, transferred to a recording chamber and superfused with oxygenated artificial cerebrospinal fluid (ACSF). Whole cell voltage and current-clamp recordings of deep dorsal horn neurons were performed with 5-9 MΩ pipettes. Tetrodotoxin, CsCl, mibefradil, NiCl and NNC 55-0396 were employed to unravel the nature of the ionic currents responsible of rebound behaviour.
Rebound behaviour was observed in 78% of neurons studied (122 out of 156). In 60 neurons rebound presented fast kinetics and high amplitude and was usually accompanied by spike firing. When more than 1 action potential occurred instantaneous firing frequency was very high (79 ± 4 Hz, range 20-128 Hz, n=43). In these neurons the presence of a low threshold, transient inward current was documented. This current and its related rebound were partially sensitive to blockade with mibefradil, NNC 55-0396 and low concentrations of NiCl. Calcium-free ACSF and higher concentrations of NiCl completely abolished the current and the rebound. Pharmacologic and kinetics analysis suggest that the T-type calcium current underlies this fast rebound.
The rebound observed in the remaining 62 neurons was slow and of low amplitude and was rarely associated with spike firing (35%). When more than 1 action potential was fired, instantaneous frequency was low (8 ± 1 Hz, range 5-15 Hz, n=11). In this subset of neurons T-like currents were absent but presented hyperpolarization activated current (IH). This slow rebound and the IH were fully blocked by 4 mM CsCl.
We conclude that the existence of T- and/or H-like currents in deep dorsal horn neurons determines the presence of rebound behaviour at end of hyperpolarization pulses. T-type calcium currents were associated to a strong and fast rebound with high frequency firing. H currents were associated to small rebound, normally without spiking. Rebound depolarization and firing may constitute a mechanism to integrate somatosensory information in the spinal cord.

Prion protein mediates synaptic vesicle formation

S.W. Robinson, M.L. Nugent, D. Dinsdale and J.R. Steinert

MRC Toxicology Unit, University of Leicester, Leicester, UK

The cellular prion protein (PrP) plays important roles in many neuronal processes including memory, circadian rhythm, neuroprotection and neurotoxicity[1]. Although physiological roles of PrP remain elusive, its neurotoxic signalling has been investigated more thoroughly. As a consequence of PrP misfolding, several mammalian species develop neurodegenerative conditions known as scrapie, bovine spongiform encephalopathy or Creutzfeldt-Jacob and Gerstmann-Sträussler-Scheinker syndrom (GSS) in human.
The current study investigated synaptic effects of expressing mouse PrP and a mutated form of PrP (PrP^{P101L}, resembling a GSS-like disease in mice) in *Drosophila* to elucidate synaptic functions of PrP. The UAS/Gal4 bipartite expression system was used to drive pan-neuronal expression with the *elav-GAL4* driver[2].
Two-electrode voltage clamp experiments were conducted to record miniature and evoked excitatory junctional currents (m/eEJCs). Intracellular recordings from larval muscle 6 were performed (Milticlamp 900A, pClamp 10, Axon Instruments) in haemolymph-like solution 3 at 25ºC. Data are expressed as mean±SEM (n). Statistical analyses were carried out using ordinary ANOVA and Kolmogorov–Smirnov (K-S) tests, * indicates $p<0.05$.
PrP expression induced an increase in mean mEJC from 0.77±0.03nA (31) in wild type (WT) to 1.17±0.12nA* (4). This augmentation was also observed following expression of PrP^{P101L} (0.92±0.04nA* (17)) although to a lesser extent. The increase in mEJCs is due to a shift in the distribution of single mEJC amplitudes. Relative cumulative frequency histograms for mEJC amplitudes showed an increased probability of larger amplitudes and hence a right shift in mEJC distributions in PrP expressing larvae (K-S test: PrP: D=0.28, $p<0.0001$, PrP^{P101L}: D=0.24, $p<0.0001$) relative to WT. mEJC decay (τ) values did not differ between genotypes (τ_{WT}=10.0±0.4ms; τ_{PrP}=12.1±1.3ms; $\tau_{PrP^{P101L}}$=10.8±0.4ms) nor did τ distributions, indicating that postsynaptic receptor composition was not affected. The frequency of mEJCs was not different between the genotypes (f_{WT}=1.6±0.2s^{-1}; f_{PrP}=1.6±0.4s^{-1}; $f_{PrP^{P101L}}$=1.3±0.2s^{-1}). In agreement with electrophysiological data, electron microscopy revealed that PrP and PrP^{P101L} (but to a smaller degree compared to PrP) expression caused an increase in vesicle diameters (1s boutons: WT: 43.4±0.7nm (6); PrP: 55.4±2.3nm* (3); PrP^{P101L}: 47.5±0.4nm* (4)) suggesting that larger vesicles are responsible for the augmented mEJC amplitudes. Further, PrP expression caused an increase in foraging behaviour as detected in greater crawling distances per 30min (WT: 1.2±0.1m (23); PrP: 1.9±0.1m* (23); PrP^{P101}: 1.8±0.1m* (13)).
This data indicate that PrP mediates some of its physiological effects via formation of synaptic vesicles and that mutated PrP (PrP^{P101L}) as present in prion disease loses this ability thereby contributing to disease progression on the synaptic level.

PCB098

The role of orexin in morphine tolerance and its effect on neural activity of Lateral Paragigantocellularis nucleus

M. Ghaemi Jandabi, Y. Ranjbar-Slamloo, H. Azizi and S. Semnanian

Physiology, Tarbiat Modares University, Tehran, Islamic Republic of Iran

Repetitive administration of opioid agonists rapidly develops tolerance to the effects of these substances and limits their application. Orexin is involved in morphine tolerance and withdrawal. The Lateral Paragigantocellularis (LPGi) is a key brain region implicated in the tolerance and dependence to opiates. In the current study, the effect of OXR1 blockade on tolerance to antinociceptive effect of morphine and also on the neural activity of LPGi during the development of morphine tolerance was studied.

Male Wistar rats weighing 250-300g were used in these studies. To incite tolerance, morphine sulfate was injected intraperitonealy (10mg/kg, i.p.) once a day for 7 days. Tail flick test was used to survey morphine analgesic tolerance. A selective orexin type 1 receptor antagonist (SB-334867) was microinjected into the right cerebral ventricle (10μg/10μl, i.c.v.) immediately before morphine injection. To evaluate tolerance at the cellular level, On day 7 the effect of morphine (10mg/kg, i.p.) on neural activity of LPGi was investigated using in vivo extracellular single unit recording.

In the behavioral studies, daily injections of morphine in a 7-day period caused morphine analgesic tolerance in rats. There was a significant difference of %MPE between saline and morphine treated rats until day 6 but not on day 7 (Data was presented as mean±SEM. $^{*}P < 0.05$, $^{**}P < 0.01$ and $^{***}P < 0.001$ vs. saline group, n = 6 for both groups; one-way ANOVA followed by Tukey's post test). The analgesic effects of morphine (%MPEs) were significantly higher in SB-334867 plus morphine treated rats (n=9) than SB vehicle plus morphine treated (n=11) ones on days 4-7 (Data was presented as mean±SEM. $^{*}P < 0.05$, $^{**}P < 0.01$ and $^{***}P < 0.001$ vehicle plus morphine, one-way ANOVA followed by Tukey's post test). In the electrophysiological studies, 6 days injection of morphine caused significant tolerance in LPGi neurons as a decreased responsiveness of neurons to morphine (10 mg/kg, i.p.) during single unit recording. In a way that on day 7 morphine has not created any significant change in the firing rate of LPGi nucleus. (Data was presented as mean±SEM, n=10; Student's paired t-test). In SB plus morphine treated group (n=17), Microinjection of SB before each morphine injection inhibited the development of tolerance to morphine in comparison to the morphine treated group (Data was presented as mean±SEM, Student's paired t-test).

These studies have shown that central blockade of orexin type 1 receptor inhibits the development of morphine tolerance in both studies. The impediment of tolerance to analgesic effect of morphine by ICV administration of orexin type 1 receptor antagonist may be mediated in part via LPGi neurons. Further studies are required to determine molecular and anatomical mediators which are thought to be involved in this phenomenon.

Opotogenetic investigation in astrocyte-neurone signalling in locus coeruleus

F. Tang, S. Lane, M. Figueiredo, A.G. Teschemacher and S. Kasparov

School of Physiology and Pharmacology, University of Bristol, Bristol, UK

According to astrocyte-neurone lactate shuttle hypothesis, lactate released from astrocytes, is used by neurones as preferred metabolic substrate (Pellerin and Magistretti, 1994). Here, we used optogenetics to investigate signalling between astrocytes and noradrenergic neurones of the locus coeruleus (LC). In organotypic slice cultures of Wistar rat pups containing LC astrocytes were transduced with an AVV (Adenoviral vectors) to express a mutant version of the light sensitive channel rhodopsin 2 (ChR2-H134R33) fused with a far- red shifted fluorescent protein mKate and NAergic neurons were targeted to express DsRed2 with AVV-PRS8-Dsred (Gourine et al., 2010). Patch clamp recordings were made from DsRed2-positive neurones in LC. Activation of astrocytes with blue light evoked long lasting depolarisations of adjacent LC neurones (depolarisation + 3.08 ± 0.33 mV, n=14). This depolarisation could be blocked by an inhibitor of glycogen breakdown, 1,4-dideoxy-1,4-imino-D-arabinitol (DAB; 500 μM, pre-incubation 1h, depolarisation + 0.96 ± 0.15 mV, n=5, $p<0.001$) or D-lactate (2mM; +1.27± 0.38 mV, n=5, $p<0.01$) but not with the inhibitor of monocarboxylate transporters 4-CIN (100 μM, +2.9± 0.46mV,n=4, $p>0.05$). In the other set of experiments we applied fast scan cyclic voltammetry (FCV) to measure noradrenalin (NA) release from LC neurones in organotypic slices. To selectively stimulate Gs-protein-mediated signalling cascade in astrocytes, we used AVV to express rhodopsin chimera with β2 adrenergic receptors (optoβ2AR; Airan et al., 2009). Light activation of optoβ2AR-expressing astrocytes resulted in a clear increase in noradrenalin release (83.23 ± 10.6 mM*Sec, n=32), which again was abolished by DAB (500 μM, 0.75 ± 7.35 mM*Sec, n=6, $p<0.001$) and D-lactate (400 μM, -0.59±1.107mM*Sec, n=8, $p<0.001$). This was interpreted as evidence for the involvement of L-lactate in this effect. To confirm that optoβ2AR can trigger L-lactate production in astrocytes, we measured pH with SNARF-5AM in primary dissociated glial cultures and found that light simulation resulted in the emission ratio shift, indicative of acidification (144.4% ± 2.206%, n=58) which could be blocked by pre-incubation with DAB (101.3±0.6872%, n=32, $p<0.001$). These experiments imply that activation of astrocytes excites LC neurons and potentiates NA release via release of L-lactate. The mechanism by which L-lactate modulates neuronal activity is currently under investigation.

Characteristics of dorsal root ganglia neurons sensitive to substance P

E.R. Moraes, C. Kushmerick and L.A. Naves

Fisiologia e Biofísica, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Some nociceptors produce and release Substance P (SP), a peptide cotransmitter with well-described effects on second-order sensory neurons. However, the effects of SP on primary sensory neurons are less clear. We tested the hypothesis that, among primary sensory neurons, SP targets mainly nociceptors. We therefore examined the biophysical and pharmacological profile of rat DRG sensorial neurons that are sensitive to SP. Whole-cell patch clamp was used to measure the response of 92-94 cells to brief applications of pH 7 (26 positive cells), pH 6 (38 positive cells), capsaicin (25 positive cells), and ATP (13 P2X3-type current positive cells). Sensitivity to SP was determined in 87 cells by its effect on cell excitability during stimulation at 1-4 times threshold. The number of action potentials at the threshold, and the slope of the stimulus-response curve were compared before and after SP application. We found that in 14 of the 87 cells examined, SP increased the slope of the stimulus-response curve, and in 12 cells SP increased the number of action potentials at the threshold. In total, 17 out of 87 cells tested (19%) increased excitability measured by one parameter or the other. There was also a decrease in excitability in 11 out of 87 cells. Among the cells responding to SP, the frequencies of sensitivity to pH 7 (61%) and pH 6 (78%) were statistically (Chi-squared test) higher than the frequencies of the non-responding cells (18% and 29% to pH 7 or 6, respectively). The frequencies of sensitivity to capsaicin had a tendency to be higher in the SP responding cells (20% versus 46%). P2X3-type ATP currents were present in 16% of cells that did not respond to SP, while one of the 17 (6%) substance P positive cells presented this current. Also, substance P responsive neurons had the largest diameters, and had broader action potentials with more pronounced after hyperpolarizations. We conclude that the majority of SP sensitive neurons exhibit a profile typical of nociceptors, although P2X3 currents were almost absent in these cells.

PCB101

Synaptic vesicles expressing adaptor protein 3 contribute primarily to asynchronous release and regulate the fidelity of neurotransmission at hippocampal mossy fibre terminals

A. Evstratova[1], V. Faundez[2] and K. Toth[1]

[1]Universite Laval, Quebec City, QC, Canada and [2]Emory Univresity, Atlanta, GA, USA

Endocytosis is an important step in the synaptic vesicle recycling; it helps to maintain reliable neurotransmitter release. Two major pathways of endocytosis co-exist in the same presynaptic terminal: clathrin-dependent endocytosis of single vesicles utilizing adaptor protein AP-2 and bulk endocytosis leading to the formation of endosomes and dependent on adaptor protein AP-3. Vesicles derived in these two pathways differ in their molecular content and represent distinct vesicular pools. We used AP-3 knockout mice (Ap3b2-/-) lacking endosomal vesicle formation to explore physiological role of vesicular pool formed via this pathway in synapses between mossy fiber boutons and hippocampal CA3 pyramidal cell. Spontaneous and evoked EPSCs had similar amplitude and kinetic properties, moreover quantal parameters (p, Q and N), ready releasable pool size and its recovery speed were comparable between WT and KO mice. However, in KOs decay time constant of release was significantly faster (3.7 ± 0.4 ms vs 5 ±0.4 ms) and was accompanied with reduced asynchronous release (3.8 vs 7.4 Hz). In addition, stimulation with natural spike trains revealed significantly reduced probability of postsynaptic APs and increased variability of responses, especially prominent at ~100 Hz increase of stimulation frequency. Our data suggest that vesicles generated via bulk endocytosis contribute primarily to asynchronous release. The lack of asynchronous release renders information transfer from granule cells to hippocampal pyramidal cells less reliable, and therefore it could influence spatial memory.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB102

Contribution of endogenous VIP VPAC1 receptor activation during hypoxia and interictal-like activity induced in vitro by 0-Mg2+ to subsequent changes in LTP expression in the rat hippocampus

D. Cunha-Reis

Laboratório de Função Autonómica Cardiovascular, Unidade de Fisiologia Clínica e Translacional,, Instituto de Medicina Molecular, Universidade de Lisboa, Portugal, Lisboa, Portugal

VIP, a modulator of synaptic transmission present in hippocampal interneurones, was shown to inhibit long-term potentiation in the CA1 area of the rat hippocampus through activation of VPAC1 receptors (1). VIP release is triggered by electrical activity, VIP receptors are enhanced in TLE patients (2) and VIP promotes neuronal survival in the absence of electrical activity (3), a situation observed during hypoxic depression. In this work we investigated if VPAC1 receptor activation during brief hypoxia and in vitro interictal-like activity could influence the subsequent expression of LTP in the CA1 area of the hippocampus.

Male wistar rats (6-7 week-old) were decapitated under fluothane anaesthesia. Extracellular electrophysiological recordings of field-excitatory post-synaptic potentials (fEPSPs) evoked by electrical stimulation in hippocampal slices were used to access synaptic transmission. Hypoxia was induced by 3 min superfusion with 95% N2–5% CO2 (normoxia: 95% O2–5% CO2). In vitro interictal-like activity was induced by 30 min superfusion with aCSF containing no 0mM MgCl2 and 6mM KCl (normal comp.: 1mM MgCl2 and 3mM KCl). LTP was induced by θ-burst stimulation (five 100Hz bursts, 4 stimuli, separated by 200 ms) and potentiation of fEPSP slope evaluated 50-60 min after LTP induction. The selective VPAC1 antagonist PG 97-269 was used to block endogenous VPAC1 receptor activation during both insults. Student's t test was used to evaluate the statistical differences between control and test groups.

Θ-burst stimulation in control conditions induced a long-lasting enhancement of fEPSP slope (29.0±2.9%, n=7, 50-60 min after stimulation). Hypoxia caused a brief but marked decrease in fEPSP slope that recovered to basal values 30 min after hypoxia in control conditions but was not complete (89.0±1.8%) after hypoxia in the presence of 100nM PG 97-269. Θ-burst-induced LTP was enhanced to 44.9±1.3% (n=4) and 43.8±1.3% (n=4) when θ-burst stimulation was delivered 30 min and 60 min after hypoxia, respectively. This enhancement was not observed in slices subjected to hypoxia in the presence of PG 97-269 (100nM). Following interictal-like activity induced by 0Mg2+ aCSF, θ-burst-induced LTP was impaired to 17.9±2.3% (n=3) and 24.8±1.5% (n=3) when evoked 30 min and 60 min after interictal-like activity, respectively. When interictal-like activity was induced in the presence of PG 97-269 (100nM), this impairment was not observed (n=3).

These results suggest that activation of VPAC1 receptors by endogenous VIP during brief hypoxia contributes to a subsequent facilitation of LTP induction. In contrast, activation of VPAC1 receptors during interictal-like seizures may contribute to the inhibition of LTP that follows this insult.

The maturation of AMPA receptors in human pluripotent stem cell-derived cortical excitatory neurones

M. Livesey[1], B. Bilican[2], G. Haghi[2], G.E. Hardingham[1], S. Chandran[2] and D.J. Wyllie[1]

[1]Centre for Integrative Physiology, University of Edinburgh, Edinburgh, UK and [2]Euan MacDonald Centre and MRC Centre for Regenerative Medicine, University or Edinburgh, Edinburgh, UK

The ability to generate regionally defined neuronal populations from human pluripotent stem cells (hPSCs) provides an important new experimental resource for the investigation of human neuronal physiology. We have developed a protocol in which H9 hPSCs are neuralised in suspension using chemically defined medium. Such an approach is based upon the default model of neurogenesis that minimizes extrinsic and intrinsic signals that lead to alternative cell fates. Analysis of the resulting neural stem cells (NSCs) reveals a forebrain identity as assessed by FOXG1 and OTX2 expression. Subsequently NSCs are plated as a monolayer to generate PAX6-positive precursors that terminally differentiate into an enriched VGLUT1 positive population of cortical neurones that express the cortical layer specific markers CTIP2, SAT2B or Reelin. Importantly, glia and inhibitory interneurones are only nominally present (<10% of total population). In the present study we have used this population of human cortical excitatory neurones (hCENs) to assess the developmental expression and biophysical properties of 2-amino-3-hydroxy-5-methyl-isoxazol-4-yl propanoic acid receptors (AMPARs).

The responsiveness of the cells to AMPA (50 μM) was assessed weekly for 5 weeks following differentiation and significant increases in current densities from week 1 (0.12 ± 0.08 pA/pF, n = 22) to week 5 (1.14 ± 0.2 pA/pF, n = 35) were observed. As would be anticipated AMPAR-mediated currents were blocked by 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX; 5 μM). Non-stationary noise analysis indicated that the mean weighted single-channel conductance of AMPARs expressed by hCENs decreased from 11.1 ± 1.2 pS (week 2; n = 8) to 4.5 ± 0.4 pS (week 5; n = 12). In addition AMPAR-mediated currents at week 5 were insensitive to intracellular block by the polyamine, spermine (100 μM; n = 5). Similar experiments with neurones derived from the 31D1 induced pluripotent stem cell line also indicated the presence of low-conductance AMPARs at week 5 (4.1 ± 1.2 pS; n = 3).

Our data are consistent with the notion that at week 5 hCENs express AMPARs that contain the edited form of the GluA2 subunit. Furthermore, the developmental switch from an AMPAR population possessing higher unitary conductances to one expressing lower unitary conductances is tetrodotoxin insensitive (i.e. action potential independent). In addition this switch is not blocked when neurones are cultured in presence of antagonists of ionotropic glutamate receptors.

Deafness related to hyperbilirubinaemia is associated with transmission failure at central auditory synapses

E. Schiavon, H. Parker and I.D. Forsythe

cell physiology and Pharmacology, University of Leicester, Leicester, UK

Acute and chronic bilirubin encephalopathy (ABE and kernicterus) are serious neurological conditions associated with Jaundice. When plasma free bilirubin is high, it crosses the blood-brain-barrier and causes neuronal damage in the CNS. This investigation focuses on the damage in the brainstem auditory pathway, using the calyx of Held giant glutamatergic synapse, which forms between the anterior ventral cochlear nucleus and the neurons of the medial nucleus of the trapezoid body (MNTB). Hyperbilirubinaemia was induced in CBA/Ca mice (11-20 days old) by a single intraperitoneal injection of bilirubin (0.5 mg/g) and sulfadimethoxine (0.3mg/g). Auditory function was monitored in vivo by auditory brainstem responses (ABR) using click stimulation under anesthesia (Hypnorm/Midazolam/water, ratio 1/1/2: 0.1μl/g intraperitoneally). Electron microscopy (EM) and immunohistochemistry (IHC)

for the presynaptic marker VGLUT2 (vesicular glutamate transporter 2) were performed and patch clamp recording in MNTB neurons were made under voltage clamp in order to record miniature excitatory postsynaptic currents (mEPSCs). Evoked responses were recorded, stimulating the presynaptic trapezoid body fibers at the midline, and clamping the MNTB membrane potential at -65mV or +80mV to investigate AMPAR or NMDAR currents, respectively. ABRs were largely abolished at 4h, but they recovered 24h and 5 days after bilirubin injection. IHC showed reduced staining for VGLUT2 in the calyx of Held at both 4h and 24h after injection. An EM study 4 h after bilirubin injection showed two changes at the calyx of Held synapse: first, the terminals were packed with vesicles and second, the presynaptic terminals were detached from the postsynaptic membrane. 24h after bilirubin injection, the presynaptic terminals had rejoined with the postsynaptic membranes, but the calyx of Held synapses were still abnormally overfilled with vesicles. Whole cell experiments validate the damage of the Calyx of Held synapses showing a significant decrease in the amplitude (62.3±3.5 pA n=7 vs control 83.4±7.3 pA n= 6) and in the frequency of spontaneous mEPSCs, (2.5±0.4 Hz n=7 vs control 7.2±1.1 Hz, n=6) that had recovered after 24h (84.4±8.2, vs control 62.3±3.5 pA, frequency 5.4±0.9 Hz vs control 7.2±1.1 Hz, n=4 and 6 respectively). Evoked AMPAR and NMDAR EPSCs showed a decreased amplitude in 4h injected animals (-4.6±0.3nA and 3.5±0.3nA, respectively vs control -6.9 ±1.2 nA and 4.8 ±0.7nA). We conclude that the acute injection of bilirubin causes short-term damage to the auditory system, involving the calyx of Held and provides a good model for further understanding the mechanisms of bilirubin toxicity in disease.

Non-genomic effects of estradiol on the excitability of Locus Coeruleus neurons in neonatal rats

A.J. Silva[1,2] and C. Kushmerick[1,2]

[1]Physiology and Biophysics, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil and [2]Graduate Program in Physiology and Pharmacology, UFMG, Belo Horizonte, Minas Gerais, Brazil

17β-estradiol (E2) is a sex hormone that regulates gene expression in the reproductive system. In addition to these genomic effects that take place over a relatively long time scale, a growing body of evidence points to rapid effects of E2 mediated by a plasma membrane receptor. In the present study, we examined the acute effects of E2 on the electrical excitability of neurons from the Locus Coerulus. Brain slices containing the Locus Coerulus were obtained from neonatal Wistar rats of post-natal day p5-7, and membrane potentials were recorded using standard intracellular techniques with sharp glass microelectrodes. Resting membrane potentials were -65±6 mV (N=27). Locus Coerulus neurons presented spontaneous action potentials or subthreshold oscillations. Spontaneous action potentials (N=3) or sub-threshold oscillations (N=8) were reversibly abolished within minutes of application of E2 encapsulated in hydroxypropyl-β-cyclodextrin (HBCD; 200 nM). In addition, application of E2 caused a membrane hyperpolarization of 4.9±2.5 mV (N=8). Effects of E2 were completely reversible upon washout, and could be repeated multiple times in the same cell (up to 8 applications over 6 hours) with similar results. Application of the encapsulation vehicle HBCD alone caused no effect (N=4). To determine if the receptor activated by E2 was on the cell surface or intracellular, we tested E2 conjugated to Bovine Serum Albumin (E2-BSA) on LC activity. Similar to encapsulated E2, E2-BSA inhibited spontaneous activity and hyperpolarized the membrane (N=4). We conclude that E2 can inhibit the spontaneous activity of Locus Coerulus neurons by interaction with a plasma membrane receptor.

Pharmacological investigation of triheteromeric NMDA receptors in rat substantia nigra dopaminergic neurones

R. Ammari[1], S.J. Scott[2], S. Jones[3] and A. Gibb[1]

[1]Neuroscience, Physiology and Pharmacology, University College London, London, UK, [2]Biomedical Sciences, University of Queensland, Brisbane, QLD, Australia and [3]Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK

The dopaminergic neurons of the substantia nigra pars compacta (SNc) are important in the circuitry of the basal ganglia, and their degeneration underlies the development of motor symptoms in Parkinson's disease. Several mechanisms may contribute to this degeneration, one of which could be excessive activation of N-methyl-D-aspartate (NMDA) receptors. NMDA receptors are tetrameric assemblies of GluN1 and at least one type of GluN2 (A,B,C and D) subunit which confer distinct and unique characteristics to these receptors. Dopaminergic neurones of the substantia nigra pars compacta (SNc) express a combination of GluN2B and also GluN2D subunits and here we investigated the hypothesis that these receptors are expressed as 'triheteromeric' GluN1/GluN2B/GluN2D receptors. Using patch-clamp whole-cell recordings from SNc neurones in coronal brain slices from 3 week old rats (humanely killed by decapitation under deep isofluorane anaesthesia), we investigated how these unusual NMDA receptors are regulated by the subunit selective allosteric inhibitors, ifenprodil (GluN2B) and DQP-1105 (GluN2C/D) during repeated activation (15s durations at 100s intervals, of 100μM NMDA over a 10 minute time scale). NMDA-evoked currents displayed a maximal inhibition of 58 ± 11% by ifenprodil (10μM, n = 10) with an estimated IC50 = 0.21 μM while DQP-1105 (10μM, n = 9) inhibited currents by 64 ± 7.9%. These results suggest that a proportion of NMDA receptors on dopaminergic neurons of the substantia nigra are triheteromeric GluN1/GluN2B/GluN2D receptors.

Cilostazol does not inhibits KCl and capcaicin induced increase in intracellular calcium signaling in rat sensory neurons

S. Kutlu[1], E. Kacar[2], O. Burma[3] and A. Uysal[3]

[1]Department of Physiology, NE University Faculty of Medicine, Konya, Turkey, [2]Department of Physiology, Firat University Faculty of Medicine, Elazig, Turkey and [3]Department of Cardiovascular Surgery, Firat University Faculty of Medicine, Elazig, Turkey

Cilostazol, a specific cAMP phosphodiesterase III inhibitor, is used for medical treatment of intermittent claudication in peripheral artery disease to prevent leg pain during physical activity. Dorsal root ganglion (DRG) neurons are eligible experimental model for pain investigations. Aim of this study was to figure out the effect of cilostazol on intracellular calcium ([Ca2+]i) signaling in cultured rat DRG neurons. DRG neurones were grown in primary culture following enzymatic and mechanical dissociation of ganglia from 2-day-old Wistar rats. DRG neuronal cultures were loaded with 1μmol Fura-2AM and [Ca2+]i responses to stimulation were assessed by using fluorescent ratiometry. Cultured cells were excited at 340 and 380nm, and emission was recorded at 510nm. Responses were determined by the change in 340/380 ratio (basal-peak) for individual neurons. After basal recordings, KCl (30mM) and capcaicin (1μM) applied to medium for induction of [Ca2+]i . Cilostazol treated alone or co-administered with KCl and capcaicin for determining the possible changes in calcium signaling. Data were analyzed by using one-way analysis of variance followed by a post-hoc Tukey HSD test, with a 2-tailed P level of <0.05 defining statistical significance.
Firstly exposure to cilostazol failed to cause any significant change in basal [Ca2+]i response (basal=100.0±0.0 and cilostazol =99.8±0.2 %). KCl and capcaicin had significant increase in [Ca2+]i responses to 164.71±4.1 % and 191.55±6.4 % (respectively, p< 0.001). But co-application of cilostazol with KCl and capcaicin didnot alter the KCl and capcaicin induced elevation in [Ca2+]i (166.14±3.7 % and 188.26±4.7 %, respectively). In conclusion, the results of present study suggest that cilostazol has no effect on [Ca2+]i signaling in rat sensory neurons in vitro. It seems cilostazol may activate other mechanism(s) at cellular level rather than modulating calcium signaling in DRG neurons.

Detecting purines, catecholamines and glutamate with a mutant α-haemolysin pore one molecule at a time: a synthetic mutant sniffer patch

K.L. Brain[1], A. Boersma[2], P. Sidaway[1] and H. Bayley[2]

[1]Clinical and Experimental Medicine, University of Birmingham, Birmingham, West Midlands, UK and [2]Department of Chemistry, University of Oxford, Oxford, Oxfordshire, UK

We have recently developed a genetically and chemically-modified α-haemolysin pore for the simultaneous measurement of a range of neurotransmitters, including purines, catecholamines and glutamate (Boersma *et al*., 2012). Building upon a previous purine-sensitive pore (Cheley *et al*., 2002), a catecholamine binding side that incorporated Cu^{2+} allowed several catecholamines, including noradrenaline, adrenaline and dopamine, to bind. These measurements were made in a Cl^--free, HCO_3^--free physiological saline containing (mM): 118 NaCl, 10 MOPS, 4.7 KCl, 1.8 $CaCl_2$, 1.8 $MgCl_2$, 11.1 D-glucose; pH 7.4. When such pores are incorporated into an artificial bilipid membrane, and then voltage-clamped, single molecules of these neurotransmitters can be detected as they block the α-haemolysin pore. The identity of each molecule can be determined my measuring both the amplitude of the conductance block and the dwell time of the molecule on the pore. We have demonstrated the ability of this technique to distinguish separate molecules in a cocktail of ATP (5 μM), ADP (5 μM) and noradrenaline (1μM), and describe a technique for calculating the concentration of each component of the mixture. Glutamate (<5 μM) is also detectable with the same pore. Altering the clamp voltage modifies the relative sensitivity of the pore, which provides an additional method for identifying binding molecules. Such a need might arise if very similar species need to be distinguished. We have tested this probe on the spontaneous and epibatidine-evoked release of transmitters from PC12 cells, and in pilot experiments can simultaneously identify ADP, ATP and noradrenaline, as well as a small set of other binding events for which the chemical species responsible have not yet been identified.
The stable nature of α-haemolysin implies that this approach may be developed to produce a relatively simple-to-use method for single-molecule detection of neurotransmitter release in small sample volumes, although several technical challenges remain including the optimization of suitable bilipid membranes (or other methods of supporting the channel), reducing the binding site affinity (to increase the off rate and hence increase the sampling frequency, particularly for catecholamines) and the identification of all biologically relevant binding molecules.

TR(i)P to automation

I. Rinke, C. Haarmann, N. Becker, A. Obergrussberger, S. Stölzle, A. Brüggemann, M. George and N. Fertig

Nanion Technologies, Munich, Germany

Transient receptor potential (TRP) channels are an important class of receptors widely distributed in the mammalian central and peripheral nervous systems. TRP receptors have been shown to be activated and regulated by a variety of stimuli including temperature, mechano-stimulation, divalent cations, pH and different kinds of molecules, which mediate the sensation of taste. Dysfunction of TRP channels can cause various pathological conditions, including an inherited pain syndrome, multiple kidney diseases and skeletal disorders. Hence, TRP channels become potential targets for the treatment of such disorders. Currently within drug development, much attention is paid to the TRP ankyrin 1 (TRPA1) channel. Preclinical data and data from a recent human genetic study[1] highlight TRPA1 antagonists as a promising new approach for the treatment of acute and chronic pain.

Patch clamp electrophysiology remains the gold standard for studying ion channels. We have employed planar patch clamp instrumentation for medium and high-throughput screening (Patchliner and SyncroPatch 96 platforms) to study the TRPA1 channel stably expressed in HEK cells.

TRPA1 is activated by a range of environmental irritants, pungent compounds found in foods, as well as metabolites produced during oxidative stress. Here, we demonstrate the activation of TRPA1 by mustard and cinnamon. Induced currents could be reversibly blocked by the potent antagonist HC030031.

The most challenging characteristics of TRPA1 within screening are the channels` mechano-sensitivity, fast desensitization and its regulation by intracellular calcium. Using a combination of excellent fluidics, allowing for fast solution exchange whilst brief compound application, and the usage of calcium buffered external solution, we have achieved recording of high quality data with a high success rate for obtaining stable giga-seals (typically 60 to 80%), and reliable pharmacology.

Neuroprotective potential of N-nitro-L-arginine-methylester in transient cerebral ischemia and reperfusion in rats

H.A. Awooda[1], G.M. Sharara[2] and A.M. Saeed[3]

[1]Department of Physiology, Al Neelain UIniversity, Khartoum, Sudan, [2]Department of Biochemistry, Alexandria University, Alexandria, Egypt and [3]Department of Physiology, University of Khartoum, Khartoum, Sudan

Stroke is the second leading cause of death and permanent disability worldwide. The role of nitric oxide (NO) inhibition in cerebral ischemia/reperfusion (I/R) remains controversial (1). Rho-kinases (ROCK) are serine–threonine kinases that play a vital role in cell migration and survival, interaction between NO and ROCK isn't clear (2). Nuclear factor kappa β (NF-kβ) is a transcription factor that contributes to infarction in experimental stroke and its inhibition associated with neuroprotective effects (3). This study investigated the potential neuroprotective effect of nonselective nitric oxide synthase inhibitor (L-NAME) in rat's transient cerebral I/R. 30 adult male Wistar rats (150-250g) were divided into three groups 10 rats in each: first group was sham-operated and served as a control, I/R group of rats infused with 0.9% normal saline intraperitoneally 15 minutes prior to 30 minutes of left common carotid artery occlusion, followed by 24-hour of reperfusion, anesthesia was induced by ether inhalation and maintained by thiopental sodium (2.5mg/kg) (4). A test group infused with L-NAME (15 mg/kg per weight) intraperitoneally 15 minutes prior to same I/R period. Neurobehavioral assessments were evaluated (5), NF-κβ via western blotting and ROCK using enzyme-linked immunosorbent assay were estimated in the left cerebral hemisphere. NO metabolites (nitrite and nitrate) were measured colorimetrically in plasma and brain tissue. Values are means ± S.E.M., compared by ANOVA. The L-NAME group showed a significant improvement in neurological deficit (15.07±0.584) compared to both I/R and control groups (12.798±0.689, 17.50±0.707, respectively P <0.001). In I/R group; NF-κβ was significantly increased (129.2±1.7 RGB unit/mg protein) compared to the control group (53±1.03RGB unit/mg protein, P <0.001) and L-NAME pretreatment resulted in significant decrease in NF-κβ (44.4±1.3RGB unit/mg protein, P <0.001) compared to I/R rats. In I/R group brain tissue levels of ROCK and NO significantly increased (0.022±0.0054 ng/mg protein, 8.88±0.572 nmol/mg protein) compared to the control group (0.013±0.003 ng/mg protein, 3.48±0.228 nmol/mg protein, P <0.001). The L-NAME group showed a significant decrease in tissue level of ROCK and NO (0.005±0.0006 ng/mg protein, 4.47±0.392 nmol/mg protein, P <0.001) compared to the I/R group. Serum level NO was significantly increased in I/R group (42.03±4.558 μmol/L) compared to the control group (17.84±0.701 μmol/L, P <0.001), while L-NAME administration resulted in significant decrease in serum NO (18.44±0.513μmol/L, P <0.001) compared to the I/R group. Thus, L-NAME significantly improved neurological deficit and inflammation evidence by decrease NF-κβ and ROCK in the affected cerebral hemisphere following cerebral ischemic injury.

Endocannabinoid modulates developmental plasticity of central vestibular synapses and the expression of vestibular behaviors in rats

W. Shi[1], H. Hu[1], D. Shum[1,2] and Y. Chan[1]

[1]Physiology, The University of Hong Kong, Hong Kong, Hong Kong and [2]Biochemistry, The University of Hong Kong, Hong Kong, Hong Kong

Endocannabinoid (eCB) has been found to mediate retrograde signaling and long-term depression of inhibitory responses (iLTD) in neurons of the amygdala, hippocampus and visual cortex. It remains unexplored whether eCB regulates long-term synaptic plasticity in the vestibular nucleus and behavioral expression of vestibular functions. Whole-cell patch-clamp experiments were performed on brainstem slice of postnatal rats. Theta-burst stimulation delivered to vestibular afferents could induce iLTD of GABAA receptor-mediated evoked-IPSCs in medial vestibular neurons. Such iLTD was induced in 70% of the neurons tested in P5-7 rats but was reduced to 30% in P8-10 rats. In P5-7 rats, the proportion of these neurons was reduced to 30% with bath application of AM251 (antagonist of type 1 cannabinoid receptor). Similar results were obtained in P5-7 rats that had been implanted at P1 with a slice of AM251-loaded Elvax that allowed controlled release of the drug into the underlying vestibular nucleus. In normal P8-10 rats, the proportion was increased to 60% with bath application of WIN55 (agonist of type 1 cannabinoid receptor). Similar results were obtained in P8-10 rats implanted at P1 with WIN55-loaded Elvax slice. To attest the effects of eCB in the expression of vestibular behavior, the Elvax-implanted rats were tested with negative geotaxis, a behavioral indicator of gravity-detection. When compared with normal controls which acquired the re-orienting behavior by P7, emergence of this reflex was accelerated to P5 in AM251-treated rats but was delayed to P11 in WIN55-treated rats. Notably, similar accelerated and delayed emergence of negative geotaxis was observed in rats pre-treated with muscimol (a GABAA receptor agonist) and bicuculline (a GABAA receptor antagonist) respectively. Our results therefore indicate that eCB plays an age-dependent role in modulating the efficacy of GABAergic synapses in the vestibular nucleus, thereby regulating activities of neural network responsible for the expression of gravity-detection behavior.

The development changes of iLTD by eCB

	P5-7	P8-10	P11-14
Normal	70-80% iLTD	20-30% iLTD	20% iLTD
CB1 agonist	70-80% iLTD	50-60% iLTD	30 iLTD
CB1 antagonist	30-40% iLTD	20-30% iLTD	20 iLTD

Glutamine transport by System N and System A in astrocytes adjacent to the calyx of Held glutamatergic synapse

M. Marx and B. Billups

Department of Pharmacology, University of Cambridge, Cambridge, UK

Glutamine is thought to play an integral role in the recycling pathway of glutamate. The glutamate-glutamine cycle proposes that perisynaptic astrocytes release glutamine which is then taken up by the presynaptic neuron as a glutamate precursor. Using fluorescent pH_i measurement and whole-cell patch-clamp, we have investigated the transport mechanisms that may mediate this release of glutamine from astrocytes *in situ*. Brainstem slices containing the medial nucleus of the trapezoid body were obtained from P10-15 Wistar rats and perfused with aCSF containing glutamate, GABA and glycine receptor inhibitors. Astrocytes were whole-cell patch-clamped. Transporter substrates were dissolved in external solution and either applied via perfusate or by pressurised ejection from a puffer pipette. For imaging pH_i, 0.5 mM 8-hydroxypyrene-1,3,6-trisulfonic acid (HPTS) was included in the patch pipette and the fluorescence emission ratio measured following illumination at 465 and 405 nm. Values are means ± S.E.M., compared by ANOVA. System A (SA) transporter function was probed using the substrate inhibitors α-methyl-aminoisobutyric acid (MeAIB), alanine and serine, while system N (SN) function was isolated using its unique ability to transport Li^+ in place of Na^+. Histidine was used as a substrate inhibitor of both SA and SN. Puff application of glutamine (5 s) generated a membrane current (-20.0 ± 2.4 pA, n=21) which was blocked by bath applied

alanine (10 mM; 1.6 ± 2.1 pA, p<0.05, n=8) and MeAIB (20 mM; -6.2 ± 2.1 pA, p<0.05, n=6). Substitution of external Na^+ with Li^+ abolished the glutamine current (0.4 ± 1.0 pA, p<0.05, n=6). MeAIB also blocked glutamine-induced currents after membrane conductance was reduced by substituting internal K^+ with Cs^+ (from -25.6 ± 7.3 pA to -1.9 ± 1.0 pA, p<0.05, n=6). Fluorescent pH_i measurement revealed an alkalinisation during puff application of glutamine ($\Delta F/F0 = 0.27 \pm 0.02$, n=34). While bath application of histidine (20 mM) abolished the pH change (p<0.05, n=3), MeAIB only attenuated this change by 50 ± 5% (n=3; p<0.05) and serine (20 mM) blocked the pH change to a comparable extent (41 ± 8%; n=5; p<0.05). In addition, a substantial proportion of the pH change (63 ± 11%; n=7) was insensitive to the substitution of Na^+ with Li^+ (p<0.05).
Together, these data identify two distinct glutamine transport systems within astrocytes. Properties of the glutamine-induced membrane currents indicate expression of SA while pH imaging reveals a second non-electrogenic glutamine transport system with properties identifying it as SN. Furthermore, the lack of effect of serine on SN transport suggests that the SN1 not the SN2 isoform predominates. SN is known to be readily reversible under physiological conditions and we propose that this mediates the astrocytic glutamine release mechanism within the glutamate-glutamine cycle.

Infraslow brain potential oscillations are implicated in multisensory mechanisms of information processing: evidence from intracortical field potential recordings

K.S. Pugachev, I.V. Filippov and A.A. Krebs

Physiology and Biophysics, Yaroslavl State Medical Academy, Yaroslavl, n/a, Russian Federation

INTRODUCTION AND AIM: Multisensory information processing in the brain (e.g. visual in the auditory cortex and auditory in the visual cortex, etc.) is an important direction of current sensory neurophysiology. Although our previous experiments have shown the implication of infraslow brain potential oscillations (ISO) in mono-modal sensory information processing in the brain, the role of ISO (frequencies <0.5 Hz) in multisensory neuroprocessing remains unknown. The aim of this study was to identify the role of ISO dynamical shifts (if any) in multisensory processing of visual, auditory and gustatory information in the primary sensory cortical areas of the brain.
METHODS: Experimental procedures were done in accordance with European Parliament and Council Directive (2010/63/EU) on the protection of animals used for scientific purposes. Experiments were performed on urethane anesthetized (1mg/kg, i.p.) 30 male adult albino rats (n=720 repeated sessions) with stereotaxic electrodes implanted in primary visual (V1), auditory (A1) and gustatory (G1) cortical areas. ISO were rerecorded from V1 during animal exposure to the auditory and gustatory sensory stimuli; ISO from A1 were recorded under application of visual and gustatory stimuli; ISO from G1 were recorded during auditory and visual sensory stimulation. We analyzed ISO dynamics by means of mathematical (power spectral analysis) and statistical (one-way ANOVA) procedures.
RESULTS: In V1, A1 and G1 cortical areas we found various domains of infraslow brain potentials, these were: ISO in the domain of seconds (0.1-0.5 Hz), multisecond ISO (0.0167-0.05 Hz) and ISO in the range of minutes (<0,0055 Hz). Statistically significant shifts (P<0.05) of ISO (mainly in the range of seconds) were observed: in V1 during application of auditory and gustatory stimuli, in A1 during animal exposure to visual and gustatory stimuli, and in G1 under visual and auditory sensory stimulation (e.g. modality-specific and stimulus-specific patterns of ISO arose in V1 in response to the presentation of not only visual stimuli but to auditory and gustatory, in A1 in response to the presentation of not only auditory but to visual and gustatory stimulation, in G1 in response to the presentation of not only gustatory but to visual and acoustic stimuli). In some cases we also documented implication of multisecond ISO dynamical changes in multisensory information processing, but not the ISO in the domain of minutes.
CONCLUSIONS: Based on these results, we suggest that ISO in the domain of seconds and multisecond oscillations are specifically involved in multisensory processing/analysis of afferent sensory information of different modalities in primary sensory cortical areas of the brain.

Infraslow brain potentials (<0.5 Hz) in primary sensory cortical areas of the rat brain: effects of brain neurotransmission centers electrical stimulation

A.A. Krebs, I.V. Filippov and K.S. Pugachev

Physiology and Biophysics, Yaroslavl State Medical Academy, Yaroslavl, Russian Federation

OBJECTIVE: It was shown in our previous works the presence infraslow brain potential oscillations (ISO) in primary visual (V1), auditory (A1) and gustatory (G1) cortical areas, as also we demonstrated ISO implication in CNS mechanisms of sensory information processing. However, the processes of cortical ISO modulation are little known. The aim of this study was to find how the dynamics of ISO is modulated in V1, A1, and G1 by the influences of locus coeruleus (LC), dorsal raphe nucleus (DRN), and nucleus basalis magnocellularis (NBM), that send noradrenergic, serotoninergic and cholinergic projections, respectively, to neocortex.
METHODS: Experiments were guided by European Parliament and Council Directive (2010/63/EU) on the protection of animals used for scientific purposes. All experiments were performed on 30 (n=75 experiments) adult albino rats anesthetized by urethane (0.7 g/kg, i.p.) with stereotaxic electrodes implanted to V1, A1, G1; LC, DRN, and NBM. The recordings of ISO from these structures were obtained before and after successive electrical stimulation of aforementioned brain nuclei. The positions of electrodes were verified morphologically. ISO recordings were analyzed by means of power spectral analysis and statistical significances of differences were evaluated using one-way ANOVA (an alpha level of 0.05 was adopted for all significance tests).
RESULTS: It was detected that before electrostimulation of LC, DRN, and NBM, multisecond ISO were correlated between these nuclei and aforementioned cortical sites (0.44<r<0.66). We found that electrical stimulation of LC, DRN and NBM induced statistically significant alterations of ISO in V1, A1 and G1, these changes were manifested as specific power patters

of ISO in the domain of seconds (0.1-0.3 Hz) and multisecond waves (0.0167-0.043 Hz) without any alterations of dynamics of fluctuations in the range of minutes (<0.0167 Hz). Each cortical site (e.g. V1, A1, G1) responded to the activation of LC, DRN, NBM by specific power spectral pattern configuration in the range of seconds and dozens of seconds, as also each neurotransmitter center (e.g. LC, DRN, NBM) influenced on ISO neurodynamics of different cortical sites in a highly specific way.

CONCLUSIONS: Based on obtained results, it is possible to conclude that activation of noradrenergic (LC), serotoninergic (DRN) and cholinergic (NBM) systems of the brain have different but specific and powerful effects on neuromodulation of ISO dynamics in the primary sensory cortical areas. We assume that such pre-tuning of ISO in the primary cortical sensory areas by different neurotransmission systems plays an important role for further optimal sensory information processing background.

PCB119

HCN channels regulate spontaneous firing rate of olfactory receptor neurons for glomerular formation

N. Nakashima, T.M. Ishii and H. Ohmori

Physiology, Kyoto University, Kyoto, Japan

Genetic instruction is one of the principal aspects of a body plan including the neural network formation. In the olfactory receptor neurons (ORNs) as well, odorant receptor genes are a key determinant of the axonal targeting to the glomeruli in the olfactory bulb to form the network called the olfactory map. Interestingly, ORNs periodically regenerate and also utilize spontaneous firing activity for establishing and maintaining this olfactory neural map. However, (1) the generation mechanism of spontaneous activity and (2) the its role as a guidance cue in the olfactory bulb are not established. Here we addressed these two questions by investigating the nature of the spontaneous ORN firing activity in the acute slice preparations of mouse olfactory epithelium.

We detected the predominant immunoreactivities of hyperpolarization-activated cyclic nucleotide-gated (HCN) channel subtypes 2 and 4 in soma of ORNs. By applying extracellular recording, we found that HCN channels depolarized the membrane of ORNs and boosted the spontaneous firing activity by sensing the cAMP levels that was largely maintained by the basal activation of Gs-coupled beta2-adrenergic receptor; the basal activity of beta2-adrenergic receptor was inhibited by ICI 118,551 (IC50 = 4 μM). We also demonstrated by a whole-cell voltage-clamp configuration that the activation of the olfactory HCN channels (control: V1/2 = –115.7 ± 3.5 mV) was positive-shifted by 1 μM intracellular PIP2 (V1/2 = –98.2 ± 4.6 mV) and further by 1 mM 8-Br-cAMP (V1/2 = –86.0 ± 1.5 mV). The results indicate that HCN channels can be operational at the resting membrane potentials of ORNs (about –70 to –90 mV). Furthermore, we generated mice with HCN4 channel over-expressed by Tet-system, in which the spontaneous ORN firing rate was much higher than that in non-transgenic littermates. Strikingly, the histological architecture of the olfactory map was severely deteriorated; the olfactory bulb became much smaller and the size and number of the olfactory glomeruli were drastically reduced especially in the dorsal region (the maximum numbers of glomeruli was 42.5 ± 1.8 glomeruli in control mice and 23.1 ± 0.5 glomeruli in HCN4 over-expressing mice). Finally, we confirmed that the knockdown of the over-expressed HCN4 by tetracycline derivative successfully recovered these structural changes.

Thus we conclude the rate of the spontaneous electrical activity is a unique guidance cue intrinsically regulated within an optimal range to maximize the diversity and integrity of the olfactory map (Nakashima et al., 2013).

Expression of purinergic P2Y12 receptors in rat trigeminal ganglion neurons

A. Kawaguchi[1,2], Y. Shibukawa[1,3], H. Kuroda[1,2], M. Soya[1,2], M. Satou[1], M. Tazaki[3] and T. Ichinohe[2]

[1]Oral Health Science Center hrc8, Tokyo dental college, Chiba, Japan, [2]Dental Anesthesiology, Tokyo Dental College, Chiba, Japan and [3]Physiology, Tokyo dental college, Chiba, Japan

Nerve injury in trigeminal ganglion (TG) neurons occasionally induces neuropathic pain in maxillofacial region. As a part of developmental mechanisms in neuropathic pain, ATP receptors play key roles in pain signaling. These ATP receptors are exists on cell membrane and classified into ionotropic P2X (subdivided into P2X1-7) and G-protein-coupled P2Y (subdivided into P2Y1, 2, 4, 6, 11-14) receptors. Sufficient evidence shows expression of P2X3, and P2X2/3 on sensory neurons, and that of P2X4, P2X7 and P2Y12 on glial cells. Activation of Gαi following P2Y12 receptors activation inhibits adenylate cyclase in cells at brain (in particular glial cells), spinal cord and

platelets. The P2Y12 receptors interact with some molecules (e.g. P2X4 receptors, chemokine receptors, toll-like receptors, mitogenactivatedprotein kinase, Src-family kinase and cathepsin S) in activated micro or satellite glial cells and induces neuropathic pain. P2Y12 receptors are also expressed in satellite glial cells in injured TG neurons, and its activation enhances neuronal activity. Thus, expression and neuro-pathological role of P2Y12 receptors has been well described in the glial cells, however, their expression and physiological roles of P2Y12 receptor in the TG neurons remain to be clarified. In the present study, we investigated expression, localization, physiological and pharmacological properties of P2Y12 receptors by mmunofluorescence analysis, and measurement of intracellular free Ca2+ concentration ([Ca2+]i) with fura-2 fluorescence in the primary cultured rat TG neurons. We observed intense immunoreactions for P2Y12 receptors on soma, dendrites and axons in TG neurons, which co-localized with Pan-neuronal marker, neurofilament 200, isolectin B4, and substance P. In the presence or absence of extracellular Ca2+, application of P2Y1,12,13 agonist (2-MeS-ADP) increased [Ca2+]i transiently with dose-dependent manner. These increase in [Ca2+]i was not observed in the presence of sarcoplasmic reticulum Ca2+-ATPase inhibitor (cyclopiazonic acid) with or without extracellular Ca2+. Moreover, these 2-MeS-ADP-induced increase in [Ca2+]i were significantly inhibited by selective P2Y12 receptor antagonists (AR-C66096 and PSB0739) in the presence of extracellular Ca2+ . These results showed that P2Y12 receptor distribute A-, non-peptidergic C- and peptidergic C-neurons; and indicate that activation of P2Y12 receptors induced release of Ca2+ from the intracellular Ca2+ stores. Further study is needed how an activation of P2Y12 receptors in TG neurons contribute to pain signaling in oral and maxillofacial region.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Ischemic preconditioning as induction of ischemic tolerance after transient cerebral ischemia and reperfusion in rats

H.A. Awooda

physiology, Al Neelain university, Khartoum, Sudan

Ischemic preconditioning (IPC) is a brief episode of ischemia/reperfusion (I/R) that protects the brain from the damage induced by subsequent prolonged ischemia. It confers both early and delayed tolerance over a period of a few minutes to days (1). Rho-kinases (ROCK) are serine–threonine kinases that critical in cell migration and survival, activation of ROCK pathway was observed in cerebral ischemia (2). The aim of the present work was to study the neuroprotective potential of IPC. 24 adult male Wistar rats (150-250g) were divided into three groups 8 rats in each; first group was sham-operated and served as a control, I/R group of rats subjected to 30 minutes of left common carotid artery occlusion followed by 24-hour of reperfusion, anesthesia was induced by ether inhalation and maintained by thiopental sodium (2.5mg/kg) (3). IPC group were treated with three episodes of 5-minutes of ischemia with 10 minutes of reperfusion in between, followed by 30 minutes of ischemia and then allowed for reperfusion for 24-hours. Neurobehavioral assessments were evaluated (4); ROCK using enzyme-linked immunosorbent assay was measured in affected cerebral hemisphere. Values are means ± S.E.M, compared by ANOVA. The IPC group showed a significant improvement in neurological deficit (16.9±0.50) compared to both I/R and control groups (12.798±0.689, 17.50±0.707, respectively P <0.001). In I/R group ROCK was significantly increased (1.13±0.17 ng/mg protein, P <0.001) as compared to IPC group, but not to control group (p=0.198). Rats subjected to IPC demonstrated a significant decrease in ROCK level (0.39±0.19 ng/mg protein, P <0.001) to both control (1.3±0.30 ng/mg protein) and I/R group. So IPC affords protection against a subsequent I/R challenge. We established an Ischemic preconditioning model in which rats showed improvement in neurological deficits and decreased ROCK level following transient focal cerebral ischemia reperfusion in rats.

Bio-inspired peptide modulators of calcium dependent inactivation revealed the role of $Ca_V1.3$ channels in neuronal development

M. Liu[1] and X. Liu[1,2]

[1]Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, China and [2]School of Life Sciences, Tsinghua University, Beijing, China

Ca^{2+} signaling via voltage-gated Ca^{2+} channels has been suggested to play prominent roles in the development and degeneration of neurons. To elucidate the specific role of L-type $Ca_V1.3$ channels, we designed and tested a series of peptides, derived from the competitive mechanism between calmodulin (CaM) and distal carboxyl tail (DCT) of L-type Ca_V channels, with the capability to enhance or inhibit calcium dependent inactivation (CDI), a negative-feedback mechanism regulating actual Ca^{2+} flux through the channel. Under whole-cell patch-clamp, CDI of rat/human $Ca_V1.3$ was strongly attenuated for co-transfections of $Ca_V1.3$ with derivative peptides from DCT of $Ca_V1.4$. Such inhibitory peptides, termed as iCaMp (inhibitors of CaM pre-association), exerted significant inhibitions on the number and averaged length of dendrites if expressed in cultured cortical neurons, supposedly as the downstream consequence of $Ca_V1.3$ / Ca^{2+} dysregulations. Moreover, peptide $ICDI_{V41A}$, with single point mutation on iCaMp, completely lost its effects on dendritic growth of cortical neurons, in consistence with its loss of CDI effects on

recombinant $Ca_V1.3$ channels. On the other hand, peptide modulators of eCaMp (enhancers of CaM pre-association) opposite to iCaMp have also been sought after. The prototype of eCaMp significantly enhanced CDI of $Ca_V1.3$ from the intermediate level up to the extreme level, at which apparent DCT effects diminish. Taken together, our peptides provide an innovative way to perturb Ca^{2+} signaling specific to L-type $Ca_V1.3$ channels, shedding light on physiological roles of neuronal $Ca_V1.3$ channels as well as its potential relevance with neural degenerative diseases such as Alzheimer's.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Patterning neurons and informing neurite geometry on photolithographically defined parylene-C coated SiO_2

M.A. Hughes[1], A.S. Bunting[2], K. Cameron[2], A.F. Murray[2] and M.J. Shipston[1]

[1]Centre for Integrative Physiology, University of Edinburgh, Edinburgh, UK and [2]School of Engineering, University of Edinburgh, Edinburgh, UK

Interfacing neurons with silicon semiconductors is a challenge being tackled through varied bioengineering approaches. The resulting constructs inform our understanding of neuronal coding and learning, and ultimately guide us towards creating intelligent neuroprostheses and brain-machine interfaces. A fundamental pre-requisite is to dictate the spatial organization of neuronal cells on silicon. We fabricated photolithographically defined designs of parylene-C on SiO_2 wafers. These chips are activated with fetal calf serum, resulting in a culture environment that is differentially cell-adhesive (parylene) or repulsive (SiO_2). LUHMES (Lund human mesencephalic) neurons cultured in isolation find the entire chip cell-repulsive. Applying another cell type (HEK 293 cells) enables LUHMES neurons to secondarily adhere. Over 3-4 days, patterned neurons extend neurites and form networks. Seeking to gain better control of neurite behaviour, we created different geometric arrays of parylene. The basic pattern was a circular node of parylene with four 'spokes' at 0°, 90°,180°, and 270°. Three different versions were trialed (node dia. 50μm, spoke length 125μm; node dia. 100μm, spoke 100 μm; node dia. 250μm, spoke 100 μm). Nodes were arranged orthogonally with respect to one another, with a 100μm interval separating adjacent node/spoke complexes. To quantify the impact of the parylene/SiO_2 construct on neurite orientation, neurites were traced from start point (centred on a parylene node) to end point (defined either as branching point, termination, or encountering another cell body). Traced segments were divided into 100μm sub-segments. A tangent was taken to each sub-segment and the angle, θ, of each segment measured and categorized into 11.25° intervals. This process was conducted for areas encompassing each of the three different node geometries, and for differentiated LUHMES cultured randomly on a polystyrene surface treated to promote homogenous cell adhesion. Entries 180° apart were summed. 12 independent chip experiments enabled acquisition and measurement of 200 neurite sub-segments (each of 100μm length). A radial plot (figure 1) illustrates the orientation of neurite segments. Neurite directionality differed significantly according to parylene geometry (Kolmogorov-Smirnov tests: unpatterned substrate vs 250μm diameter nodes D=0.200, P=0.001; 250μm vs 100μm nodes D=0.204, P=0.001; 100μm vs 50μm nodes D=0.147, P=0.028). There is a trend towards increasingly orthogonal growth as parylene configuration changes from 250μm to 100μm to 50μm diameter nodes. For the generation of patterned neuronal networks capable of meaningful interrogation, there must be control over neurite growth direction and connectivity. We have developed a method of generating orthogonally arranged neuronal networks.

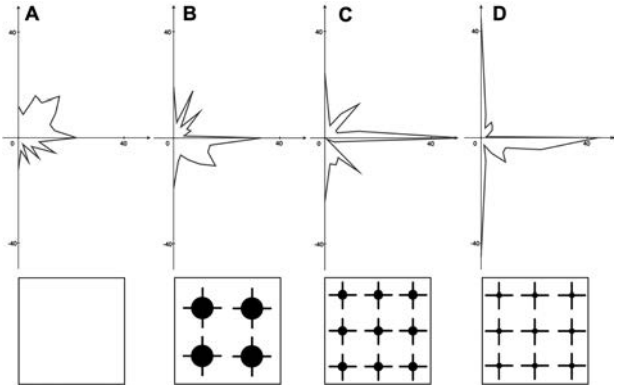

Figure 1: Directionality of neurite growth illustrated in radial plots. (A) LUHMES on plain polystyrene, (B) co-culture on 250μm diameter parylene nodes, (C) co-culture on 100μm diameter nodes, (D) co-culture on 50μm diameter nodes.

Orexin-A differentially modulates AMPA responses of ganglion cells and amacrine cells in rat retina

C. Zheng[1,2], M. Wang[2], X. Yang[1] and Y. Zhong[1]

[1]Unit of Retina Research, Institute of Neurobiology, Institutes of Brain Science and State Key Laboratory of Medical Neurobiology, Fudan University, Shanghai, China and [2]Cell Electrophysiology Laboratory, Wannan Medical College, Wuhu, Anhui, China

Two novel neuropeptides, orexin-A and orexin-B, are identified as endogenous ligands of two orphan G-protein-coupled recep-

tors: orexin 1 and orexin 2 receptors (OX1R and OX2R). Orexins are implicated in regulating a variety of physiological processes, such as wake/sleep states, feeding behaviors etc. A previous work (Liu et al, 2011) in this laboratory revealed the expression of orexin-A and orexin-B in rat retinal neurons. In the present work we investigated how orexin-A modulated current responses mediated by AMPA receptor (AMPAR) of ganglion cells (GCs) and amacrine cells (ACs) in rat retina. Animal treatments in this work coincide with the NIH guidelines for animal experimentation and the guidelines of Fudan University on the ethical use of animals. Male Sprague-Dawley rats (P15-20 d) were anaesthetized by intraperitoneal injection with 25% urethane (0.4 ml/100 g) and killed by decollation. By immunofluorescence double labeling, we first showed that OX1R was mainly expressed in GCs, whereas OX2R was present in both ACs and GCs. Using whole-cell patch clamp techniques, we further examined effects of orexin-A on AMPAR-mediated currents recorded from isolated GCs and ACs and explored mechanisms underlying these effects. Administration of orexin-A suppressed AMPAR-mediated currents in GCs, and the effect was abolished by co-application of SB334867, a selective OX1R antagonist, but not by TCSOX229, a selective OX2R blocker. In contrast, orexin-A increased AMPA responses of ACs, which could be reversed by TCSOX229, but not by SB334867. As expected, either preincubation with the Gi/o inhibitor pertussis toxin or intracellular dialysis of the Gi/o activator mastoparan eliminated both the orexin-A effects on GCs and ACs. Signaling pathways mediating the two effects were further explored. Firstly, the two effects involved activation of PKC, as evidenced by the elimination of those by PKC antagonists. Secondly, U73122, a phosphatidylinositol (PI)-phospholipase C (PLC) inhibitor, and D609, a phosphatidylcholine (PC)-PLC inhibitor, abolished the effects on AMPA currents of GCs and ACs respectively. Thirdly, the two effects were different in utilizing intracellular Ca2+. Whilst the effect on GCs may be mediated by the release of intracellular Ca2+ through the IP3-sensitive pathway, that on ACs was independent of intracellular Ca2+. Furthermore, neither cAMP-PKA nor cGMP-PKG pathway was involved in both the effects. In consequence, a distinct PI-PLC/IP3/Ca2+/PKC signaling pathway, following the activation of OX1R, is most likely responsible for the orexin-A-induced suppression of AMPA currents of rat GCs, whereas a PC-PLC/PKC signaling pathway, following the activation of OX2R, mediates the orexin-A-induced potentiation of AMPA currents of ACs.

Optogenetically-evoked Ca^{2+} release from intracellular store in the calyx-type presynaptic terminal of the embryonic chick ciliary ganglion

R. Egawa[1,3], S. Hososhima[1,3], H. Katow[1,2], T. Ishizuka[1,2] and H. Yawo[1,2]

[1]Dept Dev Biol and Neurosci, Tohoku Univ, Sendai, Japan, [2]JST, CREST,, Tokyo, Japan and [3]JSPS, Tokyo, Japan

Optogenetics has become a powerful tool in neuroscience either as sensors to survey the function at the cellular level or as actuators to regulate the neuronal activity. The calyx-type presynaptic terminal of embryonic chick ciliary ganglion (CG) is relatively large and therefore accessible to physiological recording methods such as the patch clamp. As it innervates the postsynaptic ciliary neuron in a one-to-one manner at embryonic day 14 (E14), its physiology corresponds to the morphology and electrophysiological responses of its postsynaptic cell. Further progress can be expected if the presynaptic mechanisms of these large terminals can be studied using optogenetics. Here, we carried out simultaneous optogenetic probing and manipulation of this presynaptic terminal and evaluated optogenetics for the presynaptic research. We transfected the plasmid vectors containing one of chimeric variants of channelrhodopsins, channelrhodopsin-fast receiver (ChRFR), and a red-shifted fluorescent Ca^{2+}-sensor, R-GECO1, into the midbrain preganglionic neurons at E2 using *in ovo* electroporation technique (Odani et al., 2008). At E14, the presynaptic terminals in the ciliary ganglion were used for the physiological experiments under high-speed confocal microscopy. The presynaptic Ca^{2+} elevation was triggered by a direct photostimulation of the presynaptic terminal via optical fiber. Although this optically-evoked Ca^{2+} elevation was mostly dependent on the action potential, a significant component remained even in the presence of TTX and N-type voltage-dependent channel inhibitor, ω-conotoxin GVIA, or in the absence of extracellular Ca^{2+}. The remaining component was depleted by repetitive stimulations with sarco/endoplasmic reticulum Ca^{2+}-ATPase (SERCA) inhibitor, thapsigargin. These results suggest that the photo-activation of ChRFR facilitated the Ca^{2+} release from endoplasmic reticulum Ca^{2+} stores directly or indirectly. Therefore, it is necessary to keep in mind that such background Ca^{2+} elevation could modify the biochemical milieu regulating the transmitter release.

Electrophysiological characterisation of neuronal excitability of l-LNv neurons and their role in controlling circadian rhythm

M.L. Nugent[1,2], J. Steinert[2], I. Forsythe[3] and E. Rosato[1]

[1]Genetics, University of Leicester, Leicester, UK, [2]MRC Toxicology Unit, Leicester, UK and [3]Cell Physiology and Pharmacology, University of Leicester, Leicester, UK

A conserved circadian clock provides the temporal framework for rhythmic behaviour and metabolism across the phylla, and is regulated or entrained by environmental factors such as light and temperature, known as zeitgebers (ZT). In flies, entrainment to light is mediated by the blue-light sensitive protein CRYPTOCHROME (CRY). When activated it is able to interact with core clock components to ensure the molecular clock is optimised to the light-dark cycle, as well as many other proteins involved in various physiological processes such as magnetoception, courtship behaviour and metabolism.

This project investigates the role of CRY in the regulation of neuronal excitability in a specific subset of neurons of the Drosophila CNS called the large ventral lateral neurons (l-LNvs). Overexpression of a constitutively active form of CRY (CRYΔ) is used to study the role of CRY within the circuitry involved in circadian clock regulation.

Whole cell patch clamp recordings of l-LNvs in whole brain preparations of adult Drosophila were performed (Multiclamp 700B, pClamp 10, Axon Instruments). Female flies w1118 /UAS cryΔ72.3; tim-GAL4/ UAS GFP co-expressed CRYΔ and GFP in clock cells, including the l-LNvs. w1118 /+; tim-GAL4/ UAS GFP females were used as controls. Recordings were conducted during ZT10-12 to eliminate any changes in the activity seen in the l-LNvs due to a circadian effect. Larval foraging activities were measured as crawling distance in 10min (ANYmaze) using female larvae that were w1118; elav_GAL4/+; UAS-cryΔ4.1/+ and compared to w1118; elav_GAL4/+; +/+ for control. Data are expressed as mean ±SEM (n). Statistical analyses were carried out using standard unpaired t-test, * indicates $p<0.05$.

Electrophysiological recordings revealed that overexpression of CRYΔ in l-LNvs induces increased outward currents at 0mV from 167 ±8pA (3) to 234 ±20pA* (3) and at -10mV from 79 ±4pA (3) to 124 ±17pA* (3). Investigations of the spontaneous action potential (AP) firing frequencies were also conducted but have thus far not shown a significant difference, although there is a trend of increased AP firing rates in response to current injection.

Larval foraging assays to investigate the motor effects of CRYΔ overexpression at the larval neuromuscular junction (NMJ) have shown an increase in the distance travelled by CRYΔ expressing larvae from 0.5 m (14) to 0.67 ±0.04 m* (17).

This data indicates that CRYΔ expression is able to mediate changes in activity at the NMJ as well as in CNS clock cells. Further CNS recordings are needed to allow firm conclusions from the electrophysiological data collected so far.

Short term synaptic plasticity defines neuronal groups firing together in cultures of cortical cells

V.G. Lopez-Huerta[1], L. Carrillo-Reid[2], M. Garcia-Munoz[1] and G.W. Arbuthnott[1]

[1]Brain mechanisms for behavior unit, Okinawa Institute of Science and Technology, Onna-son, Okinawa, Japan and [2]Physiology, Feinberg School of Medicine, Northwestern University, Chicago, IL, USA

Synchronized and sequential activity patterns in neural networks have been proposed as a mechanism underlying many complex behaviors, such as procedural memories and decision-making. Hebb (1949) suggested that neuronal assemblies were formed by the strengthening of synaptic connections between cells that often fire together. However, the role of short-term synaptic dynamics in network activity patterns and sequence formation has not been widely studied in living neural networks. We used optical and electrophysiological recordings to describe synaptic properties that accompany co-operative firing and sequential activity patterns of groups of neurons in cultures of mouse cortical cells (>15DIV). Spontaneous activity and connectivity was studied in whole cell patch clamp recordings from a total of 42 neuronal pairs. Oscillatory firing activity was recorded in 26 cells and connectivity rate was 52% (22/42 pairs). Some of the pairs had nearly synchronous up states (starting within <10ms) whereas others were more out of phase. When short term plasticity was tested in these pairs, cells firing together mainly displayed short-term synaptic depression (n=5, i.e., high release probability), whereas cells firing in sequence, mostly displayed short-term synaptic facilitation (n=6, i.e., low release probability). To further investigate the impact of short-term synaptic dynamics in cell assembly behavior we performed calcium imaging with single cell resolution in groups of several hundred cells. The release probability was modified by changing the extracellular calcium concentration. At low extracellular calcium concentrations (1mM) synaptic connections were mainly facilitating (n= 5/7 pairs) and the transitions of activity among groups of neurons were increased showed by calcium imaging (n=6 dishes). On the contrary, at a higher extracellular calcium concentration (4mM) we observed short-term depression in all the connections (n=7 pairs) and a reduced variability of cell assemblies (n=6 dishes). These results suggest a direct relationship between neuronal groups firing together and short-term synaptic plasticity in living neural networks, and suggest that a given microcircuit might be reprogrammed by the targeted modification of the excitatory synaptic dynamics due to the presence of neuromodulators.

Mechanism of nitric oxide dependent LTP revealed by kinetic analysis of AMPAR trafficking in rat cerebellar Purkinje cell

K. Yamaguchi

BSI, RIKEN, Wako, Saitama, Japan

Nitric oxide (NO), produced by repetitive activation of the cerebellar parallel fiber (PF), induces long-term potentiation (LTP) of synaptic transmission between PF- Purkinje cell (PC) synapse. Underlying mechanism of this LTP is known to be increase in density of surface expressed AMPA type glutamate receptors (AMPA-Rs), mediated by receptor exocytosis (1). NO directly S-nitrosylates N-Ethylmaleimide Sensitive Factor (NSF) and this S-nytrosylated NSF increase its affinity to GluA2 carboxy-terminus (CT) region, and interaction of NSF – GluA2-CT enhances insertion of AMPA-Rs into the synaptic membrane (2). However, whether actually NO enhanced AMPA-Rs exocytosis or suppress endocytic elimination from the synaptic membrane remained elusive. Here, we quantitatively analyzed interaction between constitutive endocytosis and NO-induced LTP with an aid of data-driven kinetic model of AMPA-R trafficking.
Slice of cerebellar cortex was prepared from rat (P19-23) cerebellum ectomized after decapitation during deep anesthesia with ethyl ether. EPSC evoked by electrical stimulation of the molecular layer was recorded from PC by means of a whole-cell recording method. In basal condition, NO-donor (NOR3 30microM) itself enhanced PF-PC EPSC amplitude to 170% of the basal amplitude (LTP) in rat cerebellar slice. When constitutive endocytosis was blocked by dynamin inhibitor, similar amount of increase in EPSC-amplitude through a constitutive exocytosis of AMPA-R was observed. Because LTP occluded with the constitutive exocytosis of AMPA-Rs, both pathways had to share common mechanism. When EPSC amplitude was reduced to the minimum steady state level by tetanus toxin (TeTx) infusion through a whole-cell patch-pipette (3), NOR3 had no effect on EPSC amplitude. However, when NOR3 was applied early phase of TeTx-action, NO intermitted constitutive endocytic reduction of EPSC amplitude with a slight rebound. By using our kinetic model of AMPA-R trafficking, I successfully reconstituted this time course including a slight rebound of EPSC amplitude by assuming that AMPA-R endocytosis was blocked, but not that exocytosis was enhanced, by NO. Because NSF and AP-2, an adaptor protein required for clathrin dependent endocytosis, compete binding to the overlapping NSF/AP-2 domain at GluA2-CT, S-nitrosylated NSF would competitively inhibit binding of AP-2 to this domain, and consequently suppress endocytosis of GluA2. We conclude that NO induces LTP by blocking GluA2 endocytosis at PF-PC synapse.

Expression and function of Kir7.1 in neurons and glia of the mouse CNS

M. Papanikolaou, J. Hallett, A. Lewis and A.M. Butt

Pharmacy and Biomedical Science, University of Portsmouth, Portsmouth, Hants, UK

The inward rectifying potassium channel subtype Kir7.1 has been studied in a variety of potassium transporting epithelia in the retina, thyroid, intestine and kidney. The expression and function of Kir7.1 in the CNS is unresolved, although expression of these channels has been reported in cerebellar Purkinje neurons, hippocampal pyramidal neurons and neural stem cells. Here, we have assessed the expression and function of Kir7.1 in neurons and glia of the mouse CNS. Mice were euthanized humanely in accordance with the UK Animals Act (1986) and tissue was used for RT-PCR, Western blot, immunohistochemistry, tissue culture or isolated intact optic nerves for oxygen and glucose deprivation (OGD). Expression of Kir7.1 in adult brain and optic nerve was demonstrated by rtPCR and western blot. Immunolabelling with the Alomone aKir7.1 antibody confirmed previous reports of Kir7.1 expression in cerebellar Purkinje and hippocampal pyramidal neurons, and demonstrated immunolabelling in astrocytes and oligodendrocytes, the myelinating cells of the CNS. Glial and neuronal expression of Kir7.1 was confirmed in cultures of cells from the neonatal cortex and optic nerve. Like neurons, glial cells are susceptible to hypoxic/ischaemic injury, such as those that occur during stroke. A key factor in hypoxic/ischaemic episodes is that they cause depolarization of the resting membrane potential, resulting in cell dysfunction and death. Kir7.1 are highly sensitive to pH and are suppressed by extracellular acidification, such as occurs in ischemia. We therefore examined whether Kir7.1 may play a role in the susceptibility of glia to ischemia, in isolated intact optic nerves from mice aged postnatal day (P)10 mice subjected to oxygen and glucose deprivation (OGD). Incubation of optic nerves with the Kir7.1 channel blocker VU590 significantly increased cell death of optic nerve glia, measured using propidium iodide (PI) labelling (measured in a constant field of view (FOV), 6 FOV per nerve, n=4 nerves per group; 80 + 30 PI+ cells in controls and 189 + 49 PI+ cells in VU590; $p<0.001$, Anova). Our results demonstrate widespread expression of Kir7.1 in CNS neurons and glia, and indicate a functional importance in protecting glial cells from ischemic damage. Further studies are required to determine the biophysical properties of Kir7.1 and their pathophysiological function in neurons and glia.

Decreased excitability of neurons in the ventral nucleus of the trapezoid body may contribute to medial olivocochlear system dysfunction in the C57BL/6

J. Sinclair[1], M. Barnes-Davies[2] and I.D. Forsythe[1]

[1]Cell Physiology & Pharmacology, The University of Leicester, Leicester, Leicestershire, UK and [2]Medical Education, The University of Leicester, Leicester, UK

Hearing loss is the most prevalent sensory disorder effecting humanity and dysfunction in the medial olivocochlear (MOC) system is thought to be involved. The MOC regulates and protects auditory sensitivity by modifying the activity of the outer hair cells in the cochlea. The majority of MOC neurons in mice are present in the ventral nucleus of the trapezoid body (VNTB) in the brainstem. The C57BL/6 (C57) inbred strain of mouse has early-onset hearing loss, preceded by a failure in the efficacy of its MOC system (Zhu et al., 2007). We examined the neurons of the VNTB in the C57 and compared them with those of a strain which retains auditory sensitivity into old age: the CBA/Ca (CBA). We aimed to determine if differences in excitability in VNTB neurons exist between the strains which could influence MOC function. Mice were decapitated in accordance with the UK Animals (Scientific Procedures) Act 1986 and brainstem slices prepared (Barnes-Davies & Forsythe, 1995). Whole cell recordings were taken from visually identified VNTB cells in pre-hearing onset (P8) and post hearing onset (P16) CBA and C57 mice (Fujino et al., 1997). Prehearing onset, CBA and C57 VNTB cells have similar in current-voltage relationships and action potential (AP) thresholds. Under voltage clamp, cells of both strains display outward currents around -30mV which inactivate rapidly. During a 200ms pulse to -30mV, currents in both strains drop from around 2nA (CBA: 1.77±0.35nA (n=10), C57: 2.36±0.36nA (n=12) to 0.6nA (CBA: 0.75±0.09nA, C57: 0.52±0.08nA). Current clamp recordings indicate that AP thresholds are around -38mV for both strains (CBA:-38.4±2.5mV (n=7), C57:-38.2±1.7mV (n=7). Both strains produce few APs during 200ms current injection of +50pA (CBA: 0.6±0.4, C57: 1.0±1.2). Post-hearing onset, the CBA VNTB neurons develop greater sustained currents at hyperpolarised potentials than in the C57. During a 200ms pulse to -30mV, currents of CBA VNTB cells demonstrate little inactivation (1.73±0.36nA to1.57±0.45nA over 200ms (n=8)). C57 VNTB neurons retain inactivation of low voltage activated currents similar to those present in P8 mice (1.91±0.31nA dropping to 0.49±0.61nA after 200ms(n=7)). Post-hearing onset CBA VNTB neurons also demonstrate greater excitability under current clamp conditions, generating more APs than age matched C57 (CBA: 6.2±1.4 (n=6), C57: 1.5±0.75 (n=4), (P =0.02)) despite having similar thresholds (CBA: -43.6±2.2, C57: 39.5±3.1). These experiments indicate lower excitability of neurons of the VNTB in the C57: a strain of mouse with MOC functional deficits. Decreased activity of MOC neurons in the VNTB would impede efferent control of the sensitivity of the ear and could contribute to the C57 strain's vulnerability to hearing loss. Data ± SEM. Means compared using unpaired t-tests. P : post natal day.

Regulation of excitatory synaptic function by estrogen: implications for health and disease

A. Ibrahim and J. Harvey

University of Dundee, Dundee, UK

It is well established that activity dependent changes in the efficacy of hippocampal synaptic transmission is a cellular correlate of learning and memory. Trafficking of AMPA-receptors to and from synapses is an important mechanism underlying hippocampal synaptic plasticity. Increasing evidence implicates hormonal systems in the influence of AMPA-receptor trafficking, and thus synaptic plasticity. Estrogen, primarily known for its reproductive effects, has long been implicated in influencing cognitive processes. Estrogen receptors (ERs), classically found in the nucleus, act as ligand-activated transcription factors in mediating genomic responses. ERs can also mediate rapid non-genomic responses via membrane-associated ERs. Two well characterised ERs, ERα and ERβ, are widely expressed in the hippocampus. However, little is known about how these ER subtypes influence cognitive processes. Moreover, the novel G-protein-coupled receptor, GPR30, has been identified as an estrogen target, and recent studies suggest possible cross-talk between ERα and GPR30.[1] In pilot studies, we have found that the broad-spectrum agonist, 17β-estradiol, induces bidirectional changes in AMPA-receptor trafficking. In addition, recent studies have implicated ERβ-activation in improving performance in hippocampal-dependent memory tasks and increasing key synaptic proteins such as the AMPA-receptor subunit GluR1. In this study, we have examined how estrogen influences AMPA-receptor trafficking by utilising ERα-, ERβ-, and GPR30-selective agonists in an immunocytochemical approach. We show that activation of ERα and GPR30 results in a decrease in GluR1 surface expression likely to be mediated by an exocytosis-dependent mechanism, and that activation of ERβ results in an increase in GluR1 surface expression likely to be mediated by an endocytosis-dependent mechanism. In addition, we demonstrate that the effects of GPR30-activation on GluR1 surface expression are unlikely to be due to ERα-activation. These findings have important implications for the role of estrogen in cognitive decline and neurodegenerative disorders.

Cocaine preferentially potentiates fast releasable vesicle pool in mouse dopaminergic striatum in vivo

P. Zuo[1], L. Zhou[1], X. Kang[1], H. Xu[1], B. Zhang[1], H. Dou[1], F. Zhu[1], L. Liu[1], S. Guo[1], C. Wang[1], Q. Li[1], S. Wang[1], W. Yao[1], H. Gu[2] and Z. Zhou[1]

[1]Peking University, Beijing, China and [2]Ohio State University, Columbus, DC, USA

Cocaine, an addictive drug, increases extracellular dopamine (DA) concentration in basal ganglion. This effect has been commonly assumed mainly through the inhibition of the uptake activity of DA transporters (DAT). Whether cocaine may also potentiate DA release under physiological conditions remains unclear. To investigated cocaine's effect on DA release in striatum in vivo, C57 and DAT-CI mice (male, 25 g) anaesthetized with urethane (0.15 g/100 g, i.p.) were used. The use and care of animals was approved and directed by the Institutional Animal Care and Use Committee of Peking University. We found that two kinetically distinct DA releasable vesicle pools, a fast releasable pool (FRP) and a prolonged releasable pool (PRP), existed following physiological field stimulations at medial forebrain bundle (MFB) in mouse striatum in vivo. Surprisingly, cocaine selectively enhanced the DA release and replenishment from the FRP. Using a cocaine-insensitive-DAT (DAT-CI) mouse model, we found that cocaine-facilitated FRP release is mediated by DAT. In contrast, PRP release is selectively sensitive to D2 receptor (D2R). Finally, FRP and PRP have distinct impacts on locomotor behaviours. Our findings indicate that in addition to blocking DA reuptake, cocaine increases DA release by selectively activating DAT, increasing FRP size, and accelerating FRP replenishment in mouse striatum in vivo.

Investigating neuronal morphology and physiology in the rat lateral reticular nucleus

R. Jordan, S.A. Edgley and S. Jones

Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK

The lateral reticular nucleus (LRN) in the medullary reticular formation is a major source of mossy fibre afferents to the cerebellum. We have previously shown that many LRN neurones fire extremely regularly and respond to peripheral sensory stimulation with an initial brief pause in firing followed by a resumption of spiking with 'reset' timing (Xu et al., 2012). Here we have investigated the morphology and physiology of rat LRN neurones. Whole-cell patch-clamp recordings were made from 18 LRN neurones in brain slices prepared from rats aged postnatal day (P) 5 to P15 (decapitated under isoflurane anaesthesia), using a K+-based intracellular solution with biocytin. Neuronal morphology was deduced from 9 of these LRN neurones in which biocytin labelling was recovered. Of these, 8 had a morphology consistent with 'triangular' cells (Kapogianis et al., 1982). These triangular neurones showed spontaneous firing (mean frequency, 3.1 ± 0.5 Hz; CV of inter-spike intervals, 0.17 ± 0.04) and a hyperpolarisation-activated Isag (mean amplitude, 63.7 ± 55.6 pA). In 6 of the 8 triangular cells, glycine was applied via a picospritzer (1 mM, 0.1-1 s, 10 p.s.i) and evoked currents that reversed at -38.5 ± 17.5 mV. These triangular neurones in the LRN may be the source of spontaneously firing mossy fibre inputs to the cerebellum.

Investigating synaptic regulation of neurones in the rat lateral reticular nucleus

J.R. Heckenast, S.A. Edgley and S. Jones

Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK

The lateral reticular nucleus (LRN) in the medullary reticular formation is a major source of mossy fibre afferents to the cerebellum. We have previously shown that many LRN neurones fire extremely regularly and respond to peripheral sensory stimulation with an initial brief pause in firing followed by a resumption of spiking with 'reset' timing (Xu et al., 2012). Here we have investigated synaptic inputs to rat LRN neurones that might elicit the pause-reset in firing. Whole-cell patch-clamp recordings were made from brain slices containing the LRN, prepared from rats aged postnatal day (P) 5 to P15 (decapitated under isoflurane anaesthesia), using a CsCl-based intracellular solution (E_{Cl} = 0 mV). Synaptic currents were evoked by local electrical stimulation. The glutamate receptor antagonist, kynurenic acid (1 mM) caused 25 ± 11 % inhibition of synaptic currents recorded at -60 mV (n = 4), while the glycine receptor antagonist, strychnine (3 μM) caused 55.6 ± 7.6% inhibition of the kynurenic acid-insensitive synaptic current (n = 6). A combination of strychnine and the $GABA_A$ receptor antagonist, picrotoxin (50 μM) caused 75.8 ± 8.4% inhibition (n = 4). In recordings from anaesthetised rats, iontophoretic application of strychnine reduced, and in some cases abolished, the pause in LRN neuronal firing evoked by peripheral sensory stimulation. These data suggest that glycinergic inhibition contributes to the pause-reset response in LRN neurones.

PCB139

Reproduction of transducin timecourse of rod and cone cells under various light intensities

Y. Hosoki[1], C. Koike[2], Y. Takeda[1] and A. Amano[1]

[1]Life Sciences, Ritsumeikan University, Kusatsu, Shiga, Japan and [2]Pharmaceutical Sciences, Ritsumeikan University, Kusatsu, Shiga, Japan

The rod and cone cells have a common phototransduction mechanism. First, the visual pigments are stimulated by absorbing light and activate a G-protein called transducin. This transducin subsequently activates phosphodiesterase, which in turn decreases the cGMP concentration. Subsequently, the cGMP sensitive current reduces, leading to depolarization. In this process, the activated visual pigments are phosphorylated several times by rhodopsin kinases. Although the phototransduction mechanisms are common with rod and cone cells, the response speed and the light sensitivity are considerably different. The phosphorylation rate of the activated visual pigments by the rhodopsin kinases and the transducin activation rate by the stimulated visual pigments are reported in detail for both rod and cone cells by Tachibanaki, Kawamura et al. [1]. In their report, the relation between the phosphorylation rate per activated visual pigment and light intensity shows strong negative exponential characteristics. Also, the relation between the activated transducin per activated visual pigments and the light intensity are not monotonous. A strong light activates less transducin compared to a moderate light. For the quantitative understanding and analysis of the phototransduction mechanism, a detailed model is proposed by Hamer et al. [2]. This includes the transducin activation process by activated visual pigments and the phosphorylation process of the visual pigments by rhodopsin kinase. However, the transducin time course reported by Tachibanaki et al. could not be reproduced by the model. Thus, we propose a modified phototransduction model. In our model, we made two modifications to the Hamer model: First, the calculation of the free rhodopsin kinase was refined. Second, the transducin activation by the activated visual pigment was modified such that it is dependent on the ratio of the activated visual pigments to the total visual pigments. With these modifications, the transducin production and the phosphorylation of the visual pigments under various light intensities were successfully reproduced.

The analysis of the simulation results showed that the amount of the free rhodopsin kinase decreases with the increase in light intensity since the complex of the visual pigment and the rhodopsin kinase increase. This mechanism leads to the nonlinear relation between the phosphorylation rate of the activated visual pigments and light intensity. However, this modification could not reproduce the non-monotonous relation between the transducin activation and light intensity. Although the mechanism is not clear, by introducing the the nonlinear relation between the transducin activation and the visual pigment activation ratio, we could successfully reproduce the non-monotonous relation of the transducin activation.

Methylphenidate enhances NMDA-receptor response in the rat medial prefrontal cortex via sigma-1 receptor: a novel mechanism for methylphenidate action

C. Zhang[1], Z. Feng[1], Y. Liu[1], X. Ji[1], J. Peng[1], X. Zhang[1], X. Zhen[3] and B. Li[1,2]

[1]Institute of Neurobiology and State Key laboratory of Medical Neurobiology, Institutes of Brain Science, Fudan University, Shanghai, China, [2]Center for Neuropsychiatric Disorders, Institute of Life Science, Nanchang University, Nanchang, China and [3]Neuropharmacological Laboratory, State Key Laboratory of Drug Research, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China

Methylphenidate (MPH), commercially called Ritalin or Concerta, has been widely used as a drug for Attention Deficit Hyperactivity Disorder (ADHD). Noteworthily, growing numbers of young people using prescribed MPH improperly for pleasurable enhancement, take high risk of addiction. Thus, understanding the mechanism underlying high level of MPH action in the brain becomes an important goal nowadays. As a blocker of catecholamine transporters, its therapeutic effect is explained as being due to proper modulation of D1 and α2A receptor. Here we show that higher dose of MPH facilitates NMDA-receptor mediated synaptic transmission via a catecholamine-independent mechanism, in layer V-VI pyramidal cells of the rat medial prefrontal cortex, using in vitro whole-cell patch-clamp recording technique. To indicate its postsynaptic action, we next found that MPH facilitates NMDA-induced current and such facilitation could be blocked by sigma-1 but not D1/5 and α2 receptor antagonists. And this MPH enhancement of NMDA-receptor activity involves PLC, PKC and IP3 mediated intracellular Ca2+ increase, but does not require PKA and extracellular Ca2+ influx. Our additional pharmacological studies including western blot analysis and receptor binding assays, confirmed that higher dose of MPH increases locomotor activity via interacting with sigma-1 receptor. Together, the present study demonstrates for the first time that MPH facilitates NMDA-receptor mediated synaptic transmission via sigma-1 receptor, and such facilitation requires PLC/IP3/PKC signaling pathway. This novel mechanism possibly explains MPH-induced addictive potential and other psychiatric side effects.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB142

Natriuretic peptides decrease calcium transients and neurotransmission in cardiac sympathetic nerves

D. Li, H. Wright, E. Vergari, C. Lu, N. Herring and D.J. Paterson

University of Oxford, Oxford, UK

Natriuretic peptides (NPs) are a family of peptide hormones known to be potent regulators of the cardiovascular system. They play a pivotal role in the regulation of intravascular volume by modulating blood vessel tone and renal function. How-

ever, their effects on sympathetic neurons remain poorly understood considering that NP receptors are present on neurons. We aimed to elucidate the effects of brain natriuretic peptide (BNP) on calcium transients in sympathetic neurons, and on neurotransmission in isolated atria tissue. Four week old SD rats were humanely killed by an approved Home Office schedule 1 method, and the stellate ganglia enzymatically isolated. Immunofluorescent staining and RT-PCR were used to determine NP receptor expression. Intracellular free Ca2+ concentration ([Ca2+]i) was measured by ratiometric fluorescence imaging using fura-2/AM in neurons. The evoked [Ca2+]i transient was evaluated following 30 sec exposure to 50 mM KCl in the Tyrode solution. Fura-2/AM was excited alternately at 350 nm and 380 nm and the emitted fluorescence measured at 510 nm. Natriuretic peptide receptor (NPR) type A and B were expressed in sympathetic neurons. BNP significantly reduced the depolarization evoked [Ca2+]i transient (100 nM BNP: -21.15 ± 4.90 %, n=18, P<0.01; 250 nM BNP: -23.89 ± 6.42 %, n=12, P<0.05). The action of BNP was significantly reduced by the PKG inhibitor (5 μM RP-8-Br-PET-cGMP, n=11, P<0.05) and NPR-A inhibitor (10 μM Isatin, n=15, P<0.01). BNP (250 nM) decreased [3H]-noradrenaline release from isolated spontaneously beating atrial in response to 5Hz field stimulation (n=6), and also significantly reduced the heart rate (HR) responses to sympathetic nerve stimulation (1-7Hz) in- vitro compared to control (n=10). We conclude that BNP reduces cardiac sympathetic neurotransmission by decreasing [Ca2+]i and subsequent noradrenaline release via a pGC-cGMP-PKG coupled pathway downstream from the NPR.

Ionotropic purine receptors P2X in frog and turtle retina: an immunocytochemical study

L. Vitanova and P.N. Kupenova

Physiology, Medical University, Sofia, Bulgaria

Purinergic signaling is represented in both peripheral and central nervous system (CNS), and in retina in particular which may be regarded as a part of CNS. Two types of purinergic P2 receptors, which mediate effects of cyclic nucleotides, exist: ionotropic (P2X) and metabotropic (P2Y) ones. While relatively well studied in mammalian retinae, little is known about these receptors in lower vertebrate retinae. That's why the aim of present study was to investigate the distribution of the ionotropic P2X receptors in frog and turtle retinae which possess mixed and predominantly cone type of retina respectively. All procedures with a frog and a turtle were in accordance with the Bulgarian law for scientific experiments. The animals were deeply anesthetized with halothane and decapitated. The eyes were dissected, and the posterior eyecups with retinae were immediately immersed in 4% (w/v) paraformaldehyde in 0.1 M phosphate buffer for 15–30 min. After fixation, the retinae were dissected from the eyecups and cryoprotected in graded sucrose solutions (10%, 20%, and 30% w/v). Cryostat sections were cut at 14 μm and stored at –20 °C. More than 10 primary antibodies directed to all seven P2X1-7 receptors, in addition to an anti-Vimentin antibody, a marker of Müller glial cells, were applied. The indirect immunocytochemical method was used.

The results showed wide-spread expression of all seven purinoreceptors P2X1-7 in both frog and turtle retinae. They were predominantly expressed in Müller cells, the principal glial cells in the retina. All structures typical of Müller cells: the outer and the inner limiting membranes, the cells bodies in the inner nuclear layer, the radial processes in the inner plexiform layer (IPL), and the so called endfeet (frog) or the orthogonal arrays of particles (turtle) in the ganglion cells layer were stained. The colocalizations between P2X1-7 and Vimentin proved that the immunostaining was in the Müller cells. In addition to the glial staining, a neuronal staining was also evident expressed by fine puncta in the inner and outer plexiform layers. Some cell bodies of horizontal and ganglion cells were stained as well.

In order to elucidate how the different purinergic subunits combine to form the ion channels, double labeling studies with different couples of P2X antibodies were performed (when it was possible). The results obtained allow us to suggest that the purinergic P2X receptors contribute significantly to neuron-glia signaling in both mixed-type and cone-type retinae of the lower vertebrates.

Neuroprotective effects and the underlying mechanisms of Paeoniflorin

L. Feng

Dept. of Neuropharmacology, Shanghai Institute of Materia Medica, CAS, Shanghai, China

Paeoniflorin (PF) is a compound isolated from Paeoniae Radix. PF ameliorated brain ischemia on middle cerebral artery occlusion (MCAO) model in rats which was probably mediated by activating adenosine A1 receptor (A1R) to exert its neuroprotective effect. The aim of this study was to investigate the molecular mechanism underlying the neuroprotective effect of PF pretreatment on primary cultured cortical neurons exposed to oxygen-glucose deprivation and reoxygenation (OGD/R). Primary cultured cortical neurons of rats were subjected to OGD/R injury and treated with PF and the survivability of neurons was determined by MTT assay. Phosphorylation of the proteins in the signaling pathways involved in the PF effects was evaluated by Western Blot or immunoprecipitation (IP). Receptor interactions were identified by co-IP and immunofluorescence staining. PF, with concentrations ranging from 10nM to 1μM, was applied to promote the survival of cortical neurons suffered from OGD/R injury. PF phosphorylated Akt and ERK1/2 that contributed to improve the neu-

rons viability. On HEK293 cells stably transfected with A1R (HEK293/A1R), PF induced Akt and ERK1/2 phosphorylation mediated by A1R transactivation of EGFR. Furthermore, both Matrix Metalloprotease (MMP) and Src kinase were involved in signaling pathways regulated by PF. Our results showed that PF promoted neurons survival and relied on Akt and ERK1/2 phosphorylation which was mediated by A1R transactivation of EGFR.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB145

Imaging the motility of inositol trisphosphate receptors in intact mammalian cells using single particle tracking photoactivated localization microscopy (sptPALM)

I. Smith[1], D. Swaminathan[1] and I. Parker[1,2]

[1]Neurobiology and Behavior, University of California, Irvine, Irvine, CA, USA and [2]Physiology and Biophysics, University of California, Irvine, Irvine, CA, USA

Inositol trisphosphate receptors (IP_3Rs) are Ca^{2+}-permeable channels in the membrane of the endoplasmic reticulum (ER) that liberate Ca^{2+} sequestered in ER stores to generate cytosolic Ca^{2+} signals that control diverse cellular functions including gene expression, secretion and synaptic plasticity (Berridge et al., 2000). The spatial distribution of these channels is crucial in determining the patterning of intracellular Ca^{2+} signals. The mechanisms underlying the aggregation and maintenance of IP_3Rs in clusters are controversial. Local Ca^{2+} signals arise at just a few, fixed locations within a cell, suggesting clusters are stable entities; and Ca^{2+} blips generated by 'lone' IP_3Rs are also immotile (Smith et al., 2009). In contrast, GFP-tagged or immunostained IP_3Rs show a dense distribution throughout a cell. Moreover, the majority IP_3Rs can diffuse freely within the ER membrane, and aggregate into clusters following sustained (minutes) activation of IP_3 signaling and/or cytosolic Ca^{2+} elevation, or even undergo clustering in response to IP_3 within just a few seconds (Taufiq Ur et al., 2009).
These apparently different behaviors may be explained because Ca^{2+} imaging studies detect only functional IP_3Rs, whereas imaging studies utilizing immunostaining or GFP-tagged IP_3Rs report on the entire population of IP_3R proteins. We therefore hypothesize that a majority of IP_3Rs are motile, but functionally unresponsive. Local Ca^{2+} signals arise, instead, from a small subset of IP_3Rs that are anchored, individually or in clusters, by association with static cytoskeletal structures and possibly as a consequence of this anchoring, display high sensitivity to IP_3 to Ca^{2+} signals.
To test this hypothesis we have created a fusion protein of the IP_3R tagged with the photoactivatable genetically encoded protein mEos2 to track the motility of thousands of single IP_3Rs with nanoscale spatial and millisecond temporal resolution following transfection in cells (single-particle tracking photoactivated localization microscopy: sptPALM (Manley et al., 2008)). By tracking the movement of single IP_3Rs using sptPALM we show that two populations of molecules exist with differing motilities. A larger (70%) of fast moving molecules ($0.093 \pm 0.009\ \mu m^2\ s^{-1}$) and a smaller (30%) population of IP_3Rs that are essentially immotile ($0.0074 \pm 0.0006\ \mu m^2\ s^{-1}$, $n > 25{,}000$ tracks, 5 cells). Further, we find that these apparently immotile IP_3Rs are preferentially grouped within tight clusters and may correspond to the static Ca^{2+} release sites responsible for generating local Ca^{2+} signals.

Opiorphin inhibits calcium signaling response in capsaicin sensitive rat sensory neurons

M. Ozcan[1], A. Ayar[2], E. Kacar[3] and H. Kelestimur[3]

[1]Biophysics, Firat University Faculty of Medicine, Elazig, Turkey, [2]Physiology, Karadeniz Technic University Faculty of Medicine, Trabzon, Turkey and [3]Physiology, Firat University Faculty of Medicine, Elazig, Turkey

Opiorphin is an endogenous human peptide mediator constituent of human saliva. Initial research with mice shows opiorphin has highly effective analgesic activity than morphine. Effect of opiorphin on capsaicin sensitive sensory neurons was investigated by using in-vitro calcium imaging technique in this study.
Dorsal root ganglions (DRGs) were removed from 1-2 day old (any gender) Wistar neonatal rats after decapitation and DRG neurons were grown in primary culture following enzymatic and mechanical dissociation and cultured in a tissue culture containing nerve growth factor for a short time. Neurons were loaded with 1μmol Fura-2 AM. After loading, the cells were washed 3-4 times for 20min with standard recording medium to remove the extracellular fura-2 AM. [Ca2+]i responses were quantified by the changes in 340/380 ratio by using fluorescence imaging system. Based on the size of cell trunk, DRG neurons were divided into three categories: small, medium and large. Responses to capsaicin (1μM) (small and medium size) was studied by monitoring changes in [Ca2+]i with a microscobic digital image analysis system in fura-2 loaded single neurons. We tested the effects of different concentration of opiorphin treatment after recording of basal [Ca2+]i.
The application of 10μM,100μM and 1000μM opiorphin had significant decrease on capsaicin evoked [Ca2+]i to 99.4±2.0% (n = 48), 51.2±5.8% (n=38, P<0.001) and 2.5±1.2% (n=24, respectively, P<0.0001) in small size neurons. Same doses of opiorphin had significant decrease on capsaicin evoked [Ca2+]i to 99.1±2.3% (n=36), 53.4±5.8% (n=15, P<0.001) and 7.6±1.9% (n=15, respectively, P<0.0001) in medium size cells.
Data from this study revealed that opiorphin inhibits intracellular calcium signaling in cultured rat DRG neurons in a dose dependent manner. Further studies are needed to find out the efficency of opiorphin on pain modulation.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB148

TRPA1 and TRPV4 activation in human odontoblast-like cells stimulates ATP release

O. Egbuniwe[3], S. Grover[1], M. Yazdi[2], T. Renton[2], L. Di Silvio[3] and A. Grant[1]

[1]Wolfson Centre for Age-Related Diseases, King's College London, London, UK, [2]Dept of Oral Surgery, Dental Institute, King's College London, London, UK and [3]Biomaterials, Biomimetics and Biophotonics, Dental Institute, King's College London, London, UK

Brännstrom's hydrodynamic theory postulated that dental pain results from the activation of dental sensory neurons in response to dentinal fluid movement under thermal expansion and contraction. It is not clear whether this is a direct mechanotransduction by neurons or whether other dental structures contribute to the mechanosensation. Immunohistochemical and functional studies suggest the expression of thermosensitive and mechanosensitive Transient Receptor Potential (TRP) A1, M8 and V1 Ca^{2+} permeable cation channels in human and rat odontoblasts. However, a mechanism by which odontoblasts could modulate neuronal activity has not been demonstrated. In this study we investigated functional TRP channel expression in human odontoblast-like cells (OBs) and aimed to identify chemical transmitter release in response to TRP channel activity. Human immortalized dental pulp cells were driven towards an odontoblast-like phenotype by culture in media conditioned with ascorbic acid, β-glycerophosphate and dexamethasone (Egbuniwe *et al*., 2011). Functional expression of TRP channels was determined using RT-PCR and ratiometric calcium imaging with Fura-2. ATP release was measured using a luciferin-luciferase assay. Expression of mRNA for TRPA1, TRPV1 and TRPV4 but not TRPM8 was detected in OBs by RT-PCR. Exposure to the TRPA1 agonists allyl isothiocyanate (AITC) and cinnamaldehyde (1μM–500μM) or the TRPV4 agonist GSK1016790A (1nM–1μM) caused a concentration-dependent increase in intracellular Ca^{2+} concentration that was inhibited by the selective antagonists HC030031 (TRPA1) and HC067047 (TRPV4) (n=5-7 independent triplicate measurements). In contrast, exposure to the TRPV1 agonist capsaicin (1nM–1μM) or the TRPM8 agonist icilin (1nM–1μM) had no effect on intracellular Ca^{2+} concentration (n=3). Treatment for 15 min with AITC (500μM; 28.2±5.1 vs. 10.4±4.5 nM), cinnamaldehyde (500μM; 29.9±8.6 vs. 9.0±2.3 nM) or GSK1016790A (1μM; 15.9±3.5 vs. 6.5±1.2 nM) caused an increase in ATP concentration in culture medium, compared to vehicle treatments (mean±S.E.M; $p<0.05$; t-test with Welch's correction; n=9-10). These data demonstrate that activation of the mechanosensitive TRPA1 and TRPV4 channels in human odontoblast-like cells can stimulate ATP release, which may modulate the activity of adjacent dental sensory neurons *in situ* via purinergic receptors. We were unable to confirm the presence of thermosensitive TRPV1 and TRPM8 that has previously been reported in odontoblasts.

Inflammation is a complex biological response involved in pathogenesis of a variety of diseases. Although steroids and NSAIDs are the main therapeutic agents in inflammation they cause serious side effects. Therefore, the development of new materials with comparable results and no side effects is needed. The purpose of our study is to investigate the biological activity of materials based on gold (Au-VO) and silver (Ag-VO) nanoparticles and natural compounds extracted from European cranberry bush - Viburnum opulus L. (VO) on acute inflammation model in Wistar rats. The inflammation was induced by intraplantar injection of 100 μl 1% carrageenan and the response was compared to indomethacin (5 mg/kgc) as positive control and saline solution as negative control. The VO extracts (15 and 30 mg/kg b.w.) and the materials based on gold and silver nanoparticles functionalized with VO extract (0.3 mg/kg b.w.) were administrated orally during 4 days before injection of carageenan. At 2h, 24h and 48h after carageenan injection the paw edema were measured and plantar tissue were taken for histopathological and immunohistochemical investigations (iNOS and COX-2) and to evaluate malondialdehyde (MDA), glutathione reduced/glutathione oxidized (GSH/GSSG), IL-1 and IL-6 levels. In addition, catalase and glutathione peroxidase activities were assessed from plantar tissue and erythrocyte lysates. Values are means ± S.E.M., compared by ANOVA and Tukey posttest. Low dose of VO significantly inhibited edema formation (44.54% vs. control group treated with vehicle; $p<0.05$), particularly at 2h, and increased GSH levels, both at 2h (2.98±1.63 nmoles/mg protein; $p<0.01$) as well as at 48h (21.66±14.36 vs. 7.01±1.34 nmoles/mg protein in control group; $p<0.0001$). The inhibition was higher to those produced by indomethacin (22.52%) and Ag-VO (22,52%) and was maintained at 24 h and 48 h, but at lower levels. In parallel, IL-1 and IL-6 levels and iNOS expression decreased ($p<0.01$). Ag-VO and Au-VO remarkably inhibited generation of MDA (0.13±0.09 respectively 0.11±0.04 vs. 0.29±0.12 nmoles/mg protein; $p<0.05$) and GSSG (1.79±0.75 respectively 1.85±0.46 vs 3.52±2.09 nmoles/mg protein in control group; $p<0.001$) in the plantar tissue, decreased IL-1 and IL-6 levels and increased GPx activity in paw tissue (89.25±10.90 respectively 86.25±17.06 vs 38.00±12.11 U/g protein in control group). This findings suggested that the nanoparticles func-

tionalised with natural compounds may be useful in the treatement of inflammatory disease.

This work was elaborated in the frame project no 147/2012, through the program "Partenerships in priority areas-PN II", developed with the support of ANCS, CNDI-UEFISCDI.

Adaptive sampling of visual information by photoreceptor ultrastructure and stochastic reactions

Z. Song[1], M. Postma[2], S. Billings[1], D. Coca[1], R. Hardie[3] and M. Juusola[1]

[1]University of Sheffield, Sheffield, UK, [2]University of Amsterdam, Amsterdam, Netherlands and [3]University of Cambridge, Cambridge, UK

The physical world is vast, noisy and dynamic. Nonetheless, sensory perception of it is reliable, allowing accurate judgments and actions. This conjunction of the variable world and trustworthy perception of it, suggests that sensory neurons are under selective pressure to exploit environmental regularities, such as contrast or colour in natural scenes, generating structural and functional adaptations, which improve sensory information estimates [1]. However, little is understood how the sensory structures and their neural information processing evolved together.

Here we show that by sequestering "unreliable" biochemical reactions into semi-autonomous transduction units, insect phototransduction evolved to generate reliable neural representations of natural light changes, from single photon regimes to full sunlight [2]. To better understand the mechanistic basis of this performance, we synthesized a virtual Drosophila photoreceptor from its biophysical parts. By combining stochastic simulations with intracellular experiments in Drosophila photoreceptors, we show how discrete sampling by phototransduction units (~30,000 microvilli), each producing variable quantum bumps to captured photons, governs macroscopic responses to light changes. Feedbacks and stochasticity in these reactions oppose saturation, dynamically adjusting availability of microvilli, whilst intracellular calcium and voltage adapt their sample size (bump waveform), generating reproducible responses. We further demonstrate how these rules for adaptive sampling predict information processing across a range of species with different visual ecologies. Our results clarify why fly photoreceptors are structured the way they are and function as they do, linking sensory information to sensory evolution and highlighting the benefits of stochasticity for neural information processing [3].

ATP signals in supporting cells of the organ of Corti in the adult mouse

P. Sirko[1,2], J. Gale[2] and J. Ashmore[2]

[1]MRC Laboratory for Molecular and Cellular Biology UCL, London, UK and [2]UCL Ear Institute, London, UK

It has been suggested that extracellular ATP signalling is implicated in protecting the auditory epithelium of the inner ear from noise-induced damage (Housley et al., 2009). Although ATP receptors have been found on several types of cells in the organ of Corti, these studies have focussed on either dissociated or a limited class of cells (Lagostena et al., 2001). Supporting cells show parallels with glia (Rio et al., 2002), however it is unclear if and how such cells, positioned near the first auditory synapse, might act in a protective manner. Multiple types of supporting cells are present and it is unknown whether ATP affects them similarly or activates different processes in them (Gale et al., 2004). To address these issues we have studied features of ATP-dependent signalling in the adult organ of Corti in an in situ system.

The temporal bone of adult mice (ages P30-P90) was removed after killing the animals by cervical dislocation and the organ of Corti was exposed through a small opening at the apical end of the cochlea. For immunochemistry, antibodies against P2X2 (Alomone Labs) were used on 4% PFA fixed tissue. For calcium imaging, opened cochlear bones were incubated for 40 min in buffer containing 20 μM OGB1-AM, washed and then fluorescent signals were collected by widefield epifluorescence microscopy. Whole cell tight seal patch clamp recordings were made from inner sulcus and phalangeal cells identified visually. In some cases cells were decoupled with the gap junction blocker flufenamic acid (100 μM) to improve voltage clamp.

There was extensive P2X2 immunoreactivity in the supporting cells of the organ of Corti. Comparatively, outer hair cells showed a limited degree of P2X2 on their apical surface. Consistent with these observations, 100 μM ATP puff applied to the organ of Corti produced a rise in intracellular (Cai) in supporting cells measured by OGB1. There was no detectable increase in Cai levels in the inner hair cells.

ATP (100μM) applied to the inner sulcus and phalangeal cells surrounding the inner hair cells produced inward currents in

both types of cells. The ATP gated currents showed inward rectification in both types of cells consistent with the properties of recombinant P2X channels. The ATP dependent currents in inner sulcus cells desensitized ($\tau 1/2$ = 1.6s) whereas little or no desensitization to prolonged application (15s) was observed in recorded phalangeal cells. We suggest that these results indicate differential expression of P2X receptor subunits and could reflect different roles for extracellular ATP signalling in these two cell types.

Neuronal damage and tau pathology in a murine model of cerebral ischemia

S. Khan, N. Yuldasheva, T.F. Batten and S. Saha

Division of Cardiovascular & Diabetes Research, Leeds Institute of Genetics, Health & Therapeutics, Leeds, UK

Cerebral ischemia is a major cause of death and the later development of neurodegenerative diseases (de la Torre, 2004), which are characterized by neuronal damage and accumulation of phosphorylated tau protein (Alonso et al., 1997). However, cerebral ischemia induced cellular damage that initiates neurodegerative disease remain poorly understood and does not receive proper attention for developing new drug treatment strategies. This is primarily due to lack of clinically relevant models that are highly reproducible as the pathophysiology of cerebral ischemia in animal models is modulated by numerous factors including the species, type of blood vessels occluded, occlusion period and reperfusion time (Hossmann, 1998). The present study aims to optimise a murine model of cerebral ischemia and examine neuronal degeneration and tau pathology in this model. Experiments were performed on 10-12-week-old (26–30 g) C57BL/6 mice (Harlan-Olac, Bicester, UK) under appropriate UK Home Office licence and adhered to regulations as specified in the Animals Scientific Procedures Act (1986). Cerebral ischemia was induced by transient bilateral occlusion of the common carotid arteries using arterial clips under anaesthesia (4% isoflurane saturated with oxygen). Following 5- 20 minutes occlusion the clips were removed and skin wound closed. Sham-operated mice underwent the same procedure except that the carotid arteries were not occluded. Following 1-7 days reperfusion time the mice were re-anesthetised and perfused with 4% paraformaldehyde in phosphate buffered saline (pH 7.0-7.2). Brain sections (50 um) cut on a vibratome were either stained with cresyl violet to assess neuronal damage or processed for immunohistochemistry using specific antibodies to neuronal specific nuclear protein, myelin associated protein, glial fibrillary acidic protein, glutamine synthetase and hyper- phosphory-lated Tau protein to examine the extent of neuronal, glial cell and myelin sheath damage and tau pathology. Antigen-antibody reaction sites were detected either by standard avidin-biotin complex and diaminobenzidine reaction or by using species specific anti-rabbit immu-noglobulin G conjugated to Cy3/ Alexa488. Sections were analysed using an AxioImager Z.1 epifluorescence microscope (Carl Zeiss, Welwyn Garden City, UK). The results showed consistent neuronal and white matter damage and tau pathology in the cortex, striatum and the hippocampus following 15 minutes occlusion and 3-7 days reperfusion. This murine model of cerebral ischemia may be an ideal model to study ischemia induced neurodegen-eration and to develop therapeutic strategies for prevention and treatment of these diseases.

Visual evoked potentials in primary open angle glaucoma

M.K. Jha

Physiology, Kathmandu University School of Medical Sciences, Dhulikhel, Nepal

Jha MK, Paudel BH, Badhu BP*, Limbu N, Thakur D. Department of Basic and Clinical Physiology and *Department of Ophthalmology, BPKIHS, Dharan, Nepal.

Background: Visual evoked potentials (VEPs) assess the integrity of the visual pathways from the optic nerve to the occipital cortex. Primary open angle glaucoma is bilateral condition with optic atrophy and visual field defect. Optic disc cupping and visual field loss have been associated with prolongation of latency of VEP. Therefore, we studied the ocular glaucomatous damage and VEP abnormalities.

Objectives: To study VEPs and ophthalmic variables in primary open angle glaucoma (POAG).

Methods: Pattern reversal and flash VEP tests were done in consenting 20 primary open angle glaucoma eyes and 40 normal control eyes in Electrodiagnosis Lab II at BPKIHS. Statistical tests (paired t-test and Mann-Whitney test) were applied depending on distribution of observations.

Results: In POAG cases the refractive error [3.51±1.88 vs. 1.88±1.11, D, p=0.001], cup disc ratio in percent [66.00±16.98 vs. 28.50±5.80, p=0.000], intraocular pressure [19.55±2.08 vs. 11.65±1.64, mmHg, p=0.000] and automated visual field pattern standard deviation [4.13±6.96 vs. 1.64±0.45, dB, p=0.000] were significantly more than in control. The visual acuity [0.41±0.29 vs. 1.00±0.00, p=0.000], foveal visual sensitivity [25.92±6.88 vs. 33.48±1.75, dB, p=0.000] and automated visual field mean deviation [-9.63±10.58 vs. 0.07±1.54, dB, p=0.000] were significantly less in cases than in control. Among VEP variables pattern reversal latency N145 [149.00±15.75 vs. 137.52±15.20, ms, p=0.011], flash amplitude N75 [2.18±.57 vs. 1.47±.38, μV, p=0.000] and flash amplitude N145 [1.99±.39 vs. 1.43±.38, μV, p=0.000] were increased in cases. The pattern reversal amplitude N75 [1.97±.35 vs. 2.47±.58, μV, p=0.001], amplitude P100 [3.09±.46 vs.

6.07±1.44, μV, p=0.000] and amplitude N145 [2.21±.58 vs. 4.45±1.99, μV, p=0.000] were decreased in cases.
Conclusion: POAG caused deterioration in all the ophthalmic variables measured with increase in latency of N145. The amplitude is different between pattern reversal and flash methods.

Effect of transcutaneous auricular vagus nerve stimulation on refractory epilepsy

P. Rong[1], H. Ben[1], L. Li[1], X. Li[1,2] and B. Zhu[1]

[1]Institute of Acu.-Mox., Beijing, China and [2]Beijing University of Chinese Medicine, Beijing, China

Objective:To examine whether transcutaneous auricular vagus nerve stimulation (ta-VNS) is an effective approach for patients with refractory epilepsy.
Patients and Methods:This study was conducted on 191 epilepsy patients who were randomly assigned to the ta-VNS group (n=124), and the transcutaneous non-auricular vagus nerve stimulation (tn-VNS) control group (n=67) from December 2010 to June 2012. The seizure frequency were assessed in week 8, 16 and 24 of the treatment according to the percentage of seizure frequency reduction.
Results:For 124 patients in the ta-VNS group, after 8 week's treatment, 10 were seizure free and 31 had a 50-99% reduction in seizure frequency; after 16 week's treatment, 14 were seizure free, 40 had a 50-99% reduction in seizure frequency; after 24 week's treatment, 17 were seizure free, 46 had a 50-99% reduction in seizure frequency. For 67 patients in the tn-VNS control group, 3 were seizure free, and 11 had a 50% reduction in seizure frequency after the first 8 weeks' treatment. After 16-week treatment of ta-VNS, of the 46 patients, 5 were seizure free, 17 had a 50-99% reduction in seizure frequency. The differences in seizure frequency reduction among groups were significant (P < 0.05).
Conclusion:Our result indicated that ta-VNS can significant suppress epileptic seizures. As a safe, effective, simple, economic therapeutic method with mild side-effect, it may have great potential in treatment of epilepsy.

Cyclooxygenase-2 mediates striatum activation in the mouse 6-Hydroxydopamine model of Parkinson's disease

D. Oliveira-Tavares[2,3], C.A. Da-Silva[1,2], F.E. Padovan-Neto[2,3] and E. Del Bel[1,3]

[1]Physiology, FORP-University of Sao Paulo, Ribeirão Preto, Sao Paulo, Brazil, [2]Neurology/Neurosciences, FMRP-University of Sao Paulo, Ribeirao Preto, Sao Paulo, Brazil and [3]-, Núcleo Apoio à Pesquisa em Neurociência Aplicada (NAPNA), Ribeirao Preto, Sao Paulo, Brazil

BACKGROUND: Recent studies described inflammation play a role in the abnormal involuntary movements that occur as a consequence of the chronic therapy for Parkinson's disease through the dopamine precursor 3,4-dihydroxyphenyl-L-alanine (L-DOPA). Exogenously administered corticosterone, which inhibit cyclooxygenase (COX) activity, decrease L-DOPA-induced dyskinesia in unilateral dopamine-depleted rats. Between many inflammatory factors found in the Parkinson's disease brain, the inducible isoform COX-2 is a critical enzyme in the mechanism of central nervous system inflammation. In this study we examined the effects of chronic L-DOPA treatment on the appearance of the COX-2 in the striatum of C57BL/6Jmice brain.
METHODS: Dyskinetic symptoms were triggered by repetitive administration of a constant dose of L-DOPA (25 mg/kg, twice a day, for 25 days) in unilaterally 6-hydroxydopamine (6-OHDA) lesioned (striatum) adult male mice (25-30gr, n=6-8/group). Lesioned or sham animals were treated chronically (25 days) with either saline or L-DOPA (25mg/kg, i.p. +benseraside). The animals were anaesthetised with a mixture of ketamine (100mg kg-1) and xilazine (14mg kg-1, both i.m.). After perfusion and fixation, the brains were cut, immuno- stained for tyrosine hydroxylase (TH) immunoreactivity (ir) Cyclooxige-

nase-2 (COX-2)-ir in the striatum and substantia nigra. Comparisons were made between controls (saline microinjected) lesioned (6-OHDA microinjected) and dyskinetic (6-OHDA lesioned, L-DOPA-treated) and non-dyskinetic (6-OHDA lesioned, saline-treated) mice .
RESULTS: Dyskinetic symptoms appear toward the end of the first week of treatment. TH-ir and COX-2-ir were found in neurons in the striatum after dopamine depletion. Dyskinesia was associated with L-DOPA-induced changes in the TH-ir and COX-2-ir in the neurons. Elevated COX-2 expression occurs within completely lesioned regions of the striatum, displaying an inverse correlation with remaining dopaminergic terminals.
CONCLUSIONS: Our results suggest that the presence of COX-2-ir neurons in the striatum may underlie the long-duration response to L-DOPA in Parkinsonian mice. Promotion of these striatal COX-2-ir neurons might be involved in the development of aberrant striatal circuits and the appearance of L-DOPA induced dyskinesia

Effects of duration of hyperthermic hypoxia on neonatal rats assessed after growth by behavior

T. Hosono[1], M. Yamamoto[1], C. Igi[1], K. Akasaka[1], M. Arakawa[1], M. Nakamoto[1] and K. Minato[2]

[1]Graduate School of Biomedical Engineering, Osaka Electro-Communication University, Shijonawate, Osaka, Japan and [2]Graduate School of Medicine, Osaka University, Suita, Osaka, Japan

Introduction. Neonatal hypoxic-ischemic (HI) encephalopathy (HIE) is often related to long-term neurological impairment, and HI insult with hyperthermia worsens the neonatal prognosis more than with normothermia. Although neonatal rat model of HIE has been generally developed by unilateral carotid artery (CA) ligation followed by 8% oxygen exposure at an ambient temperature (Ta) of 37°C for 1 – 2 hrs, we produced brain insults after 8% oxygen exposure only for 15 min at hyperthermic Ta of 40°C successfully (Hosono, 2010). However, the effects depending on the duration of hyperthermic hypoxia are still unknown. The aim of this study was to clarify the effects of the duration on brain impairment after growth using behavioral study and histology. Methods. Seven-day-old neonatal Wistar rats (n=30) were anesthetized by inspired isoflurane, and the left CA was surgically ligated (n=17, HIE-G). Sham-operated rats (n=13, S-G) without arterial ligation were also established. The pups were returned to their dams for 1 hr. All the rats in the HIE-G were divided into four groups, and placed in a chamber at Ta of 40°C with humidified 8.0% oxygen for 30 (n=4, HG30), 20 (n=4, HG20), 10 (n=4, HG10), and 5 min (n=5, HG5). Then all the pups were returned to the dams and raised. Rotarod test (RT). A 21-day-old rat was placed on the rotating rod, and the interval until falling to the floor was measured for five consecutive days with a rotational frequency of 5, 5, 7, 9, and 11 rpm on the 1st to 5th days, respectively. Step-down passive avoidance test (SPAT). On the first day of measurement, a 60-day-old rat was placed on a round rubber platform with a diameter of 10 cm in 30 cm cube box with a metal grid floor. When the rat went down to the floor, we administrated a mild electrical shock till it remained on the rubber. During the following 2nd to 6th days, the rat was placed on the rubber once a day, and the duration until it went down to the grid was recorded. After all measurements, rat brains were removed under deep isoflurane anesthesia. We prepared 4-μm brain slices, performed MAP-2 staining, and counted numbers of neurons per unit area. Results. RT revealed that the mean length of stay on the rod on the 5th day for HG30 (29 ± 13 sec, mean ± SE) was significantly ($p<0.05$, Kruskal-Wallis test) shorter than for HG20 (77 ± 38 sec), HG10 (161 ± 80 sec), and HG5 (198 ± 28 sec). SPAT revealed that staying times of HG30 (38 ± 28 sec) and HG20 (73 ± 52 sec) were significantly shorter than that of HG5 (194 ± 112 sec). The number of neurons in HIE-G was significantly lower than in SG. Discussion and Conclusion. RT and SPAT revealed reduced motor activity in HG and memory deterioration in HG30 and HG20, respectively. Histology revealed decrease of neuron numbers in HG. Hyperthermic hypoxia for more 10 min may cause brain impairment in the rat HIE model.

Transcutaneous auricular vagus nerve stimulation for the treatment of pediatric epilepsy

W. He, X. Jing, X. Wang, H. Shi, H. Shang, P. Rong, L. Li and B. Zhu

institute of Acupuncutre and Moxibustion, China Academy of Chinese Medical Sciences, Beijing, China

Background
Vagus nerve stimulation (VNS), an alternative method to manage patients with medically intractable epilepsy, has shown favorable results in reducing seizure frequency and improvements in quality of life [1]. As the only peripheral branch of the vagus nerve, the auricular branch of vagus nerve (ABVN) innervates the auricular concha in the surface of the body. It is suggested to treat epilepsy via stimulating the ABVN [2].
Objective
The present study is to investigate the safety and efficacy of transcutaneous auricular vagus nerve stimulation (ta-VNS) on pediatric patients with epilepsy.
Methods
Patients were enrolled from the Xuanwu Hospital and Tiantan hospital affiliated to the Capital Medical University. The ta-VNS was performed at the left auricular concha by using of a ta-VNS instrument. Patients or their caregiver were required to keep a detailed seizure diary. Classification of epileptic syndrome, seizure patterns, age of onset, seizure frequency and adverse effects were recorded. The baseline seizure frequency and the seizure frequency after 8 weeks, 16 weeks and 24 weeks of ta-VNS treatment were counted according to patient's seizure diary. All procedures accorded with the principles of the World Medical Association's Declaration of Helsinki.
Results
One patient aborted the study for ineffective reason after 8 weeks treatment. The remained thirteen patients completed the study for the whole 24 weeks without any changes in medication. After 8 weeks ta-VNS treatment, three patients had seizure free (classified as I), one patient has a seizure frequency reduction of more than 90% (classified as III), 10 patients had seizure frequency reductions of less than 50% (classified as IV).

After 16 weeks ta-VNS treatment, four patients had seizure free (classified as I), one patient has a seizure frequency reduction of more than 90% (classified as II), two patients has seizure frequency reductions of more than 50% (classified as III), six patients had seizure frequency reductions of less than 50% (classified as IV). After 24 weeks ta-VNS treatment, four patients had seizure free (classified as I), one patient has a seizure frequency reduction of more than 90% (classified as II), two patients has seizure frequency reductions of more than 50% (classified as III), six patients had seizure frequency reductions of less than 50% (classified as IV).

Conclusion

Our results suggest that ta-VNS is a safe and effective alternative method for pediatric patients.

Production of Tumor Necrosis Factor- alpha by Microglia in Rat Brain After Traumatic Brain Injury

C. Wang[1,2], C. Yang[3], C. Chang[4], M. Chang[5], B. Cheng[1,4], B. Chio[6] and J. Yu[6]

[1]Department of Surgery, Chi Mei Medical Center, Tainan, Taiwan, [2]Department of Recreation and Health-Care Management, Chia-Nan University of Pharmacy and Science, Tainan, Taiwan, [3]The Program for Cancer Biology and Drug Discovery (CBDD), Taipei Medical University, Taipei, Taiwan, [4]Department of Biotechnology, Southern Taiwan University of Science and Technology, Tainan, Taiwan, [5]Department of Electrical Engineering, Southern Taiwan University of Science and Technology, Tainan, Taiwan and [6]Department of Chinese Medicine, Chi Mei Medical Center, Tainan, Taiwan

Tumor necrosis factor-alpha (TNF-α) is elevated early in injured brain after traumatic brain injury (TBI), in humans and in animals. However, it is not known whether etanercept (a TNF-α antagonist) improves outcomes of TBI by attenuating microglia-associated, astrocytes-associated, and/or neurons-associated TNF-α expression in ischemic brain. A well clinically relevant rat model, where a lateral fluid percussion is combined with systemic administration of etanercept (50mg/kg, i.p.) after TBI, was used. To examine the neuronal and glial production of TNF-α, we performed Immunofluorescence staining to identify neurons-TNF-α, astrocytes-TNF-α, and microglia-TNF-α double positive cells in the injured brain of the cortex, white matter, hippocampus, and hypothalamus in TBI animals treated with or without etanercept. The rats were anesthetized with sodium pentobarbital (25 mg/kg, i.p.) and a mixture containing ketamine (4.4 mg/ kg, i.m.), atropine (0.02633 mg/kg,i.m.), and xylazine (6.77 mg/kg, i.m.), and received a 4.8-mm craniotomy to anchor the modified plastic syringe hub over the exposed dura of the right parietal cortex. A moderate FPI (2.2 atm) was produced by rapidly injecting a small volume of saline into the closed cranial cavity with a fluid percussion device (VCU Biochemical Engineering, Richmond, VA, USA). Behavior on an inclined plane was used to assess changes in limb strength. In addition to inducing brain contusion as well as motor deficits, TBI caused significantly higher numbers of microglia-TNF-α double positive cells, but not neurons-TNF-α or astrocytes-TNF-α double positive cells in the injured brain areas than did the sham operated controls, when evaluated 3 days after TBI. The TBI-induced cerebral contusion, motor deficits, and increased numbers of microglia-TNF-α double positive cells in the injured brain were all significantly attenuated by etanercept therapy. Early microglia overproduction of TNF-α in the injured brain region after TBI contributes to cerebral contusion and motor deficits, which can be attenuated by etanercept therapy.

Protective effect of melanin derived from White Silky Fowl on rat model of Parkinson's disease induced by 6-Hydroxydopa

Y. He, F. Zhang and X. Wang

Physiology, China Capital Medical University, Beijing, China

The Protective effect of melanin from White Silky Fowl on on rat model of Parkinson's disease (PD) induced by 6-Hydroxydop (6-OH DA) were studied. PD model were induced by unilateral intrastriatal injection of 6-OH DA to destroy the nigrostriatal dopamine system in the rat (all the operation were performed on anaesthetised rats). The apomorphine-induced rotation test was applied to screen out parkinsonism rats after 5 weeks operation. The melanin (6 or 20mg/Kg) were used on Parkinsonism rats by intragastric administered per day for 4 weeks, normal saline administration as control group. After the 3 and 4weeks drug administration, the rats were detected by rotation test and open-field Test. The results were as shows: In rotation test, 6mg/Kg melanin administration could reduce the rotation movement at 4 weeks significantly and 20mg/Kg melanin administration reduced the rotation at 3 and 4 weeks. In open-field Test, 20mg/Kg melanin administration could increase the loco motor distance of Parkinsonism rats at 4 weeks significantly. Therefore, melanin in White Silky Fowl could be a novel drug candidate for treatment of PD.

Key words: melanin from white silky fowl; Parkinson's disease ; 6-Hydroxydopa

Perioperative buprenorphine infusion influences recovery following experimental stroke

D. Corbett[1,2], K.D. Langdon[2], M. Jeffers[1], S. Smith[2] and S. Granter-Button[2]

[1]Cellular & Molecular Medicine, University of Ottawa, Ottawa, ON, Canada and [2]Division of BioMedical Sciences, Memorial University, St. John's, NF, Canada

Buprenorphine administration is recommended following certain surgical procedures in laboratory animals. Although this opioid analog is thought to reduce post-operative discomfort, little research has been undertaken to assess the effects that buprenorphine may have on neuronal and behavioural function, especially in stroke research. This study assessed the effects of buprenorphine administration on survival, histological and functional outcome after cortical stroke. Sprague-Dawley rats (n=73) underwent endothelin-1 (ET-1) forelimb motor cortex stroke under 2% isoflurane anesthesia and were pseudorandomized into one of three experimental conditions that received either 3 (Bupe-3), or 1 (Bupe-1) injection(s) of buprenorphine (0.04 μg/kg, s.c.) or vehicle (Saline). Lidociane injections (2%) and Xylocaine gel (1%) were applied prior to incisions and at wound closure in all animals. Buprenorphine significantly increased core temperature (~0.5o C) for 3 hours immediately post-stroke, but only in the Bupe-1 animals. An overall wellness score consisting of post-operative weight gain, sensory reactivity, respiration rate, etc. revealed that Saline treated animals recovered more quickly than Bupe-3 animals ($p<0.025$). Buprenorphine resulted in a decrease in skilled reaching in the Montoya staircase test (~10%) and increased infarct volume (~20%) and neuroinflammation (~45%), although neither of these results attained statistical significance. Further, buprenorphine significantly increased the mortality rate compared to the Saline group. Based on these results it may be difficult to compare studies where investigators use different drugs and dosing regimens to control pain and discomfort, thereby posing a challenge to successful translation of preclinical research findings.

Research support was provided by the Canadian Institutes of Health Research (CIHR) awarded to DC.

Effect of slow frequency repeated transcranial magnetic stimulation on pain modulation status of female fibromyalgia patients: An electrophysiological study

A.H. Ansari[1,2], S. Jain[1], R. Mathur[1] and M. Bhattacharjee[3]

[1]Physiology, All India Institute of Medical Sciences, New Delhi, Delhi, India, [2]Physiology, Nepalgunj Medical College, Chisapani, Banke, Nepal and [3]Physiology, Vardhman Mahavir Medical College, New Delhi Safdarjung, Delhi, India

Fibromyalgia (FM) is a chronic pain disorder characterized by widespread musculoskeletal pain, tender points and fatigue, secondary to altered pain perception and modulation system. Most of the patients also report muscle stiffness, sleep disorder, irritable bowel syndrome, and mood disorder. There is a lack of appropriate management of pain and associated emotional component. We report the beneficial effect of non-invasive, non-pharmacological and inexpensive management of pain and associated anxiety in FM by transcranial magnetic stimulation (TMS).Female FM patients (n=90) were recruited from our Rheumatology Clinic. Patients received TMS (0.5 Hz, 80% of motor threshold) at right dorso-lateral prefrontal cortex, in 8 sessions of 5 min at 5 min interval /day. The TMS sessions were repeated every day for 5d/week x 4 (TMS group), while controls (sham group) received only sham stimulation. Pre and post TMS at wk 0, 4 and 6, pain was assessed objectively by nociceptive flexion reflex (RIII reflex) from left biceps femoris muscle; the emotional component of pain by Beck Depression Inventory second edition (BDI-II) and the negative strategies for coping with pain by Coping Strategy Questionnaire (CSQ), while pain modulation by diffuse noxious inhibitory control. We also analyzed the potential role of single nucleotide polymorphisms (SNPs) in catechol-O-methyltransferase (COMT) (rs4680) and 5-hydroxytryptamine (serotonin) 2A (5-HT2A) receptor (rs6313) genes on susceptibility to fibromyalgia. Polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method was used for the genotyping analyses. Genotype and allele frequencies were calculated and Chi square test was done for statistical analysis. Post-TMS (wk4), RIII threshold increased ($p<0.01$) in FM patients from 27.4±5.5V to 36.7±5.87V indicating analgesia, while it did not ($p<0.62$) change (28.6 ±6.04V to 29.1±5.5V) in sham group. The latency of RIII also increased ($p<0.045$) from 108.29 ±34.34 ms to 123.56±28.41 ms, post-TMS but not post-sham (112.37±28.65 to 109.78 ±30.21, $p<0.84$), while BDI-II score (12.46±3.21) at wk 0 which reduced ($p<0.03$) post-TMS to 7.45±1.87.The beneficial effect persisted till wk 6. : There were no significant differences in the frequencies of alleles and genotypes between patients and controls for the COMT and the 5-HT2A receptor gene polymorphisms ($P > 0.05$) in present case control study.

Genetic polymorphisms T102C of 5HT2A gene and val158met of COMT gene have no association with fibromyalgia susceptibility. The study showed that repeated TMS in FM patients relieved pain, associated anxiety and depression as indicated by RIII reflex and BDI-II, respectively. We suggest that it may be a valuable and safe new therapeutic option for FM patients.

Altered nerve structure and electrophysiological responses to mechanical stress in the *Trembler-J* mouse model of Charcot-Marie-Tooth disease

B.J. Power, M. Pickering and J.F. Jones

School of Medicine and Medical Science, University College Dublin, Dublin, Ireland

Charcot-Marie-Tooth (CMT) disease is the most common hereditary peripheral neuropathy encompassing a group of heterogeneous disorders characterised by distal limb areflexia and muscle atrophy, high-arched feet (known clinically as *pes cavus*), and decreased axonal conduction velocities. At present, there is no effective drug therapy for CMT despite intensive investigation of the molecular genetics of the condition. Our laboratory has recently found that normal nerve striations (the "bands of Fontana") appear to be absent on the surface of *Trembler-J* mouse nerves, an animal model of CMT type 1A, suggesting structural abnormalities in the underlying undulating course of component nerve fibres in an unstretched specimen. Previous studies have identified a correlation between peripheral nerve injury and the loss of observable striations on whole nerve fascicles (Zachary *et al.*, 1993). In light of these findings, the current study investigated the hypothesis that the chronic progressive peripheral neuropathy of CMT1A is a result of disordered nerve biomechanics and increased susceptibility to stretch-induced axonal injury. *Trembler-J* (*PMP22*$^{Tr\text{-}J}$/+; 21-27g; n=8) and wild-type C57BL/6 (*PMP22*+/+; 20-27g; n=8) mice were killed humanely by stunning and cervical dislocation in accordance with institutional guidelines. Sciatic nerves were isolated and examined using a sealed humidity chamber and stimulated electrically with simultaneous application of uniaxial tensile stresses. Young's modulus of elasticity was derived from the slope of the stress-strain curve and used as a measure of the biomechanical properties of each nerve. Electrophysiological responses to nerve deformation were also recorded as a measure of the capacity of nerves to propagate electrical potentials. Results are presented as mean ± S.E.M. with a criterion for statistical significance set at $p<0.05$. Upon application of tensile force, a significant difference was observed between the change in compound action potential (CAP) peak amplitude per unit of change in percentage (%) strain in both groups; with control mice showing an average decline in CAP of -0.07 ± 0.03mV per unit % strain, while *Trembler-J* nerves showed an average increase of 0.02 ± 0.02mV ($p=0.028$, two-tailed Student's *t*-test) despite no significant difference in Young's moduli ($p=0.5$, Mann-Whitney *U* test). The findings lead to rejection of the original hypothesis and indicate that the peripheral nerves of *Trembler-J* mice are not more prone to stretch-induced failure of impulse conduction.

Glucocorticoid negative feedback alters electrical excitability of murine anterior pituitary corticotroph cells

P.J. Duncan and M.J. Shipston

Centre for Intefgrative Physiology, The University of Edinburgh, Edinburgh, UK

Anterior pituitary corticotroph cells are an integral component of the hypothalamic-pituitary-adrenal (HPA) axis which governs the physiological stress response. In response to a stressor, corticotrophin-releasing hormone (CRH) and arginine vasopressin (AVP) from the hypothalamus stimulate adrenocorticotrophic hormone (ACTH) release from corticotrophs. ACTH, in turn, releases glucocorticoids from the adrenal gland which negatively feedback to inhibit ACTH secretion. Corticotroph cells are electrically excitable and fire single-spike action potentials as well as showing complex bursting patterns. The aim of this project was to establish whether glucocorticoid negative feedback changes the electrical properties of murine corticotroph cells.

Corticotrophs were acutely isolated from male mice (aged 2-5 months) constitutively expressing green fluorescent protein (GFP) under control of the POMC promoter (POMC-GFP). Electrophysiological recordings were obtained using the perforated patch clamp technique in the current clamp configuration. Under basal conditions, cells had a resting membrane potential of -53.7 ±1.5mV (n = 7, Data are Means ± SEM) and showed low frequency spontaneous action potentials (0.34 ±0.14Hz). Stimulation with physiological concentrations of CRH and AVP (0.2nM and 2nM respectively) results in an increase in firing frequency and a transition from single spikes to bursting-like behaviour.

Cells pre-treated for 1.5 hours with corticosterone (100nM) were significantly ($p < 0.01$) hyperpolarised compared with controls (-62.9 ±2.2mV) under basal conditions (n = 8). Although CRH and AVP could depolarise resting membrane potential in corticosterone treated cells, this was still significantly ($p < 0.05$) hyperpolarised (-55.7 ±2.6mV) compared with controls treated with CRH and AVP. Basal firing rate was lower in cells treated for 1.5 hours (0.12 ±0.1Hz) and although CRH/AVP was still able to increase firing frequency (0.49 ±0.13Hz), it was significantly ($p < 0.05$) reduced compared with control cells exposed to CRH and AVP. Furthermore, in corticosterone pre-treated cells, CRH and AVP failed to induce a significant transition from single spikes to bursting behaviour.

To summarise, treatment of corticotrophs with corticosterone causes an overall suppression of both spontaneous and CRH/AVP-evoked firing frequency. Interestingly, corticosterone treated cells fail to transition from single spike to complex bursting patterns. This highlights a potential mechanism for corticosterone negative feedback although molecular targets remain to be defined.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Chronic exposure to intermittent hypoxia in lead intoxicated growing rats impairs bone biology

M.I. Conti, A.R. Terrizzi, C.M. Lee, P.M. Mandalunis, C. Bozzini and M.P. Martinez

Physiology, University of Buenos Aires. School of Dentistry, Buenos Aires, Argentina

High-altitude is a physiological stress which induces hypertrophy of the erythropoietic marrow leading to deterioration of bone biomechanical competition (1). Lead (Pb) is a persistent air pollutant implicated in bone disorders (2). The increase in mining activities at high altitude frequently results in populations chronically intoxicated with Pb under hypoxic conditions. We reported growth retardation and damages on femoral bone that predispose to fractures in a rat model performed intoxicating the animals with Pb and exposing them to intermittent hypobaric hypoxia (IHH) (3). These findings aimed us to investigate the deleterious effect of Pb under IHH on bone biology, evaluating the intrinsic stiffness and the efficiency of spatial distribution of bone material to resist deformation, bone mass in terms of histomorphometry and some stress indicators. Sixty female Wistar growing rats were divided into: C (control); Pb (1000 ppm of lead acetate in drinking water for 90 d); IHH (exposed to 506 mbar, 18 h/d during 90 d in a simulated high altitude chamber) and PbIHH (both treatments together). After euthanasia, blood samples were collected to evaluate tumoral necrosis factor-alpha (TNFα); adrenal glands were resected and hemimandibles, femurs and tibiae were dissected to assess cortical mechanical properties (Instron 4442) and histomorphometric studies in decalcified sections stained with H&E. Values are means ± SD, compared by ANOVA and Student-Newman-Keuls. TNFα plasmatic concentration was greater in Pb and IHH animals (53.71±9.65 and 184.11±28.18 vs 2.91±0.78, $p<0.01$). Adrenal gland weight from Pb and IHH groups rose to similar levels (10.78±1.08 and 10.77±0.90 g/100g BW vs 7.99±1.00 for control rats, $p<0.01$) being the increase even greater for the PbIHH group. Stress, a bone material quality indicator, was reduced either by Pb or IHH in both kinds of bones (femur: Pb 90.36±8.91; IHH 59.95±4.89 and PbIHH 80.61±5.03 vs C 102.08±13.84 Nmm-2 and hemimandible: Pb 22.96±5.96; IHH 26.39±4.68 and PbIHH 24.69±3.92 vs C 39.25±8.50 Nmm-2, $p<0.01$). Treatments reduced only the hemimandible cross sectional geometry (Pb 3.78±0.67; IHH 4.13±0.51 and PbIHH 4.23±0.13 vs C 5.02±0.49 mm4, $p<0.01$) and the intrinsic stiffness (Pb 565.32±46.31; IHH 555.39±49.31 and PbIHH 526.31±45.31 vs C 796.32±59.36 Nmm-2, $p<0.01$). Combined treatments reduced tibia and hemimandible bone volume (-45 % and -40% respectively, $p<0.01$) and growth plate cartilage thickness (-19%). These results show a previously unreported effect of heavy metals under intermittent hypoxia on bone. Longer studies should be necessary to evaluate if an adaptation of the architecture to maintain structural properties may occur and if an association between the impairment of bone material quality and the degree of oxidative stress exists. PCB166

Impact of lead intoxication under intermittent hypoxia on oral health of growing rats

M.P. Martinez, A.R. Terrizzi, C.M. Lee, J. Fernandez Solari, J.C. Elverdin and M.I. Conti

Physiology, University of Buenos Aires. School of Dentistry, Buenos Aires, Argentina

Objective: We recently reported in growing rats chronically intoxicated with lead (Pb) and exposed to the stress of intermittent hypobaric hypoxia (IHH) deleterious effects on periodontal and dental tissues that could be due to a greater vulnerability of them to inflammatory processes (1). Periodontitis is characterized by inflammation of the supporting tissues of the teeth and periodontal pocket formation that result in alveolar bone resorption and soft tissue attachment loss. It has been suggested that the submandibular gland functions are a key regulatory organ in the oral neuroimmunoregulatory network (2). The aim of the present study was to establish in the same rat model, the macroscopic, biochemical and histological parameters consistent with a periodontal disease. Methods: Sixty female Wistar growing rats were randomly divided into 4 groups: C (control); Pb (intoxicated with 1000 ppm of lead acetate in drinking water for 90 d); IHH (exposed to 506 mbar, 18 h/d during 90 d in a simulated high altitude chamber) and Pb-IHH (both treatments together). At the end of the experimental period the submandibular glands (SMG) were extracted to measure TBA-RS, as a marker of cellular oxidative stress and prostaglandin E2 (PGE2) known to be increased under oral inflammatory conditions (3). Hemimandibles were resected to assess bone loss by measuring the distance between the cemento-enamel junction and the alveolar bone crest of the first molars roots and to perform histomorphometric studies in decalcified sections stained with H&E. Values are means ± SD, compared by ANOVA followed by Student-Newman-Keuls tests. Results: Hypoxia enhanced TBA-RS content in SMG being the increase even greater in PbIHH group (C: 11.11±0.73; Pb: 11.59±0.46; IHH: 13.89±0.88 and PbIHH: 15.49±0.70 nmol/mg SMG wet weight, $p<0.01$). Both treatments enhanced PGE2 content in the SMG, showing an additive effect in the PbIHH group (C: 332.69±123.99; Pb: 476.19±135.02; IHH: 546.24±122.42 and PbIHH: 1165.09±204.51, $p<0.01$). IHH showed significantly higher buccal alveolar bone loss vs their control but surprisingly it was lower in the PbIHH group. Conclusion: Treatments enhanced some systemic and oral tissues inflammatory parameters, which could lead to a periodontal disease in individuals living in lead contaminated high altitude areas. Interstitial calcium modulates cholinergic-induced eccrine sweating

K. Metzler-Wilson[1,2] and T.E. Wilson[1,3]

[1]Ohio Musculoskeletal and Neurological Institute, Ohio University, Athens, OH, USA, [2]Department of Physical Therapy, Lebanon Valley College, Annville, PA, USA and [3]Deapartment of Biomedical Sciences, Ohio University Heritage College of Osteopathic Medicine, Athens, OH, USA

Ca^{2+} is an important second messenger in eccrine sweating, with both internal and external sources identified in isolated rhesus monkey palm sweat glands[1]. It is unclear if these isolated gland studies can be translated to *in vivo* interstitial Ca^{2+} level modulation and if this *in vivo* modulation has the capacity to modulate sweat rate (SR) and skin blood flow (SkBF) in intact human forearm skin, which unlike palm skin, is vital to thermoregulation. We hypothesized that lowering interstitial Ca^{2+} levels or attenuating its influx would cause a rightward shift in the SR to acetylcholine (ACh) dose-response relation. 1) To identify that our methods had the capacity to modulate Ca^{2+} concentrations, osmolality was measured during Ca^{2+} or Ca^{2+} chelator (43 mM EDTA) perfusion through a microdialysis membrane into 2 ml distilled water with no Ca^{2+}, 200 mM Ca^{2+}, or EDTA. EDTA decreased perfusate and bath osmolality. To quantify Ca^{2+} in physiologic concentrations, EDTA in distilled water or lactated Ringers (2 mM Ca^{2+}) was perfused through a bath containing the opposite solution. EDTA decreased perfusate and bath Ca^{2+} concentrations via microbore ion chromatography with conductivity detection. 2) 9 healthy human subjects received 6 ACh doses ($1x10^{-5}$ - $1x10^{0}$ M, 10-fold increments) with and without EDTA via forearm intradermal microdialysis. Capacitance hygrometry SR measures were completed directly over microdialysis membranes. SR to ACh dose-response modeling via nonlinear regression curve fitting (mean R^2 0.97±0.05 with, 0.95±0.03 without EDTA) identified maximal responsiveness (E_{max}) and ED_{50} (ACh dose causing 50% E_{max}). EDTA right shifted the ED_{50} (1.5±0.1 -logM) compared to ACh alone (1.0±0.1 -logM; p=0.01). E_{max} was not different between groups (0.60±0.078 and 0.58±0.34 mg/cm^2/min, respectively; p=0.85). 3) The EDTA microdialysis protocol was repeated in 5 subjects, measuring SkBF via laser-Doppler flowmetry to control for the potential of SkBF affecting SR independently. Neither E_{max} nor ED_{50} was significantly different between groups. 3) 10 healthy human subjects received the same 6 ACh doses with and without L-type Ca^{2+} channel blocker (1 mM verapamil) via forearm intradermal microdialysis. SR to ACh dose-response curve fitting (mean R^2 0.96±0.01 with, 0.97±0.01 without verapamil) identified a right shifted ED_{50} (0.9±0.1 -logM) compared to ACh alone (1.6±0.2 -logM; p<0.01). E_{max} was not different between groups (0.45±0.08 and 0.35±0.06 mg/cm^2/min, respectively; p=0.07). Thus, local in vivo Ca^{2+} chelation has the capacity to decrease interstitial Ca^{2+} concentration and to attenuate eccrine sweat gland cholinergic sensitivity. L-type Ca^{2+} channel antagonism also attenuates eccrine sweat gland cholinergic sensitivity. These data suggest that interstitial Ca^{2+} and its influx play a SkBF-independent role in human cholinergic-induced eccrine sweating that is important in thermoregulation.

Effects of non-lethal cold stress on the mitochondrion-rich cells in gills of the euryhaline milkfish (*Chanos chanos*) acclimated to seawater and fresh water

C. Kang, Y. Chen and T. Lee

Life Sciences, National Chung-Hsing University, Taichung, Taiwan

Milkfish (*Chanos chanos*) is an aquaculture species which could be cultivated in the rearing ponds with different salinities. In the Southern Taiwan, large numbers of milkfish died in the cold current of the winter leading to economic loss of the fisherman. Being an ectothermal species, low temperature seriously influences the homeostasis of the milkfish. In the teleosts, the gills exposed to the external environment are the major osmoregulatory organ. Mitochondrion-rich (MR) cells conduct ion excretion and uptake by ion transporters in gills of seawater (SW) and fresh water (FW) fish, respectively. The present study focused on the remodeling of cellular morphologies and modulation of ion transporters in the gill MR cells of SW and FW milkfish raised in the non-lethal cold stress (18°C) for 1 week compared to the control temperature (28°C) group. The juvenile milkfish (15-20 g, n=12) were fed a daily diet of commercial pellets. Following the experiment, the fish were not fed for 1 day and anaesthetized with Tricaine mesylate (MS-222, 100-200 mg/l) before collecting blood and excising the gill tissues. The facilities and protocols for experimental animals were approved by the Institutional Animal Care and Utility Committee of the National Chung-Hsing University (Approval No. IACUC 96-48 to THL). Values were mean ± SEM, compare by Students' t-test. The plasma osmolality (28°C vs. 18°C: 403.4±4.2 vs. 377.0±3.1 mOsmo/kg, p<0.05) and Na+ concentrations (28°C vs. 18°C: 141.1±3.6 vs. 128.3±3.4 mM, p<0.05) were decreased in SW milkfish exposed to 18°C, while the Cl- concentrations (28°C vs. 18°C: 108.6±6.4 vs. 175.6±5.9 mM, p<0.05) were increased in the FW fish at 18°C. No effect of nonlethal cold was found on the protein abundance of Na^+, K^+-ATPase (NKA) α-subunit and cell size and density of NKA-immunoreactive (IR)/MR cells in gills of the milkfish. In gills of the SW milkfish exposed to 18°C, constant NKA activity and the low percentage of cystic fibrosis transmembrane conductance (CFTR)-IR/NKA-IR cells (28°C vs. 18°C: 43.8±5.5 vs. 14.6±1.6 %, p<0.05) were found. On the other hand, our results revealed that the NKA activity decreased (28°C vs. 18°C: 36.8±6.4 vs. 18.7±4.2 μmol Pi/mg protein/hr, p<0.05) and the apical openings with Na^+, Cl^- cotransporter (NCC) of MR cells reduced (28°C vs. 18°C: 18.5±1.6 vs. 9.7±1.3 %, p<0.05) in gills of the FW milkfish at 18°C. This study was the first to figure out different responses of MR cells with hypo- and hyperosmoregulation in gills of the milkfish when exposed to non-lethal cold stress. The functional morphologies of gill MR cells

played an important role in cold resistance of the euryhaline milkfish.

L-arginine-nitric oxide pathway in neutrophils from chronic renal failure patients under haemodialysis

D.C. Abrantes[1], T.M. Brunini[1], M.B. Oliveira[1], N.O. Pinto[3], C.L. Correa[1], C.S. MAchado[1], S.F. Santos[2] and A. Mendes-Ribeiro[1,3]

[1]Pharmacology, State University of Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil, [2]Medical Clinic, Discipline of Nephrology, State University of Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil and [3]Physiological Sciences, Federal University of the State of Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil

Chronic renal failure (CRF) promotes endothelial cells and neutrophils damage in the severe stages of disease [1]. Disturbances in nitric oxide (NO) bioavailability are involved in the pathogenesis of CRF. [2]. NO is a potent vasodilator, inhibitor of platelet activation and aggregation. Recent studies have demonstrated that activated neutrophils promotes an inhibitory effect on platelet aggregation, contributing to vascular homeostasis [3] . The aim of this study was to evaluate the transport of L-arginine, the activity of the enzyme nitric oxide synthase (NOS) and the platelet-neutrophil relationship in CRF. Six CRF patients under haemodialysis and six healthy controls matched for sex and age were included in this study. The Pedro Ernesto Hospital Ethical Committee approved this study (451– CEP/HUPE), and informed consent was obtained from each participant. Basal NOS activity was measured by the conversion of L-[3H]-arginine into L-[3H]-citrulline. L-arginine transport into neutrophils was analysed in these patients. Saturable influx of L-arginine into neutrophils was mediated by systems y+ and y+L. Platelet aggregation was induced by ADP 5 μM, incubated by neutrophils at different times (5 and 30 minutes) and monitored for 8 min in a four-channel aggregometer. Student's t and Mann Whitney tests were used for statistical analysis and values were considered significant when $p<0.05$. Values were expressed as means ± SEM. Results: Total L-[3H]-arginine transport (controls: 1.56 ± 0.46 vs. CRF: 0.50 ± 0.12 pmol/106cells/min), transport by y+ system (controls: 0.5 ± 0.18 vs. CRF: 0.25 ± 0.05 pmol/106cells/min) and transport by y+L system (controls: 1.06 ± 0.4 vs. CRF: 0.24 ± 0.08 pmol/106cells/min) were reduced in CRF patients. There was a significant decrease in NOS activity (pmol/106 cells/min) in neutrophils from CRF patients (0.18 ± 0.03) compared to controls (0.62 ± 0.02).There was no change in platelet aggregation induced by ADP in CRF patients compared to controls. In the presence of neutrophils, there was a reduction-time dependent in platelet aggregation in both groups with no difference between them.

Conclusion: This study demonstrated a lower L-[3H]-arginine influx associated with a reduction in NOS activity in neutrophils from CRF patients compared with controls. These data suggest alterations in the L-arginine-NO pathway that may lead to a decrease in NO bioavailability in patients under haemodialysis.

Identification of ARAP3 function as a novel modulator of lymphatic vessel morphogenesis

J. Kartopawiro[1], E. Frampton[1], T. Karnezis[2], K. Koltowska[1], N. Bower[1], S. Schulte-Mercker[3], M. Achen[2], J. Kazenwadel[4], N. Harvey[4], B. Hogan[1] and M. Francois[1]

[1]Institute for Molecular Bioscience, The University of Queensland, Brisbane, QLD, Australia, [2]Peter McCallum Cancer Institute, Melbourne, VIC, Australia, [3]Huebrecht Institute, Huebrecht, Netherlands and [4]Center for Cancer Biology, Adelaide, SA, Australia

The process of lymphatic vascular development also known as lymphangiogenesis occurs in the embryo from a sub-population of venous endothelial cells that acquire a lymphatic endothelial cell fate. The main molecular switch responsible to drive the transition from venous to lymphatic identity is the transcription factor SOX18.

We took advantage of Sox18 mutant mice to perform a microarray analysis of purified lymphatic endothelial cells from the skin of both wild type and Sox18 heterozygous mutant mice and identified a subset of Sox18-regulated genes with no previously implicated function in lymphangiogenesis.

To validate on a large scale top gene candidates (>100) from the micro-array, an expression pattern and morpholino knockdown screen was performed in zebrafish and identified the arap3a gene (ArfGAP with RhoGAP domain, ankyrin repeat and PH domain 3) as enriched in zebrafish vasculature throughout embryogenesis. At 56 hours post fertilization (hpf) in zebrafish, we observed that arap3a knock down generates a severe decrease in lymphatic precursor cells and block thoracic duct formation. By contrast, arterial and venous differentiation and sprouting of venous derived intersegmental vessels remained unaffected, demonstrating the specific lymphatic function of arap3a in this model system.

In mice, Arap3 is expressed in a polarized fashion in lymphatic endothelial cell precursors in the cardinal vein suggesting a conserved role in lymphangiogenesis. Conditional loss of Arap3 function in endothelial cells triggered severe subcutaneous edema at 14.5 days post coitum (dpc) and skin lymphatic vessels display severe mis-patterning defects whereas the blood vasculature remained unaffected. Finally, we found in fish and in cultured LECs that ARAP3 acts downstream of vascular endothelial growth factor-c (Vegfc) and may be considered an effector of Vegfc/Vegfr3 signaling to modulate lymphatic endothelial cell migration.

Our work reveals a major regulator of lymphatic vessel morphogenesis and network assembly downstream of the VEGF-C pathway and provides the molecular basis to further target VEGF-C signaling with the view to blocking lymphatic remodeling during solid tumour metastasis.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Interleukin-1β-induced decrease of NHE3 interacting protein PDZK1, as well as sh-RNA-mediated PDZK1 knockdown, is associated with NHE3 dysfunction in the colonic epithelial cell line Caco-2bbe

G. Chodisetti[1], M. Luo[1], A. Klöpper[1], B. Riederer[1], P. He[2], C.C. Yun[2], S. Yeruva[1] and U. Seidler[1]

[1]Dept.of Gastroenterology, Hepatology and endocrinology, Hannover medical school, Hannover, Germany and [2]Div. Of Gastroenterology, Dept. Of Medicine, Emory University, Atlanta, GA, USA

Background: Inflammatory bowel disease (IBD) is a major gastrointestinal disease with diarrhea being a leading symptom. The pathophysiology of inflammatory diarrhea is multifactorial and still ill understood. We have previously reported a dysfunction of the major intestinal sodium absorptive transporter, the Na+/H+ exchanger NHE3, in inflamed colonocytes of ulcerative colitis patients and mouse models of colitis as well as a downregulation of the NHE3-interacting PDZ-protein PDZK1 (NHERF-3) in chronically inflamed murine colonic mucosa.
Aim: The present study investigates whether the inflammation induced reduction of PDZK1 expression is causally related to the defective function of its binding partner, NHE3.
Methods: We used cytokine-treated Caco-2bbe cells as an in vitro model of intestinal inflammation. Real-time PCR and western blots were done to measure PDZK1 and NHE3 mRNA and protein expression. pH-fluorometry using the pH sensitive dye, 2',7'-bis-(2-carboxyethyl)-5-(and-6)-carboxyfluorescein (BCECF), was performed to measure acid activated NHE3 activity. Confocal microscopy was done to analyze NHE3 localization in interleukin-1β (IL-1β) treated Caco-2bbe cells stably expressing human NHE3 (C2N3cells).
Results: Treatment of Caco-2bbe cells with Th1 pro-inflammatory cytokines revealed, IL-1β as the main cytokine with a significant inhibitory effect on PDZK1 expression (50% of decrease in both mRNA and protein compared to control). Treatment of C2N3 cells with IL-1β lead to a significant decrease in PDZK1 protein to approx. 50% of control value, but no change in NHE3 protein expression and membrane localization. However, acid activated NHE3 transport rates were significantly decreased after IL-1β treatment in these cells (22% less than control). When PDZK1 expression was decreased by lentiviral shRNA knockdown in NHE3-transfected Caco2bbe cells to approx 80% of control value, and NHE3 transport activity assessed, an even stronger decrease in acid-activated NHE3 activity (49% less than control) was observed than in IL-1β treated cells. This demonstrates a causal relationship of PDZK1 downregulation and NHE3 dysfunction, independent of inflammation.
Conclusion: A marked decrease in the PDZ-adaptor protein, PDZK1, was observed in the IL-1β treated Caco-2bbe cells. This corresponded to a decrease in NHE3 transport function but no change in NHE3 expression and membrane localization. We therefore conclude that during intestinal inflammation, cytokine mediated PDZK1 down regulation is likely an important causative factor for inflammation-associated NHE3 dysfunction and diarrhea.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Lubiprostone activates CFTR in human bronchial epithelial cells via a protein kinase A independent dependent process

J. Przeworek[1], H. Samvelyan[1], A. Hassouni[1], R. Muimo[2], C. Taylor[3] and L. Robson[1]

[1]Biomedical Science, University of Sheffield, Sheffield, UK, [2]Department of Infection and Immunity - Medical School, University of Sheffield, Sheffield, South Yorkshire, UK and [3]Paediatric Gastroenterology, Sheffield Children's Hospital, Sheffield, South Yorkshire, UK

In human bronchial epithelial cells the cAMP-activated Cl^- channel CFTR, plays a critical role in mediating Cl^- secretion. This important role is highlighted in cystic fibrosis, where CFTR mutations impact significantly leading to defective muco-ciliary clearance and an increased risk of infection. Previous work has suggested that the fatty acid lubiprostone (Lp) activates CFTR in ovine airway [1]. In the current study the impact of Lp on human bronchial cells (16HBE14o–) was tested.
Cells were grown on permeable supports until confluent and a transepithelial resistance of at least 200 Ωcm^2 was achieved. Inserts were mounted in an Ussing chamber with standard Krebs (basolateral side) and low Cl^- Krebs (apical side). Solutions were bubbled (5% CO_2), and all potential and resistance measurements corrected. 10 μA of current was injected to calculate the equivalent short circuit current (I_{SC}). Control measurements were taken for 5 minutes and then 1 μM Lp added apically. At steady-state 10 μM $CFTR_{inh172}$ was then added to provide an indication of CFTR function. This was repeated in unpaired inserts in the presence of inhibitors for either protein kinase A (protein kinase inhibitor - PKI), adenylate cyclase (SQ22,536) or tyrosine phosphatase (phenylarsine oxide - PAO). Statistical significance was tested using ANOVAs or Student's t test as appropriate and assumed at the 5% level.
Addition of Lp increased I_{SC}. Under control conditions I_{SC} was 10.1 ± 1.74 μA/cm^2 and increased to 26.2 ± 2.63 μA/cm^2 with Lp (n=23, mean increase 17.7 ± 2.40 μA/cm^2). Addition of $CFTR_{inh172}$ reversed this increase, a fall of 20.2 ± 2.29 μA/cm^2. Pre-incubation with PKI or SQ22,536 prior to the addition of Lp was without effect. The change in I_{SC} with Lp in the presence of both compounds was not significantly different to control: 20.3 ± 2.05 μA/cm^2 (n=11) and 18.8 ± 4.77 μA/cm^2 (n=8), with PKI and SQ22,536, respectively. The $CFTR_{inh172}$-sensitive I_{SC} was also unaffected: 14.0 ± 1.10 μA/cm^2 (PKI, n=11) and 21.0 ± 4.74 μA/cm^2 (SQ22,536n=8). Conversely, pre-incubation with PAO inhibited the response to Lp. The shift in I_{SC} with Lp was 8.58 ± 1.95 μA/cm^2 (n=10) approximately half of the observed control response. The $CFTR_{inh172}$-sensitive I_{SC} was also reduced at 8.86 ± 2.17 μA/cm^2 (n=10), again approximately half of the control response.
These data indicate that Lp has the ability to activate CFTR in human airway epithelial cells. The action of Lp appears to be independent of cAMP and PKA, the typical CFTR activation pathway, but, given the effect of PAO, appears to involve activation of a tyrosine phosphatase.

Lubiprostone activates CFTR in human bronchial epithelial cells via a prostanoid receptor dependent process

J. Przeworek[1], H. Samvelyan[1], A. Hassouni[1], C. Taylor[2] and L. Robson[1]

[1]Biomedical Science, University of Sheffield, Sheffield, UK and [2]Paediatric Gastroenterology, Sheffield Children's Hospital, Sheffield, UK

In human bronchial epithelial cells the cAMP-activated Cl^- channel CFTR mediates Cl^- secretion. This critical role is highlighted in cystic fibrosis, where CFTR mutations impact significantly leading to defective muco-cilliary clearance and an increased risk of infection. Previous work has suggested that the fatty acid lubiprostone (Lp) activates CFTR in ovine airway via a prostanoid receptor-dependent process [1]. In the current study the mechanism of action of Lp in human bronchial cells (16HBE14o–) was investigated.

Cells were grown on permeable supports until confluent (transepithelial resistance of at least 200 Ωcm^2). Inserts were mounted in an Ussing chamber with standard Krebs (basolateral side) and low Cl^- Krebs (apical side). Solutions were bubbled (5% CO_2), and all potential and resistance measurements corrected. 10 μA of current was injected to calculate the equivalent short circuit current (I_{SC}). Control measurements were taken for 5 minutes and then 1 μM Lp added apically. At steady-state 10 μM $CFTR_{inh172}$ was then added to provide an indication of CFTR function. This was repeated in unpaired inserts in the presence of inhibitors for EP4 receptors (GW627368X or L161,982). Statistical significance was tested using ANOVAs and assumed at the 5% level.

Addition of Lp increased I_{SC} from 10.1 ± 1.74 μA/cm^2 to 26.2 ± 2.63 μA/cm^2 (n=23), a mean increase of 16.1 ± 2.21 μA/cm^2. In the presence of GW627368X or L161,982 the response to Lp was blunted, with mean increases of 6.26 ± 1.21 μA/cm^2 (n=14) and 7.64 ± 1.98 μA/cm^2 (n=9), respectively. Under control conditions $CFTR_{inh172}$ reversed the increase observed with Lp, a fall of 20.2 ± 2.29 μA/cm^2 (n=23). This effect of $CFTR_{inh172}$ post Lp was reduced by around 50% on pre-incubation with GW627368X or L161,982. The $CFTR_{inh172}$–sensitive I_{SC} was 10.7 ± 1.79 μA/cm^2 (n=14) and 9.55 ± 1.99 μA/cm^2 (n=9), respectively.

These data suggest that Lp activates CFTR in human airway via an EP4 receptor dependent process. Further work is needed to elucidate the downstream pathway involved and determine if any other EP receptors play a role in the response to Lp.

PCB176

Carbonic anhydrase II enhances activity of endogenous Na-H exchangers and not the Na/HCO_3 cotransporter, NBCe1, when expressed in *Xenopus* oocytes

F.J. Moss and W.F. Boron

Physiology & Biophysics, Case Western Reserve University, Cleveland, OH, USA

The carbonic anhydrase II (CAII) metabolon hypothesis predicts that CAII binds to electrogenic Na/HCO_3 co-transporters (NBCe1), enhancing their transport of HCO_3-related species. Using a short current-voltage (I-V) protocol (60 ms steps from the reversal potential, E_{rev}), the Boron Lab (BL) showed in 2006 that neither CAII injected into *Xenopus* oocytes expressing NBCe1 nor CAII fused to the NBCe1 C-terminus changed NBCe1 slope conductance (G), the proper measure of NBCe1 activity. Yet in 2007, using 10 s I-V steps and a holding potential (V_h) +100 mV from E_{rev}, Becker & Deitmer (BD) concluded the opposite. We hypothesized that the BD protocol accentuated CAII-mediated dissipation of long-distance HCO_3 and intracellular pH (pH_i) gradients in the cytoplasm, enhancing NBCe1 activity. However, we find that G is unchanged when V_h steps are increased to as long as 30 s. Even when NBCe1 carries large currents (approaching 2.5 μA; V_h= 0 mV), CAII does not enhance recovery rates of pH_i from CO_2-induced acidification, the magnitude of the peak NBCe1 current (ΔI), or G. NBCe1 functional expression levels were typically 3-fold greater in BL vs. BD experiments. However, CAII does not enhance ΔI, G, or the rate of sodium influx ($d[Na]_i/dt$) in oocytes expressing NBCe1 at BD-equivalent levels. These experiments used an N-terminally GFP-tagged NBCe1 construct, EGFP-e1 and purified recombinant human CAII. To replicate the entire BD protocol, we expressed non-EGFP-tagged NBCe1 and injected bovine CAII purified from blood, observing a small but significant CAII-mediated change in ΔI but not G (paired t-test $p<0.05$). However, EGFP-e1 expressing oocytes demonstrate no CAII-dependent changes in ΔI or G. Notably, both recombinant human and purified bovine sourced-CAII enhance, in a concentration-dependent manner, $d[Na]_i/dt$ in control oocytes not expressing NBCe1. The increase is 69% inhibited by 10 μM EZA and is completely and reversibly blocked by 50 μM EIPA. Repeating the BD protocol with oocytes expressing non-EGFP-tagged NBCe1 under constant 50 μM EIPA superfusion abolishes the CAII-mediated increase in ΔI. These data indicate that the catalytic activity of CAII enhances endogenous *Xenopus*-oocyte Na-H exchange, and not the activity of heterologously expressed NBCe1.

Confocal microscope observation on paracellular fluid transport in the vascularly perfused submandibular gland

M. Murakami[1], F. Wei[1], T. Narita[2], M. Fukushima[3], S. Hashimoto[4], Y. Shibukawa[4] and M. Sato[4]

[1]National Institute for Physiological Sciences, Okazaki, Japan, [2]Nihon University College of Bioresource Sciences, Fujisawa, Japan, [3]Nihon University School of Dentistry, Matsudo, Japan and [4]Tokyo Dental College, Chiba, Japan

Primary saliva is a mixture of fluid secreted through paracellular route and transcellular route. By quantification of luminal dye-dilution in the isolated acini with confocal microscopy, the transcellular fluid secretion was estimated as 25 μl/g-min. By subtraction of the transcellular fluid secretion from the whole fluid secretion, a paracellular fluid secretion was estimated to be 60 μl/g-min (1). By measurement of the 3H-labeled dextran in saliva, the two different sized paracellular routes were proposed; one is smaller than 5 Å in radius and the other is larger than 5Å (2). In addition the paracellular fluid secretion could include a pressure-dependent and a pressure-independent components; 20 and 40 μl/g-min, respectively (3). In the present study, to assess whether the pressure-dependent paracellular transport corresponds to the wider paracellular route, the submandibular salivary gland was surgically isolated from the rat (Wistar male) under anesthesia with pentobarbitone sodium (50 mg/kg body weight, i.p.). The isolated gland was perfused arterially on the stage of confocal microscope. Using sulfo-rhodamine B in the perfusate, we observed the appearance of the fluorescent dye in the intercellular canaliculi, which can pass through the larger route. The system allowed us to obtain 30 sliced images every 2 s and gave 3D reconstructed image every 2 s (5 Live, Zeiss). When the fluid secretion was induced by alpha1-adrenergic stimulation with phenylephrine, the fluorescence of intercellular canaliculi increased dose-dependently. Combined stimulation with phenylephrine and xamoterol (beta1 agonist) increased the fluorescence more than only phenylephrine. Single stimulation with isoproterenol (1 μM) decreased the fluorescence intensity in the canaliculi, suggesting lowering fluid secretion through pressure-dependent paracellular route. The present findings lead the conclusion that we could observe entry of fluorescent dye from intercellular space to luminal space by pressure-dependent paracellular route by solvent-drag, and that the fluid secretion through pressure-independent route is still open for further studies.

PCB178

Organic cation transporter subtypes of isolated mouse proximal tubules are differently regulated by protein kinases

E. Schlatter, S.K. Holle, D. Guckel, P. Klassen, V. Massmann and G. Ciarimboli

Medzinische Klinik D, University of Münster, Münster, Germany

This study characterizes the complex acute regulation of organic cation transporters (OCT) expressed in the basolateral membrane of isolated mouse proximal tubules (PT). A profound understanding of OCT transport regulation in mouse kidney is required especially as transgenic mouse models play a preeminent role in several pharmacological and physiological studies and in translational medicine and these transporters are involved in renal excretion of many drugs and organic substances used in experimental settings. The main OCT subtype in mouse PT is OCT1, and to a lesser extent (30%) OCT2, while OCT3 is only weakly expressed (1%). The fluorescent substrate ASP, 4-(-4-(dimethylamino) styryl-N-methylpyridinium, was used to quantify OCT transport across the basolateral membrane of isolated mouse proximal tubules (S2 and S3 segments) using a microtiter plate based fluorescence reader (excitation at 450 nm, emission at 590 nm). Tubules were mechanically isolated and transferred into a well of a 384 well microtiter plate. In PT (S2/S3 segments) of wildtype mice (WT) inhibition of phosphatidylinositol-3-kinase (PI3K) by wortmannin, of p56 tyrosine kinase (p56lck) by aminogenistein, stimulation of PKC by dioctanoyl glycerol and inhibition of PKA by KT5720 reduced ASP-uptake. Angiotensin II increased ASP-uptake via stimulation of Ca^{2+}/calmodulin (CaM). In PT isolated from OCT2-deficient mice, which express mostly OCT1, the regulation pattern was identical. In PT from OCT1/2 double knockout mice, expressing only OCT3, ASP uptake was grossly reduced and only the p56lck inhibition altered transport. In HEK293 cells, stably expressing OCT1, 2 or 3 identical findings were observed as in wildtype or OCT2-ko mice. In cells expressing OCT2 only inhibition of CaM activated transport while in cells expressing OCT3 again only the p56lck pathway altered transport. Analysing ASP-kinetics in PT of WT mice revealed that the PI3K, the p56lck, PKC or PKA pathways altered Vmax of the transport, suggesting a modification of transporter trafficking, while activation of CaM resulted in a decrease in Km suggesting an increase in substrate affinity.

In conclusion, acute regulation of mouse OCT in proximal tubules involves similar regulation of the main subtypes OCT1 and OCT2 by various pathways, while the OCT3, which shows only very low expression, is only regulated by p56lck. These effects mostly involve transporter trafficking and only in the case of CaM a modification of substrate affinity. This is the first report unveiling the complex pattern of short-term regulation of OC-transport in freshly isolated mouse PTs.

Adenosine regulates Cl^- channels in human adenocarcinoma cell monolayer

M. Hayashi[1], A. Inagaki[2] and H. Matsuda[1]

[1]Department of Physiology, Kansai Medical University, Hirakata, Japan and [2]Department of Physiology, University of Tokushima, Tokushima, Japan

Introduction: Pancreatic acini secrete ATP and nucleotide-modifying enzymes that include CD39 and CD73. Adenosine, the end product of ATP, elicited Cl^- efflux in pancreatic duct cells that express adenosine receptors (Novak *et al.* 2008). However, effect of adenosine receptors on anion secretion has not been extensively investigated. **Objectives:** The present study aimed to determine whether adenosine receptors regulate anion channels in pancreatic duct cells. **Methods:** Pancreas was obtained from male Wistar rats. Protocols involving handling of animals were approved by the Animal Experimentation Committee, Kansai Medical University. Animals were killed by cervical dislocation. The molecular basis of adenosine receptors was revealed by RT-PCR analysis and immunostaining. We measured equivalent short-circuit current (I_{sc}) in human adenocarcinoma cell line (Capan-1) monolayer. Statistical significance was evaluated using ANOVA. **Results:** Pancreas expressed adenosine A_{2A} receptor (*Adora2a*), confirming findings in previous study. Adenosine A_{2A} receptors localized in luminal membrane of rat ducts and Capan-1 monolayer. The luminal addition of adenosine (100 μM) significantly increased I_{sc} in Capan-1 monolayer (n = 25). The effect was consistent with Cl^- secretion in epithelia. This increase was inhibited by 5-nitro-2-(3-phenylpropylamino) benzoic acid, niflumic acid, or CFTRinh-172 (n = 5). **Conclusion:** These results indicated that the adenosine A_{2A} receptors regulate both Ca^{2+}-activated Cl^- channels and cystic fibrosis transmembrane conductance regulator in Capan-1 cells. Furthermore, the adenosine A_{2A} receptors may be involved in anion transport in pancreatic ducts.

Changes in Na+ metabolism and their effects on nutrient absorption in claudin 15 knockout mice

H. Hayashi, Y. Komatsu, M. Watanabe and Y. Suzuki

University of Shizuoka, Shizuoka, Japan

It is known that the claudin family of tight junction proteins is critical in determining paracellular ionic permeability and selectivity. We have shown that loss of claudin 15 results in decreased luminal Na+ concentration and glucose malabsorption in the small intestine. To gain further insight into the relationship between intestinal Na+ metabolism and changes in nutrient absorption induced by the loss of claudin 15, we investigated the site of absorption of electrolytes and nutrients in claudin 15 knockout (cldn15KO) mice and compared this with wild-type mice under in vivo conditions. Mice were fed a powdered diet supplemented with 14C-polyethylene glycol (PEG) 4000 as a non-absorbable marker and 3H-Gly-Sar (non-hydrolyzable dipeptide) or glucose. Three hours after feeding, the small intestine was isolated and divided into six segments, the luminal contents collected for analysis of Na+, K+, and Cl- concentrations and the level of 14C-PEG4000. Na+, K+, and Cl- concentrations were determined using ion-selective electrodes. Glucose concentration was determined by colorimetry. Gastric emptying time, assessed by measuring 14C-PEG4000, was decreased in cldn15KO compared to wild-type mice. Total luminal contents in the small intestine were increased in cldn15KO mice and the retention time of digesta in the upper jejunum was increased approximately 3-fold compared with wild-type mice. Robust Na+ secretion and rate of absorption were observed in the upper jejunum in wild-type mice and this was attenuated in cldn15KO mice. The rate of K+ absorption was increased in cldn15KO mice in the lower ileum. Total luminal glucose and Gly-Sar were increased, while absorption rates of glucose and Gly-Sar were decreased, in the upper jejunum of cldn15KO mice. These results suggest that the sites of absorption and secretion of electrolytes and nutrients are changed by adaptation to the loss of claudin 15.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB181

Erythrocyte Na+-K+ ATPase activity in normotensive underweight, overweight and obese women

A.O. Soladoye, O.E. Ayoola and L.A. Olatunji

Cardiovascular and Membrane Physiology Unit, Department of Physiology, University of Ilorin, Ilorin, Nigeria

Altered activity of transmembrane cation transport has been linked to non-communicable diseases (NCDs) related to obesity. The present study therefore sought to determine the activity of Na+-K+-ATPase in erythrocytes of underweight, normal weight, overweight and obese women. A total of 36 normotensive non-smoker Nigerian women categorized as underweight, normal weight, overweight and obese were enrolled to participate in the study. Membranes of their erythrocytes were harvested and processed for Na+-K+ ATPase activity. Written consent was obtained from the participants for the study. The result showed that Na+-K+ ATPase activity of underweight as well as those of the overweight and obese women were significantly reduced when compared with that of the normal weight women. Impairment of the activity of Na+-K+ ATPase in obese women was significantly greater than those observed in overweight and underweight individuals. Multivariate regression analysis indicated that age is the strongest independent determinant of the activity of Na+-K+ ATPase in underweight women. However, body weight was indicated as the strongest independent determinant of the activity of Na+-K+ ATPase in overweight and obese women. The findings in the present study demonstrate that overweight and obesity as well as underweight are associated with impaired erythrocyte Na+-K+ ATPase activity in women. Furthermore, advanced age may seem to explain the reduced activity of the erythrocyte Na+-K+ ATPase activity in underweight while increase body weight may explain the activity in overweight and obese women.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB182

Mathematical modeling of bicarbonate versus carbonate transport by the electrogenic Na^+/HCO_3^- cotransporter

R. Occhipinti, S. Lee and W.F. Boron

Physiology and Biophysics, Case Western Reserve University, Cleveland, OH, USA

The electrogenic Na^+/HCO_3 cotransporter (NBCe1) regulates acid/base movements in many epithelia (e.g., renal proximal tubule, pancreatic duct) and regulates intracellular pH in numerous cell types (e.g. neurons, glia). In glia, NBCe1 plays an important role during neuronal activity. As neurons fire action potentials, they release K^+ into the extracellular microenvironment, depolarizing glia and causing NBCe1 to import HCO_3^-, thus acidifying the extracellular microenvironment. In 1994, Grichtchenko and Chesler observed that this depolarization-induced extracellular acidification is accentuated by inhibition of extracellular carbonic anhydrase (CA), and suggested that NBCe1 carries one carbonate (CO_3^{2-}) rather than two HCO_3^-. The theory that NBCe1 transports CO_3^{2-} is supported by the results of experiments performed by Lee and Boron in our own laboratory in which acetazolamide (ACZ), a CA blocker, accentuates surface pH (pH_S) changes in oocytes co-expressing NBCe1 and CAIV.
Here we use a three-dimensional mathematical model of a *Xenopus* oocyte to investigate the consequences on pH_S of the influx of two bicarbonate ions (HCO_3^- model) versus the influx of one carbonate ion (CO_3^{2-} model) when CAIV is active or not. The CO_3^{2-} model predicts a change in pH_S that is markedly enhanced by ACZ, in agreement with the experimental data. Thus, we conclude that NBCe1 cannot be a pure bicarbonate transporter. We performed additional simulations in which we implemented simultaneous transmembrane fluxes of carbonate and bicarbonate, with different carbonate/bicarbonate molar ratios but assuming the same total net flux. These simulations lead us to conclude that carbonate is the dominant substrate of NBCe1.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB183

Expression of human heteromeric amino acid transporters in the yeast Pichia pastoris

A. Rosell[1,3], M. Costa-Torres[1,3], E. Álvarez-Marimon[1,3], A. Zorzano[1,3], D. Fotiadis[2,4] and M. Palacín[1,3]

[1]Institute for Research in Biomedicine, Barcelona, Spain, [2]Institute of Biochemistry and Molecular Medicine, Bern, Switzerland, [3]University of Barcelona, Barcelona, Spain and [4]University of Bern, Bern, Switzerland

Human heteromeric amino acid transporters (HATs) play key roles in renal and intestinal re-absorption, cell redox balance and tumor growth. These transporters are composed of a heavy and a light subunit, which are connected by a disulphide bridge. Heavy subunits are the two type II membrane N-glycoproteins rBAT and 4F2hc, while L-type amino acid transporters (LATs) are the light and catalytic subunits of HATs. We tested the expression of human 4F2hc and rBAT as well as seven light subunits in the methylotrophic yeast Pichia pastoris. 4F2hc and the light subunit LAT2 showed the highest expression levels and yields after detergent solubilization. Co-transformation of both subunits in Pichia cells resulted in overexpression of the disulphide bridge-linked 4F2hc/LAT2 heterodimer. Two sequential affinity chromatography steps were applied to purify detergent-solubilized heterodimers yielding ~1 milligram of HAT from 2 liters of cell culture. Our results indicate that Pichia pastoris is a convenient system for the expression and purification of human 4F2hc/LAT2 for structural studies.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Carbonic anhydrase II enhances transport activity of monocarboxylate transporters via direct interaction

H.M. Becker[1], H. Heidtmann[1,2], S. Noor[1], S. Dietz[1], M.H. Stridh[2], M. Klier[2], C.D. Boone[3], R. McKenna[3] and J.W. Deitmer[2]

[1]Division of Zoology / Membrane Transport, Department of Biology, University of Kaiserslautern, Kaiserslautern, Germany, [2]Division of General Zoology, Department of Biology, University of Kaiserslautern, Kaiserslautern, Germany and [3]Department of Biochemistry and Molecular Biology, University of Florida, Gainesville, FL, USA

The proton-linked monocarboxylate transporters MCT1-4 play a crucial role in the shuttling of lactate between glycolytic and oxidative cell types in different tissues like muscle and brain. Using heterologous protein expression in *Xenopus* oocytes, we have recently reported that carbonic anhydrase isoform II (CAII), a ubiquitous enzyme catalyzing the equilibration of carbon dioxide, protons and bicarbonate enhances transport activity of MCT1 and MCT4, while leaving transport activity of MCT2 unaffected. This interaction is independent of CAII catalytic activity, but is mediated by an intramolecular H^+-shuttle within the enzyme (1-4). In a further study we could demonstrate that endogenous CAII co-localizes with MCT1 in mouse astrocytes in which it enhances lactate flux by a non-catalytic mechanism (5).
Comparison of the protein sequence of MCT1, 2 and 4 revealed potential binding sites for CAII in the C-terminal of MCT1 and 4, but not in MCT2. For identification of the binding sites, truncation and single site mutations were placed in the C-terminal tail of MCT1 and MCT4. The transporters were heterologously expressed in *Xenopus* oocytes with and without CAII and transport activity was determined with pH-sensitive microelectrodes. Oocytes were surgically removed under sterile conditions from *Xenopus laevis* females anaesthetized with 1 g/l of 3-amino-benzoic acid ethylester (MS-222) in their bath. The experiments revealed that the acidic amino acid clusters $E^{489}EE$ in MCT1 and $E^{431}EE$ in MCT4 are crucial for the functional interaction with CAII. Direct binding of CAII to MCT1 and MCT4, respectively, via these acidic clusters was confirmed by protein biochemical analysis. To confirm that the inability of CAII to enhance transport activity of MCT2 is due to the absence of an appropriate binding site within the transporters C-terminal, we exchanged the last seven amino acids of the MCT2 C-terminal with the corresponding amino acids of the MCT1 C-terminal (R^{483}DKESSI to P^{483}AEEESP), creating a putative CAII

binding site. Expression of the mutant in *Xenopus* oocytes showed that the insertion of this binding site indeed enabled CAII to enhance transport activity of MCT2.
Our results suggest that the modulation of MCT1/4 transport activity by CAII requires direct interaction between transporter and enzyme, which is mediated by a glutamic acid cluster within the C-terminal tail of the MCTs.

PCB186

y^+LAT1 conditional KO mice as the first animal model for LPI

S. Bodoy[1], M. Espino[2], R. Artuch[3] and M. Palacín[1,4]

[1]Institute for Research in Biomedicine, Barcelona, Spain, [2]Medical and Molecular Genetics Center, IDIBELL, L'Hospitalet de Llobregat, Spain, [3]Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain and [4]Universitat de Barcelona, Barcelona, Spain

Lysinuric protein intolerance (LPI, MIM 222700) is an inherited aminoaciduria caused by defective cationic amino acid (CAA) transport at the basolateral membrane of epithelial cells in kidney, and also intestine. As a consequence, intestinal absorption and renal reabsorption of CAA are impaired. LPI is caused by mutations in the SLC7A7 gene, which encodes y^+LAT1 transporter [1]. Typically, symptoms begin after weaning with refusal of feeding, vomiting, diarrhea, and consequent failure to thrive. Hepatosplenomegaly, osteoporosis, hematological anomalies, neurological involvement, including hyperammonemic coma are recurrent clinical features [2]. Major complications are immune-like disorders, such as: pulmonary alveolar proteinosis and chronic renal disease, which are increasingly observed in LPI patients [3] without a known pathogenetic mechanism. Because null Slc7a7 mice is lethal [4], we recently generated the ubiquitous and tamoxifen-inducible ablation of Slc7a7 in mouse (*Slc7a7* $^{-/-}$). LPI patients treatment, low-protein diet and citrulline supplementation [5], is needed to maintain *Slc7a7*$^{-/-}$ mice alive. Under these circumstances (8% of protein in the diet) *Slc7a7*$^{-/-}$ mice showed hyperglutaminemia and orotic acid urine excretion suggesting urea cycle dysfunction. As in humans, low arginine and ornithine plasma concentration may be at the basis of the urea cycle dysfunction of LPI mice. *Slc7a7* $^{-/-}$ mice, like LPI patients, hyperexcrete cationic (lysine, arginine and ornithine) and some neutral amino acids (*e.g.* glutamine, alanine). Renal clearance of CAA is increased and also % of tubular reabsorption of Arg, Orn, Lys and some neutral amino acids is reduced.
In summary, we have generated the first LPI animal model that allows us to study the mechanisms of pathophysiology of LPI.

Cesium inhibited HeLa cells proliferation

D. Kobayashi, K. Kakinouchi, K. Matsumura and A. Hazama

Fukushima Medical University, Fukushima, Japan

Cesium (Cs), as well as potassium (K), is a member of alkaline metal elements. In the study of transporter, Cs has been used as a K channel blocker on cells. Doses of CsCl by the intraperitoneal route in mice indicated that a rapid transfer of Cs from blood to tissue compartments (Pinsky and Bose, 1984). Distribution of Cs in the whole bodies had been investigated. However, it is not clear that how the Cs is transported through which kinds of way at the molecular levels, and that the effect of Cs on the cell metabolisms. We examined the proliferation of HeLa cells cultured by Dulbecco's modified Eagle medium supplemented with 10% fatal bovine serum and 10 mM of different types of alkali metals such as Li, Na, K, Rb, and Cs at 37 degree C, 5% CO2. Among them, only Cs inhibited the proliferation of the cells. The proliferation decrease is dependent on Cs concentration. Microscopic examination of the Cs-treated

cells, cell membrane was not smoothly. Two different methods of live and dead assay were performed (i.e., lactose dehydrogenase-release assay and cytometry of Calcein-propidium iodide stained cells). In the Cs concentration that showed inhibition of cell proliferation, the HeLa cell membrane was not damaged by Cs. To confirm extracellular Cs uptake into the cell, intracellular cations were analyzed by capillary electrophoresis (P/ACETM MDQ). The intracellular cation content was analyzed as magnesium-based intracellular cation ratio. The intracellular Cs was detected in Cs-treated cells but not in control cell. The intracellular pH was measured by use of the pH-sensitive dye indicator BCECF. Alkalization of intracellular pH was occurred in the cells cultured with CsCl, but not in the cells cultured with the other alkali metals. Generally, intracellular pH of tumor cells was lower than normal cells. It is considered that Cs added to extracellular media uptake into the cells, and inhibition of cell proliferation possibly due to intracellular alkalization induced by Cs administration.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Human pancreatic duct cells express functional gastric and non-gastric H^+/K^+ ATPases and are sensitive to proton pump inhibitors

I. Novak and J. Wang

Department of Biology, University of Copenhagen, Copenhagen, Denmark

The mechanism by which pancreatic ducts secrete high HCO_3^- has not been fully resolved. This alkaline secretion can be achieved by transporting HCO_3^- from serosa to mucosa or by moving H^+ in the opposite direction. Earlier studies have been focusing on HCO_3^- transport. In the accepted secretion model, basolateral Na^+/H^+ exchangers (NHE) and/or Na^+-HCO_3^- cotransporters (NBC) contribute to cellular HCO_3^- accumulation, while luminal Cl^-/HCO_3^- anion exchangers (AE) release HCO_3^- to lumen. Recently, we have considered the active H^+ transporters, i.e. H^+/K^+ ATPases, and found them expressed and functional in rat pancreatic ducts (1). The aim of the present study was to determine whether also human pancreatic ducts express functional H^+/K^+ ATPases. The expression of H^+/K^+ ATPases was analyzed in human pancreatic duct cell lines (CAPAN-1, CFPAC-1 and PANC-1) by RT-PCR, western blot and immunostaining. Function of H^+/K^+ ATPases was estimated by intracellular pH (pHi) measurements in CAPAN-1 cells. Values are given as mean ± S.E.M., compared by paired student t-test. Both gastric and non-gastric alpha subunits of H^+/K^+ ATPases were found in CAPAN-1, CFPAC-1 and PANC-1 cells on both mRNA and protein levels (n=3 in each series). Also gastric beta-subunit of the pump was detected in duct cell lines (n=3). Localization of H^+/K^+ ATPase subunits in CAPAN-1 monolayers was confirmed by immunohistochemistry and confocal microscopy (n>10 preparations). In order to verify the function of pumps, we used Na^+ and HCO_3^- free solutions to eliminate the contribution of NHE, NBC and AE on pHi. In ducts stimulated with secretin (1 nM), Na^+ independent pHi recovery from acidosis was reduced by 75% in the presence of gastric H^+/K^+ ATPase inhibitor omeprazole (10 μM, n=6, $p < 0.05$); SCH28080 inhibited the recovery by 52% (10 μM, n=5, $p < 0.05$). We demonstrated both types of H^+/K^+ ATPases in human pancreatic duct cell lines, and their sensitivity to H^+/K^+ ATPase inhibitors indicates their potential role in the acid-base transport in human pancreas. We propose that the evidence for expression of H^+/K^+ ATPases in pancreas calls for revision of the model for HCO_3^-/H^+ transport as well as for the use of proton pump inhibitors.

Chimeric constructs endow human CFTR with the sub-conductance state of murine CFTR

Z. Cai[1], I. Callebaut[2], D. Lea-Smith[3], B.J. Stevenson[3], A. Doherty[3], H. Davidson[3], D.J. Porteous[3], J. Mornon[2], P. Lehn[4], A. Boyd[3] and D.N. Sheppard[1]

[1]School of Physiology and Pharmacology, University of Bristol, Bristol, UK, [2]UMR7590, CNRS, Université Pierre et Marie Curie-Paris 6, Paris, France, [3]Medical Genetics Section, Molecular Medicine Centre, Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, UK and [4]INSERM U1078, Université de Bretagne Occidentale, Brest, France

Cystic fibrosis transmembrane conductance regulator (CFTR) is an anion channel with complex regulation. To explore CFTR structure and function, we exploited functional differences between human and murine CFTR. When compared with human CFTR, murine CFTR has a reduced single-channel conductance (human, 8.29 ± 0.18 pS; murine, 5.76 ± 0.16 pS; [1]) and a distinct pattern of channel gating, characterised by prolonged residence in a sub-conductance state [2]; transitions to sub-conductance states are rare for human CFTR. In previous work, we demonstrated that transfer of both NBDs of murine CFTR endowed human CFTR with dramatically prolonged channel openings similar to those of the sub-conductance state of murine CFTR [3]. However, transfer of both NBDs failed to endow human CFTR with a sub-conductance state like that of murine CFTR [3]. To investigate whether the membrane-spanning domains (MSDs) define the sub-conductance state of murine CFTR, we constructed the human-murine CFTR (hmCFTR) chimeras hmTM1-6, hmTM7-12 and hmTM1-6:TM7-12 containing MSD1, MSD2 and MSD1+2 of murine CFTR and studied their single-channel behaviour in excised inside-out membrane patches. All hmCFTR chimeras exhibited a hybrid gating pattern intermediate between that of human and murine CFTR. Reminiscent of murine CFTR, channel openings were very flickery with open probability decreasing in the rank order: human CFTR > hmTM7-12 > hmTM1-6 > hmTM1-6:TM7-12. The single-channel current amplitude of the full open state of hmCFTR chimeras was smaller than that of human CFTR, decreasing in the rank order: human CFTR > hmTM7-12 > hmTM1-6 ≥ hmTM1-6:TM7-12. Like human CFTR, hmTM7-12 opened predominantly to the full open state; transitions to sub-conductance states were unusual. However, hmTM1-6 resided in multiple sub-conductance states, which were visualised in heavily filtered single-channel recordings and current amplitude histograms. Of note, like murine CFTR, hmTM1-6:TM7-12 resided in a tiny sub-conductance state and only sojourned infrequently to the full open-state. Consistent with hmTM1-6:TM7-12 possessing human NBDs, this construct resided in the sub-conductance state for much shorter periods than murine CFTR. Taken together, our data suggest that amino acid sequences from both MSDs specify the sub-con-

ductance state of murine CFTR and determine intraburst gating.

Impact of urate on prostate cancer development

E. Rodrigues and A. Bahn

Department of Physiology, University of Otago, School of Medical Sciences, Dunedin, New Zealand

Prostate cancer is among the four most diagnosed cancers worldwide and it is the most common cause of death in men above the age of 60 in New Zealand. Zinc levels play an important role in normal prostate cells and possibly prostate cancer development due to the fact that the metabolism of prostate glands is mainly based on zinc. It also is a co-factor for many proteins, of which the most prominent one is transcription factor p53. Zinc therefore has an important role in other cell processes. Recently, studies have indicated that patients diagnosed with prostate cancer have elevated levels of urate. This study is attempting to understand the implications of these elevated urate levels on prostate cancer development and to identify the urate transporter involved in these processes. Based on our gene array analysis we examined the regulation of two zinc transporters by urate, namely ZIP1 and ZIP3, in the normal prostate cell line PNT1A and in three prostate cancer cell lines LNCaP, DU145 and PC-3. ZIP1 mRNA and protein expression increased in PNT1A and PC-3 cells upon urate treatment, while they decreased in LNCaP cells and didn't change in DU145 cells. ZIP3 mRNA and protein expression was elevated in PNT1A cells in the presence of 500 μM of urate, but only protein levels were significantly reduced in DU145 and PC-3 cells. Similar to ZIP1 mRNA levels of ZIP3 were down-regulated in LNCaP cells after urate treatment. These results indicate that hyperuricemia has a significant impact on ZIP1 and ZIP3 expression in different stages of prostate cancer and especially in the non-aggressive stages, suggesting that urate may be involved in initial stages of cancer development. Using array analysis and real-time PCR, we were able to delineate the impact of urate on several miRNAs, especially miR-34a, which we have identified as a possible regulator for ZIP3. Exposure to high urate concentrations has significantly down-regulated miR-34a in all prostate cancer cell lines indicating that regulation of miR-34a may be the key mechanism to induce the transition from a normal prostate epithelial cell to a malignant proliferating and metastasising cell. We have identified other miRNAs such as miR-21, miR-106, miR-125 and miR-331, which are vital for the cell cycle and which are up-regulated by high urate plasma levels as well as miR-126 that is down-regulated by hyperuricemic conditions. Two of these, miR-21 and miR-126, are putative regulators of drug and zinc transporters. Further analysis of transporters facilitating the urate effect on prostate cancer cells identified GLUT9, which is known as the major renal urate transporter, as the main candidate. Investigations on primary prostate epithelial cells are underway to prove that high plasma urate levels contribute to the development of prostate cancer by regulating the p53/miR-34a pathway as well as zinc homeostasis, which are or are becoming the hallmarks of cancer.

Investigation of UT-B urea transporter isoforms in the human Ileum

C. Walpole[1], S. Edwards[1], D. Winter[2], A. Baird[3] and G. Stewart[1]

[1]School of Biology and Environmental Science, University College Dublin, Dublin, Ireland, [2]Institute for Clinical Outcomes Research and Education, St. Vincent's University Hospital, Dublin, Ireland and [3]Conway Institute of Biomedical and Biomolecular Science, University College Dublin, Dublin, Ireland

The entry of urea into the lumen of the gastrointestinal tract is facilitated by the urea transporter protein UT-B1. This stage is crucial to our intestinal wellbeing as it is the first step in the urea nitrogen salvaging mechanism which is necessary for healthy gut bacteria. In a previous study a 35kDa glycosylated signal of UT-B1 was strongly expressed in the ascending colon whereas it was almost absent in the descending colon. Our aim was to investigate the expression of UT-B in the whole gastrointestinal tract.

To investigate whether there are multiple UT-B isoforms in the GI tract, a number of primer sets were designed from the human UT-B gene. UT-B1 has been identified as the major, if not sole UT-B urea transporter at the RNA level. Using an antibody raised against bovine UT-B1 we found that the small intestine had the strongest 35kDa signal. Surprisingly the ileum had the highest percentage glycosylation, which deglycosylated to 30kDa as expected. There was a significant decrease in the amount of glycosylated UT-B1 from the ileum to the left colon. This may show importance of UT-B further up the GI tract than previously thought.

In the rat we found that UT-B was solely expressed in the large intestine. According to our results, unlike the rat, UT-B1 is expressed throughout the human GI tract. It is highly glycosylated in the ileum, which suggests it is functionally active here. Further investigation is needed to establish the physiological significance of these findings.

F508del and A561E: cystic fibrosis mutations that disrupt the trafficking, thermostability and gating of CFTR have differential sensitivity to small-molecule CFTR modulators

Y. Wang, J. Liu, C.V. Gorard, J.N. Povey, D.N. Sheppard and H. Li

Physiology & Pharmacology, University of Bristol, Bristol, UK

Cystic fibrosis (CF) is caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) Cl^- channel. In search of transformational drug therapies for CF patients, small-molecules have been identified that target defects in the expression and function of the commonest CF mutation F508del. However, relatively little is known about the mechanism of dysfunction of other CF mutations and their responses to small-molecules. Here, we investigate A561E, the second most common CF mutation in Portugal. CF patients homozygous for A561E have a clinical phenotype similar to that of F508del homozygotes (1, 2). Like F508del-CFTR, A561E-CFTR is a temperature-sensitive folding defect located in the first nucleotide-binding domain (1). To learn whether A561E perturbs CFTR thermostability and function, we investigated the single-channel activity of A561E-CFTR in excised membrane patches from BHK cells at 37 °C following rescue of its cell surface expression by low temperature incubation. Wild-type CFTR had robust channel activity that was stable over time. By contrast, A561E-CFTR exhibited paltry channel activity characterised by brief openings separated by prolonged closures that deactivated rapidly at 37 °C; like F508del-CFTR, A561E-CFTR rundown was complete within 8 minutes and irreversible. To learn whether small-molecules restore expression and function to A561E-CFTR, we studied the CFTR corrector VX-809 and the CFTR potentiators genistein, P2, P3, P4, P5 and P9 (all from Cystic Fibrosis Foundation Therapeutics (CFFT) except VX-809 (Selleck) and genistein (LC Laboratories)) using the iodide efflux technique. Incubation of BHK cells with VX-809 (3 μM) for 24-48 h at 37 °C restored some cell surface expression to F508del-CFTR, but little or none to A561E-CFTR. However, following low temperature incubation, all CFTR potentiators (genistein (50 μM), test potentiators (10 μM)) restored partial function to A561E- and F508del-CFTR. For wild-type CFTR, the rank order of potentiation was genistein ≥ P2 ≥ P9 ≥ P5 ≥ P4 > P3; for F508del-CFTR, it was genistein >> P2 ≥ P5 ≥ P4 ≥ P3 ≥ P9 and for A561E-CFTR, it was genistein > P4 > P9 ≥ P2 > P5 ≥ P3. We conclude that A561E perturbs CFTR thermostability and gating. Thus, the consequences of the A561E mutation are similar to those of F508del, despite the different impacts of the mutations on CFTR structure (3, 4). We further conclude that CFTR potentiators restore, albeit incompletely, function to A561E-CFTR, whereas the corrector tested had little or no effect. Therefore, transformational drug therapy for F508del- and A561E-CFTR will likely require different combinations of CFTR correctors and potentiators.

Na,K-ATPase studies in Mel-290 uveal melanoma cells that display unusual sodium and potassium concentrations

N. Delamere, E. de Turco and M. Shahidullah

Department of Physiology, University of Arizona, Tucson, AZ, USA

Among tumors of the eye, uveal melanoma is the most common. When metastases occur, mortality approaches 90 %. In studies on a particular uveal melanoma cell line, Mel-290, we discovered what appear to be abnormal steady state cellular levels of sodium and potassium. Measured by atomic absorption spectrometry, the ratio of sodium concentration to potassium concentration in Mel-290 cells was 0.57 compared to 0.1 in a different melanoma cell, OCM-3, and 0.15 in pig ciliary epithelium. Assuming the sum of Na + K concentration totals ~140 mM, Mel-290 cells have resting sodium concentration of approx. 50 mM which is considerably higher than the concentration expected in normal cells. Western blot studies were conducted to examine the Na,K-ATPase alpha 1 which is the most common isoform of Na,K-ATPase in human cells. Mel-290 displayed a lower abundance of Na,K-ATPase alpha 1 subunit protein compared to OCM-3. Differences in Na,K-ATPase alpha subunit phosphorylation also were observed. In contrast to Na,K-ATPase alpha 1, H/K-ATPase beta subunit and H-ATPase (v-ATPase) beta subunit were found by Western blot to be higher in Mel-290 compared to OCM-3. A high sodium:potassium ratio was detected in two other melanoma cell types, suggesting the possible existence of a high sodium sub-group of melanomas. More studies are required to determine whether the high-sodium phenotype is linked to a particular pattern of ATPase expression or regulation. It is noteworthy that high cytoplasmic sodium has been reported in certain liver, breast and brain tumors.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB194

Extracellular cysteine residues form a disulphide bridge in the amino acid transporter PAT2 (slc36a2)

N. Edwards and D.T. Thwaites

Institute for Cell & Molecular Biosciences, Newcastle University, Newcastle upon Tyne, UK

The proton-coupled amino acid transporters PAT1 (slc36a1) and PAT2 (slc36a2) are members of the SLC36 family of mammalian solute carriers (Thwaites & Anderson, 2011). PAT1 is expressed at the brush-border membrane of the small intestine whereas PAT2 is found at the luminal surface of the proximal convoluted tubule (Anderson *et al*. 2004, Bröer *et al*. 2008). Although both carriers transport a broad range of dipolar amino acids and derivatives, there are clear differences in substrate selectivity and affinity suggesting differences in substrate recognition and translocation. Using an *in silico* modelling approach, a high degree of structural homology (>97%) for PAT2 was detected against crystal structures for a number of apparently unrelated prokaryotic transporters. Homology modelling against the LeuT template (Yamashita *et al*. 2005) identified that the cysteine residues in PAT2 in extracellular loops 2 (C185) and 4 (C334) are likely in close spatial proximity. These cysteine residues are conserved in human, rat and mouse PAT1 and PAT2. In human PAT1, these residues form a disulphide bond that is essential for function (Dorn *et al*. 2009). The purpose of this investigation was to determine whether a similar disulphide bond was found in PAT2 and what role it might play in transporter function. Site-directed mutagenesis of rat PAT2 was performed and [^{3}H]amino acid uptake measured in *Xenopus laevis* oocytes in the presence or absence of the reducing agent DTT. The results were compared with those in mouse PAT1 and the *D. melanogaster* ortholog CG1139 (which does not possess cysteine residues at equivalent positions). [^{3}H]Proline uptake (mean ± SEM, n=17-20) in the presence of 30mM DTT showed a 90% reduction in PAT1 (3.42±0.34 pmol.oocyte^{-1} to 0.37±0.06 pmol.oocyte^{-1}), 50% reduction in PAT2 (4.67±0.41pmol.oocyte^{-1} to 2.37±0.25 pmol.oocyte^{-1}) but no change in CG1139 (8.42±0.99 pmol.oocyte^{-1} and 8.09±1.11 pmol.oocyte^{-1}). In PAT1, replacement of either C179 or C328 with serine or alanine reduced amino acid uptake by 70-80% whereas only a 55-60% reduction was observed in the equivalent PAT2 C185 and C334 mutants. Confocal microscopy revealed no apparent differences in membrane localisation. The double PAT1 mutant C179A/C328A was inactive whereas the double PAT2 mutant C185A/C334A retained ~50% activity. The PAT2 double mutant was insensitive to 30mM DTT. These observations demonstrate that conserved extracellular cysteine residues in PAT1 and PAT2 form disulphide bonds that appear to be essential for PAT1 and important in PAT2 for optimal function. The role of the disulphide bridge is not known but is likely important in optimisation of substrate binding and translocation. The relative dependence of PAT1 and PAT2 on the disulphide bond may partly account for differences observed in transporter function.

PCB195

Plasmonic gold nanoparticles as a possible potassium channel opener in vascular smooth muscle cells

A. Soloviev[1], I. Ivanova[1], T. Novokhatska[1], S. Zelensky[1], A. Raevska[2], A. Stroyuk[2], V. Ephanov[2] and I. Parneta[2]

[1]Institute of Pharmacology and Toxicology, Kiev, Ukraine and [2]NanoMedTech LLC, Kiev, Ukraine

Potent perspectives of noble nanoparticles (NPs) for biomedical applications are well known but fundamental studies of their molecular interaction with target cell remain largely unexplored. Potassium channels play an important role in the membrane potential regulation in vascular smooth muscle (SM) cells and closely involved in vascular tone regulation. Voltage-gated ionic channels are expected to be modulated by plasmon resonance occurred on surface of gold nanoparticles (AuNPs) leading to alterations in their functionality but the amplitude and directionality of this effect need to be investigated.

Colloidal AuNPs, having plasmon resonance of 525 nm, were synthesized by modified Turkevich method (2006) via reduc-

tion of sodium tetrachloroaurate by sodium ascorbate in aqueous solutions at room temperature. A dynamic light scattering study showed that AuNPs have average hydrodynamic size ~ of 5 nm core size and Zeta-potential of - 35 mV. Experimental design of the study comprised SM contractile recording combined with simultaneous fluorescent intracellular calcium concentration ([Ca2+]i) measurement in isolated rat aortic rings and ionic currents measuring in enzymatically isolated from rat aorta a single cells using patch clamp technique in whole-cell modification.

When externally applied to the organ bath solution, AuNPs (10-6–10-4 M) decreased amplitude of norepinephrine-induced contractions in dose-dependent and endothelium-dependent manner but endothelium disruption did not abolished AuNPs-induced relaxation completely. AuNPs relaxed SM in the absence of decrease in [Ca2+]i. while [Ca2+]i in endothelial cells had increased. All cells demonstrated clearly expressed tail currents suggesting that the currents measured were mainly due to activation of outward potassium channels. Being added to the bath solution in doses close to EC50, AuNPs significantly increased whole cell peak K+ current density (IK) at + 70 mV from 33± 2pA/pF to 57±5 pA/pF (n=14, P < 0.05). Outward current oscillation associated probably with a MaxiK+ channels opening and correlated with [Ca2+]i were seen under AuNPs treatment. When irradiated by 5 mW/532 nm green laser to facilitate plasmon resonance, AuNPs significantly increased both the amplitude of maximal AuNPs-induced relaxation from 46.4±4.7% to 61.3±5.3% (n=10, P<0.05) and sensitivity of SM to AuNPs. Mean value of pD2 were 4.5±0.002 and 4.4±0.04, respectively (n=10, P<0.05). External irradiation increased AuNps-induced increment in IK from 57±5 pA/pF to 98±6 pA/pF (n=10, P < 0.05).

In summary, plasmonic AuNPs are able to open K+- channels and relax SM in both endothelium-dependent and independent manner. One plausible explanation for AuNPs action is the interaction of the channel voltage sensors with local electric field on AuNPs surface. In case of laser irradiation this local electrical field enhanced due to local plasmon resonance which, in turn, increases IK and SM relaxation. In the absence of external irradiation such plasmon may be excited by natural tissue chemoluminescence in the presence of nonlinear effects on AuNPs surface. Of course, further research of AuNPs toxicity and functionality are necessary to create a safe and effective tool for pharmacological intervention which would be able to modulate IK but the data obtained clearly indicate that AuNPs possess the ability to initiate or facilitate K+ channel opening in vascular SM.

Time-resolved spectroscopy and imaging of mitochondrial metabolic state in living cells

J. Horilova[1,2], D. Chorvat[1], A. Mateasik[1] and A. Chorvatova[1]

[1]International Laser Centre, Bratislava, Slovakia and [2]Faculty of Science, Pavol Jozef Safarik University, Kosice, Slovakia

Monitoring processes underlying mitochondrial homeostasis is crucial for understanding of the cell energetics. Nevertheless, we still lack appropriate non-invasive methods capable to evaluate these processes directly in living systems. In the last decades, time-resolved spectroscopy of endogenous fluorescence has been shown a perspective approach for non-invasive investigation of metabolic changes. Combination of time-resolved fluorescence measurement and imaging, known as Fluorescence Lifetime Imaging (FLIM), provides a deeper insight into natural mitochondrial metabolism and has thus been proven as an advanced diagnostic and imaging tool. We studied cell autofluorescence, derived from endogenous fluorophores present in living cells naturally, without need of fluorescent dyes or probes. To evaluate fluorescence lifetimes in combination with fluorescence spectra and/or images, we have applied Time-correlated Single Photon Counting (TCSPC), after excitation with pulsed picosecond lasers. We focused at fluorescence derived from NAD(P)H (excitation 375nm) and flavins (excitation 450-477nm) to characterize changes in the mitochondrial metabolic state in living cells. Activators and inhibitors of the respiratory chain were applied to quantify recorded metabolic changes. Different cell types were compared, ranging from cardiac cells to cancer cell lines. Separation of individual components from complex fluorescence signals is crucial for correct analysis of measured data. Spectral characteristics, unique for each fluorophore, are one way of fluorophore identification in complex biological samples. However, spectra of endogenous fluorophores are often overlapping, which is complicating data analysis. Time-resolved fluorescence decay patterns are additional effective means of

separation of distinct fluorophores. We demonstrate application of advanced analytical approaches for the the extraction of individual fluorescence components from the recorded time-resolved spectroscopy datasets, including the spectral linear unmixing, principal component analysis and blind source separation. Presented study of the time-resolved spectroscopy and imaging of mitochondrial metabolic state in living cells has great potential to improve several biomedical applications, including early diagnostics and treatment of complex diseases, which are often linked with modifications in cellular energetics.

Hepatoprotective role of ashwagandha (withania somnifera) root extract against gentamicin induced liver damage in rats

N. Sultana

Physiology, Sir Salimullah Medical College, Dhaka, Dhaka, Bangladesh

Liver damage can be occurred due to prolong use of some drugs, exposure to some chemicals or infectious agents1. But liver protective drugs are not available. Many hepatoprotective herbal medicines are often used in the treatment of liver damage. Ashwagandha belongs to the family of solanaceae, is the traditional ayurvedic medicine2, has free radical scavenging activity3 and can be used for the prevention of liver damage4. So, the study was undertaken to observe the hepatoprotective role of ashwagandha root extract against gentamicin induced liver damage in rats. This study was conducted from January to December' 2011 in the Department of Physiology, Sir Salimullah Medical College (SSMC), Mitford, Dhaka, Bangladesh. Total 35 apparently healthy Wistar albino male rats, weighing between 150 to 200 grams, age from 90 to 120 days were used. The animals were purchased from animal house of Bangladesh Council of Scientific and Industrial Research (BCSIR), Dhaka. Ethical permission was taken from the Institutional Ethics Committee (IEC) of SSMC, Mitford, Dhaka and also from the Bangladesh Society of Physiologists (BSP). Prior conducting the study, the animals were acclimatized for 14 days at 23±2degree centigrade room temperature under 12 hour dark- light cycle. During this period, they had free access to food and water ad libitum. After 14 days of acclimatization, body weights were measured, again final body weights of rats before anaesthetized on 23rd day were taken. The rats were divided into control (Group A) and experimental (Group B) groups. Control group was again subdivided into baseline control, (Group A1, consisted of 10 rats) and gentamicin treated control group (Group A2, consisted of 10 rats). Again, experimental group (gentamicin treated group after ashwagandha treatment) consisted of 15 rats. All groups of animals received basal diet for 22 consecutive days. In addition to this, gentamicin treated control group also received gentamicin subcutaneously (100mg/kg body weight/day) for the last eight days. Again, experimental group received ashwagandha root extract (500mg/kg body weight/day, orally) for 22 consecutive days and gentamicin subcutaneously (100mg/kg body weight /day) for last eight days. Then all animals were anaesthetized with the help of chloroform and sacrificed on 23rd day. Their blood samples were collected and liver was removed and was washed in ice cold saline. Then it was wiped in tissue paper, weighed by electric balance analyzer. Blood was centrifuged at the rate of 4000 rpm for 5 minutes and supernatant serum was collected. Out of 35 serum samples, four were hemolyzed. So, 31 samples were estimated. Liver function was assessed by estimating serum levels of aspartate amino transferase (AST), alanine amino transferase (ALT) and bilirubin. However, histological findings of liver tissue were observed under microscope to assess their changes. Values were expressed as mean+SD. Statistical analysis were done by one way ANOVA and Bonferroni test as applicable. Mean serum levels of AST and ALT were significantly higher in gentamicin treated control (90.89+4.53 and 99.11+ 5.26 IU/L respectively, $p<0.001$) and gentamicin treated group after ashwagandha treatment (50.62+2.14 and 54.69+2.93 IU/L respectively, $p<0.05$) in comparison to those of baseline control group (47.33+3.74 and 50.11+2.47 IU/L respectively). Again, these levels of gentamicin treated group after ashwagandha treatment (50.62+2.14 and 54.69+2.93 IU/L respectively) were significantly ($p<0.001$) lower than those of gentamicin treated control group. Serum level of bilirubin was significantly higher in gentamicin treated control group (2.40+1.03 mg/dl, $p<0.001$) and gentamicin treated group after ashwagandha treatment (1.45+0.49 mg/dl, $p<0.01$) in comparison to that of baseline control (0.64+0.12 mg/dl). Again, this level of gentamicin treated group after ashwagandha treatment was significantly ($p<0.01$) lower than that of gentamicin treated control group. Histological examination of liver revealed abnormal findings in 100% of rats in gentamicin treated rats. Again, 84.62% of rats in gentamicin treated group after ashwagandha treatment showed almost normal structure in liver. This data suggests that higher doses of gentamicin produce hepatocellular damage, which can be prevented by taking ashwagandha, due to its antioxidant property5. Some active components of aswagandha have anti-inflammatory property6 thus may be responsible for this hapetoprotectine role 7.

The roles of hepcidin and ferroportin in autocrine regulation of iron levels

S. Lakhal-Littleton, D. Biggs, R. Diaz, A. Santos, C. Peerce, B. Davies and P. Robbins

DPAG, University of Oxford, Oxford, UK

Liver-derived hepcidin Hamp regulates iron homeostasis by downregulating ferroportin Fpn expression at the sites of iron absorption (duodenal enterocytes), recycling (reticuloendothelial macrophages) and storage (liver). However, Fpn and Hamp are also expressed in tissues not associated with systemic iron handling, such as the heart, skeletal muscle, lung and brain, raising the possibility of autocrine iron regulation in these tissues. Current mouse models of ubiquitous gene deletion do not enable us to address this hypothesis due to the confounding effects of ubiquitous loss of Hamp and Fpn on systemic iron levels. To overcome this limitation, we have used the LoxP Cre technology to enable tissue-specific manipulation of Hamp and Fpn expression in the mouse. Here we describe, for the first time, the generation and biochemical validation of three mouse models: 1) tissue-specific Hamp knockout, 2) tissue-specific Fpn knockout and 3) tissue-specific Fpn C326Y knock-in (hamp-resistant). Our animal models are valuable tools for micro-dissecting iron regulation at a single-tissue level in health and in disease. They will help achieve the mechanistic understanding necessary for the development of evidence-based iron manipulation therapies for diseases where iron dysregulation contributes to pathogenesis

The antioxidant effect of water melon on paracetamol induced liver toxicity

M. Pipedi-Tshekiso, P. Chaturvedi and A. Kefentse Tumedi

Department of Biological Sciences, Faculty of Science, University of Botswana, University of Botswana, Botswana

Vegetables and fruits are well known for their protective effects against oxidative stress because of their antioxidant properties. In the present studies locally available watermelon has been evaluated for its protective effects against paracetamol induced oxidative stress in albino rats. Three doses of fresh water melon extract (2.5ml, 5.0 ml and 7.5 ml per Kg body weight) along with paracetamol (125mg/Kg body weight) have been administred orally to three groups (5 each) of experimental rats for 30 days. Paracetamol control group was administered only paracetamol (125mg/Kg body weight) and normal control group was given equal volume of distilled water.. Rats were killed on day 31 after ether anaesthesia and blood was collected from brachial artery in heparin coated centrifugation tubes. Blood was centrifuged and plasma was separated to measure thiobarbituric acid reactive substances, serum glutamate oxaloacetate transaminase, serum glutamate aspartate transaminase, reduced glutathione, tocopherol, glutathione per oxidase and super oxide dismutase. Results indicate that fresh watermelon extract inhibits lipid peroxidation, boosts the levels of glutathione and tocopherol. It also enhances the activity of super oxide dismutase and glutathione peroxidase. Carotenoid contents of watermelon might be the cause of its protective effects which are absorbed readily from the intestine after its intake.

Key words Carotenoids, thiobarbituric acid reactive substance, glutathione, super oxide dismutase, glutathione peroxidase.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Expression and function of Slc26a9 member of the Slc26 anion transporter family in the gastrointestinal tract

X. Liu[1,2], T. Li[1,3], B. Riederer[1], A. Singh[1], W. Xia[1,4], Q. Yu[1,5], P. Song[4], B. Tuo[2], D. Tian[5], M. Soleimani[6] and U. Seidler[1]

[1]Clinic for Gastroenterology, Hepatology and Endocrinology, Hannover medical school, Hannover, Germany, [2]Department of Gastroenterology, Affiliated Hospital of Zunyi Medical College, Zunyi, China, [3]Department of Gastrointestinal Surgery, Affiliated Hospital of Zunyi Medical College, Zunyi, China, [4]Key Lab of Combined Multiorgan Transplantation, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China, [5]Department of Gastroenterology, Tongji Hospital, Huazhong University of Science & Technology, Wuhan, China and [6]Center on Genetics of Transport and Epithelial Biology, University of Cincinnati, Cincinnati, OH, USA

Background: We recently identified Slc26a9 as an anion conductance that is upregulated in airway inflammation and prevents bronchial mucus obstruction (Anagnostopoulou et al. JCI 2012). Slc26a9 variants were recently found associated with meconium ileus in cystic fibrosis infants (Sun et al. Nature 2012). Aim: The association with meconium ileus raises the question where Slc26a9 is expressed in the gastrointestinal tract and what is its function. Methods: Acid, HCO_3^-,short circuit current (Isc) measurements were performed in isolated mucosa and acid, HCO_3^- and fluid absorptive and secretory rates were measured by single pass perfusion and back titration in anesthetized Slc26a9 KO and WT mice by inhalation of 2.0% isoflurane. Slc26a9 cellular expression was studied by laser dissection and qPCR, and quantitative morphometry was performed in the different segments of the murine gastrointestinal tract. Results: Slc26a9 was found highly expressed in the mucosae of the upper gastrointestinal tract, with abrupt decrease of expression levels to virtually undectable levels beyond the duodenum. As previously reported, Slc26a9 KO mice had completely lost the ability to secrete acid in adulthood. However, Slc26a9 was found highly expressed along the whole gastric gland, even in areas without H^+,K^+- ATPase expression. Proximal duodenal bicarbonate and fluid secretory rates, which are higher in the proximal than the distal duode-

num in WT mice, as well as the ability to stimulate these rates with forskolin, were reduced in the absence of Slc26a9 expression. The gastric antrum, as well as the fundus (after omeprazole treatment to rule out any residual acid secretory capacity) was studied to test whether Slc26a9 transports HCO_3^- itself. Gastric antrum, while expressing high Slc26a9 levels in WT mice, had lower basal and forskolin-stimulated HCO_3^- rate as well as lower Isc response in WT than KO mice, arguing against a role of Slc26a9 as a HCO_3^- transporter. Morphometry revealed strongly elongated fundic as well as antral glands, and slightly elongated proximal duodenal villi as well as crypts. Conclusions: Slc26a9 expression is necessary for normal gastric acid and proximal duodenal bicarbonate secretion, but it is not expressed in more distal parts of the gastrointestinal mucosa. The increased risk for meconium ileus may be due to loss of digestive function of the stomach and proximal duodenum.

Slc26a6 (PAT-1) mediates dipeptide and CO2/HCO3- induced stimulation of jejunal fluid and HCO3- absorption in murine small intestine

Q. Yu[1,2], W. Xia[1,4], A. Singh[1], B. Riederer[1], R. Engelhardt[1], P. Song[4], D. Tian[2], M. Soleimani[3] and U. Seidler[1]

[1]Dep Gastroenterology, Hannover Medical School, Hannover, Germany, [2]Dep Gastroenterology, Tongji Hospital, Tongji Medical College, Huazhong University of Science & Technology, Wuhan city, China, [3]Center on Genetics of Transport and Epithelial Biology, University of Cincinnati, Cincinnati, OH, USA and [4]Key Lab of Combined Multiorgan Transplantation, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Background and aim: The jejunum is known to be capable of absorbing large amounts of fluid and HCO3-, but the molecular mechanisms are not clear. We speculated that the large amounts of luminal CO2 and HCO3- generated in the upper jejunum by mixture of HCO3—rich pancreatic juice and H+-rich gastric juice, as well as the jejunal enterocyte proton load generated by H+-coupled dipeptide and aminoacid absorption, are major stimulants of jejunal fluid and Na+HCO3- absorption, and that both the apical Na+/H+ exchanger NHE3 and the multi anion transporter Slc26a6 (PAT-1) may be involved in dipeptide- and CO2/HCO3- induced jejunal fluid and Na+HCO3- absorption. Methods: Two photon fluorometry was applied to measure intracellular pH (pHi) in SNARF1-loaded villous enterocytes of exteriorized jejunum in anesthetized C57BL6 background mice. Jejunal fluid absorption was assessed by single pass perfusion of jejunal segments in anesthetized acid/base-status controlled mice with prewarmed, isotonic solutions of different ionic compositions but constant pH of 7.4; volume and pH of the inflowing and outflowing solution was measured. Results: WT jejunum absorbed fluid and acidified the lumen. Slc26a3 (DRA)-deficient jejunum absorbed less fluid than WT, and acidified the lumen more strongly, consistent with the action of DRA as a Cl-/HCO3- exchanger. Slc26a6 (PAT-1)-deficient jejunum also absorbed less fluid, but resulted in less luminal acidification. NHE3-deficient jejunum also absorbed less fluid, and markedly alkalinized the lumen. Switching the luminal perfusate from isotonic NaCl/O2 gassed to isotonic NaCl/HCO3-, 5%CO2/95%O2 gassed solution, pH 7.4, resulted in stable decrease of villous enterocyte pHi by approx. 0.2 pH units, and a marked stimulation fluid absorption in a PAT-1 - and NHE3- but not DRA-dependent fashion. Switching the solution from CO2/HCO3- buffered Mannitol-containing saline to an isotonic solution where the mannitol was preplaced by 20 mM of the dipeptide GlySar further acidified enterocyte pH and resulted in a further increase of fluid absorption that was dependent on PAT-1 as well as NHE3. Conclusions: The results suggest that luminal CO2/HCO3-, as well as luminal dipeptides, strongly stimulates of jejunal fluid absorption, which occurs to a large part percentage secondary to Na+HCO3- absorption. NHE3 and Slc26a6 (PAT-1) are required for this CO2/HCO3— and dipeptide-augmented Na+HCO3- absorption, and Slc26a6 (PAT-1) may operate in a 2 HCO3-/1 Cl- mode under those circumstances. The results demonstrate an important role of Slc26a6 (PAT-1) in jejunal fluid and HCO3- absorption.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

The development of an *in-vitro* mouse proximal tubule cell model as a platform for drug transporter and drug-drug interaction studies

S.F. Billington, G. Chung and C. Brown

Institute of Cell and Molecular Bioscience, Newcastle University, Newcastle Upon Tyne, UK

Accurate prediction of human drug toxicity is a major challenge in drug development. It is estimated that 50% of pre-clinical *in-vivo* screening of novel drug molecules in rodents fails to predict subsequent human toxicity. Regulatory authorities have recognised the poor performance of current *in-vivo* screening and have called for the development of *in-vitro* based screening assays to reduce current animal testing in pre-clinical screening. To address this, we are developing predictive *in-vitro* primary renal cell models, to replace poorly predictive *in-vivo* screening studies.

Aim: To develop an *in-vitro* primary renal proximal tubule model from male CD1 mouse kidney. The initial focus was to optimise the isolation protocol, to generate viable cell monolayers of differentiated renal tubule cells and demonstrate the retention of expression and function of ATP-binding cassette (ABC) transport proteins within primary mouse proximal tubule cells.

Proximal tubule cells were isolated using a collagenase digest protocol followed by isopycnic centrifugation on a Percoll density gradient. A range of collagenase concentrations were tested to determine the optimum digestion protocol. After 7 days of cell culture, relative mRNA expression levels of ABC transporters were determined using a quantitative RT-PCR array (SABiosciences). To demonstrate functional expression of these transporters, cell monolayers were loaded with either Hoechst 33342 or 5-Chloromethylfluorescein Diacetate (CMFDA) fluorescent dyes in the presence and absence of transporter inhibitors.

The highest viable cell yields were found at 0.16 collagenase units per milligram tissue (n=3, $P<0.001$, t-test). The relative mRNA expression levels of the ABC transporters multidrug resistance protein 1 (ABCC1) and multidrug resistance protein

4 (ABCC4) were higher ($2^{-avg\Delta CT}$ values of 6.06 & 11.87 respectively) than multidrug resistance protein 3 (ABCC3) (0.70) or multidrug resistance protein 5 (ABCC5) (1.03). We found no expression of multidrug resistance protein 2 (ABCC2) (0.03). Breast cancer resistance protein (ABCG2) and multidrug resistance protein 1b (ABCB1b) expression levels were 0.39 and 0.21 respectively, giving a rank order of ABCC4>ABCC1>>ABCC3>ABCC4>>ABCB1b>ABCG2. Inhibition of Hoechst 33342 efflux from the cell by cyclosporin A (n=3, IC_{50} 3.60±0.10μM, mean ± SEM) and Ko-143 (n=3, IC_{50} 0.52±0.01μM, mean ± SEM) demonstrated expression of multidrug resistance protein 1 (ABCB1) and breast cancer resistance protein (ABCG2) transporters. Inhibition of CMFDA dye efflux by MK-571 (n=3, IC_{50} 2.60±0.06μM, mean ± SEM) demonstrated expression of multidrug resistance protein (ABCC) transporters.
This data provides the first steps in the characterisation of a primary renal proximal tubule model from mouse kidney.

Sarah Billington is funded by an NC3Rs PhD studentship.

Estrogen increases Na^+ absorption and ENaC channel expression in kidney collecting duct cells

M.Y. Yusef Robles, W. Thomas and B.J. Harvey

Molecular Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland

The active estrogen, 17β-estradiol (E2), exerts a gender-specific anti-secretory effect in distal colon (1). This could provide an explanation for the fluid retention observed in females during periods of high circulating plasma E2. However, an effect of E2 on ion transport in other organs contributing to electrolyte and fluid homeostasis is unknown. The aim of this study was to determine whether E2 has a chronic effect on Na^+ absorption in the renal cortical collecting duct using the M1 kidney cortical collecting duct cell line and to reveal the molecular mechanisms underlying effects of E2 on the amiloride-sensitive epithelial Na^+ channel ENaC.
Electrophysiological experiments using the Ussing chamber technique, demonstrated that treatment with E2 (25 nM) for 24 hrs increased the amiloride-sensitive short-circuit current (I_{SC}) in M1 cells (Control 1.4±0.2 μA/cm^2, E2 3.1±0.6 μA/cm^2; n=7). This increase in Na^+ current was not attributable to changes in the ouabain-sensitive Na^+/K^+-ATPase pump current (Control 11.3±1.6 μA/cm^2, E2 8.9±1.5 μA/cm^2; n=4). Moreover, there were no changes in the abundance of the α- or β-Na^+/K^+ -ATPase subunits.
The increase in the amplitude of the Na^+ current could be explained by changes in the expression of the Na^+ channel ENaC subunits. To test this hypothesis, we looked at changes in the abundance of α-, β-, and γ-ENaC subunits using Western-blotting. We found that the treatment with E2 for 24 hrs did not produce any detectable change in the abundance of the α- or β-ENaC subunits. However, E2 induced a 2-fold increase in the abundance of the γ-ENaC subunit (2.0±0.1, n=4). In conclusion, E2 chronically increases the ENaC mediated absorption of Na^+ in CCD cells. The results suggest that the pro-absorptive effect of E2 could be explained by an up-regulation of the γ-ENaC subunit expression in the apical cell membrane.

PCB208

Hypercapnia reduces cAMP-dependent HCO_3^- transport across human airway epithelial cells

M.J. Turner[1], M.J. Cann[2] and M.A. Gray[1]

[1]Institute for Cell and Molecular Biosciences, Newcastle University, Newcastle Upon Tyne, UK and [2]School of Biological and Biomedical Sciences, Durham University, Durham, UK

Hypercapnia is a symptom of chronic lung disease and is caused by inefficient gas exchange at the alveoli. We have recently shown that CO_2 modulates cAMP/PKA signalling through changes in G-protein responsive transmembrane adenylyl cyclase (tmAC) activity (1). Since, cAMP signalling plays a vital role in regulating the volume and composition of the airway surface liquid (ASL) we have investigated whether changes in pCO_2 impacts upon cAMP-regulated ion and fluid transport in polarised cultures of human submucosal gland derived airway epithelial cells (Calu-3). Using a radiolabelled cAMP assay, raising pCO_2 from 5% to 10% for 20 mins reduced forskolin-stimulated cAMP levels by 36 ± 8.6% (n=6; p<0.05). Under normocapnic conditions, cAMP agonists produce a drop in intracellular pH of Calu-3 cells due to stimulation of CFTR-dependent HCO_3^- secretion (2). Acute exposure to 10% CO_2 increased both the rate and magnitude of this intracellular acidification by the cAMP agonists adenosine or forskolin approximately 3 fold (n=6; p<0.05). This CO_2 augmentation was independent of changes in either external or internal pH (n=3) and was prevented by either tmAC or PKA inhibition (n=4) suggesting that CO_2 alters the activity of cAMP-dependent HCO_3^- transporters in Calu-3 cells. Pre-loading cells with the Ca^{2+} buffer, BAPTA-AM, and the phospholipase C inhibitor U77312 blocked the effect of 10% CO_2, while carbachol, in normocapnia, mimicked the effect of hypercapnia, indicating that raising CO_2 also changes cytosolic Ca^{2+} levels via the G_q receptor/phospholipase C pathway. Because inhibition of basolateral HCO_3^- transporters abolished the effect of CO_2 whilst CFTR-dependent apical Cl^-/HCO_3^- anion exchange (2) was unaffected, strongly suggests that a change in the activity of a basolateral HCO_3^- transporter underlies the effect of 10% CO_2. Surprisingly, the cAMP-dependent HCO_3^- co-transporter, NBCe1, was unaffected by hypercapnia implying another, as yet unknown, basolateral HCO_3^- transporter is involved. Finally, exposing Calu-3 cells to chronic hypercapnia reduced forskolin-stimulated fluid secretion by 37 ± 6.1% (n=3; p<0.05). Together, these results indicate that raised CO_2 decreases airway anion and fluid secretion by reducing tmAC-derived cAMP levels, and the activity of an unidentified basolateral HCO_3^- importer, through a process that involves crosstalk with Ca^{2+} signalling mechanisms. Since both the quantity and pH of the fluid bathing the airways determines the efficiency of the innate defence mechanisms of the lung, our results suggest that raised CO_2

could have deleterious effects on lung function and contribute to the pathophysiology of chronic airway disease.

Bile acid modulation of Cl^- secretion in Calu-3 airway epithelial cells

S. Hendrick, C.M. Greene, S.J. Keely and B.J. Harvey

Royal College of Surgeons in Ireland, Dublin, Ireland

Bile acids are often present in the lower airways of people with cystic fibrosis, probably resulting from the aspiration of gastroesophageal refluxate, but the effects of bile acids on airway epithelium have not yet been investigated (1,2). In the colon, bile acids have been reported to acutely stimulate or chronically inhibit epithelial Cl^- secretion (3).

We investigated the effects of the conjugated secondary bile acid taurodeoxycholic acid (TDCA, 25 μM) on basal transport and carbachol (100 μM) or forskolin (10 μM)-induced ion transport in Calu-3 airway epithelial cells grown in an air-liquid interface and mounted in Ussing chambers. Electrogenic transpeithelial ion transport was measured as short-circuit current (I_{sc}). Data given as Mean ± S.E.M. Statistics were generated using the Student's paired t-test or one-way Anova analysis, where $p \leq 0.05$ is considered significant.

We found that acute (5 min) basolateral TDCA treatment of Calu-3 cells stimulated basal I_{sc} by 39 ± 7% ($p = 0.0001$, $n = 13$) but had no effect on the I_{sc} responses induced by carbachol or forskolin treatment. The I_{sc} responses to TDCA were abolished in Cl^- -free Krebs solution ($n = 4$) indicating that TDCA modulates Cl^- secretion in Calu-3. Prolonged (24hr) TDCA treatment of Calu-3 had no effect on I_{sc} responses to carbachol or forskolin. In Ussing chambers where CFTR I_{sc} was measured, we found that acute treatment with TDCA produced a 32 ± 9% increase in I_{sc} that was abolished by pre-treatment with $CFTR_{inh172}$ ($p = 0.043$, $n = 5$). We also found that TDCA increases Cl^- secretion through calcium-activated chloride (CaCC) channels in the apical membrane by 18 ± 7 % ($p = 0.01$, $n = 4$). In addition, when Na^+/K^+ATPase generated currents were measured, acute treatment with TDCA increased Na^+/K^+pump activity by 13 ± 3%, while pre-treatment with ouabain eliminated this effect ($p = 0.0005$, $n = 9$). This further supports TDCA stimulation of secretion in Calu-3 cells.

Calcium imaging of Calu-3 cells, grown on glass, revealed that acute treatment with TDCA resulted in a rapid 88 ± 12% increase in calcium mobilization ($p = 0.0002$, $n = 8$). The Ca^{2+} mobilization response to TDCA was abolished in Ca^{2+} -free buffer indicating that TDCA induced Ca^{2+} influx into the cell.

This study shows for the first time that TDCA modulates Cl^- secretion in Calu-3 cells, a model of airway epithelium. Effects of TDCA are dependant upon both the duration and sidedness of exposure to the bile acid. TDCA stimulates Cl^- secretion in Calu-3 cells through CFTR and apical CaCC channels. The activation of basolateral Na^+/K^+ ATPase can indirectly sustain this secretory response. Activation of Cl^- secretion in Calu-3 cells could possibly be initiated through intracellular Ca^{2+} mobilization. This study provides leads for further investigation of the signalling pathways involved in TDCA modulation of airway Cl^- secretion.

PCB210

Development and characterisation of rat primary proximal tubule cells

G. Chung[1], S. Billington[1], N. Soomro[2] and C. Brown[1]

[1]ICAMB, Newcastle University, Newcastle Upon Tyne, UK and [2]Urology, Freeman Hospital, Newcastle Upon Tyne, UK

The kidney is a key organ in the elimination of drug molecules from the body. Renal drug elimination is mediated by a series of membrane transporters expressed in proximal tubular cells that form effective secretory pathways for drug molecules. Transporter-mediated drug-drug interactions leading to nephrotoxicity is common. Current animal models of renal drug transport are not predictive of human exposure. In parallel to our established human proximal tubule cell model, we have developed primary cultures of rat proximal tubule cells which may allow the comparison of the renal handling of drug molecules in both species. Here we report the characterisation of rat primary proximal tubule cells as a model for drug transporter studies.

Tubular cells were isolated from the kidneys from male Sprague-Dawley rats via collagenase digest protocol followed by Percoll gradient centrifugation to purify the proximal tubule cell (PTC). A PCR Transporter array of 86 key transport proteins was used to screen the total cell RNA isolated from cultured rat PTC and native kidney cortical tissue. The results showed Abcc2, Abcc3, Abcc4, Abcc6 and Abcg2 had apparent lower level of expression levels in rat PTC cultured on flasks compared to isolated cells from native tissue. In contrast, Abcb1b expression level was 2-fold higher in cultured cells. The SLC–family members: Slc22a1, Slc22a2, Slc22a6, Slc22a7, Slc16a1 and Slc16a2 were also down-regulated.

To measure the functional expression of key efflux transporters, H33342 and CMFDA cellular retention assays were performed. Rat PTC were loaded with H33342 or CMFDA in the presence or absence of CsA, Ko143 and MK-571, inhibitors of Abcb1b, Abcg2 and Abcc1-6 respectively. In the presence of CsA (5μM), cellular retention of H33342 was significantly higher ($P<0.001$) compared to controls. CsA resulted in a significant reduction in the concentration of H33342 that produced half maximal fluorescence (Km) from 3.44±1.10μM to 0.14±0.03μM, a result consistent with inhibition of transporter-mediated dye efflux. The presence of Ko143 (1μM) also increased cellular retention of H33342 ($P<0.01$) with a significant change in Km for dye loading from 3.44±1.10μM to 0.22±0.08μM. Similarly, retention of CMFDA metabolite GSMF in the presence of Mrp inhibitor MK-571 (10μM) was significantly higher than control. To recapitulate monolayer formation, rat PTC were grown on Transwell filter supports and the transepithelial electrical resistance (TEER) measured. The TEER of the cells after 2 days of

growth increased by 2-fold compared to baseline (P<0.05) and by day 4, TEER peaked at 4.5 times the base resistance (P<0.001). These data suggest that rat cells form confluent cell monolayers on permeable filter supports.
In summary, these results show rat PTC have the potential to be used as an important in vitro model for drug transporter and drug-drug interaction studies.

N-acetylcysteine stimulates glutamate efflux in Xenopus oocytes expressing xCT/4F2hc

E.M. Lofthouse, S.E. Brooks, J.K. Cleal, M.A. Hanson, K.R. Poore, I.M. O'Kelly and R.M. Lewis

University of Southampton, Southampton, UK

Background: The amino acid transporter xCT (SLC7A11) is a sodium independent, chloride dependent exchanger which must form a heterodimer with 4F2hc (SLC3A2) in order to function. xCT mediates the exchange of glutamate and cystine. Cystine is essential for the synthesis of the antioxidant glutathione and it has been suggested that xCT activity is a rate limiting factor for glutathione synthesis [1]. N-acetylcysteine (NAC) is reported to be a substrate for xCT and due to its higher solubility has been used in place of cystine for physiological studies. However it is not clear how it was demonstrated that NAC is a substrate for xCT. Therefore the aim of this investigation was to investigate whether or not NAC is a substrate for human xCT expressed in Xenopus oocytes.
Methods: Xenopus laevis oocytes were detached and defolliculated in oocyte Ringer's 2 buffer, transferred to ND91 buffer and incubated at 18° C overnight before being microinjected with xCT-GFP and 4F2hc cRNA and incubated for a further 48 hours. To determine relative ^{14}c-glutamate uptake rates injected and non-injected oocytes were incubated with 20 μM ^{14}c-glutamate for 5 min before uptake was stopped with 1 ml ice cold ND91 and washed twice. Uptake of ^{14}c-glutamate into oocytes was determined by liquid scintillation counting. To demonstrate efflux by exchange batches of ten injected oocytes (3 batches/condition/experiment) were incubated with 20 μM ^{14}c-glutamate for 30 min at room temperature to preload the oocytes. Oocytes were then washed twice in ND91 buffer and incubated with ND91 buffer alone or 10 mM glutamate, 10 mM NAC, a saturated solution of cystine or 10 mM glycine for five min. The media was removed and efflux of ^{14}c-glutamate determined in a liquid scintillation counter. Parallel experiments were carried out in non-injected oocytes. Data are median fold change from stated control groups (range).
Results: ^{14}c-glutamate uptake into injected oocytes was 1.9 (±0.29) fold higher compared to non-injected controls (n=3). Compared to oocytes incubated with ND91 alone, the efflux of ^{14}c-glutamate into the media was 5.1 (3.3-8.8) fold higher for NAC (n=3 ovaries), 3.4 (1.8-4.4) fold higher for glutamate (n=2) and 4.1 fold higher for cystine (n=1) while glycine (n=2) did not appear to stimulate efflux with a fold change of 1.0 (1.01-1.02). In non-injected oocytes NAC, glutamate, cystine or glycine did not stimulate efflux of ^{14}c-glutamate.
Conclusions: xCT/4F2hc injected oocytes showed increased uptake of ^{14}c-glutamate and efflux of ^{14}c-glutamate was observed in response to NAC, glutamate and cystine but not to glycine which is not an xCT substrate. This study demonstrates that NAC is a substrate for xCT.

Cystathionine is a physiological substrate of cystine/glutamate transporter, System x_c^-

S. Kobayashi[1,2], T. Kasakoshi[1], T. Tsutsui[1], S. Azumi[1], T. Okada[1], T. Soga[3], K. Igarashi[1], S. Bannai[1] and H. Sato[1,2]

System x_c^- is one of amino acid transporters expressed in the plasma membrane of mammalian cells and specifically exchanges anionic forms of cystine and glutamate. This transporter plays an important role in maintaining intracellular glutathione levels and extracellular redox balance. The substrate-specific component of System x_c^-, xCT, is strongly induced by various stimuli, including oxidative stress. Constitutive expression of xCT is observed only in specific regions of the brain and immune tissues such as thymus and spleen. We generated xCT deficient mice and performed metabolite analysis of various tissues using capillary electrophoresis time-of -fight mass spectrometry, and found that no cystathionine was detected in thymus and spleen of xCT-deficient mice, although a significant amount of cystathionine was detected in these tissues in wild-type mice. These results suggest that cystathionine may be a physiological substrate of System x_c^-. Embryonic fibroblasts derived from wild-type mice did not survive more than 24 h in cystine-free medium, due to a marked decrease in intracellular glutathione levels. However, these cells survived and proliferated when incubated in cystine-free medium containing 0.1 mM cystathionine. In contrast, cells derived from xCT-deficient mice did not survive in the cystine-free medium, even when 0.1 mM cystathionine was added to the medium. Cystine uptake in the wild-type cells was significantly inhibited by cystathionine. When wild-type cells were incubated in the 0.1 mM cystathionine-containing buffer, release of intracellular glutamate was enhanced, and cystathionine concomitantly accumulated in the cells. To induce experimental hypercystathionemia, xCT-deficient and wild-type male mice (8-9 weeks) were injected with propargylglycine, a cystathionine γ-lyase inactivator, diluted in saline (ip, 50 mg/kg) daily for 3 days, and cystathionine in plasma, liver and thymus were measured. In plasma and liver of both xCT-deficient and wild-type mice, cystathionine was significantly increased. In the thymus of wild-type mice, cystathionine was substantially increased while no cystathionine was detected in the thymus of xCT-deficient mice. From these results, we have demonstrated that cystathionine functions as a physiological substrate of System x_c^- and is exclusively transported via System x_c^- in an exchange for glutamate in thymus.

The single-channel behaviour of F508del-CFTR rescued by the CFTR corrector VX-809

Y. Wang, Z. Cai and D. Sheppard

School of Physiology and Pharmacology, University of Bristol, Bristol, UK

Mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) Cl^- channel cause the genetic disease cystic fibrosis (CF). The commonest CF mutation, F508del-CFTR causes a temperature-sensitive folding defect leading to three fundamental insults: (1) aberrant protein processing and trafficking; (2) defective channel gating and (3) thermal instability[1]. To restore CFTR function to CF patients, CFTR correctors have been developed to rescue the cell surface expression of F508del-CFTR. Here, we investigate the single-channel properties and thermostability of F508del-CFTR delivered to the cell surface by VX-809, the first CFTR corrector to be tested in the clinic[2,3]. In comparison, we studied F508del-CFTR rescued by low temperature-incubation. We incubated BHK cells expressing F508del-CFTR with VX-809 (3 μM) for 24 h at 37 °C prior to single-channel recording at temperatures between 23 - 37 °C using excised inside-out membrane patches. Alternatively, BHK cells were incubated at 27 °C for 24 h and studied as a control.

The channel activity of F508del-CFTR rescued by either low temperature or VX-809 was much reduced compared to that of wild-type CFTR. Instead of the exponential increase in open probability (P_o) observed with wild-type CFTR between 23 and 37 °C, the temperature-dependence of P_o for F508del-CFTR rescued by either low temperature or VX-809 was bell-shaped with a maximum around 30 °C. For F508del-CFTR rescued by VX-809, a subtle increase of the maximal P_o was observed compared to low temperature, although no statistical significance was achieved. (Control, 0.081 ± 0.016; VX-809, 0.098 ± 0.016, means ± S.E.M, n = 7 - 10, P > 0.05, student t-test). Over the temperature range 23 - 37 °C, no difference was observed between the single-channel current amplitude of wild-type CFTR and F508del-CFTR rescued by the two methods. However, at high temperatures, F508del-CFTR rescued by either low temperature or VX-809 frequently opened to sub-conductance states, which were very rarely observed with wild-type CFTR. Like low temperature-rescued F508del-CFTR, VX-809-rescued F508del-CFTR channels were unstable and ran down at 37 °C.

We conclude that VX-809 restores similar temperature-dependent channel behaviour to F508del-CFTR as rescue by low temperature-incubation. This suggests that VX-809 and low temperature might share a common mechanism of rescuing the F508del-CFTR folding defect. Our observation that VX-809 delivers F508del-CFTR to the cell surface without improving its gating defect and thermal instability suggests that CF patients with the F508del-CFTR mutation will likely require combination drug therapy.

Relationship between temperature and substrate affinity in GAT1, KAAT1 and PepT1

A. Vollero, A. Peres, E. Margheritis and E. Bossi

Dept. of Biotechnology and Life Sciences, University of Insubria, Varese, Italy

The effects of temperature on the functional properties of some members of two solute carrier families were investigated using heterologous expression in Xenopus laevis oocytes and electrophysiology. The kinetic parameters were determined in a range of temperatures from 20 to 30°C. The rat GABA transporter GAT1, three different orthologs of the intestinal oligopeptide transporter PepT1 and the Manduca sexta neutral amino acid transporter KAAT1, have been considered in this studies. These transporters are derived from organisms with different thermal behaviour: GAT1 from the neurons of a homeotherm mammal, KAAT1 from the intestine of a poikilotherm invertebrate, PepT1 from epithelial tissues of two poikilotherm (seabass and zebrafish) and one homeotherm (rabbit) organism. Raising the temperature from 20° to 30°C causes changes in the electrophysiological behaviour. Transport-associated currents, presteady-state currents and substrate affinity were determined for each transporter at 20-25-30°C. In all cases higher temperatures increase Imax and cause a reduction in substrate affinity. On the contrary, the transport efficiency is differently affected : it is increased with temperature in PepT1, decreased in KAAT1, and unaltered in GAT1. The Q10 of the transport-associated currents, is in the order of 3 to 8 in GAT1, 3 to 4 in KAAT1 and 2 to 4 for PepT1, according to the membrane voltage. The transient currents from rabbit PepT1 and from GAT1 show a progressively faster decline as the temperature is increased from 20 to 30 °C, and they become similar to those of KAAT1 and fish PepT1s at room temperature. The amount of charged moved, plotted in the Q/V relationship, is shifted to negative potentials by higher temperatures. The substrate affinity varies differently in the rGAT1, msKAAT1 and rbPepT1, in relation to voltages and temperature, but the effects can be generalized in an increase in the K0.5 from 20° to 30°C. Comparison of the amino acidic sequence between the mammalian and fish orthologs of PepT1 highlights the residues that may be involved in temperature sensitivity. Preliminary results on the Q10 of transport currents show an increase of this parameter when the two charged residues present in fish are introduced in the rabbit transporter (Q188E and A196K, rabbit numbering).

The results presented in this work underline the functional adaptation of transporters to temperature and suggest the presence of specific residues that establish the protein activity in relation to the thermal life condition of the organism.

A novel variant of the Na^+/HCO_3^- cotransporter 4 (NBC4) may regulate the cerebrospinal fluid production via the cAMP signaling axis

H. Fukuda[1,2], K. Kawahara[1], M. Chang[3], M.F. Romero[3] and S. Hirose[2]

[1]Department of Physiology, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan, [2]Department of Biological Sciences, Tokyo Institute of Technology, Yokohama, Kanagawa, Japan and [3]Department of Physiology & Biomedical Engineering, Mayo Clinic College of Medicine, Rochester, MN, USA

Secretion of HCO_3^- at the apical side of the epithelial cells in the choroid plexus is an essential step in the formation of cerebrospinal fluid. Recently, Na^+/HCO_3^- cotransporter 4 (NBC4), an electrogenic member of the NBC family, was identified in mouse and rat choroid plexus. The stoichiometry of NBC4 has been determined as 3 HCO_3^- : 1 Na^+, which is favorable for the efflux of HCO_3^- and Na^+ from the cell into CSF at the apical side (Millar and Brown, 2008). Very recently, we reported that a novel NBC4 isoform (NBC4g: truncated form of general isoform of NBC4c) expressed highly in rat choroid plexus and represented a DIDS-sensitive HCO_3^- transport activity (Fukuda *et al*., 2013). In the present study, we further demonstrate that (1) RT-PCR analysis using specific primers of NBC4g and NBC4c indicated that NBC4g isoform was clearly expressed, but NBC4c isoform was not detected in the rat choroid plexus. (2) Immunostaining and electron microscopy studies revealed the apical localization of NBC4g in the choroid epithelial cells. (3) Electrophysiological studies using *Xenopus* oocytes injected with NBC4g cRNA showed a forskolin, an activator of membrane adenylyl cyclase (mAC),-dependent outward current in the presence of 5% CO_2/33 mM HCO_3^- in the bathing medium. These results support the hypothesis that NBC4g activity may be regulated by cAMP-dependent protein kinase (PKA) phosphorylation at one or more of the three PKA predicted sites. In conclusion, NBC4g, densely localized to the apical surface of the choroid epithelial cells, may contribute to the production of CSF and regulate its volume and ionic composition in a cAMP-dependent manner.

Regulation of the basolateral Cl^--HCO_3^- anion exchanger by cAMP and the actin cytoskeleton in human airway epithelial cells

S.H. Ibrahim, A. Haigh, C. Comer, M.J. Turner and M.A. Gray

Institute for Cell and Molecular Biosciences, Newcastle University Medical School, Newcastle upon Tyne, UK

We have recently shown that polarised cultures of human airway epithelial cells (Calu-3) express a DIDS-sensitive basolateral Cl^--HCO_3^- anion exchanger (BlAE), which is inhibited via a cAMP-dependent, but PKA-independent, mechanism (1). The aim of this study was to investigate the downstream targets of cAMP responsible for BlAE regulation. The activity of the exchanger was assessed by measuring Cl^--dependent changes in intracellular pH using BCECF-loaded Calu-3 cells grown on Transwell supports. In the absence of cAMP agonists, exposing Calu-3 cells to a Cl^--free solution ($0Cl^-$) in the basolateral perfusate produced an alkalinisation of 0.27 ± 0.03 pH units (mean ± SEM.; $P<0.05$ n=10). Restoring Cl^- caused pH to recover at a rate of 0.62 ± 0.07 pH units min^{-1}. The response to $0Cl^-$ was completely abolished if cells were pre-treated with the adenylyl cyclase (tmAC) activators, forskolin or adenosine, the membrane-permeable cAMP analogue, dibutyryl cAMP or the phosphodiesterase inhibitor, IBMX (n=3-10), clearly implicating a rise in cAMP as a key event in the inhibition of the BlAE. The guanine-nucleotide exchange protein directly activated by cAMP (Epac) is another cAMP target. However, incubating Calu-3 cells with the Epac agonist, 8CPT-2Me-cAMP-AM, had no effect on BlAE activity, nor did it prevent forskolin inhibiting the exchanger (n=4). To investigate if a rise in cAMP was linked to a change in cytosolic Ca^{2+}, Calu-3 cells were acutely exposed to carbachol (n=7) or thapsigargin (n=3), but neither agent affected resting BlAE activity, nor the subsequent inhibition by forskolin. However, pre-loading cells with the Ca^{2+} buffer, BAPTA-AM, did reduce BlAE activity by 63.3±5.8% suggesting some dependence of exchanger function on cytosolic Ca^{2+} levels. To investigate if the actin cytoskeleton was important in cAMP-regulation of BlAE, Calu-3 cells were pretreated with cytochalasin D or lantruculin B for 60 mins. Both agents reduced transepithelial resistance (TER) by ~ 40 % after 20 mins but TER remained stable thereafter (n=3). In cytochalasin D treated cells, resting BlAE activity was similar to untreated cells but there was a marked reduction in the ability of adenosine to inhibit the BlAE (n=4, $P<0.05$). Interestingly, this was not observed for forskolin (n=4), suggesting that actin disruption specifically reduced the ability of adenosine receptors to couple to cAMP production via tmAC, thereby leading to higher BlAE activity. In contrast, lantruculin B reduced resting BlAE activity, but did not prevent cAMP inhibition. In conclusion, our results provide clear evidence that a rise in cAMP inhibits BlAE activity, through a downstream mechanism that does not involve Epac, nor a rise in cytosolic calcium, but does appear to require an intact actin cytoskeleton.

The putative gating residues Y163 and F272 are critical for PAT2 (slc36a2) mediated amino acid transport

N.J. Conlon, N. Edwards, T.R. Cheek, C.M. Anderson and D.T. Thwaites

Institute for Cell & Molecular Biosciences, Newcastle University, Newcastle upon Tyne, UK

Until recently, insights into how mammalian secondary active ion-coupled solute transporters function at a molecular level have been limited. However, a number of prokaryotic transporter structures have been resolved and used to predict key functional characteristics in their mammalian counterparts [e.g. LeuT and the SLC6 family (Yamashita *et al.* 2005)]. The proton-coupled amino acid transporter PAT2 (slc36a2) is a member of the SLC36 family of transporters within the Amino Acid Auxin Permease superfamily (Thwaites & Anderson, 2011).

PAT2 is expressed in the renal proximal tubule and defects in PAT2 contribute to iminoglycinuria (Bröer *et al.* 2008). To identify key functional elements within PAT2, an *in silico* homology modelling strategy was performed using crystal structures in the Protein Data Bank. HHPRED predicted a high degree of structural homology (>97%) for PAT2 and several prokaryotic transporter crystal structures, despite limited primary sequence identity (<20%), and differences in ion/substrate specificity and mode of action. Homology modelling of PAT2 against the LeuT template allowed prediction of functionally relevant amino acid residues. Site-directed mutagenesis of rat PAT2 was performed and transport function measured in *Xenopus laevis* oocytes. A key characteristic of secondary active transport is that during the transport cycle the substrate-bound pocket must be closed momentarily from both sides to prevent transmembrane leak. In LeuT, Y108 and F253 not only contribute to the substrate binding pocket but also form a molecular hatch that occludes bound substrate from the extracellular environment (Yamashita *et al.* 2005). In PAT2, homology modelling identified that Y163 and F272 occupy similar positions to those in LeuT. Mutation of either Y163 or F272 led to a decrease in PAT2 function. Concentration-dependent [^{3}H]proline uptake (PAT2, K_m 136 ± 27 μM, V_{max} 329 ± 14 pmol/oocyte/40min, mean ± SEM N=3) showed reductions in both affinity and capacity for Y163F (K_m 446 ± 115 μM, V_{max} 93 ± 6 pmol/oocyte/40min) and F272Y (K_m 253 ± 63 μM, V_{max} 186 ± 11 pmol/oocyte/40min). Similar observations were made when function was measured as proline-induced inward current by TEVC. Confocal imaging revealed similar membrane localisation of FLAG-tagged PAT2, Y163F and F272Y suggesting that any change in activity was not due to decreased membrane expression. The conservation of tyrosine and phenylalanine residues in these two positions in many prokaryotic and eukaryotic transporters, combined with the changes in affinity (change in the binding pocket) and capacity (reduced ability to form an occluded bound-state), support the hypothesis that these residues play a gating role in PAT2, as observed previously in LeuT (Yamashita *et al.* 2005; Piscatelli *et al.* 2010).

Roles of NHE1 activity and pH_i regulation in ATM mediated DNA-damage response

G. Lauritzen[1], B. Webb[2], S. Christensen[1], D.L. Barber[2] and S.F. Pedersen[1]

[1]Biology, University of Copenhagen, Copenhagen, Denmark and [2]Department of Cell and Tissue Biology, University of Sanfrancisco, San Francisco, CA, USA

The activation of DNA-damage checkpoints enforces growth arrest of damaged cells to allow DNA-repair mechanisms to repair the damaged DNA. Altered pH regulation and Na^+/H^+ exchanger 1 (NHE1, SLC9A1) activity are characteristic for cell division and cell death [1,2]. Checkpoint recovery constitutes a specialized form of mitotic entry and several lines of evidence suggest that this may be pH-dependent. Further, a global profile of proteins phosphorylated by Ataxia telangiectasia mutated (ATM) after UV-induced DNA damage includes NHE1 [3]. However, the possible link between pH-regulation in DNA damage response is incompletely understood.

By bioinformatic screening, we found that the distal C-terminus of NHE1 (NHE1dCT) contains a consensus motif [$_{784}$DSPSSQR$_{790}$, human sequence] for phosphorylation by ATM.

Here we investigate: *(i)* whether NHE1 is a substrate for ATM *in vitro*, using human (h)NHE1 constructs, and *(ii)* the roles of NHE1 activity and pH regulation in DNA-damage response and cell death in fibroblasts expressing wild type (WT) rat (r)NHE1 (PS120 cells) and rat NHE1-S793A (corresponding to S788 in hNHE1) (PS120-S793A cells).

By using an *in vitro* kinase assay we found, that the hNHE1-637-815 distal C-terminal tail (dCT) is phosphorylated by ATM *in vitro* in a manner fully dependent on Ser788 *(n=3)*. We further tested the influence of the specific ATM phosphorylation site on NHE1 activity and pH regulation. To induce a DNA-damage response and activation of ATM, the cells were treated with (10 μM) of the topoisomerase II inhibitor etoposide for 24 h *(n=6)* or the antibiotic zeocin for 6 h *(n=7)*. Both conditions induced a significant increase in the rate of intracellular pH (pH_i) recovery after an NH_4Cl-prepulse-induced acid load in PS120 cells expressing wild type WT rNHE1. In contrast, no increase in pH_i recovery rate was seen in cells expressing rNHE1-S793A that cannot be phosphorylationed by ATM. Additionally, inhibiting NHE1 with amiloride analogs 5-(N-ethyl-N-isopropyl) (EIPA) (10 μM) sensitized PS120-S793A cells to etoposide-induced loss of cell viability as assessed by MTT assay, whereas it enhanced viability after etoposide treatment in PS120 cells *(n=3)*.

In conclusion, we identified a specific ATM phosphorylation site at Ser788 at the distal C-terminus of hNHE1 and showed that NHE1 activity is increased during DNA damage. Analyses to address the significance of NHE1 regulation by ATM in the DNA damage response and checkpoints are ongoing.

Cooperation of basolateral epithelial amino acid transporters TAT1 and LAT2 investigated in a double knock out mouse model

E.B. Boiadjieva[1,3], C. Vilches[2], S. Bodoy[2], A. Guetg[1,3], F. Verrey[1,3] and M. Palacin[2]

[1]Institute of Physiology, University of Zurich, Zurich, Switzerland, [2]Institute for Research in Biomedicine (IRB), Barcelona, Spain and [3]Zurich Center for Integrative Human Physiology, Zurich, Switzerland

Transcellular transport of amino acids by epithelial tissues includes their import across apical membranes and sequential export through basolateral membranes. In the cell, the basolateral efflux step is driven by the amino acid concentration gradient and is strictly regulated by the cooperative action of various transporter proteins. The basolateral transporter

LAT2-4F2hc (SLC7A8-SLC3A2) is an obligatory exchanger of neutral amino acids and does therefore not directly contribute to the net amino acid transport. Another basolaterally located protein, TAT1 (SLC16A10), transports aromatic amino acids by facilitated diffusion and we have previously shown in X. laevis oocytes that it can complement the vectorial transport of LAT2-4F2hc by recycling exchange substrates[1]. Our hypothesis proposes that the interplay between exchangers and uniporters controls both the vectorial transport of amino acids and the cellular amino acid concentration. We aim at testing the cooperation of these two amino acid transporters (LAT2-4F2hc and TAT1) in a double knock out mouse model and in primary cell culture made from their proximal tubule cells. We are currently characterizing the newly generated LAT2$^{-/-}$TAT1$^{-/-}$ double knock outs and comparing different metabolic parameters with those of the LAT2$^{-/-}$ and TAT1$^{-/-}$ single knock outs, and their wild type littermates[2,3]. Preliminary results show that double knock out mice under high protein diet excrete aromatic amino acids in the urine at a much higher level compared to LAT2$^{-/-}$ and even TAT1$^{-/-}$ mice. Moreover, other neutral amino acids that are substrates of LAT2 but not of TAT1 are hyperexcreted by the LAT2$^{-/-}$TAT1$^{-/-}$ to a much higher extent than in both the single knock out models. This latter observation supports the hypothesis that the basolateral efflux of LAT2 substrates depends on the recycling activity of aromatic amino acids via TAT1.

Analysis of the human cationic amino acid transporter hCAT-1 in human T lymphocytes

A. Werner[1,2], V. Schnitzius[1,2], A. Habermeier[1], J. Boissel[1], C. Luckner-Minden[2], M. Munder[2] and E.I. Closs[1]

[1]Department of Pharmacology, University Medical Center of the Johannes Gutenberg University, Mainz, Germany and [2]Third Department of Medicine, University Medical Center of the Johannes Gutenberg University, Mainz, Germany

The cationic amino acid L-arginine is essential for the efficient function of human T cells. The absence of L-arginine, a condition found in tumor microenvironment and inflamed tissues, leads to hyporesponsiveness of human T lymphocytes. This manifests in decreased cytokine secretion and a down-regulation of their proliferation, resulting in the arrest in the G0-G1 phase of the cell cycle. Given the importance of L-arginine for T cell function, the transporter responsible for the transmembrane transport of this amino acid must play a crucial role in T cell function. We thus wondered which arginine transporters are expressed in primary human T cells and if they are regulated upon stimulation.

For that reason we examined the expression of all known human L-arginine transporter in stimulated and unstimulated T cells. In addition we studied the influence of arginine availability on the transporter expression. Reverse transcription and subsequent quantitative real time PCR experiments revealed a notable expression of y+LAT-2 and cationic amino acid transporter (CAT) 3, but only a weak hCAT-1 mRNA expression in resting T cells. Upon stimulation with anti-CD3/CD28 coupled beads a distinct hCAT-1 expression occurred, which surpassed the expression of the other transporters. In addition, the observed hCAT-1 mRNA level was even higher in arginine-depleted conditions. We also monitored a strong increase in hCAT-1 protein upon T cell stimulation, which peaked after 48 hours of stimulation.

These results lead us to assume, that hCAT-1 is primarily responsible for influx of L-arginine in activated T cells.

To investigate the subcellular localization of hCAT-1 under different conditions, cell surface expression of hCAT-1 was analyzed in biotinylation experiments. The assays revealed that the upregulated hCAT-1 protein in the absence of L-arginine resulted also in a higher abundance of the transporter in the plasma membrane. Interestingly, the proportion of hCAT-1 detected in the plasma membrane was comparable in cells stimulated in the absence or the presence of L-arginine.

hCAT-1 activity was analyzed by the uptake of [3H]-L-arginine (100 μM) into unstimulated and for 48 h stimulated T cells in either arginine-containing or –deficient medium. The experiments revealed a strong induction of L-arginine transport in stimulated compared to unstimulated T cells in both, cells stimulated for 48 hours in the presence and absence of L-arginine. Additionally, transport was completely inhibited by the irreversible CAT-inhibitor N-ethylmaleimide (200 μM).

In summary our results indicates, that hCAT-1 plays a crucial role in L-arginine transport in stimulated human T cells. This enlarges our current knowledge of T cell function, the adaptive immune system and tumor-associated immune escape.

PCB221

Modulation of the intestinal epithelial tight junction barrier in response to infection

E. Blakesley[1], S. Carding[1], A. Watson[2] and A. Jones[3]

[1]Gut Health and Food Safety, Institute of Food Research, Norwich, UK, [2]Norwich Medical School, University of East Anglia, Norwich, UK and [3]The Sainsbury Laboratory, Norwich, UK

The intestinal barrier is dependent on three junctional complexes, the tight junction (TJ), the adherens junction and desmosomes. Of these, TJ complexes separate the external lumen from the underlying mucosa. Apical TJs consisting of integral transmembrane proteins including occludin, tricellulin and claudins form a dynamic multimolecular complex that selectively regulates the paracellular flux of ions and molecules through the small intestinal epithelium. The TJ complex also constitutes a highly resistant barrier to the entry of luminal pathogens and toxins, preventing infection of the underlying tissues. How the assembly and function of the TJ complex remains unclear. Evidence suggests TJ complex formation may be regulated by cycles of phosphorylation and dephosphorylation of occludin. Occludin seals the paracellular space between neighboring cells in epithelial and endothelial cell layers and targeted phosphorylation by cellular kinases affects

occludin localisation and interaction with components of the TJ complex. Occludin comprises two extracellular loops, four transmembrane domains and two intracellular N- and C-terminus domains. The aim of my project is to investigate the role of occludin phosphorylation in TJ barrier formation in response to pathogen infection. To address this I have used the major protozoan parasite *Toxoplasma gondii* to assess TJ barrier integrity in the small intestinal epithelial cells (IEC-6). Recombinant protein fragments of occludin domains were used to assess invasion of the intestinal epithelium by *Toxoplasma gondii*. We established *Toxoplasma gondii* tachyzoites bind to the extracellular loops of occludin as a mechanism of invasion and transmigration of the small intestinal epithelium without disrupting TJ barrier function. Our results indicate that *Toxoplasma gondii* can associate with the occludin C-terminus to modulate occludin phosphorylation and assembly at the TJ. We have provided also evidence for targeted phosphorylation of occludin in response to *Toxoplasma gondii* infection using an *in vitro* kinase assay to identify IEC-6 kinases that target occludin. These findings represent a step towards understanding the pathogenesis of intestinal diseases associated with a disrupted TJ permeability barrier.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Reducing noradrenergic stimulation of the epithelial sodium channel (ENaC) may contribute to the blood pressure lowering effect of renal sympathetic denervation

M.K. Mansley, M. Bertog and C. Korbmacher

Institut für Zelluläre und Molekulare Physiologie, Universität Erlangen-Nürnberg, Erlangen, Germany

The discovery that bilateral renal sympathetic denervation significantly lowers blood pressure in patients suffering from resistant hypertension[1] has refocused attention to the renal nerves in the development of hypertension. Little is known regarding the influence of the renal nerves upon salt absorption in the aldosterone-sensitive distal nephron (ASDN), a segment characterised by the presence of the epithelial sodium channel (ENaC). Previously, we reported[2, 3] that the adrenergic transmitter norepinephrine (NE) stimulates ENaC-mediated Na^+ transport in $mCCD_{cl1}$ cells, a model of principal cells of the collecting duct. In the present study we further investigated the effects of NE on ENaC-mediated Na^+ transport. $mCCD_{cl1}$ cells were grown on permeable supports and ENaC-mediated Na^+ transport was assessed by recording equivalent short circuit currents (I_{SC}) across cell monolayers mounted in Ussing chambers. Data are given as mean ± SEM, analysed by ANOVA. NE produces a complex response consisting of an amiloride-resistant peak, followed by a brief inhibition of I_{SC} over 15min and a sustained stimulation of I_{SC} over 2.5h, both of which are amiloride-sensitive. These responses are concentration-dependent, with 100nM causing a significant inhibition of basal I_{SC} from 6.1 ± 0.8 μA cm^{-2} to 4.8 ± 0.9 μA cm^{-2} (n=10, p<0.001). Higher concentrations did not inhibit I_{SC} further. A 10-fold higher concentration (1μM) was required to elicit a stimulation of I_{SC} above baseline from 6.1 ± 0.9 μA cm^{-2} to 8.7 ± 1.0 μA cm^{-2} (n=9, p<0.01). Increasing concentrations augment this stimulatory effect. Application of the β-adrenoceptor antagonist propranolol (1μM) did not alter the response to NE (n = 4), but the α-adrenoceptor antagonist phentolamine (20μM) reduced both the inhibitory response by 88.2 ± 0.1 % and the sustained stimulation by 69.8 ± 0.1 % (n=11). Addition of the specific α_2-adrenoceptor antagonist yohimbine (100nM) did not alter the amiloride-sensitive inhibitory component or the stimulatory response (n=9). Additionally we confirmed that aldosterone (3nM) stimulates I_{SC} in $mCCD_{cl1}$ cells. Interestingly, in cells treated with aldosterone, NE failed to increase I_{SC} above the level reached with aldosterone stimulation alone. This indicates that the stimulatory effects of aldosterone and NE are not additive. We conclude that in $mCCD_{cl1}$ cells the sustained stimulatory effect of NE on ENaC is mediated by basolateral α_1-adrenoceptors. ENaC stimulation by locally elevated NE may contribute to the hypertensive effect of increased renal sympathetic activity in particular in patients with low plasma aldosterone levels, i.e. in patients on a high salt diet. Reduced noradrenergic stimulation of ENaC may contribute to the blood pressure lowering effect of renal sympathetic denervation.

Increased apical Na+ permeability in cystic fibrosis is supported by a quantitative model of epithelial ion transport

D.L. O'Donoghue[1], V. Dua[3], G.W. Moss[1,2] and P. Vergani[2]

[1]Centre for Mathematics and Physics in the Life Sciences and Experimental Biology, University College London, London, UK, UK, [2]Department of Neuroscience, Physiology and Pharmacology, University College London, London, UK, UK and [3]Department of Chemical Engineering, University College London, London, UK, UK

We address the question of whether human airway epithelia have increased Na+ permeability in cystic fibrosis (CF) disease. CF is the most common lethal genetic disease among Caucasians. It is known that loss-of-function mutations in the CFTR gene, encoding an anion channel, cause reduced Cl- permeability in CF airway epithelia, however whether increased epithelial Na+ channel (ENaC) activity also arises in the disease state is an open question. We have focused on elucidating the quantitative relationships between individual transport protein activities (e.g. CFTR and ENaC) and the trans-epithelial potential difference (PD). Our study finds that the observed bioelectric properties of CF human nasal epithelial (HNE) cells can only be explained quantitatively if the loss of Cl- permeability is accompanied by a corresponding increase in apical Na+ permeability.

We arrive at this conclusion after developing a biophysically motivated mathematical model which describes the electrical, chemical and osmotic state of the HNE cell during measurement of trans-epithelial PD. Our analysis consists of three stages, first we estimate ionic permeabilities in CF and non-CF HNE cells, by directly fitting model predictions to time series of membrane potentials and intracellular concentrations recorded in primary HNE cell cultures. Then, we investigate the extent to which individual variation in the measured electrophysiological data maps to distributions of ionic permeability values in the normal and disease state. To this end we randomly permute 106 different transport parameter config-

urations, simulate trans-epithelial recordings in silico and determine which configurations allow acceptable CF and non-CF behaviour. Finally, given the distribution of acceptable parameter sets and predicted electrophysiological data, we perform a multivariate sensitivity analysis, to determine which transport parameters have most influence on the recorded properties of interest, such as the trans-epithelial PD and the amiloride sensitive PD.
With these approaches we find that a relative increase in Na+ permeability is necessary to produce the observed differences in bioelectric properties between non-CF and CF airway epithelia, and we find this conclusion holds despite the large variation observed in these electrophysiological properties. The results of our sensitivity analysis show that trans-epithelial PD is relatively insensitive to CFTR permeability, and very sensitive to changes in ENaC permeability, and this gives us the insight into why the apical Na+ permeability must differ in CF, as a loss of Cl- permeability is simply not sufficient to hyperpolarize the trans-epithelial PD to the extent seen in CF.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Molecular cloning and kinetic characterization of fish amino acid transporter B^0AT1 (SLC6A19)

E. Margheritis, R. Cinquetti, G. Terova, A. Cardillo, A. Peres and E. Bossi

Dept. of Biotechnology and Life Sciences, University of Insubria, Varese, Italy

In kidney and intestine, epithelial resorption of various amino acids, across the luminal brush border membrane, is mediated by different cotransporters. Neutral amino acids are thought to be transported by system B^0, in particular an important player is the cotransporter (symporter) B^0AT1 (SLC6A19) that belongs to a cluster of orphan transporters within the family of Na^+- and Cl^--dependent neurotransmitters and amino acid transporters (SLC6).
B^0AT1 is a Na^+ – dependent, nutrient transporter that accepts a wide variety of neutral amino acids. The first fish ortholog of this transporter, sea bass B^0AT1 (*Dicentrarchus labrax*) was cloned and electrophysiologically characterized by heterologous expression in *Xenopus laevis* oocytes. The substrate selectivity was estimated by recording the transport associated currents generated in the presence of different amino acids by the classical two-electrode voltage-clamp technique. The apparent affinity for Na^+ and substrates was determined and our data were compared with those reported for the mouse and human orthologs displaying high similarities. The results showed that the most transported substrate was Leucine and despite the fact that B^0AT1 could transport a broad range of neutral amino acids, this transporter, was also able to transport, with high efficiency, the charged Histidine. pH and ion-dependence was also analyzed; sbB^0AT1 presented a weak pH-dependence and the substitution of Na^+ with Li^+ gave rise only to a small current like the mammalian orthologs. The characterization of this transporter in fish has a nutritional importance, in particular in cultured species, for its ability to transport EAA (essential amino acids).

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Interaction of murine and human organic cation transporters with tyrosine kinase inhibitors and platin derivatives

D. Zeeh[1], S. Harrach[1,2], M. Fischer[1], E. Schlatter[1], J. Bertrand[2] and G. Ciarimboli[1]

[11]Experimentelle Nephrologie, Med. D, University Hospital, Münster, Germany and [22]Experimentelle Muskuloskelettale Medizin, University Hospital, Münster, Germany

Transporters are important mediators of specific cellular uptake and thus for effects, but also side effects, metabolism and excretion of many drugs. In particular, cellular uptake of the tyrosine kinase inhibitor (TKI) imatinib and the cytostatic cisplatin seems to be critically mediated by organic cation transporters (OCT). Three subtypes of OCT exist (OCT1, OCT2 and OCT3) with specific organ and species dependent expression. In this work, we have compared the interaction of several TKIs and of platin derivatives with OCT from humans and, to add translational relevance, from mice cloned into human embryonic kidney (HEK) cells. The interaction of these drugs with OCT was examined fluorimetrically with the cation 4-(4-(dimethyl-amino)styril)-methylpyridinium iodide (ASP, 1 μM) as substrate.
All TKI tested and cisplatin interacted with the ASP uptake by OCT. The IC50 differed both between the paralogs within a species and also between human and murine orthologs. Oxaliplatin did not interact with ASP uptake in any OCT. For this reason, we compared the toxicity of oxaliplatin in cells expressing or not hOCT2 by a colorimetric cell viability assay using 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT). Incubation of hOCT2 expressing cells with oxaliplatin resulted in a higher cell toxicity than in cells without the transporter. In conclusion, our data show that TKI and cisplatin interact with OCT with different apparent affinities depending on the OCT subtype. Moreover, the interaction strength can be different between mouse and human OCT, indicating that translational studies should be interpreted with caution. As evident in the case of oxaliplatin, a drug can be unable to interact with the ASP transport mediated by OCT, but the transporters seem to be of critical importance for the development of drug-associated toxicities, suggesting that OCT have a broad binding site with different interaction domains for diverse substances.

Table I. IC50-values (μM) for the inhibition of ASP uptake by the tested drugs

Substance/Transporter	mOCT1	mOCT2	mOCT3	hOCT1	hOCT2	hOCT3
Imatinib	0.8 [a,c]	3 [a]	58 [a,c]	5 [c]	3	53 [a,c]
Saracatinib	0.7 [a,c]	2 [a,c]	284 [a,c]	60 [c]	0.8 [a,c]	94 [c]
Tofacitinib	35 [b,c]	69 [c]	135 [c]	158 [a,c]	13 [a,c]	29 [a,c]
Cisplatin	31 [a,c]	360 [a,c]	1398 [a,c]	717 [c]	84 [a,c]	512 [c]

[a] = significantly different from the paralogs ($p<0.05$); [b] = significantly different from mOCT3 (both ANOVA tests); [c] = significantly different from the corresponding ortholog (unpaired t-test)

Exploring with the anticancer gold-based compound-Auphen the mechanism(s) by which Aquaporin-3 participates in cell proliferation

A. Galán-Cobo[1], A. Serna[1], I. Sánchez-Gomar[1], J. Toledo-Aral[1], A. Casini[2], G. Soveral[3] and M. Echevarría[1,4]

[1]Physiology and Biophysics, Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Seville, Spain, [2]Pharmacokinetics, Toxicology and Targeting, Research Institute of Pharmacy, University of Groningen, Groningen, Netherlands, [3]Research Institute for Medicines and Pharmaceutical Sciences (iMed.UL), Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal and [4]Centro de Investigación Biomédica en Red sobre Enfermedades Respiratorias (CIBERES), Madrid, Spain

The increment in the uptake of glycerol across the cell membrane by Aquaporin-3 has been associated with large ATP content and intracellular phosphorylation status, conditions associated with a larger proliferation capacity (1,2). Recently, the gold (III) complex Auphen has been described as a very selective and potent inhibitor of AQP3 glycerol permeability (3). Then, we decided to further explore the effect that this selective inhibitor produces on the cell proliferation of cell lines that considerable express AQP3 in a natural way (A431) or cells which are stably or transiently transfected for expression of this protein (PC12 or HEK293T), and compare it with cells with low/or none AQP3 expression (NIH-3T3 and PC12-wt). Proliferation rate was evaluated by two methods: first, by counting the number of viable cells that exclude the trypan blue colorant, after 24 and 48h of culture in the presence or not of 5μM Auphen, using a Neubauer haemocytometer; and second, calculating by immunofluorescence staining, the percentage of cells that incorporate BrdU after 2, 4, 6, 8 and 24h of treatment, in the presence or not of Auphen. Lack of cytotoxic effect of Auphen was previously confirmed by cell counting and using a colorimetric assay that evaluates cellular mitochondrial dehydrogenases activity as readout of number of viable cells. Treatment with Auphen strongly reduced the proliferation process of cells that express AQP3. Conversely, Auphen did not reduce the proliferation of cells with low/ or none expression of AQP3. Flow cytometric analysis of the cell cycle phases performed in PC12 over expressing AQP3 showed that the percentage of cells in the G2/M phase, the most proliferative phase, was higher, and lower the percentage of cells in G0/G1 phase, compare to PC12-wt. Additionally, lower percentage of cells in subG0/G1 phase during cell cycle analysis, as well as lower Annexin V specific staining performed in the presence of Nocodazole (5μM), a potent apoptotic inducer, indicates higher resistance to apoptosis in the over expressing AQP3 cells. Finally we analyzed the possible effect that Auphen may have over the cell cycle pattern that could explain the cell proliferation arrest indicated previously. Overall our results demonstrate a significant role of AQP3 in the cell proliferation process and may indicate a potential therapeutic effect of Auphen over tumorogenis. In tissues with large expression of AQP3 as the skin, epidermoid carcinomas and other skin cancer types could benefit from Auphen treatment due to its capacity of interfere in the cell proliferation associated with AQP3, but more studies are necessary to dig inside the molecular basis that underline to this mechanism(s).

PCB227

Bile acids regulate proinflammatory cytokine secretion from human airway epithelial cells

A. Ghatak[1], J. Ward[2], S. Keely[2] and E. Caraher[1]

[1]Centre for Microbial Host Interactions (CMHI) and Centre of Applied Science for Health (CASH), Institute of Technology Tallaght Dublin, Dublin, Ireland and [2]Molecular Medicine Laboratories, RCSI Education and Research Centre, Smurfit Building, Beaumont Hospital, Dublin, Ireland

Bile acids, produced by liver and classically known for their roles in facilitating digestion, are also known to have important roles in regulating several aspects of intestinal physiology, such as epithelial barrier and transport function and mucosal immune responses Although, levels of bile acids can also be elevated in the airways in several diseases, such as gastro-oesophageal reflux disease and cystic fibrosis, little is known about their effects on lung physiology and pathophysiology. The aim of this study was to investigate the effects of bile acids on cytokine secretion from human airway epithelial cells. Calu-3 lung epithelial cells were cultured on permeable supports and transepithelial electrical resistance (Rte) was recorded as a measure of barrier integrity. Cytokine secretion into the bathing medium was measured by sandwich ELISA and stimulated with Poly (I:C) and TNF-α, specific agonists for TLR3 and TNFR1, respectively. Lactate dehydrogenase (LDH) release was used as a measure of cell viability. Statistical analysis was performed by One-way ANOVA with the Tukey-Kramer post-test. p values < 0.05 were considered statistically significant.
The lipophillic bile acid, DCA (200 μM), increased secretion of the proinflammatory cytokines IL-8, IL-6 and TNF-α to 220.1 + 23.5% (n = 10, p < 0.05), 572.6 + 185.5 % (n = 9, p < 0.05), and 431.6 + 223.2 % (n=4), compared to unstimulated Calu-3 cells. In contrast, the more hydrophillic bile acid, UDCA (200 μM), was without effect, as were the taurine-conjugated derivatives of DCA and UDCA. Furthermore, DCA (200 μM) significantly enhanced IL-8 and IL-6 release from Calu-3 cells in response to both the TLR3 and TNFR1 agonists, Poly (I:C) (25 μg/ml) and TNF-α (100 ng/ml), respectively. In contrast, UDCA (500 μM) enhanced TNF-α-induced IL-8 release but did not alter either IL-6 or IL-8 release in response to Poly (I:C). Intriguingly, we found that at lower concentrations, both DCA and UDCA specifically inhibited TLR3-induced TNF-α release. Poly (I:C)-stimulated TNF-α release from Calu-3 cells was reduced from 13.4 + 2.1 pg/ml in control cells to 4.5 + 1.0 pg/ml in DCA (50 μM)-treated cells (n = 7, p < 0.05), whereas UDCA (1 μM) also attenuated Poly (I:C)-stimulated TNF-α release to 5.4 + 1.6 pg/ml (n = 7, p < 0.05). Taken together, these data indicate that bile acids play a complex role in regulating cytokine secretion from Calu-3 cells. Whether they exert anti-inflammatory or proin-

flammatory actions depends on the hydrophobicity of the particular bile acid in question and the concentration present. These findings are important to developing our understanding of the role that bile acids may play in the pathogenesis of lung inflammation.

PCB228

Different expression patterns of FXYD11 and Na+/K+-ATPase in gills of the brackish medaka (Oryzias dancena) when acclimated to hypo- or hyper-osmotic environments

C. Chang, W. Yang and T. Lee

Life Science, Chung Hsing university, Taichung, Taiwan

Upon hyperosmotic or hypoosmotic challenge, Na+/K+-ATPase (NKA) in gills of the teleosts supplied driving force for ion-secreting or ion-absorbing mechanisms, respectively. Meanwhile, FXYD11 plays important roles in modulating (NKA) activity in gills of the teleosts. Little is known, however, about the details of interaction between FXYD11 and NKA upon acute salinity challenges. The brackish medaka is a euryhaline teleost and a useful experimental animal model, which are able to tolerate a broad range of environmental salinities with efficient osmoregulatory mechanisms to maintain homeostasis. Time-course alterations in branchial FXYD11 and NKA expression (mRNA/protein), as well as NKA activity after exposure to salinity changes were first examined in this study to realize the short-term effects of different salinity stresses on FXYD11 regulated NKA activity in gills of the brackish medaka. The brackish medaka were acclimated to brackish water (BW, 15‰) for at least four weeks, and then the BW-acclimated medaka were transferred directly to fresh water (FW) or seawater (SW, 35‰). Upon hyperosmotic and hypoosmotic challenge, the NKA activity significantly increased at 1 hr (7.09 ± 0.80 vs. 5.50 ± 0.96 umol of ADP / mg protein / hr, $p<0.05$) and 12 (7.92 ± 1.05 vs. 5.50 ± 0.96 umol of ADP / mg protein / hr, $p<0.05$) hrs, respectively, while no significant difference of NKA protein abundance was found compared with the control group. Moreover, there was no significant difference found in the levels of FXYD11 mRNA in the salinity stresses. When the medaka were transferred from BW to FW, the FXYD11 protein abundance significantly increased since 12 hrs. Meanwhile, no significant difference was found in the FXYD protein abundance when transferred from BW to SW. Therefore, at 12 hrs upon hyperosmotic challenge, the branchial NKA activity and FYXD11 protein amounts were up-regulated, but NKA protein amounts did not change significantly. On the other hand, at 1 hr upon hypoosmotic challenge, the NKA activity was up-regulated, but NKA and FXYD11 protein amounts were not significantly different. The co-immunoprecipitation results further illustrated that the interaction between NKA and FYXD11 was up-regulated at 12 hrs upon hyperosmotic challenge, but not significantly different at 1 hr upon hypoosmotic challenge. The present study suggested that the brackish medaka used different mechanisms to modulate NKA activity when acclimated to hypoosmotic or hyperosmotic environments. FXYD11 might regulate NKA activity efficiently upon hyperosmotic challenge.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB229

Physiological and pathophysiological effects of various agents on ATP release in pancreatic ducts

J.M. Kowal, K.A. Haanes, N.M. Christensen and I. Novak

Department of Biology, University of Copenhagen, Copenhagen, Denmark

ATP is a signaling molecule that initiates various cellular responses after binding to P2X and P2Y receptors. These two classes of receptors are expressed in the pancreatic duct cells where they regulate ion and fluid transport (1). Our previous studies have shown that ATP is secreted from acinar zymogen granules into duct lumen (2). The aim of the present studies was to establish whether ATP is also released locally by pancreatic ducts and to determine which physiological and pathophysiological stimuli have such effects, and possible involvement of VNUT (Vesicular Nucleotide Transporter). Luciferase/luciferin bioluminescence assay was used to determine concentrations of ATP released from human pancreatic duct cells (e.g. Capan-1) in response to various stimulants and Fluo4-AM was used for detecting calcium changes. Results are given as mean changes from basal values ± S.E.M; $p<0.05$ accepted as significant. We also applied PCR and Western blot to investigate VNUT expression. We observed fast and continuous ATP release in Capan-1 cells in response to hypotonic and mechanical stimuli of 2.0±1.4 nM/10^6 cells/ml (n=6) and 0.9±0.5 μM/10^6 cells/ml (n=7). Ionomycin (5 μM) also induced similar ATP release 1.6 ± 0.9 nM/10^6 cells/ml (n=6). Ethanol (10-100 mM) had no effect on extracellular ATP (n=5). Interestingly, agents that act via receptors induced significant ATP release. For example, addition of UTP (1-10 μM) caused ATP release of 3.2 ± 0.7 nM/10^6 cells/ml (n=7). The bile acid chenodeoxycholate (CDC) induced dose-dependent (0.1-1 mM), fast and maximal ATP release of 1.0±0.3 μM/10^6 cells/ml (n=5). Concomitantly, CDC induced increase in cellular Ca^{2+} and a decrease in intracellular ATP, as detected by fluorescent markers (Fluo-4; Mg-Green) and confocal microscopy (n=4). Fluorescent ATP store markers (quinacrine, MANT-ATP), use of agents that interfere with secretory pathways (n=4) and molecular evidence for VNUT (n=5), indicated that ducts cells contain vesicular ATP stores. Together, our data show that there are various stimuli causing ATP release with different kinetics and this may indicate different releasing mechanisms, including vesicular release. In pancreatic ducts, ATP release might be an important co-stimulatory and protective mechanism for mechanical stimuli, as well as for substances that can enter lumen of pancreatic ducts, e.g. CDC and UTP. In low concentrations ATP can stimulate opening of Cl^- and K^+ channels and fluid secretion (3). However, overstimulation depletes the cells of ATP, partially via ATP release, and can therefore be involved in pathological changes in pancreas.

Roles of ezrin, radixin, merlin, and the Na^+/H^+ exchanger NHE1 in regulation of growth and motility of human breast cancer cells

G. Roest, K.F. Mark and S.F. Pedersen

Department of Biology, University of Copenhagen, Copenhagen, Denmark

Invadopodia are actin-rich membrane protrusions which play essential roles in cancer cell invasiveness [1]. Ezrin and radixin, closely related F-actin-plasma membrane linkers of the ERM protein family, have both been implicated in metastasis, while the more distantly related protein merlin functions as a tumor suppressor [2, 3]. The Na^+/H^+ exchanger NHE1 localizes to invadopodia and is implicated in regulation of cancer cell motility [4, 5]. NHE1 interacts directly with ERM proteins, however, the possible link between NHE1 and ERM proteins in regulation of invasiveness and invadopodia function, and the possible functional relation between NHE1 and merlin are both unelucidated.

The aim of this project was to characterize the roles and interactions of NHE1, ezrin, radixin and merlin in regulation of invasiveness and growth in MCF-7 breast cancer cells. Experiments were carried out in the absence and presence of constitutively active, N-terminally truncated ErbB2 (ΔNErbB2), which we and others have shown increases motility and invasiveness of these cells [5]. Expression of ezrin, but not of radixin or merlin was upregulated in ΔNErbB2 expressing MCF-7 cells. Ezrin and radixin colocalized strongly with NHE1 in invadopodial rosettes both in the absence and presence of ΔNErbB2, while merlin did not localize to these structures. siRNA-mediated knockdown of NHE1 increased the average number of invadopodia per cell from 0.23 ± 0.040 to 0.30 ± 0.020 in vector cells (n=3), yet had no effect in ΔNErbB2 cells. Overexpression of wild-type, constitutively active or dominant negative ezrin significantly decreased the average number of invadopodia per cell from 0.30 ± 0.042 to 0.21 ± 0.047, 0.12 ± 0.020 or 0.10 ± 0.017 in vector cells respectively (n=3), whereas it again had no effect in ΔNErbB2 cells. The size of the invadopodia was unaffected by knockdown of NHE1 or knockdown or overexpression of ezrin. Ongoing Boyden chamber- and zymography experiments are evaluating the impact of merlin and NHE1 and/or ezrin knockdown on MCF-7 cell invasiveness. In accordance with its known role as a tumor suppressor, siRNA-mediated knockdown of merlin significantly increased the growth rate of MCF-7 cells, in a manner more pronounced in vector- than in ΔNErbB2-expressing cells. We speculate that this may reflect the dual roles of these proteins in control of invasiveness and proliferation, however, further studies are ongoing to determine the mechanisms involved.

In conclusion, NHE1, ezrin, and radixin colocalized strongly in MCF-7 invadopodial rosettes whereas merlin was not found in these structures. Surprisingly, knockdown of not only merlin, but also of either NHE1, ezrin, or radixin, stimulated cell growth, in a manner most pronounced in the absence of ΔNErbB2 signaling.

MicroRNA miR-222 is elevated in human placenta from teenagers with low maternal folate status

B.C. Baker, K. Forbes, S. Lean, F.L. Mackie, C.E. Taylor, A.J. Garrod, S.L. Greenwood and R.L. Jones

Maternal and Fetal Health Research Centre, University of Manchester, Manchester, UK

Low folate in pregnancy leads to adverse outcomes, especially delivery of babies that are smaller than normal for gestational age (SGA), although the mechanism is as yet undefined (Tamura and Picciano 2006). A particularly vulnerable population, who have low folate status and an increased risk of delivering a SGA infant, are pregnant teenagers (Baker et al. 2009). Recent studies have shown impaired placental cell turnover and reduced nutrient transport in placentas from folate deficient teenagers. There is emerging evidence that microRNAs (miRs) regulate these processes in normal pregnancy and are altered in SGA placentas. We hypothesise that placental dysfunction associated with folate deficiency in teenagers is associated with altered miR expression. Expression of a panel of miRs including miR-143, miR-145, miR-22 and miR-222 was examined in placentas obtained from teenagers. Two groups were compared: teenagers with low folate (red blood cell folate 426nM, 324-500nM median + range, n=11)) and adequate folate status (red blood cell folate 927nM, 580-1178nM median + range, n=12; P< 0.001, Fishers exact test). Total RNA was isolated from villous tissue and expression of miRs assessed by quantitative RT-PCR using miR specific primers. Expression of the analysed miRs was normalised to 5s rRNA expression to correct for non-biological intersample variation. Of the miRs investigated, miR-143, miR-145, miR-22 and miR-222 were all expressed in the human placenta. Comparison of expression levels between teenagers with low and adequate folate status revealed that there was no significant difference in expression of miR-143, miR-145 or miR-22 in placental villous tissue. In contrast, miR-222 expression was significantly higher (30%) in placentas from teenagers with low folate status (relative expression 0.37, 0.28-0.71 median + range) compared to those with adequate folate status (relative expression 0.29, 0.15-0.54 median + range; Mann Whitney; P<0.05). Furthermore, miR-222 expression was negatively correlated with maternal folate status (Spearman rank: P<0.05, r = -0.3745). This study demonstrates that expression of miR-222 is elevated in placental tissue in teenage mothers with low folate status. Data from non-placental tissues suggest that miR-222 regulates components of cell cycle, proliferation and apoptotic signalling pathways. Ongoing studies are investigating the targets and functional role of miR-222 in the human placenta.

Butyrate: a potential anti-angiogenic therapy for breast cancer?

J. Longster, H. Lemar, A. Farmaki, B. Corfe and C. Staton

Oncology, University of Sheffield, Sheffield, UK

New cancer therapies are being sought that target both the tumour cells and the surrounding microenvironment. Butyrate is thought to be an HDAC inhibitor and has been shown to cause cell cycle arrest and apoptosis in colon cancer. More recently studies have suggested that butyrate can also down-regulate the pro-angiogenic factor VEGF in colon cancer. Therefore this study aimed to test the hypothesis that butyrate will stimulate breast cancer cell apoptosis and concomitantly inhibit angiogenic factor expression.
Treatment of MCF-7 and MDA-MB-231 breast cancer cells with increasing concentrations of butyrate (0-20mM) resulted in a significant decrease in breast cancer cell proliferation ($P<0.005$) as measured by MTS assay (EC50 3mM), cell cycle arrest in G1 ($P<0.04$), and a significant increase in apoptosis as measured by BAK expression using high content analysis ($P<0.001$). Protein array analysis following 48 hours of treatment with 5mM butyrate demonstrated a significant ($P<0.05$) decrease in the anti-apoptotic proteins survivin, XIAP, CIAP-1 and CIAP-2 and an increase in the pro-apoptotic p21 and p27 proteins. Analysis of angiogenesis related proteins revealed that the pro-angiogenic factors HIF1-a, VEGF, PDGF-AA and PDGF-AB/BB were consistently down-regulated, there was little change in the angiopoietins and that angiogenin was up-regulated. Further analysis revealed that both VEGF mRNA and protein were significantly ($p<0.02$) down-regulated in MDA-MB-231 cells in a dose dependent manner following butyrate treatment.
These data suggest that butyrate will have dual effects as a treatment for breast cancer; causing apoptosis of the breast cancer cells and indirectly inhibiting angiogenesis. Work is currently underway to establish whether butyrate will also be efficacious under hypoxic conditions.

PCB234

Corticospinal excitability map in less than 2 minutes

M.L. van de Ruit and M.J. Grey

School of Sport and Exercise Sciences, University of Birmingham, Birmingham, UK

Introduction: Corticospinal excitability maps obtained with transcranial magnetic stimulation (TMS) are used to assess plasticity of the central nervous system in motor learning and rehabilitation. With conventional methods, a single map usually takes 15-20 min to acquire (1-3). Due to this poor temporal resolution this method is not feasible in a clinical research setting. This study aimed to optimise the method in order to reduce the acquisition time. In addition, we investigated the effect of inter-stimulus interval and stimulation intensity on the map. Methods: TMS was used to elicit motor evoked potentials (MEPs) in first dosal interosseous. Frameless stereotaxy (BrainSight 2, Rogue Research) was used to record the 3D position and orientation of 100 stimuli within a 6 x 6 cm2 area over the hand area of the primary motor cortex. The stimulation positions and EMG records were combined and projected on a 2D plane using an off-line custom written Matlab script. The effect of two parameters on the map were studied: inter stimulus interval (ISI; 1, 1.5, 2, 3 and 4 s) and stimulation intensity (SI; 110%, 120% and 130% of resting motor threshold (rMT)). Maps were characterised by centre of gravity (COG), area (A) and volume (VOL). A repeated measures ANOVA with planned comparisons was used to compare ISIs at 1, 1.5, 2 and 3 s with the control ISI of 4 s. Finally, the minimum number of stimuli was determined by randomly removing stimuli and recalculating the correlation coefficient relative to a full map. The minimum number of stimuli required for a map was determined when the correlation coefficient dropped below 0.9. Results: *ISI:* No effect for ISI was found with area ($p=0.738$), volume ($p=0.981$) or COGx ($p=0.648$). A significant main effect was found for COGy ($p<0.001$). However, planned comparisons failed to show any difference for any parameter between 1 s and 4 s ($p=0.737$), suggesting stimuli could be delivered at 1 s or greater without affecting the map. *SI:* The map scaled with SI (A: $p<0.001$; VOL: $p< 0.001$). A Bonferroni post hoc comparison revealed all pairs being different.
The minimum number of stimuli to create a reliable map was 51 ± 19. Conclusion: We have shown that maps may be produced an ISI of 1 s, however some operators reported difficulty at the speed, therefore we suggest 1.5 s may be better. At 1.5 s and 120% rMT, a reproducible map may be created with 70 stimuli (mean + 1 SD), i.e. less than 2 min. Maps were less reproducible at 110% rMT due to greater MEP variability. With this significant reduction in acquisition time the method becomes feasible to be used in the clinic and in motor learning studies where greater temporal resolution is required.

Autonomic nervous response and subjective evaluation about sleep quality for sleep in menstrual cycle

M. Tanaka[1], M. Nagasaka[2], C. Egami[1], M. Kondo[1] and Y. Sakakibara[3]

[1]Nursing, Fukuoka prefectural Univ., Tagawa, Fukuoka, Japan, [2]Nursing, Miyazaki prefectural nursing Univ., Miyazaki, Miyazaki, Japan and [3]Kanazawa Institute of Technology, Kanazawa, Ishikawa, Japan

This study is to investigate the change of sleep in daily life during the follicular and luteal phases of the menstrual cycle. The seven healthy women, subjects aged 19-47 years participated in this study for two days during sleep. The protocol was approved by the institutional ethics review committee. All participants gave their consent to this study. We examined the RR interval variability for two and a half hours from the onset of sleep. After the night experimental, Subjects answered the following questionnaire such as sleep onset latency, awaked

time during sleep, subjective evaluation of the sleep by using visual analog scale. Autonomic function was estimated by the Lorenz plot and time domain for RR interval.
The hours of sleep and sleep onset latency in the follicular and luteal phases was 359.1±80.5 min and 357.0±43.1 min, 25.4±10.3 min and 20.0±11.5 min, respectively. The RR interval during sleep was increased in the beginning, and decreased, and then increased again in both phases. The ultradian rhythm in the sleep cycle of RR interval in both the follicular and the luteal phase was 76.5±11.5 min and 72.8±8.0 min, and there was no significant difference during 2 hours and a half from the onset of sleep between both phases. The correlation between the subjective sleeping quality and hours of sleep was statistically significant (R=0.580, R2=0.336) in the luteal phase, but not in the follicular phase (R=0.208, R2=0.043).
We concluded that although autonomic nervous activities during sleep, the subjective quality of sleep and hours of sleep did not show individually significant differences between the follicular and the luteal phases, the sensation score on sleep quality might be correlated with not only the hours of sleep but also the other thing, especially in the follicular phase.

The correlation between the quality of sleep and the hours of sleep

Renal vasoconstriction occurs during isometric calf exercise in humans: role of the muscle mechanoreflex

R.C. Drew[1], M.D. Muller[1], R. Cui[2], C.A. Blaha[1], J.L. Mast[1], M.D. Herr[1] and L.I. Sinoway[1]

[1]Penn State Hershey Heart and Vascular Institute, Penn State University College of Medicine, Hershey, PA, USA and [2]Penn State University, State College, PA, USA

Cardiovascular control during exercise is regulated in part by reflex feedback from muscle afferent nerve fibres (McCloskey and Mitchell, 1972). Handgrip exercise causes renal vasoconstriction in humans (Middlekauff et al., 1997) and muscle mechanoreflex and metaboreflex activation can each cause renal vasoconstriction (Momen et al., 2003). However, it is unknown whether renal vasoconstriction occurs during calf exercise or the extent to which muscle mechanoreflex and metaboreflex activation contribute to this reflex. Therefore, this study examined renal vascular responses during isometric calf exercise, muscle mechanoreflex and/or metaboreflex activation in humans. Nine subjects (4 men, mean ± standard error of the mean 27 ± 1 y, 71 ± 3 kg, 1.72 ± 0.03 m) performed 1.5-min one-legged, isometric calf exercise at 70% maximal voluntary contraction (MVC), 3.5-min post-exercise circulatory occlusion (PECO) of the exercised leg and 3-min passive calf muscle stretch with continued occlusion. A 0% MVC (rest) control trial was also performed. Mean arterial blood pressure (MAP; Finometer), heart rate (HR; ECG) and renal blood flow velocity (RBFV; Doppler ultrasound) were measured. Renal vascular resistance (RVR), an index of renal vasoconstriction, was calculated as MAP / RBFV. Statistical analysis involved repeated measures ANOVA and paired samples *t*-tests. Baseline MAP, HR and RVR were similar between trials (84 ± 3 vs. 84 ± 3 mmHg, 62 ± 2 vs. 64 ± 2 b.min^{-1} and 1.48 ± 0.13 vs. 1.43 ± 0.09 arbitrary units for 0% and 70%, respectively). 70% exercise significantly increased MAP, HR and RVR above baseline and 0% (p<0.05; Table 1). After exercise, these values fell but PECO caused MAP and HR to remain significantly elevated from baseline (p<0.05), whereas RVR returned to resting levels. Stretch significantly increased MAP, HR and RVR from baseline in both 70% and 0% (p<0.05). In conclusion, these findings suggest that renal vasoconstriction occurs during isometric calf exercise in humans. Additionally, muscle mechanoreflex activation via calf stretch increased RVR, both in the presence and absence of local metabolite accumulation. Therefore, muscle mechanoreflex activation may contribute towards renal vasoconstriction occurring during calf exercise.

Table 1 – Relative mean arterial blood pressure (MAP), relative heart rate (HR) and percentage renal vascular resistance (RVR) changes from baseline during the 0% and 70% MVC trials.

	0% MVC trial			70% MVC trial		
	Rest/Exercise	Occlusion/PECO	Stretch	Rest/Exercise	Occlusion/PECO	Stretch
MAP (mmHg)	0±1	2±1	3±1*	9±2*#	4±2*	5±1*
HR (b.min^{-1})	0±1	2±1	5±1*	16±3*#	5±1*#	6±1*

PCB237

Effect of a controlled respiratory rate on oxygen uptake kinetics during cycling exercise

T. Saitoh, H. Kobayashi, J. Yanai, R. Nomura, H. Tsutsui, H. Takana and K. Niizeki

Bio-Systems Engineering, Yamagata University, Yonezawa, Japan

Although previous studies have investigated the effect of hyperventilation induced respiratory alkalosis on oxygen uptake kinetics during exercise for the transition on oxygen uptake, the mechanism is still unclear. This study aimed to investigate the effect of a controlled respiratory rate on oxygen uptake kinetics during cycling exercise. Five healthy men participated in this study. The subjects performed baseline cycling exercise for 4 min at 10 W, followed by primary cycling exercise for 6 min at anaerobic threshold (AT), AT minus 40% of the difference between AT and the peak pulmonary oxygen uptake (AT – Δ40%), or AT + Δ40% intensities. Throughout the experiment, respiratory rate of each subject was maintained at 20,

30, or 60 breaths/min (bpm). The pulmonary gas exchange was measured breath by breath, the heart rate was measured using a cardiogram, and the oxy- and deoxyhemoglobin concentrations of the vastus lateralis muscles were estimated using near-infrared spectroscopy at 1 Hz. The kinetics analysis was conducted by using the oxygen uptake response curves and deoxyhemoglobin concentrations during transition to primary exercise. A one-way analysis of variance was used for comparing kinetic values among respiratory rates or workloads. When a significant difference was detected, the post-hoc Scheffe's test was used to identify significant differences. As the respiratory rate was high, the end-tidal partial pressure of CO_2 was lower (20 bpm: 32.7 ± 3.2 mmHg, 30 bpm: 31.1 ± 1.8 mmHg, 60 bpm: 21.7 ± 2.1 mmHg) during baseline exercise. Similarly, as the respiratory rate was high in the analysis of oxygen uptake kinetics, the time delay significantly increased (20 bpm: 12.8 ± 2.4 s, 30 bpm: 15.4 ± 2.1 s, 60 bpm: 18.9 ± 4.2 s in AT + Δ40%; $P < 0.05$) and time constant significantly decreased (20 bpm: 52.2 ± 10.4 s, 30 bpm: 36.2 ± 8.4 s, 60 bpm: 27.9 ± 8.9 s in AT + Δ40%; $P < 0.05$). The time delay and time constant did not differ significantly according to the workload. Similarly, active muscle deoxygenation did not differ significantly according to the respiratory rate and workload. Increase in the time delay at higher respiratory rates suggest that the ATP was mainly supplied by anaerobic metabolism, because the oxyhemoglobin dissociation curve shifted to the left owing to respiratory alkalosis. Decrease in the time constant after an increase in the time delay at higher respiratory rates suggest that the oxyhemoglobin dissociation curve shifted to the right owing to acidification; this occurred because compensation of respiratory alkalosis caused a decrease in the [HCO_3^-] and anaerobic metabolism increased the lactic acid concentration.

PCB238

A metabolomic approach to investigate metabolic changes induced by acute sprint running before and after long sprint training

C. Enea[1], F. Seguin[1], O. Bernard[1], D. Bon[1], C. Hanon[2] and B. Dugue[1]

[1]University of Poitiers, Poitiers, France and [2]INSEP, Paris, France

Objectives: Metabolomics is has become as an established strategy in the exploration of various stimuli effects. We have recently shown that intense physical exercise can extensively modify the urinary metabolome in human subjects (Ref 1). We have now investigated whether physical training could induce changes at the resting level and after a physical test.
Methods: Fourteen men performed 2 sets of sprint tests separated by a long sprint training program (6 sessions performed in two weeks). Urine specimens were collected at rest and 30 minutes after both sprint tests. Samples were analysed by 1H NMR spectroscopy and multivariate statistical technique (i.e. Principal Component Analysis and Partial Least Square Discriminant Analysis).
Results: Preliminary results show clear separation of the urine profiles obtained from specimens collected before vs. 30 min after the tests and from specimens collected at rest, before and after the training program.
Discussion: Our results shown that metabolomics could provide information on the changes that physical training could induce and seems to be a promising tool to make a deep insight into physiologic states of athletes. We now need to further explore the spectrum profiles of the metabolome in order to indentify the molecules involved.

PCB240

Acidosis-induced ATP release from skeletal muscle involves activation of CFTR through the cAMP/PKA pathway

J. Tu[1], L. Lu[2] and H.J. Ballard[2]

[1]Shenzhen Key Laboratory for Neuropsychiatric Modulation, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China and [2]Department of Physiology, Institute of Cardiovascular Science and Medicine, The University of Hong Kong, Hong Kong, Hong Kong

The cystic fibrosis transmembrane conductance regulator (CFTR) is involved in the acidosis-induced ATP release from skeletal muscle. In many cells, CFTR is activated through the cAMP/protein kinase a (PKA) pathway. We investigated whether this pathway was responsible for CFTR activation in muscle at low pH, and how the signalling pathway was initiated.
Rats were anaesthetised with sodium pentobarbital (70 mg/kg i.p.); the hindquarters were perfused at 1.5 ml/min with modified Krebs Henseleit buffer (pH 7.4) and EDL muscle interstitial fluid was sampled using microdialysis. Addition of lactic acid to the perfusion medium dose-dependently elevated interstitial ATP of buffer-perfused muscle from 38 ± 8 nM in the absence to 67 ± 11 nM in the presence of 10 mM lactic acid: this increase in ATP release was abolished by the specific CFTR inhibitor, CFTRinh-172 or by the PKA inhibitor, KT5720. Forskolin increased the intersitial ATP from 99 ± 20 to 142 ± 21 nM.
Addition of 10 mM lactic acid to the bathing medium of L6 skeletal myocytes increased the intracellular cAMP from 3.2 ± 0.3 to 7.1 ± 1.0 nM, the phosphor-cAMP response element-binding protein (pCREB): β-actin ratio from 0.30 ± 0.02 to 0.71 ± 0.07 and the extracellular ATP from 0.7 ± 0.1 to 1.4 ± 0.2 nM. Addition of the phosphodiesterase inhibitor, IBMX increased extracellular ATP to 3.4 ± 0.7 nM in the absence, or 5.9 ± 1.1 nM in the presence of lactic acid. Addition of 20 μM forskolin the the bathing medium increased extracellular ATP from 0.5 ± 0.02 to 1.3 ± 0.05 nM; CFTR phosphorylation was increased by the addition of forskolin alone, and further increased by the addition of forskolin plus dibutyryl-cAMP and IBMX, but the forskolin-induced increase in CFTR phosphorylation was inhibited by KT5720.
Addition of the Na+/H+-exchanger (NHE) inhibitor, amiloride abolished the lactic-acid-induced increases in both the intracellular cAMP (4.2 ± 0.4 nM in the absence or 3.8 ± 0.4 nM in the presence of lactic acid) and extracellular ATP (0.8 ± 0.2 nM in the absence or 0.9 ± 0.1 nM in the presence of lactic acid). Similarly, the Na+/Ca2+-exchanger (NCX) inhibitor, SN6 abolished the lactic-acid-induced increases in both intracellular cAMP and ATP release from the myocytes.
These data suggest that skeletal muscle CFTR is activated through the cAMP/PKA pathway at low pH; NHE and NCX may

be involved in the signal transduction pathway linking the decreased pH to the initiation of this mechanism.

Jie Tu, Lin Lu, Weisong Cai, Heather J. Ballard. cAMP/protein kinase A activates cystic fibrosis transmembrane conductance regulator for ATP release transmembrane conductance regulator for ATP release from rat skeletal muscle during low pH or contractions. Plos One, 2012; 7(11): e50157.

PCB241

Involvement of connexin hemichannels in acidosis- and exercise-induced ATP release from skeletal muscle

H.J. Ballard[1,2], L. Lu[1,2] and W. Cai[1,2]

[1]Department of Physiology, The University of Hong Kong, Pokfulam, Hong Kong and [2]Institute of Cardiovascular Science & Medicine, The University of Hong Kong, Pokfulam, Hong Kong

ATP is an important extracellular signalling molecule which contributes to exercise vasodilation. Both acidosis and muscle contraction stimulate ATP release from skeletal muscle cells through a cystic fibrosis transmembrane conductance regulator (CFTR)-dependent mechanism [1,2]. However, it is unclear whether ATP is released through CFTR itself or whether CFTR regulates a separate ATP-release channel. We investigated whether connexin (Cx) hemichannels were involved in acidosis- or exercise-induced ATP release from rat skeletal muscle.

RT-PCR indicated that cultured rat L6 skeletal myocytes expressed mRNA for both Cx40 and Cx43, but Cx40 was expressed only weakly in western blot, whereas Cx43 was strongly expressed (n=3). CFTR was isolated from a homogenate of L6 cells using an antibody bound to magnetic dynabeads. The immunoprecipitate was shown to contain both CFTR and Cx43 using western blot (n=4).

In rats anaesthetised with sodium pentobarbital (70 mg/kg i.p.), gastrocnemius muscle contractions were induced by sciatic nerve stimulation, and interstitial fluid was sampled using microdialysis. In the absence of drugs, the muscle contracted with an initial force of 0.60 ± 0.05 N (mean ± SEM, n=5) and the interstitial ATP increased from 3.7 ± 0.8 to 119.6 ± 24.5 nM (P<0.02, ANOVA): both of these values were reproducible in repeated contractions. The specific CFTR inhibitor, $CFTR_{inh}$-172 (20 μM) abolished the contraction-induced increase in interstitial ATP without changing the contractile force. The Cx inhibitor, gadolinium (100 μM) abolished the contraction-induced increase in interstitial ATP, but the force was also reduced from 0.68 ± 0.04 to 0.47 ± 0.04 N (n=5). However, another Cx inhibitor, carbenoxolone (100 μM) also abolished the contraction-induced increase in interstitial ATP, and did not significantly alter the contractile force, suggesting that Cx hemichannels may be involved in the contraction-induced ATP release.

A Cx43 over-expression model was created by transfecting the L6 myocytes with a Cx43 plasmid using the Qiagen HiPerFect transfection medium: Cx43 over-expression was confirmed using western blot. In control myocytes, reducing the medium pH from 7.4 to 6.8 increased the extracellular ATP from 0.7 ± 0.07 to 1.2 ± 0.09 nM (n=6; P<0.001, t-test). Cx43 over-expressing myocytes released significantly more ATP than control myocytes at pH 7.4, and reducing the pH from 7.4 to 6.8 increased the extracellular ATP from 1.3 ± 0.1 to 2.1 ± 0.2 nM, suggesting that Cx43 may be involved in acidosis-induced ATP release.

These data suggest that Cx43 co-localises with CFTR in the skeletal muscle cell membrane, and that a connexin may be involved in the release of ATP from skeletal muscle cells during acidosis or muscle contractions; further investigation is required to determine whether and how CFTR interacts with a Cx to induce ATP release.

Amino-terminal propeptide of C-type natriuretic peptide (NT-ProCNP) levels are altered following anaerobic exercise in physically active young men

H. Akseki[1], S.A. Vardar[1,2], M. Demir[3], O. Palabiyik[4], A. Karaca[1], Z. Guksu[1], A. Ortanca[5] and N. Sut[6]

[1]Physiology, Trakya University Medical Faculty, Edirne, Turkey, [2]Department of Sport Physiology, Trakya University Medical Faculty, Edirme, Turkey, [3]Department of Hemotology, Trakya University Medical Faculty, Edirne, Turkey, [4]Department of Biophysics, Trakya University Medical Faculty, Edirne, Turkey, [5]Trakya University Medical Faculty, Edirne, Turkey and [6]Department of Statistics, Trakya University Medical Faculty, Edirne, Turkey

It has been known that plasma level of atrial natriuretic peptide increases following exercise in healthy subjects (Vogelsang et al, 2006). However, no alteration has been found in level of urine C-type natriuretic peptide following exercise in healthy subjects (Bentzen et al, 2004). Amino-terminal propeptide of C-type natriuretic peptide (NT-proCNP) is known as an equimolar product of CNP synthesis. In this study, plasma levels of NT-proCNP were compared in young men who are physically active or sedentary before and after exercise.

Healthy young men (aged between 18 and 25 years) who defined the exercise duration more than 2.5 hours per week at least one year were accepted as physically active (n=10) and those lower than 1.5 hours per week were accepted as sedentary (n=10). Daily energy expenditure of the subjects was recorded by an accelerometer during seven days. Level of maximal oxygen consumption was determined by Astrand test on the first day of the study. Wingate test was applied for anaerobic exercise on the following day. Plasma NT-proCNP levels were measured before anaerobic exercise and one, five and thirty minutes after the exercise. Values were shown as means±SD. Two groups comparisons were made by Mann-

Whitney U test and comparison of continuous variables were made by Wilcoxon Signed Ranks test.
Basal NT-proCNP levels, body mass index and body fat of the groups were similar. Exercise duration of physically active group was reported as 11.3±5.0 hours per week. Daily energy expenditure was found higher in physically active group than the sedentary group (1488.8±169.6 kcal, n=3 vs. 741.8± 299.2 kcal, n=8, respectively, p<0.05). NT-proCNP levels in the fifth minute (0.93±0.23 pmol; p<0.05) and in the thirty minute (0.77±0.21 pmol p<0.05) after exercise were higher than the basal measurements (0.64±0.29 pmol) in physically active group. However, the serial comparison of NT-proCNP levels did not differ in the subjects who are sedentary. The plasma levels of NT-proCNP after fifth minute of exercise were higher in physically active group (0.93±0.23 pmol) than the sedentary group (0.74±0.16 pmol, p<0.05).
The present study demonstrated that plasma levels of NT-proCNP increases following the short term anaerobic exercise in healthy subjects who are physically active but not in sedentary subjects. Physical activity may be a factor affecting the alteration of the secretion of NT-proCNP following exercise.

Bathing with artificial high concentration CO_2-water affected quiet standing posture control

N. Yamamoto[1] and M. Hashimoto[2]

[1]Department of Health Science, Japanese Red Cross Hokkaido College of Nursing, Kitami, Japan and [2]Laboratory of Physiology, Department of Physiotherapy, Teikyo University of Science, Tokyo, Japan

Clinical observations of CO_2-hot spring (CO_2 ≥1000 ppm) immersion revealed the effects, an immersed part reddening, skin blood flow improvements, heart rate reduction[3)] , etc. The previous study was indicated that CO_2-water immersion activates parasympathetic nerve activity in humans[2)]. It is well known that not only systemic nervous system but also autonomous one are involved in posture control in quiet-standing position. CO_2-water immersion may also influence the posture control through the autonomic nervous system activities. This study aimed to reveal the effect of CO_2-water immersion on postural sway during quietly standing in healthy young adults. The healthy male college students (n=5) participated in this study. Body sway was evaluated by recording horizontal ground reaction force for 1 min continuously with a force platform equipped with a data processor. The recording was performed at pre-water immersion and post-water immersion under eyes open condition (EO) and then eyes closed condition (EC). Spectrum analysis by fast Fourier transform (FFT) method of body sway in the medio-lateral and antero-posterior axes was performed. Power spectra of body sway were evaluated by comparing powers in tow frequency bands: 0.02–1.0 (BAND 1), 1.0–10.0 Hz (BAND 2). Each subject was immersed up to the nipples for 15 min in tap and CO_2-water (35°C), respectively. Cutaneous blood flow (BF) was measured on the upper chest and on abdomen by laser-Doppler flowmetry. Statistical evaluation of the data was done by repeated-measures two-way ANOVA, using Turkey test for post hoc multiple comparisons at the 0.05 level of significance. BF was significantly larger in CO_2-water immersion throughout the recording period compared to tap-water immersion. Tap-water immersion changed neither path length of nor area of COP trace measured both under EO and EC conditions. However, the path length of COP was significantly decreased at post CO_2-water immersion in EO (66.1±11.8 vs 55.5±15.7 cm, p<0.05) and EC (88.9±21.8 vs 76.9±17.7 cm, p<0.05). Body sway of BAND 1 was significantly decreased at post CO_2-water immersion in the medio-lateral axes of EO (1.41±0.15 vs 1.13±0.26 cm^2, p<0.05) and the antero-posterior axes of EC (1.72±0.19 vs 1.49±0.33 cm^2, p<0.05), while that of BAND2 was not affected. It is known that body sway of BAND 1 is predominantly stabilized by visual input and vestibular input from the otoliths, and body sway of BAND 2 is stabilized by somatosensory input from the ankles and feet[1)]. Present results indicate that CO_2-water immersion can stabilize standing posture in human. Considering a decrease in BAND1 component, this may indicate a facilitation of visual input or vestibular input by CO_2-water immersion.

PCB244

Are motor units with different activation thresholds spatially distributed in human *gastrocnemius medialis*?

E. Hodson-Tole[1], I.D. Loram[1], M.A. Minetto[2,3], A. Botter[2] and T.M. Vieira[2,4]

[1]Institute of Biomedical Research into Human Movement and Health, Manchester Metropolitan University, Manchester, UK, [2]Laboratory for Engineering of the Neuromuscular System (LISiN), Politecnico di Torino, Turin, Italy, [3]Division of Endocrinology, Diabetology and Metabolism, Department of Internal Medicine, University of Turin, Turin, Italy and [4]Escola de Educação Física e Desportos, Departamento de Arte Corporal, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

It has recently been shown that, in human medial gastrocnemius [MG], the fibres of motor units activated during standing occupy localised territories in the longitudinal plane (1). Coupled with the muscle's pennate fascicle architecture there is potential for units with similar intrinsic properties to be concentrated at different points along its length. Aponeurosis material properties and fascicle geometries tend to vary along the length of MG (2-3). Fibres may therefore be arranged within the muscle to occupy a local environment which optimizes their intrinsic properties. Recent evidence indicates that fibres of units activated during standing are more highly represented in the distal portion of MG (4), suggesting low threshold units are preferentially represented in this muscle region. We further investigate this observation by testing whether fibres of

motor units with different activation thresholds have different spatial distributions along the proximal-distal axis of MG. Twelve participants completed the study which was approved by the Local Ethics Committee. Surface EMGs were recorded using 128 electrodes placed over MG. Electrically evoked twitches were elicited by stimulating the tibial nerve branch. Pulses were delivered for 50s with current pulse amplitude increased every 10 stimuli to elicit an increase in muscle activation. Representative ankle torques were calculated from recorded force plate data. The degree of MG stimulation was determined from M-wave root mean square [RMS] values. The location of the highest M-waves along the length of the electrode grid was calculated using barycentre coordinates from the spatial distributions of the incremental M-wave values computed for each stimulation level.

There was a positive linear relationship between mean ankle plantar flexion torque and M-wave amplitude [$p<0.01$, $R^2=0.98$]. Increasing stimulation amplitude therefore increased the number of activated motor units. In eight participants the highest M-wave amplitudes occurred in proximal electrode channels for low amplitude stimulation and in more distal channels at higher amplitudes. As M-wave amplitude is spatially associated to the distribution of activated muscle fibres, the shifts in RMS distribution suggest that, in these participants, there was regional organization along the proximal-distal muscle axis of muscle units according to their activation threshold. In three participants larger M-waves moved to proximal electrode channels with increasing stimulation amplitude. In one participant no spatial shifts in M-wave distribution occurred. Such variability between participants warrants further investigation to establish whether it is the result of the experimental methodology or represents variation across the general population.

24 hours chronomics of blood pressure/heart rate in rotating night shift workers and its relation with 6- sulfatoxy melatonin

N. Verma, B. Anjum, S. Tewari, R. Singh and A. Mahdi

Physiology, KG Medical University, Lucknow, Uttar Pradesh, India

Night shift work is associated with a disruption of circadian rhythms, where a person's internal body clock is in conflict with the rotating shift schedule. The circadian rhythm of the human body is characterized with an alternating cycle of sleep and awake.[1] Among healthy subjects, sleep tends to occur during a particular phase of circadian cycle.[2] It is possible that the circadian sleep propensity rhythm and hormonal rhythm are under influence of circadian pacemaker as well as sleep habit.[3] Most rhythms are driven by an internal biological clock located in the hypothalamic suprachiasmatic nucleus and can be synchronized by external signals such as light-dark cycles.[4, 5,]

In the present prospective study, we examined the 24 hours chronomics of BP/HR in night shift workers and to find out the possible correlation with 6-sulfatoxy melatonin. 62 healthy nursing professionals, aged 20-40 year, performing day and night shift duties were recruited from the Trauma Center, KGMU. Ambulatory blood pressure and heart rate were recorded at every 30 min intervals while awake and each hour in night time synchronically with circadian pattern of urinary melatonin during night and day shift duties. Highly Significant difference was found in double amplitude (2DA) of blood pressure between night and day shift ($p<0.001$). Circadian patterns of systolic double amplitude (Night shift: 24.50 ± 15.07 vs Day shift: 35.07 ± 16.01) ($p<0.001$) was higher in day shift as compare to night shift, diastolic double amplitude (Night shift: 18.96 ± 10.96 vs Day shift : 24.85 ± 11.70) ($p<0.001$) was also increased in day shift than night shift. A circadian pattern of systolic and diastolic 2DA was higher in day shift as compare to night shift. Acrophase of systolic, diastolic blood pressure and heart rate were altered (reversed) during night shift. During night shift, hyperbaric index (HBI) of mean systolic blood pressure was found to be increased at 00-03 am (midnight) while during day shift, peak was found at 06-09 am. It exhibits the desynchronization during night shift and entrainment of circadian rhythm in day shift. Peak melatonin was to be found in early morning as compared to mid night in night and day shift. Altered melatonin at night and in the morning time was related with the symptoms of sleep deprivation.

PCB246

Mitochondrial adaptations to intense exercise training and detraining

D. Bishop[1], C. Granata[1], E. Brentnall[1], K. Renner[2] and R. da Silva Fermino de Oliveira[1]

[1]Institute of Sport, Exercise and Active Living (ISEAL), Victoria University, Melbourne, VIC, Australia and [2]Department of Hematology and Oncology, University Hospital Regensburg, Regensburg, Germany

Mitochondria are essential for life, and maintaining mitochondrial function is important to prevent the progression of many age-related diseases. We have shown that physical activity can increase mitochondrial respiration (1) and many of the proteins associated with mitochondrial biogenesis (2, 3). However, little is known about the effects of intensified training on mitochondrial function (ie mitochondrial respiration) and proteins associated with mitochondrial biogenesis. Furthermore, the effects of detraining on these exercise-induced mitochondrial adaptations are unknown. Ten active men (Peak VO2=47.0 mL/kg/min) took part in an interval training program (IT) 3x/wk for 4 wk, an intensified cycling training program (INT), in which they performed interval training 2x/day for 20 consecutive days, and a 2-wk detraining period (DT) consisting of 6 training sessions. Resting muscle biopsies were taken from the vastus lateralis muscle before the study and after the IT, INT and DT phases. Sub-maximal (0.25 mM) and maximal (5 mM) ADP-stimulated mitochondrial respiration was determined on permeabilised muscle fibers. The relative abundance of the five complexes of the electron transport system (ETS), and proteins associated with mitochondrial biogenesis, was analysed in duplicate via Western blotting. One-way ANOVA, with repeated measures for time, were used to test for the effects of training and detraining on all variables; the level of statistical significance was set at $P < 0.05$. There were no changes in mitochondrial respiration following IT. However, maximal ADP-stimulated and non-coupled mitochondrial respiration increased significantly, by 47% and 48% respectively, during the INT phase, and decreased significantly during the DT phase (17% and 22% respectively); sub-maximal ADP-stimulated mitochondrial respiration showed no significant change during any phase. Following IT, the protein content of the five complexes of the ETS did not change significantly, although there was a trend for all to increase. The protein content of all five complexes was significantly elevated from baseline at the end of INT, with Complex II increasing by ~40%, Complex I and IV increasing by ~20% and Complex V and III increasing by ~10%. Following DT all complexes returned to baseline, except for complex V. There were significant increases in most proteins associated with mitochondrial biogenesis following INT (eg PGC-1α, p53, NRF1, NRF2, TFAM), with some then decreasing towards baseline values following DT (eg p53 and TFAM). Our study demonstrates that three weeks of INT is sufficient to significantly increase mitochondrial respiration, as well as the relative abundance of ETS proteins, and proteins associated with mitochondrial biogenesis. A large proportion of these adaptations are reversed following 2 weeks of detraining, highlighting the remarkable plasticity of skeletal muscle mitochondria.

Erythropoiesis as an antioxidant response to the oxidative stress of hypoxia; focus on the inhibition of hydroxyl radical formation *in-vivo*

D.M. Bailey[1,2], C. Lundby[3], P. Rasmussen[3], S. Taudorf[4], R.M. Berg[4], B.K. Pedersen[4], M. Gutowski[1], J. Sullivan[5], J. McEneny[6], I.S. Young[6], M. Gassmann[7], E.R. Swenson[8], H. Rahmouni[2], K. Moller[4], M. Culcasi[2] and S. Pietri[2]

[1]Faculty of Health, Science and Sport, University of Glamorgan, South Wales, UK, [2]Institut de Chimie Radicalaire, Aix-Marseille Université, Marseille, France, [3]Institute of Physiology, University of Zurich, Zurich, Switzerland, [4]Department of Infectious Diseases, University of Copenhagen, Copenhagen, Denmark, [5]Burnett College of Biomedical Sciences, University of Central Florida, Orlando, FL, USA, [6]Centre for Clinical and Population Sciences, Queen's University Belfast, Belfast, Ireland, [7]Institute of Veterinary Physiology, University of Zurich, Zurich, Switzerland and [8]Department of Medicine, Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle, WA, USA

Background and Aims: Erythropoietin (EPO) is the key regulator of erythropoiesis, promoting the survival, proliferation and differentiation of erythrocytic progenitors to increase red blood cell mass for the maintenance of systemic O_2 homeostasis (Jelkmann, 2011). However, its action is not merely constrained to that of an endocrine hormone and broader interest in EPO as a cytoprotective molecule has evolved over recent years (Brines and Cerami, 2012). Emerging evidence suggests that the recombinant form of human erythropoietin (rHuEPO) may function directly as an antioxidant though the underlying mechanisms remain unclear (Katavetin et al., 2007). The present study employed an integrated approach to determine if EPO does indeed have the molecular potential to act as a biological antioxidant with a specific focus on its ability to suppress hydroxyl radical (HO•) formation.

Methods: In-vivo study: Radial arterial blood was obtained from 11 healthy males aged 27 ± 4 y old in normoxia (21% O_2) and following 12 h passive exposure to hypoxia (~13% O_2). Blood was assayed for EPO using high-sensitivity ELISA. Electron paramagnetic resonance spectroscopy was employed for the direct detection of ascorbate ($A^{\bullet-}$) and spin–trapped (*N*-tert-butyl-α-phenylnitrone) lipid-derived oxygen-centred alkoxyl (PBN-OR) radicals as an index of free radical-mediated lipid peroxidation (Bailey et al., 2011). In-vitro study: The second-order rate constant for the reaction of rHuEPO with HO• (*k*rHuEPO) generated by Fenton chemistry was determined via the deoxyribose (DR) method (Halliwell et al., 1987). Following confirmation of distribution normality using Shapiro-Wilk *W* tests, data were analysed using paired samples t-tests and relationships determined with Pearson Product Moment Cor-

relations. All data are expressed as mean ± standard deviation (SD).

Results: *In-vivo study:* Hypoxia was associated with an increase in EPO (6.2 ± 2.0 to 22.1 ± 6.3 mU.mL^{-1}, $P < 0.05$) that correlated against the elevation in $A^{\bullet -}$ [2,384 ± 166 to 3,087 ± 276 arbitrary units (AU), $P < 0.05$] and PBN-OR (16,321 ± 2,488 to 19,076 ± 2,122 AU, $P < 0.05$) as illustrated in Figure 1 A-B. *In-vitro study:* *k*rHuEPO was shown to be diffusion-controlled at 1.66×10^{11} M^{-1}.s^{-1} (Figure 2). The site-specific plot suggests that rHuEPO was able to inhibit iron ion-dependant DR degradation and thus capable of binding ions into chelates with poor ability to form HO•.

Conclusions: Collectively, these findings suggest that the cytoprotective benefits of rHuEPO may be due to its exceptional ability to suppress HO• formation subsequent to catalytic iron chelation. In addition to its traditionally accepted haematopoietic role, the systemic rise in EPO during hypoxia may also serve to counter oxidative stress.

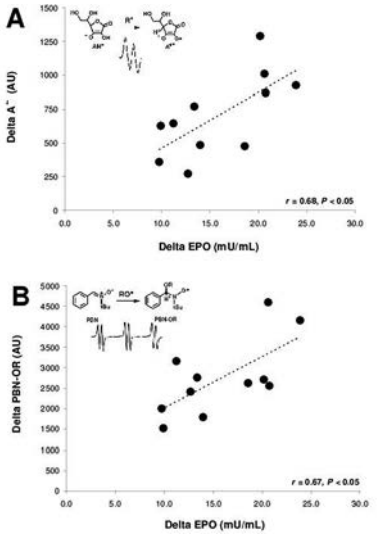

Figure 1. Relationships between the increase (delta: hypoxia minus normoxia) in the arterial concentration of erythropoietin (EPO) and systemic rate of free radical-mediated lipid peroxidation in the form of (A) ascorbate ($A^{\bullet -}$) and (B) *N*-tert-butyl-α-phenylnitrone spin-trapped alkoxyl (PBN-OR) radicals generated in-vivo. Chemical reactions and typical EPR spectra also illustrated.

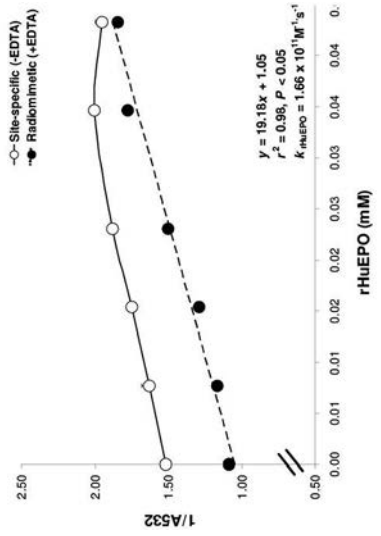

Figure 2. Competition plot of hydroxyl radical scavenging by recombinant human erythropoietin (rHuEPO). Hydroxyl radicals generated by Fenton chemistry (deoxyribose method) in the presence (+) or absence (-) of ethylene diamine pentaacetic acid (EDTA). Corresponding rate constant (*k*rHuEPO) is shown.

Intracellular DNA damage following isolated muscle contractions: a preliminary investigation into P53 gene expression

G. Davison[1], G. De Vito[2], C. Hughes[1], G. Burke[1], J. McEneny[3], C. McClean[1] and M. Fogarty[4]

[1]University of Ulster, Belfast, UK, [2]University College Dublin, Dublin, Ireland, [3]Queens University Belfast, Belfast, UK and [4]University of Hull, Hull, UK

P53 is an important gene in the regulation of aerobic metabolism and may play a central role in energy production during exercise. In response to intracellular DNA damage, P53 can initiate a series of cell responses and may even fail to function properly. This preliminary investigation was designed to test the hypothesis that high intensity single leg exercise can cause extensive cell DNA damage, which subsequently may affect the expression of the P53 gene. Six (n=6) apparently healthy male participants (age 27 + 7years, stature 174 + 12cm, body mass 79 + 4kg and BMI 24 + 4kg/m2) completed 100 isolated and continuous maximal concentric contractions (minimum force = 200 N, speed of contraction = 60°/sec) of the rectus femoris muscle. Using a spring-loaded and reusable Magnum biopsy gun with a 16-gauge core disposable biopsy needle, human skeletal muscle micro biopsy tissue samples were extracted at rest and following exercise. mRNA gene expression was determined via two-step quantitative real-time PCR using GAPDH as a reference gene. The average muscle force production was 379 + 179 N. High intensity exercise increased mitochondrial 8-OHdG concentration ($P < 0.05$ vs. rest, n=6) with a concomitant decrease in total antioxidant capacity ($P < 0.05$ vs. rest, n=6). Exercise also increased protein oxidation as quantified by protein carbonyl concentration ($P < 0.05$ vs. rest, n=6). P53 expression increased following exercise, however, due to low subject numbers this change was not significant ($P > 0.05$, n=2) These preliminary findings tentatively suggest that maximal concentric muscle contractions can cause intracellular DNA damage with no apparent disruption to P53 gene expression. However, a large-scale study incorporating a greater subject number is warranted to fully elucidate this relationship.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB250

The effect of exertional heat stress induced hypohydration on human physiology and biochemistry

M. Kapoor and L.P. Singh

Heat Physiology, Defence Institute of Physiology and Allied Sciences,Defence Research and Development Organization, Timarpur, India

Hypohydration or dehydration is the condition in which body water level falls below normal.The effects of hypohydration on thermoregulatory, cardiovascular and central nervous function become increasingly detrimental with degree of severity. Soldiers, athletes and commercial kitchen workers etc. are at a greater risk. Physical activity can result in 1-8% body mass loss.Dehydration level of 2% body mass is a threshold above which measurable changes in various physiological parameters are observed. Previous studies on hypohydration have focused on a very few and isolated parameters. The current study has a broader scope and gives and intergrated picture of the effect of 4% body mass loss due to exertional heat stress induced hypohydration in humans.

The study was approved from Institutional human ethical committee. Six healthy military personnel (age:25±4 years, height:172±4cm, weight:66±3 Kg) volunteered to participate in the study. They were informed about the purpose of the study and possible risks and signed a consent form.Volunteers were made to drink appropriate amount of water to attain euhydrated state one hour before the experiment. They were made to perform free hand exercise at 45C and 30% RH in human climatic chamber, till 4% body weight reduction was observed. Various parameters such as Heart Rate Variability, cardiac output and stroke volume, exhaled Nitric Oxide, Bio Impedance, core body and skin mean temperature were measured before and after the heat exposure. Blood samples were drawn and plasma was obtained and stored at -80C for biochemical analysis.

A significant increase in the level of hormones such as cortisol (1.9± .02nMol/L vs 2.2±.02 nMol/L, $p<0.001$), angiotensin II (0.123±0.02ng/L vs .317±0.06 ng/L, $p<0.01$), Antidieuretic hormone(56.5±12.9ng/L vs 123.3±24.4ng/L, $p<0.01$) was observed using paired T-test in plasma samples collected post 4% hypohydration compared to control. Also, a significant increase was observed in core body temperature (36.6 ± 0.1C vs 37.5 ± 0.1C, $p<0.001$), skin mean temperature (35.1±0.1C vs 36.01 ±0.1C, $p<0.001$), total body water (48.99 ± 3L vs 44.83 ± 3L, $p<0.001$), extracellular water (20.90 ±2L vs 19.64 ± 2L, $p<0.001$), the LF:HF ratio(6.20 ± 3 vs 9.04± 4, $p<0.001$) post 4% hypohydration as compared to control using paired T-test. No significant change was observed in the intracellular water volume, exhaled nitric oxide, cardiac output and stroke volume post 4% hypohydration as compared to control.

This is a comprehensive, multi-parametric study, with an aim to analyze the linkage between physiological and biochemical responses generated upon exertional heat stress induced hypohydration. Further in-depth studies are required to attain this goal. We plan to carry out experiments using Rat as model system to elucidate the exact mechanisms and pertinent pathways, which underlie hypohydration.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB251

Red blood cell oxidative stress during prolonged and strenuous exercise

D.M. Lima[1], A. Mendes-Ribeiro[1,3], C.O. Chamma[1], D.C. Abrantes[1], M.A. Martins[1], L. Cameron[2], T.C. Brunini[1] and C. Matsuura[1]

[1]Department of Pharmacology and Psycobiology, State University of Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil, [2]Department of Genetics and Molecular Biology, UNIRIO, Rio de Janeiro, Rio de Janeiro, Brazil and [3]Physiological Sciences, UNIRIO, Rio de Janeiro, Rio de Janeiro, Brazil

Background. Red blood cells (RBCs) are crucial for tissue oxygen delivery during exercise. Strenuous exercise can affect RBC membrane structure, probably due to mechanical and chemical stress, which ultimately may reduce tissue oxygen supply, and impair exercise performance. The objective of this study was to investigate oxidative stress biomarkers in RBCs during modern pentathlon.

Methods. Six athletes from the Brazilian Modern Pentathlon national team (4 men, 27 ± 4 yr, 1.8 ± 0.1 m, 70.5 ± 8.7 kg) participated in a simulated competition of modern pentathlon, which lasted about 8h. Blood samples were collected at 9 different times: T1, rest; T2, post-fencing; T3/T4, pre/post-200 m swimming; T5/T6, pre/post-horse riding; T7/T8, pre/post-combined event (3 km run interspersed by shooting); T9, after 2 h-recovery. RBCs were isolated by centrifugation for the following experiments: osmotic fragility test; oxidative damage (lipid peroxidation and protein carbonylation); antioxidant enzymes (catalase and glutathione peroxidase, GPx) activities. The procedures conformed to the Declaration of Helsinki and written informed consent was obtained form all subjects. Data were compared against resting values with a paired t-test. Significance level was set at 5%.

Results. All results are shown in Table 1. Osmotic fragility was significantly reduced after swimming (T4) and horse riding (T6) compared to rest (T1). A massive increase in lipid oxidative damage was observed after horse riding, which remained altered up to 2 hours after the end of competition. Protein oxidative damage was observed after horse riding (T6), and returned to basal levels thereafter. After horse riding (T6), a reduction in GPx activity was also observed, which remained depressed until recovery (T9). There were no significant variations in catalase activity throughout the competition, only a slight reduction before horse riding (T5).

Conclusion. Modern pentathlon induces damage to RBC lipid structures, especially after horse riding. This may result from a depletion of the antioxidant enzyme GPx, whose main biochemical function is to reduce lipid hydroperoxides to their corresponding alcohols. Future studies should investigate whether the observed damage is capable of inducing changes in RBC membrane structure, resulting in increased rigidity and impairment in tissue oxygen supply.

Table 1. Oxidative stress biomarkers [mean(SD)].

Effect of go/no-go signal on pulse volume amplitude during motor task performance

K.K. Deepak[1], C. Kharya[2], M. Pal[2], G. Jain[1], A. Jaryal[1], H. Singh[3] and S. Anand[2]

[1]Physiology, All India Institute of Medical Sciences, New Delhi, Delhi, India, [2]Biomedical Engineering, All India Institute of Medical sciences, New Delhi, Delhi, India and [3]CCRH, New Delhi, Delhi, India

Introduction: Anticipation of voluntary motor activity leads to feed-forward activation of sympathetic nervous system. No-go signal serves as an experimental paradigm for studying anticipation of voluntary motor activity, where the intended motor task needs to be suspended. It is hypothesized that no-go signal may induce sympathetic activation required for subject's preparedness for discontinuation of motor command. The present study was designed to evaluate the effect of no-go signal on sympathetic vasomotor function in a motor task performing situation.
Methods: Fifteen healthy subjects were asked to respond to either "YES" (go) or "NO" (no-go) commands. Subjects either had to press the hand grip dynamometer with maximum contraction or ignore in accordance to command structure. These were labeled as Actual Contraction (AC) and no contraction (NC) respectively for go and no-go commands.
The surface EMG was recorded from ipsilateral forearm and photo-plethysmogrpah (PPG) signal was recorded from the middle finger of the contra-lateral hand in sitting posture. The PPG amplitude (pulse volume amplitude, PVA) was used as a measure of sympathetic vasomotor function. The decrease in PVA of the PPG wave was taken as the measure of sympathetic activation.
The baseline EMG and PPG were recorded for 2 min. Average of 2 min PPG amplitudes at rest was considered as baseline amplitude. The PPG and EMG recordings were acquired for 30 sec following both the commands (go/no-go). For AC it was ensured that subjects maintained contraction for 30 sec. Both the go and no-go commands were given three times in random fashion to each subject. The 30 sec PPG records during both AC and NC were further analyzed for PPG amplitudes averaged in 10 sec bin. The amplitude value of three records was averaged for the purpose of analysis. The data was analyzed using paired t test and results are expressed as mean ± SD.
Results: The averages of 10 sec PVAs decreased significantly during AC (280.7 mv ± 103.6 to 122.7 mv ± 65.56; p<0.001; decrease of 56.3 %). The PVAs of initial 10 sec of NC were found to be significantly decreased (280.7 mv ± 103.6 to 191.4 mv ± 110.6; p ≤ 0.001; decrease of 31.81 %). The % decrease of PVA was significantly less during NC compared to AC (p<0.001). However even during no-go signal subjects showed 31.8 % of residual activity. The no-go signal alone showed a sympathetic activation of 56.5 % {(31.8/ 56.3)X100} when compared to AC.
Conclusion: In the present study no-go signal for voluntary motor activity initiated sympathetic drive to vasculature in a situation where motor task was not performed. This reflects that nearly 50 % of sympathetic activation occurs due to readiness, even before the initiation of motor activity. Therefore even to execute no-go command a substantial sympathetic activation is required. This appears to operate through feed forward mechanism.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB253

The influence of voluntary hyperventilation on a standing balance of athletes

M. Malakhov[1], E. Makarenkova[2] and A. Mel'nikov[2]

[1]Yaroslavl State Medical Acadamy, Yaroslavl, Russian Federation and [2]Yaroslavl State Pedagogical University, Yaroslavl, Russian Federation

Introduction. It is known that hyperventilation causes impairment of standing balance, since fast and deep respiratory movements perturb vertical steadiness [1]. Its common knowledge, that athletes integrate sensory information much better than untrained people, so standing balance of athletes is more perfect [2]. Thus, it can be assumed that the influences of hyperventilation on their postural stability will be less. The aim of our work was to study the influence of voluntary hyperventilation on a standing balance of athletes.
Methods. The subjects were divided into two groups: "Athletes" and "Control". The "Athletes" group included 38 participants (19 females) aged 19.8±1.0 The control group consisted of 28 healthy volunteers aged 22.4±4.6 (18 females). At first the subjects stood quietly on the force platform ("Quiet breath"), than they breathed as deep and fast, as possible ("Hyperventilation"), duration of both trials was 20 seconds. The stabilographic parameters (the mean velocity (V, mm/s) and variance of the center of pressure displacement in mediolateral (Qml, mm) and antero-posterior (Qap, mm) directions) were measured with a force platform "Stabilan" ("Ritm", Russia). The ventilation was estimated indirectly by mean of a strain gauge [3], the ventilation index (Vent) was calculated as product of the respiratory amplitude and rate.
Results. We found that Vent significantly increased in both groups during the "Hyperventilation" trial (8.4±4.5 vs. 102.5±41.8, p<0.001 in the "Control" group, 6.12±3.48 vs. 136.49±50.3, p<0.001 in the "Athletes" group). According to the ANOVA results elevation of Vent was more pronounced in the "Athletes" group (p=0.003), so the athletes breathed more deep and fast compared to the control subjects. Thus, obviously the perturbing effect of hyperventilation on the postural stability of the athletes was stronger. All stabilometric indices were also greater at the "Hyperventilation" trial in both groups (2,31±0,67 vs. 4,02±1,33 mm, p<0.001 2,11±0,81 vs. 3,98±1,35 mm p<0.001 for Qml; 3,02±1,09 vs. 6,17±2,00 mm, p<0.001, 2,7±0,82 vs. 6,55±2,40 mm p<0.001 for Qap;

8,51±2,28 vs. 25,45±11,12 mm/s group, 7,06±1,68 vs. 37,76±29,00 mm/s for V in the "Control" and "Athletes" groups respectively), hence hyperventilation leads to impairment of standing balance in all subjects. The ANOVA results showed that only an increase of V was more pronounced in athletes versus control subjects (p=0.02), other indices changed in the same way. So the steadiness in athletes was the same as in untrained subjects despite of more strong influence of the hyperventilation, but the strain of the postural control system was stronger in athletes [2].
Conclusions. The postural control system of the athletes compensated the exposure of hyperventilation more effectively, but through greater efforts.

PCB254

Gender-based EEG before and after acute exercise

N. Limbu[1], R. Sihna[2], M. Sihna[2] and B. Paudel[1]

[1]Basic & Clinical Physiology, B.P.Koirala Institute of Health Sciences, Dharan, Nepal and [2]physiology, All India Institute of Medical Sciences, Raipur, Raipur, India

Exercise is associated with changes in brain activity. Studies have examined few EEG frequency bands using few electrodes. There are few reports on EEG activity in response to acute exercise between male and female. We investigated how EEG frequency bands change in females in response to acute exercise compared to males. Consenting healthy adult females (n=15) & males (n=15) bicycled an automated ergometer at 50% HRmax for 20 min. A 16-channel EEG was recorded using international standards from mid-frontal (F4 & F3), central (C4 & C3), parietal (P4 & P3), temporal (T4 & T3) & occipital (O2 & O1). Exercise-induced EEG changes were compared between two sexes by Mann Whitney test. EEG power (μV2) is presented as median & interquartile range. The study was approved by institute ethical committee. In female, as compared to male, resting right side delta, alpha, beta & gamma activities were more in almost all recorded sites [delta: F4=49.82(44.23-63.56) vs. 35.5(32.70-44.44), p<0.001; C4=48.79(38.34-58.64) vs.37.6(26.72-43.80), p<0.01; P4=48.6(43.41-53.12) vs. 35.08(29.48-38.98), p<0.001; O2=58.88(52.65-59.52) vs.34.6(28.16-47.80), p<0.001; T4=17.78(15.77-20.95) vs.14.13(11.74-17.34), p<0.05], [alpha F4: 127.62(112.89-149.03) vs. 49.36(46.37-52.98), p<0.001; C4: 124.95(111.95-147.25) vs.57.07(51 – 59.29), p<0.001; P4=177.42(111.03-196.64) vs.89.91(66.58-98.86), p<0.001; etc], [beta F4=18.96(15.83-25.38) vs.14.77(10.34-17.55), p<0.05; C4=21.16(18.4-25.9) vs.15.48(9.66-19.40), p<0.01; P4=22.88(18.97-32.84) vs.18.7(12.32-24.09), p<0.05; etc], [gamma F4=0.58(0.44-0.87) vs. 0.24(0.20-0.42), p<0.001; C4=0.52(0.36-0.7) vs. 0.22(0.20-0.40), p<0.01; P4=0.54(0.45-0.67) vs. 0.24(0.21-0.40), p<0.001; etc]. Similarly, female resting right theta activity was more in Parietal [P4=33.04(25.1-42.41) vs.22.3 (18.36-34.33), p<0.05] & occipital [O2=50.81(30.64-66.8) vs.26.85 (22.18-34.42), p<0.001] regions than in male. They had similar picture on the left side also. The delta values (difference between post exercise and resting) of right alpha power was less in female in frontal [F4=-11.61(-45.24 -3.64) vs.9.48(1.05-16.58), p<0.01] and central [C4= -72(-32.98-9.48) vs.22.69(13.03-33.05), p<0.01] regions compared to males but they had less left central alpha [C3= -8.32(-32.65-6.1) vs.16.5(0.36-36.36), p<0.01] and temporal beta [T3= -6.29(-10.09- -1.49) vs.1.24(-0.84- 2.8), p<0.001] power compared to male. At rest, female group had more power of all the EEG frequency bands than the male. After acute exercise the female had decreased alpha in right frontocentral region whereas left alpha activity was reduced in central region and beta activity in temporal region. Although at rest females may have high EEG powers in different bands, the actual change in response to exercise, they respond in reverse way as compared to males. They seem less relaxed than the males immediately after moderate intensity of exercise.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB255

Impact of exercise training on cardiopulmonary fitness in obese Thai women

W.S. Khrisanapant, O. Pasurivong, T. Suthitum and J. Namarmarth

Physiology, Khon Kaen University, Khon Kaen, Khon Kaen, Thailand

It is well known that obesity can negatively affect health and function which may be partly restored by several aerobic exercise programmes. We quantitatively investigated the effect of aerobic exercise on the cardiopulmonary fitness in obese Thai women (BMI 29.41 ± 2.9 kg/m2, aged 45 ± 5.34 yrs). The aerobic exercise training (AET) consisted of 12 weeks of leg cycling on an electronically controlled cycle ergometer at or near anaerobic threshold (AT) (30 min/session, 3 sessions/week, 12 weeks). Peak oxygen uptake (VO2peak) and 6 minute walk test (^MWT) were used as a measure of cardiopulmonary fitness. Values are means ± SD. The AET resulted in significant reductions in body mass 2.5 kg (p<0.01), BMI 1.0 kg/m2 (p<0.01), waist circumference 4.1 cm (p<0.05), hip circumference 3.2 cm (p<0.05), % body fat 2.98% (p<0.001), FM 2.95 kg, (p<0.001), SBP 10.9 mmHg (p<0.01), DBP 8.8 mmHg (p<0.01) and MAP 9.5 mmHg (p<0.01) but not FFM. Additionally, it increased VO2peak by 21.6% (p<0.01), work load at anaerobic threshold by 14.3% (p<0.01), maximal work load by 10.7% (p<0.01) and 6MWT by 14.3% (p<0.01) compared to pre- exercise. These data suggest that a 12-week exercise training programme increased cardiopulmonary fitness, aerobic capacity and physical performance but reduced body weight, body composition, SBP, DBP and MAP in obese women.

This study was supported by the Invitation Research Grant from the Faculty of Medicine, Khon Kaen University, Thailand.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB257

Development of a four-day rapid acclimation schedule for military personnel

L.P. Singh and M. Kapoor

Heat Physiology, Defence Institute of Physiology and Allied Sciences,Defence Research and Development Organization, Timarpur, India

During Military operations, the soldiers are often deployed to hot regions. It is very important to acclimatize them in advance to heat stress to reduce the risk of heat illnesses. The existing heat acclimation protocols require eight to fifteen days. We have attempted to develop a rapid acclimatization schedule with duration of four days.

The study was approved from Institutional human ethical committee. Eighteen healthy Military personnel (n=18), age: 25±4 years, height: 172±4cm, weight: 66±3 Kg volunteered to participate in the study. They were informed about the purpose of the study and possible risks and signed a consent form. They were divided into three groups with six volunteers in each group. The volunteers in group I were subjected to a previously standardized acclimation protocol, as per which they were made to perform free hand exercise in human climatic chamber at 45°C and 30% relative humidity for one hour/day for eight days. The volunteers in group II were made to perform free hand exercise in human climatic chamber at 45°C and 30% relative humidity for one hour/day for four days.

The volunteers in group III were made to perform free hand exercise in human climatic chamber at 45°C and 30% relative humidity for two hour/day for four days. One hour exercise was performed in the forenoon followed by one hour rest, after which one hour exercise was performed again. For all the three groups of volunteers, the Core Body Temperature (CBT), Mean Skin Temperature (MST) and Mean Body Temperature (MBT) were noted before and after exercise. For individuals of group I, a significant difference was observed in post exercise CBT (37.14 ±0.14 vs 36.82 ±0.14, $p<0.05$), MST (35.90 ±0.30 vs 35.25 ± 0.23, $p<0.05$), MBT (36.77 ±0.19 vs 36.35 ±0.17, $p<0.01$) at eighth day compared to the first day. For individuals of group II, a significant difference was observed in post exercise CBT (37.16 ±0.04 vs 36.64 ±0.06, $p<0.01$), MST (36.09 ±0.05 vs 35.61 ± 0.11, $p<0.05$), MBT (36.84 ±0.04 vs 36.21 ±0.11, $p<0.05$) at fourth day compared to the first day. For individuals of group III, a significant difference was observed in post exercise MBT (36.98 ±0.02 vs 37.06 ±0.02, $p<0.05$), MST (35.58 ±0.06 vs 35.53 ± 0.10, $p<0.05$), MBT (36.56 ±0.03 vs 36.46 ±0.02, $p<0.05$) at fourth day compared to the first day. There was no significant difference between post exercise CBT, MST and MBT of group I at eighth day and group III at fourth day. A significant difference was observed post exercise in CBT (36.82 ±0.14 vs 36.64 ±0.06, $p<0.01$) MST (35.25 ± 0.23 vs 35.61 ±0.11, $p<0.05$) MBT (36.35 ±0.17 vs 36.21 ± 0.11, $p<0.05$) of eighth day of group I and fourth day of group II. We have successfully shortened the duration of acclimation schedule as can be concluded from the data. It will help to minimize the time and manpower losses suffered by Military for acclimation of personnel.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB258

Whole-body cooling modulates skeletal muscle oxygenation during aerobic exercise

D.D. Gagnon[1], H. Kyröläinen[1], S.S. Gagnon[2], K. Herzig[3,4] and H. Rintamäki[5]

[1]Biology of Physical Activity, University of Jyväskylä, Jyväskylä, Finland, [2]Health and Rehabiliation Sciences, University of Western Ontario, London, ON, Canada, [3]Physiology and Biocenter of Oulu, University of Oulu, Oulu, Finland, [4]Psychiatry, Kuopio University Hospital, Kuopio, Finland and [5]Finnish Institute of Occupational Health, Oulu, Finland

Dynamic exercise results in increased muscle, and decreased skin blood flow in addition to a progressive decrease in tissue oxygenation with increased workload (Peltonen et al. 2012). Cooling of skin and skeletal muscle also reduces tissue oxygenation, in part due to an increase in peripheral vasoconstriction and a decrease in blood volume (Yanagisawa et al. 2007). It is currently unclear whether tissue oxygenation decreases further during aerobic exercise when combined with cold exposure. Using near-infrared spectroscopy (NIRS) technology, we examined the effects of whole-body cooling on muscle tissue oxygenation during aerobic exercise. Healthy male subjects (N = 11), dressed in shorts and t-shirt, completed 6 exercise trials on separate days. They exercised at 50% (walking) or 70% (running) of maximal oxygen consumption (VO2max), for 60 min on a treadmill in a climatic chamber set at 22°C (Neutral, NT), 0°C (Cold, CO), or at 0°C following a precooling period inducing deep tissue cooling (Cold with deep tissue cooling, CD). NIRS optodes were positioned on the muscle belly of the vastus lateralis (VL) and the gastrocnemius (GM) muscles to determine changes in skeletal muscle oxygenated (O2Hb) and deoxygenated (HHb) myo/hemoglobin levels ($\Delta\mu$M.L-1). Core and skin temperatures were also measured. Measurements were collected at baseline, 10, 30 and 60 min of exercise and analyzed by ANOVA (Mean ± SE). Skin temperature decreased by 10.0 ± 0.6 and 11.1 ± 0.5°C in CO and CD, respectively, and remained low during 60 min. Core temperature decreased in CD up to 30 min only (0.65°C ± 0.08) ($p < 0.001$). A clear reduction in muscle oxygenation was observed in GM and VL (70% VO2max only) during exercise ($p < 0.001$), which was greater at 70% vs. 50% VO2max ($p \leq 0.006$). The decrease in O2Hb was greater in CO (22.26 ± 1.27 μM.L-1) and NT (23.75 ± 1.43 μM.L-1) compared to CD (17.70 ± 1.57 μM.L-1) within the GM ($p = 0.023$) at 10 min of exercise only. In VL, however, the decrease was greater in CD compared to other conditions ($p = 0.021$). The increase in HHb was lower in CD (8.77 ± 3.07 μM.L-1) compared to CO (18.92 ± 6.70 μM.L-1) and NT (18.90 ± 2.84 μM.L-1) at 10 min in GM ($p = 0.019$). This was not observed in VL ($p \geq 0.972$). Tissue oxygenation responses differed between GM and VL. Interestingly, no differences in muscle oxygenation were observed between exercise in a neutral and a cold environment without whole-body deep tissue cooling. During the early stages of aerobic exercise, tissue deoxygenation was delayed in GM with deep tissue cooling whereas a greater decrease in O2Hb and unchanged HHb was seen in VL. These results may likely be due to a change in walking and running gait mechanics to perform the same workload relying on a larger muscle mass as muscle cooling is known to reduce mechanical efficiency, thereby modulating oxygen availability and transport.

PCB259

The use of antioxidant vitamin-E supplement: a study of female athletes

P. Chatterjee

Department of Physiology, University of Calcutta, Kolkata, West Bengal, India

Sports science is one of the newly exploring areas of Physiology that is very important to improve the athletic performance in scientific way. One of such a component that has a great probability to improve the athletic performance is the Antioxidant. More recently, Vitamin E as an antioxidant has come into the picture of muscular activity. Vit. E plays a critical role in protecting the cell from reactive oxygen species (ROS)-induced oxidative stress. There is an abundance of evidence that tissue content of Vit. E is decreased as a result of exercise, narrowing its protective margin against ROS. Because, human cannot synthesize this antioxidant Vit. E, they are dependent exclusively on dietary intake. So, oral supplementation of Vit. E may be a factor that influences physical performances. Total sedentary females were divided into two groups at random. Placebo sedentary group (n=15, given placebo supplementation for one week). Vitamin E-sedentary group (n=15, given 400 mg of Vit. E capsule supplementation for one week). Total female athletes were divided into two groups at random. Placebo athletes group (n=15, given placebo supplementation for one week). Vitamin E - athletes group (n=15, given 400 mg of Vit. E capsule supplementation for one week). Endurance performance has been carried out by Magnetic brake bicycle Ergometer on separate days. The room temperature was between 30-32 degree Celsius and the relative humidity was about 72%. The present study was to find out whether any physiological changes occur after Vit. E supplementation in female athletic and non athletic females.
They are:
1. a. To investigate protective effect of Vit. E on lipid peroxidation as marker of oxidative damage during exercise.
b. To evaluate the effect of endurance exercise and Vit. E supplementation on antioxidant enzyme systems in female athletes and sedentary females.
2. To study, at what extent an additional Vit. E intake can improve the cardio-respiratory parameters of athletes and non athlete females.
On analyzing the data, it was observed that Vit. E, the fat soluble natural antioxidant, plays a critical role in protecting the cell from exercise induced free radical mediated oxidative stress. So,Vit. E supplementation (400mg) can be recommended to female athletes performing regular training and also to individual subjected to strenuous work. This study supports the idea of antioxidant effect of Vit. E which might be useful in the biological preparation of endurance athletes for improving their athletic performance.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Effects of acute ingestion of cashew apple juice on oxidative stress and white blood cells count

N. Leelayuwat, P. Prasertsri, T. Thong-un, S. Muchimapura and J. Wattanathorn

Physiology, Khon Kaen University, Muang, Khon Kaen, Thailand

Oxidative stress could be increased with high-intensity exercise. It is a significant causal factor to dysfunctional immune response. Thus, high-intensity exercise is a risk of immunosuppression. Cashew apple which is a waste product of cashew nut comprises efficient antioxidants such as vitamin C and anacardic acids. Thus, supplementation of juice produced from cashew apple (CAJ) may reduce suppression of immune function. This may prevent post-exercise infection in sport players. The present study aimed to investigate effects of acute ingestion of CAJ on oxidative stress and white blood cells (WBCs) count in healthy trained subjects. This study was randomized crossover design. Ten healthy trained men aged between 16 and 29 years old were enrolled. They randomly ingested either CAJ or placebo (PLA) by 3.5 ml/kg body mass before cycling at 85% of maximal oxygen consumption for 20 min. Blood samples were obtained at rest, 20 min after the ingestion, immediately after the exercise and at 30 min of recovery period to determine oxidative stress and WBCs count. One week later, they received the other research drink and performed similarly to the previous visit. Oxidative stress was determined by plasma vitamin C, malondialdehyde (MDA) and nitric oxide concentrations. WBCs counts were determined by total WBCs, neutrophil, monocyte and lymphocyte counts. Data are expressed as mean ± SD. The differences of variables within and between groups were analyzed by repeated measures ANOVA and Bonferonni. The results show that there were significantly lower plasma MDA concentrations immediately after the exercise (0.83 ± 0.52 vs 1.08 ± 0.65 μmol/L, $p<0.05$) and during recovery period (0.73 ± 0.18 vs 0.95 ± 0.61 μmol/L, $p<0.05$) in the CAJ group compared to the PLA group. There was significantly higher plasma vitamin C concentration at 20 min after the ingestion (0.27 ± 0.11 vs 0.16 ± 0.12 μg/mL, $p<0.05$) in the CAJ group compared to the PLA group. Plasma nitric oxide concentration was not different between PLA and CAJ groups at any time-point. WBCs, neutrophil, monocyte and lymphocyte counts were not changed at any time-point in both PLA and CAJ groups without any difference between groups. In conclusion, acute ingestion of CAJ can decrease oxidative stress by increasing plasma vitamin C and decreasing plasma MDA. However, white blood cells counts were not affected.

Relationships between resting metabolism and maximum muscle force

J. Yamauchi

TMU, Tokyo, Japan and FIfSS, Tokyo, Japan

[Introduction]
It is known that basal/resting metabolism is associated with muscle mass and that the maximum force production is related to muscle mass, so that basal/resting metabolism should be associated with the maximum force production. Accordingly, a deterioration of skeletal muscle function is one of the consequences of increase in adipose tissue or a risk of metabolic syndrome, due to a lowering of basal metabolism. However, there is no information available whether a resting metabolism is related to maximum force generation.
[Purpose]
The present study investigated the relations between resting metabolism and maximum force generation of hand and leg in young men and women.
[Methods]
Thirty-six healthy young individuals (age, 20.6±0.8 yr; height, 162.3±7.6 cm; body mass, 55.5±7.7 kg, mean±S.D.) participated in this study. The resting metabolism was measured with the metabolic analyzer. Also, maximum isometric knee extension force of the right leg was measured with the knee extension dynamometer, maximum isometric handgrip force of the right and left hand was measured with a handgrip dynamometer and maximum leg power was measured with a distance of horizontal squat jump performance. All measurements were repeated 3 times, and the mean value of the nearest two measurements was used for further analysis. Data are presented as mean±SD.
[Results]
Lean body mass (LBM) was significantly correlated with hand grip force, leg power, knee extensor force and resting metabolism ($r=0.887$; $p<0.001$, 0.762; $p<0.001$, 0.687; $p<0.001$ and 0.514; $p<0.01$, respectively). Also, a resting metabolism was significantly correlated with hand grip force, leg power and knee extensor force ($r=0.493$; $p<0.01$, 0.579; $p<0.001$ and 0.39; $p<0.05$, respectively). Although there were significant relationships between a resting metabolism and maximum force generation, it was shown that resting metabolism was differently related to force generating capacity in upper and lower body and different type of muscle actions (dynamic vs. static, single joint vs. multi-joint movements).
[Conclusion]
This suggests that resting metabolism is not only related to muscle mass, but also to muscle force. Measurement of maximum muscle force can be useful for a simple evaluation of resting metabolism.

The impact of Pilates on power, speed and endurance parameters of teenage swimmers

F. Ozyener[1], F. Coskun[2], S. Koparan[3], A. Dogan[3] and D. Ediger[2]

[1]Physiology, Uludag University Medical Faculty, Bursa, Turkey, [2]Chest Diseases, Uludag University MedicalFaculty, Bursa, Turkey and [3]Physical Education and Sports, Uludag University, Bursa, Turkey

Centring, coordination and breathing are amongst the leading principles of Pilates exercise (Latey P, 2002), which are also important respiratory functions to consider during swimming. We hypothesized, therefore, that training for swimming along with Pilates could be synergistic to improve overall physical capability, and aimed to observe whether there was any effect of Pilates on the development of motor functions and respiratory capacity of young swimmers. Following approval from the Institutional Ethics Committee, 16 competitive swimmers (CS) (who are in training for the last 5 years for 2 hours/ 4 days/wk) and 12 habitual swimmers (HS) were recruited as volunteers. They were divided into 4 groups: CS who did Pilates training, (CSpil, n=9, 16,7±2.9 years); CS controls, no Pilates (CScon, n=7, 15,7± 1,5 years); HSpil, (n=6; 19,2± 1,8 years; and HScon, (n=6, 21,2±1,7 years). The training was for 8 weeks, as reported by Muscolino and Cipriani (2004). Before Pilates training (bPT), the volunteers were asked to perform incremental exercise test (15-25 W/min) to the tolerable limit for estimation of lactate-threshold (θL) and determination of peak pulmoner oxygen uptake (VO2peak) using Vmax Encore system (VIASYS, USA). The CS group also performed at 25, 50, 100, 200 and 400m freestyle swimming, whereas HS group only at 25 and 50m. The values of hand grip and back power (Takei Kiki Kogyo dynamometers, Japan) as well as vertical jump heights (countermovement jump test) were also determined. All measurements were repeated after PT. Values are median (minimum-maximum) and analysed by Mann-Whitney U and Wilcoxon matched pairs signed-ranks tests. The level of significance is $p \leq 0.05$. CSpil group presented significant improvement at VO2peak which was bPT: 28,5 (16,8-32,3) and aPT: 43,4 (34,7-57,5) ml/kg/min ($p<0.05$), and θL was bPT 14,4 (8,02-20.5); aPT, 21,73 (14,5-34,5) ml/kg/min ($p<0.05$). There was no difference at the power variables except for HSpil group back power values which were: bPT 69,4 (49,70-101,9) and 105,9 (80,1-146,5) kg ($p<0.05$). Swimming performance in seconds did not change significantly except for 200m in CSpil group. There was no difference for flexibility, body mass index, maximum heart rate and maximum load values amongst groups. Since Pilates is relatively easy and less stressful to perform as an exercise, there is a trend to recommend it in many areas. Regarding our study, three sessions of weekly Pilates for 2 months seems to positively affecting the improvement of peak VO2 in young CS. However, the contribution from that type of exercise into the speed and power variables seems less noteworthy. Before recommending Pilates as a "supplement" to the actual exercise during training, further work needs to be done.

PCB263

Does preceding human posture predict the priority of force minimisation over position control?

I. Loram

IRM/Healthcare Science Research Institute, Manchester Metropolitan University, Manchester, UK

A fundamental physiological idea is that the current configuration, sets or reflects parameters within the neurophysiological feedback loops that translate task intentions into muscular activity (3, 4). Human standing requires maintenance of unstable equilibrium with minimal muscular cost while controlling configuration. Whether the postural system prioritises maintenance of joint angles at the expense of muscular costs or prioritises minimisation of joint moments while allowing joint angles to change is uncertain (1, 2). Using gentle perturbations at the knee and observation of the transition into standing from walking, recent evidence (1) shows a common tendency to stiffen the leg joints in a generalised and prevailing manner. This stiffening may result from prior settings within the postural system. This hypothesis is tested by applying an internal perturbation which requires changing joint angles to minimise active joint moments. Hypothesis: perturbation related change in active joint moments can be predicted from the preceding posture.

Twelve participants stood on a force-plate holding a 5 kg bar in both hands. The bar was slowly raised to shoulder level, then slowly moved horizontally forwards to the maximum extent, then held in the forward position. Acceleration was minimal. If joint resistance were low, then during forward movement of the bar, the body should move backwards leaving the combined center of mass of body and bar in the initial position. If leg and trunk position remain constant the combined center of mass would move forwards. Summarising participants over three repetitions, in response to moving the bar anteriorly, the center of gravity moved anteriorly 26±17 mm and the absolute joint moment summed over the ankle, knee and hip increased 32±39 Nm. Both quantities showed substantial difference between participants and no change in repetition (Two-way ANOVA, α=0.05), so repetitions were averaged.

Using forwards, stepwise multiple regression, the increase in summed absolute joint moment normalised by summed absolute joint rotation is predicted by the preceding knee joint extension and hip joint to gravitation vector separation ($F(4,7)=14$, adjusted $R2=0.71$, $p=0.0016$). The fullest model prediction ($F(4,7)=40$, adjusted $R2=0.93$, $p=0.00007$), confirmed trunk angle as most important. The same process applied to normalised EMG activity summed over fourteen leg muscles, also confirmed trunk angle as most important. In this task preceding posture predicts the prioritisation of force minimisation over position control. Control of trunk alignment may be hierarchically and temporally prior to the control of generalised leg stiffness.

Effect of acute hypoxia on C_2C_{12} myoblast proliferation

C. Gallagher[1], J. Sharkey[2], N. Martin[2], D. Player[2], S. Myers[1] and M. Lewis[2]

[1]Sport and Exercise Sciences, University of Chichester, Chichester, UK and [2]School of Sport, Exercise and Health Sciences, Loughborough University, Leicestershire, UK

Oxygen (O_2) is an essential component in maintaining physiological homeostasis within mammalian cells and survival is classically viewed as being dependent upon the counterbalance of O_2 supply and O_2 demand (Arthur et al., 2000). Oxygen deprivation (hypoxia), such as that experienced at altitude, provides an important challenge to the organism which may severely compromise body metabolism, promoting reversible or irreversible loss of tissue and cell homeostasis leading to organic and functional decay (Magalhães & Ascensão, 2008). Loss in skeletal muscle mass in chronic hypoxia has been demonstrated during *in vivo* studies by a reduction of muscle (10-15%) and cross sectional area, including a decrease in muscle fibre size (20-25%) above 3000 m (Green et al., 1989; Hoppeler et al., 1990). *In vitro* studies support these findings demonstrating that chronic hypoxia (> 24 hours) leads to a decrease in cell proliferation and differentiation (Chakravarthy et al., 2001). However, the acute response is substantially understudied and could be important in understanding the effects of hypoxia on skeletal muscle during brief exposures such as those observed within intermittent hypoxic training programmes. The purpose of this work was to examine the role of acute hypoxia (24 h) on C_2C_{12} proliferation and relevant gene expression in 2D culture. 15 x 103 C_2C_{12} myoblasts were seeded into six well plates. The cells were maintained in DMEM with 20% FCS. C_2C_{12} myoblasts were either exposed to 21% or 5% O_2 (Figure 1).

At 24, 48, 72 and 96 hours RNA was extracted using the Trizol® method and mRNA expression of myogenic regulatory factors, myoD, myf5 and myogenin were detected using the 2-ΔΔCT method. Cell counts and cell viability were also quantified. Results were analysed using a 2 x 2 ANOVA. MyoD, myf5 and myogenin relative mRNA expression was not significantly different ($P > 0.05$) between the two conditions. Cell counts and cell viability also showed no change in hypoxia compared with normoxia. The data demonstrate that C_2C_{12} myoblasts can be cultured in hypoxia for 24 hours with no significant effect on proliferation. Thus, exposing individuals to 24 hours of hypoxia which results in an intramyocellular O_2 pressure of 5% appears safe for use within hypoxic research studies.

Appetite hormone response and body composition changes after 8 weeks exercise training with low and high intensities in overweight/obese females

H. Kubis, M. Jackson, F. Fatahi, D. King and A. Turner

School of Sport, Health and Exercise Sciences, Bangor University, Bangor, UK

Obesity is developing to pandemic proportions world-wide. One of the common obesity treatments is the prescription of regular exercise for weight reduction. Unfortunately, outcomes of training studies for weight loss show high variability, while responsible mechanisms which limit the effect of exercise for weight loss are not clear. We hypothesised that exercise training of obese female would lead to alterations in appetite hormone levels which would induce compensatory energy intake and no weight loss. To avoid confounding factors like motivation to lose weight and knowledge about study aims, we conducted a randomised single blind study. With ethical approval, healthy female subjects (n=43; BMI 30±3; Age 24±5) were recruited deceiving them about aims and measures, as well as excluding subjects who wanted to take part for weight loss. After random assignment into two groups, subjects trained with high (HI –group = 80-90%VO2peak) or low (LI –group = 50-60VO2peak) intensities three times (~1hour) a week for 8 weeks while the energy expenditure of the groups were matched via heart rate (telemetry). Pre and post measurements included body composition measurements (DXA), venous fasting and postprandial blood samples 1 hour after a test meal, VO2peak, resting metabolic rate, and diet diaries throughout the intervention. Appetite hormones measured via ELISA were insulin, amylin, leptin, ghrelin, and PYY3-36. 22 subjects (11 subjects per group) finished the study attending about 80% of the training sessions. Both groups (HI and LI) showed no alterations in weight (LI: pre 79.9±11.9, post 80.3±11.2; HI: pre 86.2±13.0, post 86.7±13.0 (kg)), fat (LI: pre 38.8±5.0, post 39.2±5.2; HI: pre 39.2±5.1, post 39.0±5.0 (%)) or lean mass after 8 weeks training. Moreover, VO2peak and resting metabolic rate were unchanged in both groups. Appetite hormone levels revealed a significant ($p<0.05$) reduction of fasting amylin (HI: pre 14.74±3.10, post 11.57±1.66; LI: pre 16.29±2.97, post 13.05±2.90 (pM)) and postprandial amylin (HI: pre 18.00±2.22, post 16.21±2.03; LI: pre 22.15±3.08, post 16.10±2.69 (pM)) levels in both training groups. Neither fasting nor postprandial levels of insulin, leptin, ghrelin and PYY3-36 were influenced by training in both groups. Analysis of diet diaries did not reveal any alterations in macronutrient composition over the training period. Amylin is known to influence food intake and gastric emptying; administration of amylin antagonist AC187 increased energy intake and accelerated gastric emptying. We suggest, considering the lack of changes in other measured appetite hormones, that amylin, via reduction in response to chronic exercise training, might enable a long term compensation of energy expenditure for improved body weight control.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB266

Magnetic Resonance Elastography measurement of human skeletal muscle stiffness shows a decline in older adults compared with young

P. Kennedy[2], S. Semple[2], C. Gray[2], E. Barnhill[2], E. van Beek[2], N. Roberts[2] and C. Greig[1]

[1]School of Sport and Exercise Sciences, The University of Birmingham, Birmingham, B15 2TT, UK and [2]Clinical Research Imaging Centre, The University of Edinburgh, Edinburgh, EH16 4TJ, UK

Magnetic Resonance Elastography (MRE) is an emerging imaging technology that measures skeletal muscle stiffness via the study of externally induced sound waves propagating through the muscle. Evidence from mainly animal studies suggests that skeletal muscle connective tissue stiffness increases with advancing age, contributing to muscle weakness. However two recent human MRE studies measuring stiffness (shear modulus) in the relaxed state showed no statistically significant association between stiffness and age in 50-70 y old women1, and no significant differences when young and middle-aged adults were compared2. There are no MRE reports in the literature of stiffness in adults >70 y. We hypothesised that muscle stiffness measured using MRE would be higher in very elderly adults compared with young.

We studied the quadriceps group of n=18 healthy men and women (n=8 older median age 81 y range 69-87 y, BMI mean (SD) 23.8 (3.3); n=10 young median age 24 y range 21-35 y; BMI 25.6 (2.3)) using a 3 tesla MRI scanner (MAGNETOM Trio, Siemens AG, Erlangen, Germany). We used a modified single-shot EPI sequence sensitized to motion by the motion encoding gradient, aligned perpendicular to the image plane. Imaging parameters were TE=56ms, TR=1600ms, FOV=235mm, Matrix=128×128, slice thickness=10mm, scan duration=1min 6s Mechanical excitation was supplied to the muscle via a ring shaped plastic cuff positioned at mid-thigh level and which was affixed to the vibration source via a carbon fibre piston. The data were imported into MATLAB then temporally Fourier transformed, filtered, inverted and averaged as previously

reported3. The data were interpreted over three regions of interest, the whole axial slice, the extensor muscles, and the vastus lateralis. Comparison between groups was by 1-way ANOVA.
We found a significant reduction in stiffness in older muscle compared with young across all regions of interest. Mean (SD) shear modulus for young vs old were 2053.4 (115.9) vs 1783.6 (87.2), p<0.001; 2067.7 (157.2) vs 1801.9 (98.0), p = 0.003; 1929.9 (212.2) vs 1664.5 (146.5), p = 0.02 for the whole slice, extensor muscles and VL alone respectively.
Contrary to our hypothesis, these preliminary data suggest that skeletal muscle stiffness may actually decline with advancing age although this may still adversely affect force transmission. Further research on larger groups, controlling for prior physical activity, muscle length and load, are needed. MRE is non-invasive and does not entail strenuous activity. It is therefore suitable for studies with older adults and may represent a non-invasive, functional biomarker of ageing muscle function.

PCB268

Chaperone protein binding in human muscle fibres during recovery from unaccustomed exercise

R. Billeter[1], K. Miller[1], D. Thomas[1], Z. Kwan[1], K. Marimuthu[1], P. Greenhaff[1] and H. Hoppeler[2]

[1]School of Biomedical Sciences, University of Nottingham, Nottingham, UK and [2]Institute of Anatomy, University of Bern, Bern, Bern, Switzerland

αB crystallin and Hsp27 are small chaperone proteins that bind to unfolded proteins in order to block potential aggregation sites. Both are abundant cytoplasmic proteins in skeletal muscle fibres. Hsp70 is also a muscle chaperone protein, thought to be involved in folding of nascent and/or unfolded proteins. We hypothesised that unaccustomed exercise would lead to unfolding of proteins, which would be bound by these chaperones.
P70S6kinase phosphorylation at thr 421/ser 424 is increased in type II fibres following resistance exercise, which is thought to reflect increased muscle protein synthesis[1]. Given that unfolded proteins are potentially associated with sites of repair, we hypothesised that fibres with increased chaperone binding would also show enhanced p70S6K phosphorylation.
Biopsy samples were obtained from vastus lateralis muscle of healthy volunteers (n=8, age 21-35), unaccustomed to physical activity, before and after 3, 30 and 180 min of recovery following 30 min of treadmill running at a workload that elicited a steady-state plasma lactate concentration of 4 mM. Immunohistochemistry was subsequently performed on muscle cryostat sections, using classic double fluorescence, as well as in situ proximity ligation to demonstrate co-localisation.
αB crystallin bound tightly and stably to insoluble structures, likely to be myofibrils and/or the cytoskeleton. To compare the extent of αB crystallin binding over the course of recovery, an arbitrary threshold was set just above the staining background of stitched micrographs covering whole sections and the fluorescence of the supra-threshold pixels expressed per muscle fibre area.
Figure 1 shows that peak αB crystallin binding occurred after 3 min of recovery, and then declined to a value close to baseline after 3 hours. Staining was partially diffuse but also punctate, with strongly staining dots. Hsp27 also bound to the αB crystallin dots, in addition to intermediate filaments. In these dots, in situ proximity ligation co-localised the two small chaperones to within 20-40 nm, thus they are likely part of the same complex. The larger, strongest dots stained positive for Hsp70, where it also co-localised with αB crystallin.
Given their established function, we interpret the co-localisation of three different chaperone proteins to the same site to indicate the presence of unfolded proteins. In fibres with numerous αB crystallin dots we found enhanced signals for p70S6K phosphorylation, resulting in a significant correlation between p70S6K phosphorylation and αB crystallin binding (p<0.05, r =0.57, Spearman). We believe this possibly reflects increased muscle protein synthesis at sites of protein unfolding.

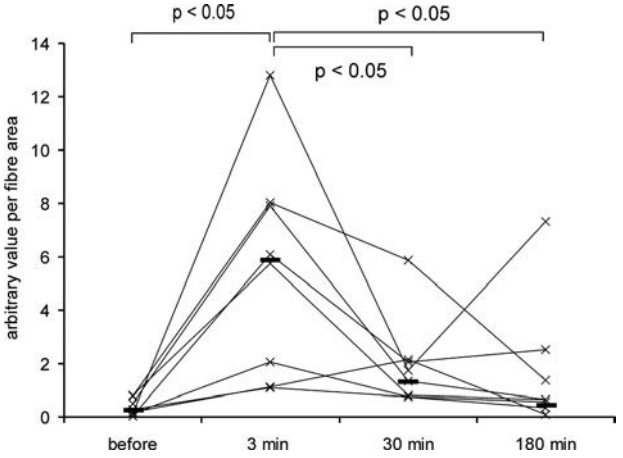

Figure 1: αB crystallin binding to insoluble structures in muscle fibres before and after 30 minutes treadmill running. x indicate bound crystallin per biopsy section, the values of individual subjects are connected. Black bars indicate medians. p values were determined using Wilcoxon's tests.

Mechanical hyperventilation enhances static cerebral autoregulation in critically ill patients with severe sepsis

M.W. Petersen[1,2], L.N. Toksvang[1], C.B. Christiansen[1], K. Møller[1,3], R.R. Plovsing[2] and R.G. Berg[1,4]

[1]Centre of Inflammation and Metabolism, Department of Infectious Diseases M7641, University Hospital Rigshospitalet, Copenhagen Ø, Denmark, [2]Intensive Care Unit 4131, University Hospital Rigshospitalet, Copenhagen Ø, Denmark, [3]Neurointensive Care Unit 2093, University Hospital Rigshospitalet, Copenhagen Ø, Denmark and [4]Renal and Vascular Research Section, Department of Biomedical Sciences, Faculty of Health Sciences, University of Copenhagen, Copenhagen N, Denmark

Background:
Hypercapnia may contribute to a functional impairment of static cerebral autoregulation in patients with septic shock (Taccone *et al*, 2010). This may predispose to irreversible brain damage by rendering the brain particularly susceptible to hypo- and hyperperfusion upon decreases and increases in mean arterial blood pressure (MAP), respectively. In the present study we hypothesized that mechanical hyperventilation would enhance static cerebral autoregulation in critically ill patients with sepsis.
Methods:
Six mechanically ventilated patients with severe sepsis were enrolled in the study following ethical approval and informed consent from the next of kin. Invasive MAP and middle cerebral artery blood flow velocity (MCAv) measured by transcranial Doppler ultrasonography were recorded before (baseline) and after mechanical hyperventilation with an intended reduction in $PaCO_2$ of 1 kPa. Steady state testing of autoregulation was achieved by increasing MAP approximately 30 mmHg by means of an intravenous infusion of norepinephrine. Data are reported as median with corresponding interquartile range (IQR).
Results:
Baseline infusion of norepinephrine (from 0.09 (0.02-0.22) to 0.16 (0.11-0.29) $\mu g \times kg^{-1} \times min^{-1}$) increased MAP from 73 (69-79) to 98 (96-107) mmHg ($p<0.05$). The concomitant MCAv values were 38 (36-48) and 47 (43-61) $cm \times sec^{-1}$. Mechanical hyperventilation decreased $PaCO_2$ by 0.7 (0.6-0.8) kPa with a concomitant increase in pH from 7.42 (7.35-7.43) to 7.46 (7.41-7.48) (both $p<0.05$). During hyperventilation, MAP was increased from 78 (74-82) to 105 (97-110) mmHg ($p<0.05$) by increasing the norepinephrine infusion rate from 0.09 (0.02-0.22) to 0.20 (0.14-0.29) $\mu g \times kg^{-1} \times min^{-1}$. The concomitant values of MCAv values were 34 (27-40) and 33 (27-49) $cm \times sec^{-1}$, respectively. The slope of the regression line between MAP and MCAv decreased from 0.19 (0.11-0.42) at baseline to 0.09 (-0.01-0.20) $cm \times sec^{-1} \times mmHg^{-1}$ during mechanical hyperventilation ($p<0.05$).
Conclusion:
Our findings may indicate that mechanical hyperventilation enhances static cerebral autoregulation in patients with severe sepsis, which highlights this intervention as a potential neuroprotective intervention in the critical care setting.

Table 1. Patient characteristics

Patient	Gender	Age (years)	APACHE II	SOFA	Focus of infection	Time from admission (hours)
1	F	74	31	12	Soft tissue	< 24
2	F	67	34	15	CNS	< 24
3	M	58	5	3	Soft tissue	< 72
4	M	43	19	14	Soft tissue	< 48
5	M	63	21	10	Lung	< 24
6	M	69	18	2	Soft tissue	< 72

APACHE II: Acute Physiology and Chronic Health Evaluation II; SOFA: sequential organ assessment score; CNS: central nervous system; F: female; M: male.

PCB270

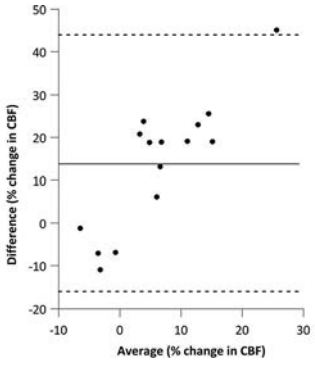
Poor agreement between transcranial doppler and near-infrared spectroscopy-based estimates of cerebral blood flow in patients with sepsis

L.N. Toksvang[1], M.W. Petersen[1,2], R.R. Plovsing[2], K. Møller[1,3] and R.M. Berg[1]

[1]Centre of Inflammation and Metabolism, Department of Infectious Diseases M7641, University Hospital Rigshospitalet, Copenhagen Ø, Denmark, [2]Intensive Care Unit 4131, University Hospital Rigshospitalet, Copenhagen, Denmark and [3]Neurointensive Care Unit 2093, University Hospital Rigshospitalet, Copenhagen, Denmark

Background. Near-infrared spectroscopy (NIRS) has been highlighted as a potentially useful non-invasive clinical tool for continuously monitoring cerebral hemodynamics in critically ill patients with sepsis (Steiner et al, 2009). This is based on the presupposition that changes in cerebral oxygen saturation (ScO2) accurately reflect changes in cerebral blood flow (CBF), but whether this is the case in critically ill patients with sepsis remains to be clarified. In the present study, we therefore compared NIRS- to transcranial Doppler ultrasound (TCD)-derived estimates of vasopressor-associated changes in CBF.
Methods. Eight mechanically ventilated, critically ill patients (mean age 62, SD 11; 2 females) diagnosed with severe sepsis were included following ethical approval and informed consent from the next of kin. In a step-wise manner, the mean arterial blood pressure (MAP) was increased by approximately 30 mmHg over 4–5 steps, remaining 5 minutes at each step, by increasing the norepinephrine infusion rate. The associated changes in CBF were assessed by simultaneous ipsilateral NIRS (ScO2) and TCD (middle cerebral artery blood flow velocity, MCAv) measurements. Data are reported as median with corresponding interquartile range (IQR).
Results. A total of fifteen simultaneous NIRS- and TCD-derived assessments of vasopressors-associated changes in CBF were obtained in the patients. The norepinephrine infusion rate was raised from 0 median (IQR, 0–0 μg/kg/min) to 0.20 μg/kg/min median (IQR, 0.15–0.30 μg/kg/min), which increased MAP from 74 (71–90) to 100 (93–115) mmHg ($p<0.05$). This was associated with an increase in MCAv of 14% (2–22) ($p<0.05$), whereas no changes were observed in ScO2; 1% ([-4]–3) (NS). The Bland-Altman plot (Bland & Altman, 1986), used to compare the two methods, showed a relative bias of 14% with limits of agreement -16 to 44 % change in CBF (Figure).
Conclusion. There was poor agreement between NIRS- and TCD-derived estimates of norepinephrine-induced changes in CBF. This is likely related to contamination of the signal by extracranial tissues, particularly blood flow through the scalp

vessels. Our findings thus question the applicability of NIRS for monitoring cerebral hemodynamics, at least in critically ill patients with sepsis.



Bland-Altman plot of transcranial Doppler vs. near-infrared spectroscopy based estimates of vasopressor-associated changes in cerebral blood flow (CBF).

PCB271

Correlation between maximal inspiratory pressure and spirometric indices in young rowers

J. Kivastik[1], M. Arend[2] and J. Mäestu[2]

[1]Department of Physiology, University of Tartu, Tartu, Estonia and [2]Institute of Sport Pedagogy and Coaching, University of Tartu, Tartu, Estonia

The pressure differences driving our ventilation are generated by respiratory muscles. Respiratory muscle weakness may sometimes explain dyspnoe and exercise intolerance, training of those muscles has shown to improve exercise performance in both healthy adults and in patients with chronic respiratory illnesses. Such training often asks to perform respiratory efforts against a pressure load equivalent to a certain percent of maximal respiratory pressures. Portable devices are available to measure those maximal pressures, but it can be highly dependent on participant effort. Our aim was to find out whether maximal inspiratory pressure (MIP) correlates with different flow-volume loop parameters in a group of college level rowers and to compare our data from athletes with published reference values.

We studied fourteen 19-33 year-old rowers (two of them female) with mean (range) height 187 (173-202) cm. Flow-volume spirometry was performed according to the international guidelines (1) to determine forced vital capacity (FVC), forced expiratory volume in 1 second (FEV_1), peak expiratory and inspiratory flows (PEF and PIF). In addition we made two forced inhalation maneuvers without previous forced expiration. Measurement of MIP was performed with a hand-held mouth pressure meter, during the forced inhalation from residual volume. The maximum average pressure sustained over a 1 second period was defined as a result, subjects repeated this test 3 times. All measured values were compared with reference data (2, 3) and correlations between MIP, lung function and anthropometric indices were expressed by Pearson correlation coefficients (r). Ethics committee approval was obtained and all participants gave informed consent.

In comparison to reference population our young rowers had values of FVC and FEV_1 mostly above average (97-130% of predicted), whereas PEF ranged from 85 to 120% of predicted. All 3 indices describing forced expiration correlated with height, the strongest correlation was found between FEV_1 and height ($r=0.89$, $p<0.01$). Often only forced expiration is assessed to diagnose airway obstruction, therefore, the measurement and reference values for PIF are less standardized. In 11 subjects the highest PIF value was obtained from the forced inspiration without previous forced expiration. When using MIP reference values depending on age only, we obtained values in a range of 88-212% pred (absolute values 98-234 cm H_2O). MIP correlated significantly only with PIF ($r=0.53$, $p<0.05$).

High lung volumes and flows compared to the reference values from untrained persons indicate an increased functional capacity of respiratory system in studied rowers. We found a wide between-individual variability of MIP in healthy young subjects. MIP values did correlate with neither anthropometric nor spirometric indices (except for PIF).

PCB272

Heterogeneity of blood flow and VO2 in exercising normal human muscle assessed by near infrared spectroscopy

P.D. Wagner[1], H. Habazettl[2], I. Vogiatzis[3], Z. Louvaris[3], H.E. Wagner[1] and S. Zakynthinos[3]

[1]Medicine, University of California, San Diego, La Jolla, CA, USA, [2]Institute of Physiology, Charite Campus Benjamin Franklin, Berlin, Germany and [3]Dept of Critical Care Medicine, University of Athens, Athens, Greece

Heterogeneity in the distribution of ventilation and blood flow in the lungs, and its effects on pulmonary gas exchange, are well known, and several methods exist for their quantification. This is not the case in skeletal muscle, where heterogeneity in the distribution of both blood flow and O_2 consumption has not been directly measurable, rendering its effects on muscle function unable to be evaluated. We used near-infrared spectroscopy (NIRS) to measure the regional distribution of VO_2, blood flow (Q), and their ratio (VO_2/Q) in six trained cyclists at rest and during constant load exercise (unloaded pedaling, 20%, 50% and 80% of peak watts) in both normoxia and acute hypoxia (FIO_2=0.12). From each of six optodes on the skin over the upper, middle and lower vastus lateralis, we recorded a) indocyanine green dye (ICG) inflow after IV injection to measure blood flow, and b) oxygenated Hb/Mb (StO_2). Varying both exercise intensity and FIO_2 provided a (directly measured) femoral venous O_2 saturation ($SfvO_2$) range of about 10 to 70%, and a corresponding range in StO_2 of about 35 to 75%. In each subject, a linear relationship was found between mean Q-weighted StO_2 over the 6 optodes and $SfvO_2$. We used this empirical relationship to compute local muscle venous blood O_2 saturation from StO_2 recorded at each optode, from which local VO_2/Q ratios could be calculated by the Fick principle. Multiplying regional VO_2/Q by Q yielded the corresponding local VO_2. Under all conditions, relative dispersion of Q (0.44 ± 0.02) and VO_2 (0.48 ± 0.02) were similar, while that for VO_2/Q was far less (0.14 ± 0.01), indicating in fit young subjects: a)

a strong capacity to regulate Q according to regional metabolic need from rest to heavy exercise in both normoxia and hypoxia, and b) a likely minimal impact of heterogeneity on overall muscle function. Future application of this novel approach, which may require recording from a larger number of optodes, should clarify the extent and importance of heterogeneity in muscle of patients with chronic diseases, and may become useful in the intensive care setting as an indicator of peripheral vascular regulatory integrity.

PCB274

A single night of fragmented sleep reduces cerebral vascular reactivity and central chemoreceptor CO_2 sensitivity

K. Pugh[1], S. Taheri[2] and G.M. Balanos[1]

[1]School of Sports and Exercise Sciences, University of Birmingham, Birmingham, UK and [2]School of Clinical and Experimental Medicine, University of Birmingham, Birmingham, West Midlands, UK

Purpose: Patients suffering from sleep disordered breathing present with a reduced cerebral vascular reactivity (CVR) [1]. The severity of this reduction is shown to be related to the number of arousals per night [2]. These changes in CVR and the fragmentation of sleep could play a role in the respiratory changes observed in this patient population. Hypotheses: We hypothesized that the change in CVR following a night of artificially fragmented sleep when compared to the CVR change following a normal night. Furthermore, we predicted a decline in respiratory CO_2 sensitivity. Methods: Participants visited the laboratory on two occasions for an overnight stay. One visit included a normal night's sleep (*control*) and the other visit included a night of fragmented sleep (*fragmentation*). During *fragmentation* micro-arousals were elicited during all sleep stages using a 500ms auditory stimulus played every minute. Continuous polysomnography was recorded throughout each night. CVR was assessed before and after each night using transcranial Doppler ultrasound of the middle cerebral artery. During the assessment of CVR participants were exposed to three five-minute steps of hypercapnia: 4, 7 and 10 mmHg above normal end-tidal partial pressures of CO_2($P_{ET}CO_2$). A hypercapnic (10 mmHg>normal $P_{ET}CO_2$) multi-frequency binary sequence test was completed following each night to assess central and peripheral chemosensitivity. A dynamic end-tidal forcing system was used for gas control during each assessment. Results: The mean (±S.E.) change in CVR following *fragmentation* is reduced across all three steps of hypercapnia when compared to the CVR change after the *control* night; -2.23±4.36%, -2.55±2.45% and -9.13±1.89%, respectively. We also observed a reduction in total CO_2 chemosensitivity following *fragmentation*, -41.97±20.25%. Additionally, peripheral chemosensitivity remained unchanged following *fragmentation* -6.20±16.62%. However, central chemosensitivity was markedly reduced -35.77±6.02%. Discussion: These results support our hypothesis of parallel alterations in breathing and cerebral vascular control following a night of disrupted sleep. The poor quality of sleep effecting patients suffering sleep disordered breathing could potentially play a role the respiratory control changes seen in this population, which may ultimately promote the further development of the disease.

Serum lipids: profile during pregnancy in women in Benin City, Nigeria

M.I. Ebomoyi[1] and C.N. Ekhator[1,2]

[1]Physiology, University of Benin, P.M.B. 1154, Benin City, Edo State, Nigeria and [2]St.Philomena's Catholic Hospital., Benin City, Edo State, Nigeria

Lipid metabolism changes during pregnancy in order to support fetal growth and development .1,2,3 It is believed that this process is under hormonal control.4 There have been reports on serum lipid profile during pregnancy in Caucasians, but very little is known in Africans.5 There has not been a prospective cohort study using the same group of subjects throughout the course of pregnancy in women in this environment, hence this study. The study was therefore to determine serum triglyceride (TG), high density lipoprotein cholesterol (HDL), total cholesterol (TC) and low density lipoprotein cholesterol (LDL) in the three trimesters of pregnancy in the same women, in Benin City, Nigeria. Subjects were 50 pregnant women at the 6th week of pregnancy (first trimester) with no history of midwifery complications or systematic disorders. They were 25-34 yrs, (mean age 28±0.44 yrs). Controls were 50 non-pregnant women of the same age group that met the inclusion criteria. Demographic characteristics and midwifery information were collected by questionnaire. Written informed consent was obtained, and fasting venous blood samples were taken during the 1st, 2nd and 3rd trimesters. Blood pressure was recorded. Mean ± S.E.M. were calculated for all groups. lipid concentrations were measured enzymatically and expressed as mg/dl. Data was analyzed using ANOVA, and $p< 0.05$ was considered statistically significant. TG was lower in the control group than in the 1st, 2nd or 3rd trimester (138.44±0.6 vs 312.3±9.3, 252±3.1 and 247.4±2; $p<0.05$). However, among the pregnant women, TG concentration in the 1st trimester was higher than in the 2nd and 3rd trimester. The 2nd and 3rd trimester TG concentrations were not significantly different. HDL was significantly lower in the 1st trimester than in the control, 2nd or 3rd trimester (48.04±0.3 vs 58.34±0.4, 60.7±1.0, 56.3±0.5). LDL was highest in 1st trimester pregnancy and least in the control group (178.1±1.3 vs 83.04±1.2, 137.7±2.2 and 125.2±0.8; $p<0.05$). TC was higher in pregnant women than in the control (224.7±0.9, 216.8±0.9 and 231.7±2.2 vs 180.44±1.6; $p<0.05$). The significantly raised TG, TC and LDL in the pregnant women compared to the controls, especially during the 1st trimester provides evidence of natural rising in plasma lipids in normal pregnancy due to hormones.4 This rise in TG, TC, and LDL may be due to an increase in hepatic lipase activity and decrease in lipoprotein lipase active, the principle modulator of which is the pregnancy-induced hyperoestrogenaemia. It is concluded that the normal pattern of pregnancy- induced variations in serum lipids is observed in the women studied.

PCB276

RFamide related peptide-1 attenuates gonadotropin-releasing hormone release in immortalized GT1-7 cells without changing intracellular calcium concentration

H. Kelestimur[1], E. Kacar[1], M. Ozcan[2] and S. Kutlu[1]

[1]Physiology, Firat University Medical School, Elazig, Turkey and [2]Biophysics, Firat University Medical School, Elazig, Turkey

Hypothalamic RFamide peptides, gonadotropin-inhibitory hormone (GnIH) and orthologous peptides, which were then discovered in mammals belonging to the RF-amide peptide superfamily (RFRP), seem to be important regulators of hypothalamus-pituitary-gonadal (HPG) reproductive axis. Kisspeptins are reported to be the most potent activators of HPG axis known to date. Kisspeptin increases intracellular calcium concentration ($[Ca^{2+}]_i$) in immortalized GnRH neurons (1). Whether RFamide peptides modulate the effects of kisspeptins on GnRH neurons has not been investigated. The goal of the present study was to examine the effects of RFamide related peptide-1 (RFRP-1), a mammalian orthologous peptide of GnIH, on kisspeptin-stimulated gonadotropin-releasing hormone (GnRH) neurons. In the study the GT1-7 cell line expressing GnRH was used as model to explore the effects of RFRP-1 on kisspeptin-activated GnRH neurons. The effects of RFRP-1 on GnRH release and calcium signaling in GT1-7 cells were investigated. GT1-7 cells were cultured on poly-D-lysine-coated coverslips and maintained in DMEM supplemented with heat-inactivated fetal calf serum, 100 U/ml penicillin and 100 μg/ml streptomycin at 37 oC in 5% CO2. After loading the cells with 1 μM Fura-2 AM, $[Ca^{2+}]_i$ responses were quantified by the changes in 340/380 nm ratio for individual GT1-7 cells. GnRH release to medium was assayed by ELISA. Kisspeptin-10 at 100 nM (n=65) caused a significant increase ($P<0.01$) in GnRH release. Co- treatment with kisspeptin in the presence of 1 μM RFRP-1 (n=43) attenuated ($P<0.05$) kisspeptin-induced GnRH release in GT1-7 cells. Kisspeptin-10 at 100 nM caused a significant increase ($p<0.001$) in $[Ca^{2+}]_i$ compared to basal levels in GT1-7 cells. RFRP-1 did not cause any change in kisspeptin-induced $[Ca^{2+}]_i$ increase in GT1-7 cells. The results suggest that RFRP-1 may have inhibitory effects on kisspeptin-activated GnRH neurons without affecting $[Ca^{2+}]_i$.

PCB277

Rat supraoptic nucleus neurons respond to glucose increase through closure of ATP dependent potassium channels

Z. Song, W. Stevens and C.D. Sladek

Physiology & Biophysics, University of Colorado School of Medicine, Aurora, CO, USA

Oxytocin (OT) is an anorexic agent. Deficits in OT are associated with human obesity. Glucokinase (GK), a hallmark of glucose-sensing cells, is expressed in the supraoptic nucleus (SON) of the hypothalamus, where OT and vasopressin (VP) are synthesized. Therefore, SON neurons may function as glucose-sensors. It has been shown previously that an increase in glucose induced a rise in intracellular calcium ($[Ca^{++}]_i$) in SON neurons (Song and Sladek, 2011), presumably through GK-driven production of ATP and subsequent closure of ATP dependent potassium channels (K_{ATP}). In our present studies, live-cell calcium imaging was thus used to determine the molecular signaling mechanisms underlying glucose-sensing of SON neurons. Rat hypothalamic explants that include SON were loaded with the calcium sensitive dye, Fura-2AM. Changes in $[Ca^{++}]_i$ were monitored by changes in the 340/380 emission in response to an increase in the glucose concentration from 0.5 to 5 mM in the presence of KCl (13 mM, to increase resting membrane potential). This increment in glucose caused an increase in $[Ca^{++}]_i$ in the majority of SON neurons. The responses still existed in the presence of TTX (3 uM, to block the influence of afferent synaptic inputs) but were abolished when cells were pretreated with either alloxan (4 mM, to inhibit GK activity) or diazoxide (0.4 mM, to open K_{ATP} channels). These findings indicate that SON neurons are capable of sensing glucose increase and respond to it by ATP-driven closure of K_{ATP} channels, which in turn induces an increase in $[Ca^{++}]_i$ and thus will potentially alter OT hormone release. This is the first demonstration that SON neurons monitor extracellular glucose, thus supports a role for OT in maintaining body nutrient homeostasis.

PCB278

Anti-diabetic and antioxidant effects of virgin coconut oil in alloxan-induced diabetic male Sprague Dawley rats

B.O. Iranloye, G.O. Oludare and O.V. Makinde

Physiology, College of Medicine, University of Lagos, Lagos, Lagos, Nigeria

Oxidative stress has been discovered to be involved in the progression of diabetes mellitus (Lenzen, 2008). The antioxidant properties of virgin coconut oil (VCO) among others might have a beneficial effect in ameliorating the disease. This pres-

ent study was aimed at determining the antioxidant property of VCO on alloxan induced diabetic rats.

Twenty-four healthy male Sprague-Dawley rats weighing between 100-150g were divided into four groups of six rats each as follows: Control (C), Diabetes untreated (DUT), Diabetes treated with 7.5ml/kg VCO (DT7.5) and Diabetes treated with 10ml/kg VCO (DT10). An intraperitoneal injection of Alloxan (100mg/kg body weight) was used to induce type 1 diabetes. Virgin coconut oil extracted from the fresh coconut was administered orally once daily. All animals were treated for 4 weeks. The fasting blood glucose level was measured on day 0 (72 hours post alloxan injection) and on the 4th week. Oral glucose tolerance test was conducted on the 4th week. At the end of the experiment, animals were sacrificed by cervical dislocation and Serum samples were and an enzyme linked immunoassay (EIA) system was employed to determine insulin level. The liver was harvested and the reduced glutathione (GSH) content was determined using the method described by Van Dooran et al (1978). Malondialdehyde (MDA) was determined based on its interaction with thiobarbituric acid (TBA).The activity of the superoxide dismutase (SOD) enzyme was determined according to the method described by Sun and Zigman(1978). Values are means ± S.E.M., compared by ANOVA and Tukey's post hoc test.

The results shows that VCO significantly reduced the fasting blood glucose level in DT7.5 rats (132.4 ± 6.911) and DT10 rats (131.6 ± 12.2) compare with DUT rats (320.4 ± 22.99) and improved the oral glucose tolerance. Serum insulin was increased in DT10 rats. GSH activities was significantly increased $P < 0.05$ in DT7.5 (0.04 ± 0.008) and DT10 rats (0.39± 0.022) when compared to DUT rats (0.032 ± 0.004). CAT activities was also significantly increased $P < 0.05$ in DT7.5 (17.63 ± 0.61) and DT10 rats (30.88 ± 0.97) when compared to DUT rats (10.98± 0.6). SOD activities significantly increased $P < 0.05$ in DT7.5 (2.634± 0.04) and DT10 rats (2.258 ± 0.32) when compared to DUT rats (1.366± 0.05) while MDA was significantly reduced $P < 0.05$ in DT7.5 (49.16± 0.5133) and DT10(33.64± 0.4185) rats when compared to DUT rats(99.93± 4.786).

This study revealed that VCO has a hypoglycaemic action enhancing insulin secretion and also ameliorating oxidative stress induced in type I (alloxan-induced diabetic) male rats.

PCB279

The effect of cyclic monoterpene menthol on blood glucose, water and electrolyte excretion in rats

C. Onwuchekwa[1], K.I. Ghandi[2] and N.D. Ndodo[3]

[1]Department of Physiology, Usmanu Danfodiyo Uniersity, Sokoto, Nigeria, [2]Department of Human Anatomy, Usmanu Danfodiyo Uniersity, Sokoto, Nigeria and [3]Department of Physiology, Usmanu Danfodiyo Uniersity, Sokoto, Nigeria

Rowachol (Rowa Ltd., Bantry, Eire), a proprietary choleretic containing the purified mono- and bicyclic monoterpenes menthol (32% w/v), pinene (17% w/v), menthone (6% w/v), borneol (5% w/v), camphene (5% w/v), and cineole (2% W/V) in olive oil, has been shown to cause dissolution of cholesterol gallstones in man (Doran et al., 1979) and to inhibit hepatic HMG-CoA reductase in rats (Middleton et al., 1979) and man (Ellis et al., 1981) when administered in vivo. The present study was therefore designed to investigate the effect of menthol on water with electrolyte excretion and blood glucose concentration in rats.

Menthol was administered in olive oil by gastric tube in a volume of 2ml/kg. In determining the dose-response relation for menthol, it was given at 1.0, 3.0 and 6.0 mmol/kg of body weight in a volume of 2 ml/kg. Water together with electrolyte excretion and blood glucose concentration were investigated using flame photometric and colorimetric techniques in rats (n= 48). Values are means ± S.E.M. and compared by one –way ANOVA using Graph Pad prism 4.

The treatment of rats with menthol resulted in a decrease in blood glucose concentration (73.0 ± 1.39, 67.5 ±1.41 and 63.9 ±2.06 mg/dl) that was significant ($p< 0.05$) in all the menthol treated animals (1.0, 3.0 and 6.0 mmol/kg) compared to that of the olive oil treated control group (75.4 ± 1.10 mg/dl). There was a significant dose ($p <0.05$) dependent increase in urine Na^+ ion level (420 ± 15.00, 450 ± 8.86, 480 ± 10.52 mmol) and urine output volume (150± 5.67, 200± 9.82, 280± 11.02 ml) in menthol treated animals compared to their control groups 400± 12.82 mmol and 135± 6.55 ml respectively, while urinary K^+ excretion showed no significant change ($p>0.05$) in all the treated animal groups (86± 2.08, 87 ± 2.38, 89±2.09mmol) with respect to the control (81.5 ± 1.75 mmol). The data obtained indicates that menthol increases water intake, urine output and urine Na^+ excretion, and decreases blood glucose concentration.

The ethical guidelines in accordance with NIH Guide for care and use of laboratory animals and with the Organization for Economic Development (OECD) guidelines on good laboratory practice (OECD, 2001) were followed in the handling of the experimental animals during the studies.

Regulation of 1,25-Dihydroxyvitamin D_3-induced intestinal calcium transport by Fibroblast Growth Factor (FGF)-23 as a part of the bone-kidney-intestinal axis

N. Charoenphandhu[1], J. Teerapornpuntakit[1], P. Khuituan[1], K. Wongdee[2] and N. Krishnamra[1]

[1]Department of Physiology, Faculty of Science, Mahidol University, Bangkok, Thailand and [2]Office of Academic Management, Faculty of Allied Health Sciences, Burapha University, Chonburi, Thailand

1,25-Dihydroxyvitamin D_3 [1,25$(OH)_2D_3$] is widely recognized as a potent stimulator of intestinal calcium absorption, but a hormone that counterbalances its action (negative feedback) has been elusive. A bone-derived hormone, FGF-23, is hypothesized to be a long-awaiting answer of this question since 1,25$(OH)_2D_3$ enhances FGF-23 release from bone whereas FGF-23 reduces the renal synthesis of 1,25$(OH)_2D_3$. In the present study, male mice [Imprinting Control Region (ICR) strain; 7-week-old; n = 6–10 per group] were used and anesthetized by an intraperitoneal injection with 70 mg/kg sodium pentobarbitone. This study has been approved by the Institutional Animal Care and Use Committee of the Faculty of Science, Mahidol University. Here, we found that the mouse duodenal epithelial cells strongly expressed FGF receptor proteins as determined by immunohistochemistry, suggesting that these cells could directly respond to FGF-23. Intravenous administration of recombinant mouse FGF-23 significantly abolished the 1,25$(OH)_2D_3$-induced transcellular and paracellular calcium transport in the mouse duodenum, as determined by Ussing chamber technique and ^{45}Ca radiotracer. However, FGF-23 did not affect the baseline duodenal calcium transport. At the molecular level, FGF-23 antagonized the 1,25$(OH)_2D_3$-induced increases in the mRNA levels of several duodenal calcium transporters, e.g., TRPV5, TRPV6, and calbindin-D_{9k}, but not claudin-2 or -12. Although FGF-23 also reduced the effect of 1,25$(OH)_2D_3$ on the transepithelial water movement (a driving force for the solvent drag-induced calcium transport), it did not alter the paracellular permeability to ^{3}H-mannitol or ^{14}C-polyethylene glycol-4000. It could be concluded that FGF-23 was an efficient negative feedback regulator of the 1,25$(OH)_2D_3$-induced calcium transport in the mouse duodenum. Our findings have thus corroborated the existence of the bone-kidney-intestinal axis of the FGF-23/vitamin D system in the regulation of intestinal calcium absorption.

Lipopolysaccharide inhibits the expression of resistin in adipocytes

Y. Li, X. Xiang, W. An, C. Jiang, X. Wang and W. Zhang

Department of Physiology and Pathophysiology, School of Basic Medical Sciences, Peking University, Beijing, China

Inflammation in adipose tissue is intimately linked with the onset and progression of insulin resistance. The link between insulin resistance and obesity is not completely understood. Resistin, an adipocyte-secreted inflammatory molecule, has been implicated as the link between obesity, inflammation and insulin resistance. During bacterial infection, endotoxin/lipopolysaccharide (LPS) elicits immune and inflammatory responses that can result in a fatal shock syndrome and a series of metabolic alterations and impaired insulin action. LPS has been reported to decrease the expression of resistin mRNA and protein in both lean and db/db obese mice, although the underlying mechanism remains unclear. In the present study, several models such as ex vivo culture of adipose tissues, primary rat adipocytes and 3T3-L1 adipocytes were used to further characterize the effect of LPS on the expression of resistin. We found that acute administration at the doses of 1mg/kg body weight or 80 μg/kg body weight significantly improved the glucose tolerance in mice. Similar results were also observed in mice received a daily intraperitoneal injection of LPS at a dose of 80 μg/kg body weight for 7 days. LPS attenuated both the resistin mRNA and protein in a time- and dose-dependent manner. In the presence of actinomycin D, LPS failed to reduce the half-life of resistin mRNA, suggesting a transcriptional mechanism. The lipid A fraction is crucial for the inhibition of resistin expression induced by LPS. Polymyxin B (PMB), which prevents the activation of toll-like receptor 4 (TLR4) by LPS, significantly attenuated the inhibitory effect of LPS on resistin expression in primary adipocytes, 3T3-L1 adipocytes and ex vivo adipose tissues, indicating that LPS activates TLR4 to inhibit the expression of resistin in adipocytes. Pharmacological intervention of c-Jun N-terminal kinase (JNK) reversed the inhibitory effect of LPS. LPS down-regulated CCAAT/enhancer binding protein α (C/EBP-α) and peroxisome proliferators activated receptor γ (PPAR-γ), while activation of C/EBP-α or PPAR-γ by either over-expressing these transcriptional factors or by rosiglitazone, an agonist of PPAR-γ, blocked the inhibitory effect of LPS on resistin. C/EBP homologous protein 10 (CHOP 10) was up-regulated by LPS, while a CHOP 10 antisense oligonucleotide reversed the decrement of resistin protein induced by LPS. Taken together, the present study demonstrates that inflammation induced by LPS can decrease the resistin expression in adipose tissues. LPS inhibits resistin expression through a unique signaling pathway involving TLR4, JNK, CHOP 10, and C/EBP-α/PPAR-γ.

Intestinal glucose uptake responses to infusion of glucose, fructose and galactose in dogs

A. Alada, T. Salman and D. Oyebola

Physiology, University of Ibadan, Ibadan, Oyo, Nigeria

Previous studies have shown significant increases in intestinal glucose uptake (IGU) following hyperglycemia of any cause. It is not clear how the intestine would respond to other sugars apart from glucose. The present study therefore was designed to investigate the effects of intravanous (i.v) infusion of fructose, galactose and glucose on canine IGU during postprandial state. Experiments were carried out on fasted, male, anaesthethized adult mongrel dogs divided into four groups with 5 dogs per group. Each of the groups was given i.v infusion of normal saline, fructose (1.1mg/dl/min), galactose (1.1mg/dl/min) and glucose (1.1mg/dl/min) respectively. Through a midline laparatomy, the upper jejunum was secured and cannulated for blood flow measurement. Blood samples were obtained for measurement of glucose content of arterial and venous blood from the upper jejunal sgment.The blood glucose was determined by glucose oxidase method and intestinal glucose uptake was calculated as the product of jejunal blood flow and arterio-venous glucose difference. Values are means ± S.E.M, compared by ANOVA and Student t-test. Fructose, galactose and glucose significantly increased arterial blood glucose from 97.60±1.78 mg/dl to 114.20±1.88mg/dl, 109.80±1.43mg/dl, and 141.20±5.65 mg/dl respectively. Glucose also significantly increased jejunal blood flow from 10.0±0.32ml/min to 14.40±0.93ml/min, however, fructose and galactose did not produce any significant effect on intestinal blood flow. IGU increased by 600%, 350%, and 700% in response to fructose, galactose and glucose respectively. There is no correlation between the increase in blood glucose levels induced by each of the sugars and its corresponding rise in IGU. The data suggest that the intestine responds to fructose and galactose in a similar manner as glucose. However, the mechanism of the responses may not be the same in the three sugars.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB286

Effects of stress hormones on testicular steroidogenesis and role of antioxidants in vitro

M. Aslam

Physiology, Shifa Tameer-e-Millat University, Islamabad, Federal, Pakistan

Hypothesis: Stress is thought to disrupt the balance between prooxidants and antioxidants by generating reactive oxygen species damaging the testicular tissue and steroidogenesis.
Objective: The in vitro model of isolated and cultured Leydig cells of male Sprague Dawley rats was designed to investigate the effects of antioxidants, ascorbic acid and alpha tocopheral separately and combined with stress, hormones [corticosterone and nor epinephrine] at Leydig cell level.
Methods: Four rats were taken per experiment, decapitated and orchitectony was done. After decapsulation and enzymatic dispersion, density gradient Percoll centrifugation method was used and through various steps, we obtained purified Leydig cells with 85,000 cells per culture tube. Purified Leydig cells were incubated with corticosterone [100 nmol/tube], nor epinephrine [10 umol/well], antioxidants ascorbic acid [100 umol/ml] and alpha tocopherol [10 ug/ml] in the presence of LH [50 ul/week]. The testosterone production and extent of lipid peroxidation and superoxide dismutase activity were evaluated by enzyme immunoassay. Data were analyzed by SPSS version 17 and independent sample t test were applied to find difference among control and treated wells.
Results: The data revealed that corticosterone decreased the Leydig cell steroidogenesis through non genomic rapid pathways because we used 3 hours short term cell culture model and genomic pathways need longer duration than this. Whereas, nor epinephrine increased testosterone synthesis at Leydig cell level beyond pregnenolone which we observed after addition of pregnenolone to the culture tubes. Combination of corticosterone and nor epinephrine resulted in decreased [p value< 0.05] testosterone production. The anti-oxidants like ascorbic acid and alpha tocopherol when superadded alone, revealed favourable preventive effects at Leydig cell level and blunted the fall in testosterone and rise in malondialdehyde levels. Combination of antioxidants, ascorbic acid and alpha tocopherol revealed synergistic effect in reducing oxidative stress (p value< 0.001) and prevented stress hormones induced derangements in testicular steroidogenesis.
Conclusion: The antioxidants, ascorbic acid and alpha tocopherol decrease the stress induced lipid peroxidation and prevent the decline in testicular steroidogenesis presumably by stabilizing the membrane of the Leydig cells.

We acknowledge National University of Sciences and Technology and Higher Education Commission for the financial support to carry out this project.

PCB287

Serum transforming growth factor β concentrations and primary antibodies immunostaining effects on Leydig and Sertoli Cells in streptozotocin-induced and insulin resistant diabetic adult male rat

A.P. Arikawe[1], K.A. Dada[2], A.O. Ogunsola[3], D. Osiagwu[4] and B.O. Iranloye[5]

[1]Department of Physiology, College of Medicine of the University of Lagos, Lagos, Lagos, Nigeria, [2]Department of Physiology, College of Medicine of the University of Lagos, Lagos, Lagos, Nigeria, [3]Department of Physiology, College of Medicine of the University of Lagos, Lagos, Lagos, Nigeria, [4]Department of Anatomic and Molecular Pathology, College of Medicine of the University of Lagos, Lagos, Lagos, Nigeria and [5]Department of Physiology, College of Medicine of the University of Lagos, Lagos, Lagos, Nigeria

The involvement of Transforming Growth Factors in regulation of cellular function in male diabetic rats' testes is less understood.
Adult male Sprague-Dawley rats (120 – 140gm) were divided into 3 groups. Control group (n = 7); fed on normal rat pellets. Streptozotocin diabetic group (n = 7); received a single IP injection of streptozotocin 45 mg/kg BW (Guneli et al., 2008) in Na+ citrate buffer pH 4.5. Insulin resistant group (n = 7); fed

ad libitum on special diet containing 25% fructose W/W for 12 weeks (Arikawe et al., 2006; Arikawe et al., 2012).
Following hyperglycaemia confirmation, blood samples were collected under light anaesthesia (IM ketamine, 10mg/kg) for serum activin and inhibin (Transforming Growth Factor β) Concentrations. Animals were perfused with 4% Paraformaldehyde (PFA). Testes were isolated and fixed in 4% PFA overnight and embedded in paraffin. 5μm thick sections were made and mounted on poly-L-lysine coated slides. Immunohistochemical analysis was assessed using Androgen receptor (C-19) and Sox-9 antibodies (Santa Cruz Biotechnology, USA) through light microscopy.
Serum inhibin was significantly lower ($P < 0.05$) in the insulin resistant group compared to the control and streptozotocin groups. There was no significant difference in serum activin concentrations amongst the three groups. C-19 and Sox-9 indexes were significantly lower ($P < 0.05$) in both experimental groups compared to control group. The results of the study indicate that streptozotocin and insulin resistance affect Leydig and Sertoli cell function.

CD4+ T cell-derived catecholamines induce a shift of Th1/Th2 balance toward Th2 profile

Y. Qiu, Y. Liu, J. Tang, H. Huang and Y. Peng

Nantong University, Nantong, China

Our previous work has shown that T lymphocytes synthesize and secrete catecholamines (CAs), which regulate T cell function by paracrine/autocrine pathway. CD4+ T cells, a largest class of lymphocyte subsets accounting for 60% of peripheral T lymphocytes, function mainly through T helper (Th) cells. Th1 cells are mainly involved in inflammatory response by secretion of cytokines, such as interleukin (IL)-2, interferon-γ (IFN-γ) and tumor necrosis factor (TNF), while Th2 cells mainly mediate anti-inflammatory response by secretion of IL-4, IL-5 and IL-10. Th1/Th2 balance in differentiation and function is highly important for maintenance of immune homeostasis. Here, we explored the regulation of Th1/Th2 balance by CD4+ T cell-endogenous CAs to extend our knowledge of neuroimmunomodulation. CD4+ T cells were purified from the mesenteric lymph nodes of 4 to 6 week-old ICR mice by using CD4+ T-cell isolation kit. The purified T cells (1.25×106 cells/ml) were incubated for 48 h with concanavalin A (Con A, 5 μg/ml) to induce cell proliferation. To change production of CAs by the cells, we added alpha-methyl-p-tyrosine (α-MT), an inhibitor of tyrosine hydroxylase (TH) that is a rate-limiting enzyme for CA synthesis, or pargyline, an inhibitor of monoamine oxydase that degrades CAs, to the cultures 30 min prior to Con A. Additionally, recombinant TH miRNA expression vector (pcDNA/miR-TH) was transfected into Con A-activated CD4+ T cells using nucleofection technology to silence TH gene in these cells. Expression of TH and cytokines at gene and protein levels in Con A-activated CD4+ T cells was examined by real-time PCR and Western blot, respectively. Concentrations of CAs and cytokines in cultured cells and supernatants were measured by HPLC and flow cytometry, respectively. The exposure to α-MT (10–6 M) reduced contents of CAs including norepinephrine, epinephrine and dopamine both in CD4+ T cells and in supernatants. Simultaneously, α-MT upregulated T-bet, a Th1-specific transcription factor, and IFN-γ expression but downregulated GATA-3, a Th2-specific transcription factor, and IL-4 expression in Con A-activated CD4+ T cells. In contrast, pargyline (10–6 M) increased the three kinds of CAs, downregulated T-bet and IFN-γ, but upregulated GATA-3 and IL-4 in these lymphocytes. In support these findings, CD4+ T cells with TH RNAi expressed less TH mRNA and protein and synthesized less CAs than control cells with mock transfection. Importantly, the silencing of TH gene in Con A-stimulated CD4+ T cells elevated ratio of IFN-γ-producing cells to IL-4-producing cells, increased levels of IL-2, IFN-γ and TNF, but decreased levels of IL-4 and IL-5 in the culture supernatants. These data suggest that CAs synthesized and secreted by CD4+ T cells regulate differentiation and function of Th cells, with an effect facilitating the shift of Th1/Th2 balance toward Th2 polarization.

Diabetes risk factors, interleukin-6 and vitamin d are modified by a short-term yoga-based lifestyle intervention in overweight/obese subjects

R.K. Yadav[1], R. Netam[2], R. Khadgawat[3], K. Sarvottam[4], R. Yadav[5] and D. Magan[6]

[1]Physiology, All India Institute of Medical Sciences, New Delhi, India, [2]Physiology, All India Institute of Medical Sciences, New Delhi, India, [3]Endocrinology and Metabolism, All India Institute of Medical Sciences, New Delhi, India, [4]Physiology, All India Institute of Medical Sciences, New Delhi, India, [5]Physiology, All India Institute of Medical Sciences, New Delhi, India and [6]Physiology, All India Institute of Medical Sciences, New Delhi, India

Introduction: Obesity is a known risk factor for type 2 diabetes mellitus (T2DM), and weight-loss seems prudential in T2DM risk reduction. In the current study, we evaluated the efficacy of a short-term yoga-based lifestyle intervention in weight-loss, and assessed its impact on interleukin (IL)-6, vitamin D, fasting plasma glucose (FPG), insulin resistance, waist/hip ratio, lipid profile, and blood pressure in overweight/obese subjects vs. apparently healthy normal weight control subjects.
Methods: A total of 68 subjects were enrolled in this study, of which 34 were overweight/obese (BMI ≥23 to <35 kg/m^2 per Asian cut-off values) and 34 were apparently healthy normal-weight control subjects. The study was conducted in two phases. In Phase I, all the 68 subjects attended a 10 day directly supervised yoga-based lifestyle intervention program, which was hospital-based. End of Phase I was end-of-study for normal weight subjects while overweight/obese subjects entered Phase II, and continued the intervention while home-based till Day 30. Weight-loss and diabetes risk factors were assessed at Baseline, Day 10 (for both the study groups) and Day 30 (for overweight/obese subjects).
Results: In overweight/obese subjects, there was a significant reduction from Baseline to Day 10 in weight (73.20±10.00 vs. 72.35±9.78 kg, $p=0.0001$), BMI (26.49±3.67 vs. 26.26±3.65

kg/m^2, p=0.004), waist/hip ratio (0.91±0.10 vs. 0.90±0.09, p=0.043), FPG (p=0.005), and a significant improvement in lipid profile (p<0.05). Also in this group, there was a significant reduction in median fasting insulin (8.50 vs. 8.30 μIU/dL, p=0.049), insulin resistance (HOMA-IR; 2.55 vs. 1.53, p=0.018), and levels of IL-6 (1.16 vs. 1.11 pg/mL, p=0.031). At Day 30, weight-loss was sustained, and systolic blood pressure was also decreased (p=0.017). The correlation analysis showed that IL-6 decreased with a decrease in waist/hip ratio. Also, serum 25-OH-vitamin D increased with a decrease in weight, FPG, and increased with increase in HDL. There were no notable changes in the control group.
Conclusions: This short-term lifestyle intervention resulted in a significant weight-loss even in a short duration, as early as 10 days. This reduction in weight resulted in a reduction in diabetes risk factors in overweight/obese subjects.

Authors acknowledge Institute Research Grant provided by All India Institute of Medical Sciences, New Delhi, for financial support for the ELISA kits, and Central Council for Research in Yoga & Naturopathy, Ministry of Health and Family Welfare, Government of India for technical support.

PCB290

The effects of *Moringa oleifera* Lam. seed oil in ovariectomized rats

P. Kusolrat and S. Kupittayanant

Physiology, Suranaree University of Technology, Muang, Nakhon Ratchasima, Thailand

Estrogen replacement therapy has been the treatment of choice for menopause symptoms, but it can increase risk of breast cancer, heart disease, and stroke. Due to these side effects, a therapy with phytoestrogens (Wuttke et al, 2002); derived xenoestrogens found in plants is currently being challenged. Moringa (*Moringa oleifera* Lam.) seed oil (MSO) has been reported to contain phytoestrogens (Anwar et al, 2007). However, it is not known whether and if it can be a treatment of choice for menopause symptoms. Thus, the aim was therefore to study the effects of MSO in menopause using ovariectomized rats (OVX) as a model. The seeds of Moringa were obtained by cold pressed. The animal cares were followed the guidelines of the Committee on Care and Use of Laboratory Animal Resources, National Research Council of Thailand. The procedure of the experiment was performed with the advice of the Institutional Animal Care and Use Committee, Suranaree University of Technology, Nakhon Ratchasima, Thailand. Adult female virgin rats (200-250 g) were overiectomized and divided into 5 groups of six rats each; sham operated rats (SHAM) received 1% tween 80 (1 ml), OVX received estrogen (0.02 mg/kg BW 17β-estradiol), OVX received 1% tween 80 (1 ml; control group), OVX received MSO (0.5 ml/100 g BW), and OVX received MSO (1 ml/100 g BW) orally/day for 6 weeks. At the end of the treatment the animals were sacrificed. The uterus was removed and weighed. Serum estradiol, total cholesterol, high density lipoprotein (HDL), low density lipoprotein (LDL) and triglyceride concentration were also evaluated. The statistical analysis of differences between groups was performed using one way ANOVA. There was a significant increase in mean relative uterine weight in MSO (1 ml/100 g BW) and estrogen treated-group as compared to the control group ($P < 0.05$). The results showed that serum estradiol (pg/ml) in SHAM, control group, MSO (0.5 ml/100 g BW), MSO (1 ml/100 g BW) and estrogen treated-group was 39.67±2.2, 13.67±1.5, 20.33±3.1, 50.67±8.9 and 82.00±18.0, respectively. There was a significant increase in serum estradiol with estrogen-treated group and MSO (1 ml/100 g BW) as compared to the control group ($P < 0.05$). The concentration of total cholesterol, LDL, and triglyceride was not significantly deferent among groups. However, there was a significant increase in the mean HDL in MSO (1 ml/100 g BW) and estrogen treated-group as compared to the control group ($P < 0.01$). In conclusion, MSO can increase relative uterine weight, serum estradiol, serum HDL in ovariectomized rats. Thus, it may be beneficial for the treatment of menopause symptoms.

PCB291

Estrogen activities of winged bean seed oil in ovariectomized rats

P. Kupittayanant[1], P. Kusolrat[2], A. Munpanich[2], A. Thaeomor[2] and S. Kupittayanant[2]

[1]Animal Production Technology, Suranaree University of Technology, Muang, Nakhon Ratchasima, Thailand and [2]Physiology, Suranaree University of Technology, Muang, Nakhon Ratchasima, Thailand

Unanticipated increase in risk for breast cancer and cardiovascular disorders among menopausal women taking hormone replacement therapy (HRT) has been reported (Rossouw et al, 2002). Plant extracts with estrogenic properties are of increasing interest as potential alternatives to using HRT (Wylie-Rosett, 2005). One such alternative includes the phytoestrogens, which are plant substances producing estrogenic effects (Lotke, 1998). Winged bean (*Psophocarpus tetragonolobus* L.) is a tropical legume grown in Southeast Asia. The chemical composition of its seeds is very similar to that of soybean, a natural source of phytoestrogens (Benito et al, 1982). However, its estrogenic activities have never been investigated. The aim of the study was to examine estrogenic activities of winged bean seed oil (WBSO) in ovariectomized rats (OVX). WBSO was obtained by cold pressed. The animal cares followed the guidelines of the Committee on Care and Use of Laboratory Animal Resources, National Research Council of Thailand and the experiment procedure was performed with the advice of the Institutional Animal Care and Use Committee. 20 Adult female virgin rats (200-250 g) were subjected to operation. 14 days after operation, the rats were divided into 4 groups (n=5); sham operated rats (SHAM) received 1% tween 80 (1 ml), OVX received 1% tween 80 (1 ml; control), OVX received estrogen (0.02 mg/kg BW 17β-estradiol), and OVX received WBSO (1 ml/100 g BW) orally/day for 6 weeks. Vaginal cornification was determined throughout the experimental period. At the end of the treatment the animals were sacrificed. The uterus was

removed and weighed. Serum estradiol was also evaluated. The statistical analysis of differences between groups was performed using one way ANOVA. The results showed that WBSO induced an opening of vagina on day 8 and cornification of vaginal epithelial cells which occurred 7 days earlier as compared to control. This was observed in all treated animals (100%). The mean relative uterine weight (RU) was significantly different among groups (P<0.05). RU (%) in SHAM, control group, estrogen-treated group, and WBSO was 0.18±0.00, 0.06±0.01, 0.13±0.01, and 0.09±0.01, respectively. Thus, WBSO significantly increased RU when compared to control, but the increase was lesser than those of estrogen. Serum estradiol (pg/ml) in SHAM, control group, estrogen-treated group, and WBSO was 39.29±1.8, 13.78±1.6, 81.93±18.2, and 52.57±3.6, respectively. Thus, there was a significant increase in serum estradiol with estrogen-treated group and WBSO as compared to control (P<0.05). Taken together, WBSO has estrogenic activities as it can induce vaginal cornification, increase relative uterine weight and raise serum estradiol. WBSO may therefore offer the same uses as soybean.

Exocrine growth hormone?

D. Giterman[1], E. Adeghate[2] and S. Harvey[1]

[1]Physiology, University of Alberta, Edmonton, AB, Canada and [2]Anatomy, United Arab Emirates University, Al Ain, United Arab Emirates

Growth hormone (GH) gene expression is not confined to the somatotrophs of the pituitary gland and occurs in many extrapituitary tissues, including those of the neural, immune and reproductive systems (Harvey, 2010). Its presence in exocrine glands is, however, largely unknown. The possible presence of GH in salivary glands (the submandibular and parotid glands), in the lachrimal gland and in the exocrine pancreas of rats was therefore investigated by confocal immunocytochemistry. Intense GH-immunoreactivity was demonstrated in the parotid and submandibular glands, particularly in the interlobular and intralobular epithelial ducts and in some (but not all) serous and some mucus acinar cells. The presence of GH immunoreactivity inside the salivary ducts indicates the exocrine secretion of GH into saliva. Within the ductal epithelia of the salivary glands, the GH-immunoreactivity was consistently colocalized with immunoreactivity for mucin-1, salivary amylase, renin and nerve growth factor. It was also colocalized with SMR-1 (submandibular rat-1) in some acinar cells. Similar, but weaker, GH staining was also seen in the lachrimal glands. In the pancreas, some acini were GH-negative and some were GH-positive, whereas intense GH-staining was seen in the intermingled alpha (glucagon-immunoreactive) islet cells, but not in the GH-negative (insulin-immunoreactive) beta cells. The GH-immunoreactivity in these tissues was also colocalized with GH-receptor immunoreactivity, suggesting local (non-endocrine) roles for GH in their exocrine activity. In summary, these novel results demonstrate the presence of GH and its receptor in exocrine tissues of the rat, in which GH may have hitherto unsuspected autocrine, paracrine or lumenocrine roles in salivary, lachrimal or pancreatic exocrine function.

PCB294

Differential modulatory activity of leukotrienes on vasopressin secretion in a hypovolemia vs. sepsis condition

L.A. Costa, P.J. Basso and M.A. Rocha

Dental School of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

Previous work revealed the presence of LTC4 synthase in vasopressinergic neurons suggesting the involvement of leukotrienes in vasopressin secretion (1). While these mediators may activate vasopressin secretion during sepsis, they seem to inhibit during an osmotic stimulus (2, 3). Our aim was to study the effect of an inhibitor of leukotrienes synthesis (MK-886) in the hypovolemia –induced secretion of arginine vasopressin (AVP). Male Wistar rats (250-300 g) were anesthetized with intraperitoneal (i.p.) injection of a mixture of ketamine (45 mg/kg) and xylazine (6 mg/kg) for stereotaxically implanting a stainless steel cannula into the right lateral ventricle 5-7 days before the experiment. They received an intracerebroventricular (i.c.v.) injection of 2 μl of MK-886 at doses of 1, 2 and 4 μg/kg. or vehicle (DMSO 5%) one hour before hypovolemia was induced by a intraperitoneal injection (2 ml/100 g body weight) of polyethylene glycol 4000 (PEG – 200 mg/ml) or PBS (0.01 M) was injected as control. Subsequently they were decapitated 90 minutes after the stimulus. and blood was collected for determination of hematocrit, plasma osmolality, serum sodium and plasma vasopressin levels (n= 6-14 per group). The hypothalamus (n=7-14 per group) was removed and a Western blot for the enzyme LTC4 synthase was performed. In order to assess whether PEG could induce hypovolemia without a decrease in blood pressure, four hypovolemic rats that received i.c.v injection of DMSO 5% had their mean arterial pressure evaluated throughout the experimental period. The results are reported as mean ± S.E.M. Analysis of variance (ANOVA) and a post hoc Student–Newman–Keuls (SNK) test were used to reveal statistical differences. The i.p. injection of polyethylene glycol increased the hematocrit (p>0.05), and the plasma vasopressin concentration (1.26±0.2 pg/ml vs.0.74±0.1pg/ml control) confirming the hypovolemic effect of this protocol. Nonetheless, it did not alter osmolality, serum sodium, and mean arterial pressure in any group. The central administration of MK-886 in any dose did not sub-

stantially affect the hematocrit, osmolality, or serum sodium in any of the groups. However, at higher doses (2 and 4 μg/kg) the drug was able to substantially increase even more the plasma concentration of vasopressin (3.13±0.8 pg/ml vs. 1.26±0.2 pg/ml vehicle) and (3.49±0.8 pg/ml vs.1.26±0.2 pg/ml vehicle) respectively. The groups did not show any statistical differences in hypothalamic LTC4 synthase content.The results lead us to infer that leukotrienes modulate a hypovolemia-induced vasopressin secretion in a different way than they do during sepsis.

Bone marrow adipose tissue as a source of serum adiponectin: The 'adiponectin paradox' explained?

W.P. Cawthorn[1,6], E.L. Scheller[1], B.S. Learman[1], D.T. Broome[1], S.S. Soliman[1], J.L. DelProposto[3], C.N. Lumeng[3], K.A. Gallagher[4], J.D. Miller[5], V. Krishnan[6], P.K. Fazeli[7], A. Klibanski[7], M.C. Horowitz[8], C.J. Rosen[9] and O.A. MacDougald[1,2]

[1]Department of Molecular & Integrative Physiology, University of Michigan Medical School, Ann Arbor, MI, USA, [2]Department of Internal Medicine, University of Michigan Medical School, Ann Arbor, MI, USA, [3]Department of Pediatrics and Communicable Diseases, University of Michigan Medical School, Ann Arbor, MI, USA, [4]Department of Vascular Surgery, University of Michigan Hospital, Ann Arbor, MI, USA, [5]Department of Orthopaedic Surgery, University of Michigan Hospital, Ann Arbor, MI, USA, [6]Musculoskeletal Research, Lilly Research Laboratories, Indianapolis, IN, USA, [7]Neuroendocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [8]Department of Orthopaedics and Rehabilitation, Yale University School of Medicine, New Haven, CT, USA and [9]Maine Medical Center Research Institute, Scarborough, ME, USA

The adipocyte-derived hormone adiponectin promotes insulin sensitivity and anti-atherogenic effects. Serum adiponectin levels are low in obese, insulin-resistant individuals but high in lean states such as caloric restriction (CR) or anorexia nervosa. Indeed, despite being produced exclusively by adipose tissue, serum adiponectin inversely correlates with % body fat. The basis for this so-called 'adiponectin paradox' is yet to be resolved.

The discovery of adiponectin preceded our current understanding of white adipose tissue (WAT) as a major endocrine organ. In contrast, research has largely neglected another adipose depot: bone marrow adipose tissue (MAT). In humans MAT accounts for ≤ 70% of marrow volume and, in contrast to WAT, MAT increases in states of leanness such as CR or anorexia nervosa. Moreover, pharmacological agents such as thiazolidinediones or fibroblast growth factor-21 increase marrow adiposity. Notably, each of these conditions is also associated with increased serum adiponectin.

Based on these observations, we investigated the hypothesis that MAT is a major source of serum adiponectin. To do so, we first isolated WAT and MAT from rabbits, mice and humans. Rabbits were sedated by i.m. injection of ketamine (40 mg/kg) and xylazine (5 mg/kg) before euthanising by i.v. injection of pentobarbital (65 mg/kg); mice were euthanised by CO_2 asphyxiation followed by cervical dislocation; and human tissues were obtained with consent from patients undergoing lower-limb amputation. Immunoblotting of tissue lysates revealed that, in rabbits (n = 9) and mice (n = 6), adiponectin expression is markedly higher in MAT than in WAT. Although this was not consistently observed in human tissues (n = 7), human MAT had increased expression of Ero1-Lα, a protein chaperone that promotes adiponectin secretion. Indeed, adiponectin secretion from cultured MAT explants was far higher than that from WAT explants of rabbits (n = 9) or humans (n = 4), as assessed by immunoblotting. We next investigated if blocking MAT formation affects serum adiponectin levels. To do so we used Ocn-Wnt10b mice, in which the anti-adipogenic effector Wnt10b is transgenically expressed in bone. Expression of adiponectin mRNA in WAT did not differ between Ocn-Wnt10b (1.00 ± 0.21; n = 10) and control mice (0.91 ± 0.11; n = 10); however, Ocn-Wnt10b mice resisted increases in MAT and serum adiponectin with CR. Moreover, we found that, in mice (n = 24), total serum adiponectin negatively correlates with WAT mass (R^2 = 0.441; P = 0.031) but positively correlates with MAT volume (R^2 = 0.524; P = 0.009). In summary, our observations support the hypothesis that MAT expansion is required for increased serum adiponectin with CR, suggesting that MAT may be a major source of serum adiponectin. Thus, adiponectin production from MAT may account, at least in part, for the adiponectin paradox.

Transcriptome responses of the intestinal epithelial cells for the upregulation of gene-related to calcium and nutrient absorption in lactating rats and pituitary-grafted hyperprolactinemic rats

J. Teerapornpuntakit[1], K. Wongdee[2], N. Krishnamra[1], N. Karoonuthaisiri[3] and N. Charoenphandhu[1]

[1]Department of Physiology, Faculty of Science, Mahidol University, Bangkok, Thailand, [2]Office of Academic Management, Faculty of Allied Health Sciences, Burapha University, Chonburi, Thailand and [3]Microarray Laboratory, National Center for Genetic Engineering and Biotechnology (BIOTEC), Pathum Thani, Thailand

Intestinal calcium absorption is markedly enhanced during pregnancy and lactation by prolactin (PRL) from the anterior pituitary. However, its cellular and molecular mechanisms pertaining to the intestinal calcium absorption are not completely understood. The present study aimed to demonstrate the transcriptome responses of intestinal epithelial cells to PRL in hyperprolactinemic animals, i.e., anterior pituitary (AP)-grafted rats and lactating rats, by using robotic spotting cDNA microarray and quantitative real-time PCR. In addition, the effects of PRL on proliferation and differentiation of IEC-6 crypt-like cells were also investigated. This study has been approved by the institutional animal care and use committees of Faculty of Science, Mahidol University. The results showed that several genes related to calcium absorption, e.g., transient receptor potential vanilloid calcium channel (TRPV)-5, TRPV6, calbindin-D_{9k}, and claudin-3, were upregulated in the 4-week AP-grafted rat. Nevertheless, such the PRL action was observed only in the villous cells, but not in the IEC-6 crypt-like cells. PRL did not

increase IEC-6 cell proliferation, suggesting that it did not contribute to the lactation-induced expansion of intestinal surface area. In early lactation, PRL was found to upregulate the expression of TRPV6 and plasma membrane Ca^{2+}-ATPase-1b, which were apical and basolateral calcium transporters, respectively. Further microarray study revealed a number of changes in the expression of genes related to calcium, nutrient, and ion transport (such as TRPM7 and sodium-dependent phosphate transporter (NaPi)-IIb for magnesium and phosphate transport, respectively) in late lactation. In conclusion, PRL increased the intestinal calcium absorption by upregulating the expression of genes related to calcium transport, presumably to provide more calcium for milk production.

The satiety molecule nesfatin-1 increases body temperature of rat

K. Könczöl[1], D. Zelena[2], O. Pintér[2], J. Varga[2], M. Palkovits[1] and Z.E. Tóth[1]

[1]Dept. of Anatomy, Histology and Embryology, Semmelweis University, Budapest, Hungary and [2]Institute of Experimental Medicine, Hungarian Academy of Sciences, Budapest, Hungary

Nesfatin-1, a fragment of the nucleobindin 2 (NUCB2) protein was described as an agent reducing food intake. However, its wide distribution in the brain suggests additional functions. We assumed that nesfatin-1 may affect also the energy expenditure, therefore we measured duration of food intake, core body temperature, locomotor activity and heart rate of male rats (250-300g) for 48h by telemetry, after icv administration of 25 pmol nesfatin-1 (n=10-12) at the beginning of the dark phase. Body weight, food and water intake were measured daily. One week before the experiment, a cannula was inserted into the lateral ventricle under anesthesia with ketamine (50mg/kg) and xylazine (15mg/kg). At the same time, VitalView biotelemetry emitters were implanted into the abdominal cavity. Telemetric data were collected in every min and calculated as sum ±s.e.m, or mean±s.e.m. Statistics were performed using two way RM-ANOVA. Nesfatin-1 reduced the duration of nocturnal food intake at the beginning of the dark phases (effect of treatment: $F(1,9)=4.63$, $P<0.05$). Food intake had a circadian rhythm (effect of time: $F(11,99)=10.5$, $P<0.01$), but the amplitude was smaller in treated animals (treatment x time interaction: $F(11,99)=3.06$, $P<0.01$). There was a reduction in food and water consumption on the first day and a compensation on the second day (food intake: effect of time: $F(1,21)=4.66$, $P<0.05$, treatment x time interaction: $F(1,21)=6.09$, $P<0.05$, water intake: effect of treatment: $F(1,9)=6.1$, $P<0.05$, effect of time: $F(1,21)=5.2$, $P<0.05$, tendency for treatment x time interaction: $F(1,21)=4.8$, $P<0.056$). Nesfatin-1 treatment elevated core body temperature immediately after injections (effect of treatment: $F(1,9)=7.85$, $P<0.05$). The most marked difference between groups was observed during the light phases of the 48 h observation period, since the circadian curve has been flattened (effect of time: $F(11,99)=10.4$, $P<0.01$). Heart rate and locomotion did not change. To elucidate morphological base of effect of nesfatin-1 on temperature regulation, we tested if cold (4 °C for 2 h) induces neuronal activation (Fos immunoreactivity) in nesfatin-1/NUCB2 (nesfatin)-positive neurons in the brain. Control animals were kept at room temperature. Cold activated nesfatin-positive neurons were present in many thermoregulatory areas of the hypothalamus and the brainstem. In the hypothalamic paraventricular nucleus Fos-nesfatin double labeled neurons colocalised with prepro-thyrotropin-releasing hormone (pTRH). pTRH also colocalised with nesfatin in the nucleus raphe pallidus and obscurus. These nuclei are known to act as sympathetic premotor neurons regulating heat production in brown adipose tissue and vasoconstriction in the skin. In summary, nesfatin has a longer effect than it was known before, and it influences the energy homeostasis not only by reducing food intake, but also by increasing the body temperature.

Nesfatin-1 exerts long-term effect on food intake and body temperature.

Neuronal and glial cell changes in a trasngenic mouse model of retinal neovascularisation

L.B. Tee[1], A. Nguyen[1], I.S. Ali Rahman[2] and C.M. Lai[2,3]

[1]School of Pharmacy, Curtin University, Perth, WA, Australia, [2]Centre for Ophthalmology and Visual Science,, The University of Western Australia, Perth, WA, Australia and [3]Molecular Ophthalmology, Lions Eye Institute,, Perth, WA, Australia

Retinal neovascularisation is a major clinical complication of diabetic retinopathy (DR) however, the exact mechanism for the progression of retinal neovascularisation and the role of inflammation in retinal neovascularisation remains to be established. There are two main hypotheses on the pathogenic mechanism underlying DR. The more established theory which has been the focus of many studies is that DR is a disorder affecting the vascular cells in the retina. It is theorised that damage to these cells as a consequence of hyperglycaemia result in the subsequent complications of DR including vision loss. The other theory is that DR causes neuronal and glial cell dysfunction which plays a crucial role in the progression of the subsequent complications. Evidence suggesting neuronal and glial cell dysfunction include; changes in electrophysiological and psychophysical activity, glial cell reactivity, altered glutamate metabolism and apoptosis of retinal cells. The aim of this project is to investigate the neuronal and glial cell changes in the retina in a transgenic mouse model of retinal neovascularisation and to assess the relationship between the vascular abnormalities with the corresponding changes in the neurons and glial cells. The transgenic mouse model, Kimba (Lai et al 2005), was used to examine the neuronal and glial cell changes in retinal neovascularisation. Retinal sections of Kimba and wild type (WT) mice were analysed for vascular neuronal and glial cells changes using immunocytochemistry. Mice aged 2, 8, and 20 weeks were used to look at neuronal and glial changes associated with the progressive stages of neovascularisation.There was an overall decrease in retinal thickness for Kimba mice at all stages with varying patterns of changing

thickness in the outer nuclear layer (ONL) and inner nuclear layer (INL) of the retina. Compared to WT, the retinal blood vessels in Kimba mice transgressed into the outer layers of the retina including the ONL which caused disruption to the normally organised retinal layers. There was a significant (P<0.001) decrease in ganglion cell count in Kimba at all age points. Whilst there was no change in the morphology of astrocytes and Muller cells, there was a significant (P<0.05) decrease in Müller cell count in 8 and 20 weeks Kimba. The study shows changes in both neuronal and glial cells in the retina associated with the different stages of retinal neovascularisation. This study further supports the role of inflammation in the progression of retinal neovascularisation.

PCB299

Targeting BACE1 to improve leptin sensitivity and reverse obesity

P.J. Meakin, S.M. Jalicy, G. Montagut, S.W. Irvine and M.L. Ashford

Division of Cardiovascular & Diabetes Medicine, University of Dundee, Dundee, UK

BACE1 (β-site amyloid precursor protein (APP)-cleaving enzyme 1) is the rate-limiting step in Aβ peptide production. Aβ aggregates and forms amyloid plaques, a major pathological feature of Alzheimer's disease. Mice lacking BACE1 have improved glucose homeostasis and are resistant to diet induced obesity [1], suggesting that BACE1 regulates energy metabolism. Therefore we have investigated whether altered leptin signalling underlies the improved metabolic phenotype of BACE1$^{-/-}$ mice. Wild-type (WT) and BACE1$^{-/-}$ mice (C57Bl/6) were fed regular chow (RC) or high fat (HF; 4% and 45% energy from fat respectively) diet from 8 weeks of age for 20 weeks. For *in vivo* studies mice were injected i.p. twice daily with saline or leptin (2mg/kg) for 3 days and food intake and body weight monitored. For biochemical analysis, mice were starved overnight and injected i.p with saline or leptin (3mg/kg) and hypothalamic arcuate nucleus (ARC) tissue harvested after 3 hours. cDNA expression was measured using Taqman gene analysis. Standard immunohistochemical and immunoblotting techniques were used to measure BACE1 hypothalamic distribution and ARC STAT3 protein levels, respectively. All data expressed as mean ± SEM, and statistical significance determined by Student's t-test.

BACE1 protein was observed in a sub-group of ARC neurons. BACE1 is not co-localised with NPY or AgRP, whereas approximately 30% of POMC neurons display BACE1 immunoreactivity. BACE1$^{-/-}$ mice, on RC diet, exhibit an increased *in vivo* response to leptin displaying a greater reduction in body weight compared to WT mice (KO -7.8±1.0%; WT -5.2±0.4%; $p < 0.05$ n=8-13). This outcome is reflected in a greater increase in ARC STAT3 phosphorylation levels for BACE1$^{-/-}$ mice compared to WT controls (KO 6.7±1.2; WT 3.5±0.6 fold; $p < 0.05$ n=6-8). Following HF diet challenge, BACE1$^{-/-}$ mice retain leptin sensitivity, while WT mice become leptin resistant (body weight change: KO -5.9±0.8%; WT -0.3±0.4%; $p < 0.001$ n=7-9). BACE1$^{-/-}$ mice display increased basal AgRP and NPY gene expression (AgRP 1.6±0.1; NPY 2.3±0.4 fold; $p < 0.05$ n=7), while POMC mRNA levels are unaltered. To investigate the mechanism by which loss of BACE1 enhances leptin sensitivity we examined the expression of negative regulators of leptin signalling. PTP1B and SHIP2 mRNA levels are unaltered in BACE1$^{-/-}$ mice on either diet. Whereas SOCS3 mRNA expression is increased in WT, but not BACE1$^{-/-}$, mice on HF diet (1.8±0.2 and -1.1±0.1 fold respectively; $p < 0.05$, n=7-8), correlating with STAT3 phosphorylation levels.

Taken together these data indicate that BACE1 is a regulator of hypothalamic leptin sensitivity in mice. Consequently, BACE1 inhibition may be a novel therapeutic intervention to recover leptin sensitivity, reduce body weight and improve glucose homeostasis in people with obesity/Type 2 diabetes.

beta-arrestin1 mediates cholecystokinin functions in pancreatic beta cells

S. Ning[1,3], N. Liang[2,4], J. Su[1], C. Liu[1], J. Dong[1,2], H. Li[1], J. Sun[2,4] and X. Yu[1,3]

[1]Institute of Physiology, Shandong University, School of Medicine, Jinan, Shandong, China, [2]Dept. of Biochemistry and Molecular Biology, Shandong University School of Medicine, Jinan, Shandong, China, [3]Qilu Hospital, Shandong University School of Medicine, Jinan, Shandong, China and [4]Shandong Provincial Hospital, Shandong University School of Medicine, Jinan, Shandong, China

Cholecystokinin (CCK), a gastro-intestinal hormone, is secreted by intestinal I cells after the meal and regulates important digestive and metabolic functions. In pancreatic islets, CCK managed insulin secretion and beta cell mass majorly through CCK A-type receptor (CCKAR), a G protein coupled receptor, while the downstream signaling of CCKAR in pancreatic beta cells were not well defined. Here, we demonstrated that CCK-8s activated CCKAR and induced both IP3 and cAMP accumulation, which coordinately regulated efficient insulin secretion. Apart from activation of G protein signaling, CCK also promotes complex formation of CCKAR and beta-arrestin1. Exploiting RNA interference and beta-arrestin1 knockout (beta-arrestin1-/-) mice, we revealed that beta-arrestin-1 was a key mediator of both CCK promoted insulin secretion and its protective effects against apoptosis in pancreatic β cells. The anti-apoptotic effect of beta-arrestin-1 was through arrestin-mediated cytoplasmic long term ERK activation, which activates the p90RSK-phosphor-BAD antiapoptotic pathway and inhibits the caspase-3 cleavage. Further, we observed that knockdown of beta-arrestin-1 decreased both CCK-8s-induced cAMP and IP3 accumulation statistically, suggesting a crosstalk between beta-arrestin-1 and G protein mediated pathways. The importance of beta-arrestin-1 function downstream of CCKAR in pancreatic beta cells could be appreciated for development of newly anti-diabetic drugs.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB301

Effects of early life leptin intervention on reward-related receptor levels and behaviour

T. South, S. Bae, J. Roberts, A. Mullier, L. Poston, P. Taylor and C. Coen

King's College London, London, UK

Background: Our previous work has shown that the offspring of obese rat dams display an exaggerated and prolonged leptin surge early in life, which may predispose them to the metabolic syndrome in adulthood. It is hypothesized that this surge of leptin influences reward behaviour and the expression of associated receptors (e.g. dopamine D2, cannabinoid CB1 and opioid Mu receptors) in the central nervous system,
Objective: This project investigated the ways in which elevated leptin levels in early life, comparable to those associated with maternal obesity, may alter the neonatal brain and lead to dysfunctional reward-seeking behaviours and obesity later in life.
Methods: Twelve male Sprague Dawley rats were treated ip from post natal day 9-15 day with either leptin (0.3mg/kg, n=6) or vehicle (saline, n=6). At day 30, rats were euthanised and brains were removed for examination of receptor levels via ligand-binding autoradiography. An overnight 'two-bottle sucrose preference test' was also carried out in separate cohorts (n=10/group) at day 30.
Results: Following an overnight sugar preference test, it was found that the leptin-treated rats had a greater preference for sucrose compared to the saline-treated control animals (94.6% vs. 84.7% preference for sucrose, $p<0.05$).Analysis of [3H]-spiperone binding indicated that the leptin treated-rats had a significantly lower D2 level than the control animals in the nucleus accumbens (64.8% lower, $p<0.05$); for CB1 binding, the leptin treatment led to a rise in the nucleus accumbens and decrease in the caudate putamen ($p<0.05$). Opioid mu receptor binding was higher in the nucleus accumbens and thalamus of the leptin-treated rats ($p<0.05$).
Conclusions: Early-life leptin exposure leads to alterations in reward-related receptors and behaviour, which may predispose those individuals to reward-related behavioural disorders later in life, such as obesity or addiction.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Effects of *Curcuma comosa* Roxb. on human osteoblast proliferation and differentiation

D. Tantikanlayaporn[1], L.J. Robinson[2], A. Suksamrarn[3], P. Piyachaturawat[1] and H.C. Blair[2,4]

[1]Physiology, Mahidol University, Rachatewi, Bangkok, Thailand, [2]Pathology, University of Pittsburgh, Pittsburgh, PA, USA, [3]Chemistry, Ramkhamhaeng University, Bangkapi, Bangkok, Thailand and [4]Veteran's Affairs Medical Center, Pittsburgh, PA, USA

Phytoestrogens have recently been receiving more attention as a promising therapeutic agent for the prevention of bone loss in postmenopausal osteoporosis. *Curcuma comosa* Roxb. (*C. comosa*) is a ginger-family plant containing phytoestrogens and has been used extensively as dietary supplement to relieve menopausal symptoms. Diarylheptanoid (3*R*)-1,7-diphenyl-(4*E*,6*E*)-4,6-heptadien-3-ol (DPHD), isolated from *C. comosa*, was identified as the active phytoestrogen. DPHD has previously been found to activate Wnt/β-catenin signaling to increase differentiation in transformed mouse osteoblasts. However, its effect on human bone cells has not been reported. In the present study, we investigated the osteogenic effect and mechanism of action of DPHD in nontransformed human osteoblasts (h-OB). In growth medium, DPHD increased h-OB proliferation, investigated by thymidine incorporation assay and it accelerated osteoblast differentiation in the differentiation medium as indicated by the increases in alkaline phosphatase activity and osteoblast-specific mRNA production at 7-21 days. The effects of DPHD were abolished by estrogen receptor antagonist ICI182780. During the differentiation, DPHD promoted early expression of osteoblast transcription factors; RUNX2 and osterix. Subsequently, DPHD accelerated production of bone structural genes, including collagen type I alpha I (COL1A1) and osteocalcin comparable to 17β-estradiol. Moreover, DPHD increased the osteoprotegerin to RANKL ratio indicated that it could promote osteoblast bone formation. It was supported by the increased bone mineralization of DPHD detected by Von kossa staining. In conclusion, DPHD effectively promotes human osteoblast proliferation, differentiation and mineralization. The stimulating effects of the phytoestrogen from *C. comosa* on human osteoblasts may have clinical relevance for assisting in maintenance of bone mass menopausal women.

Coupling between electrical and calcium oscillatory activity in beta cell networks in mouse pancreas slices

J. Dolensek[1], M. Skelin Klemen[1], A. Stozer[1,4], E. Miller[2], R. Tsien[2] and M. Slak Rupnik[1,3]

[1]Institute of physiology, Faculty of Medicine, University of Maribor, Maribor, Slovenia, [2]Department of Pharmacology, University of California at San Diego, San Diego, CA, USA, [3]Centre of Excellence for Integrated Approaches in Chemistry and Biology of Proteins, Ljubljana, Slovenia and [4]Centre for Open Innovations and Research, University of Maribor, Maribor, Slovenia

Beta cells secrete insulin in response to glucose stimulation, a process that is cytosolic calcium-dependent. During sustained physiological stimulation, beta cells express oscillatory changes in intracellular calcium concentration that spread over a given islet of Langerhans in a wave-like manner. Electrophysiological records from a single cell inside the beta cell syncytium

show that the single cell electrical activity is well synchronized with the calcium oscillations indicating tight coupling between calcium and electrical changes. However, network properties of beta cells in vivo remain elusive, mostly because of the inherent limitation of electrophysiological recording with the pipette – namely the "one pipette - one cell" rule. To circumvent this limitation and to assess the properties of the tightly electrically coupled network of beta cells at a systems level, simultaneous recording of a large number of cells is needed, a task most suitable for voltage sensitive dyes. Recently, a new generation of voltage sensitive dyes was reported (1) that utilize photo-induced electron transfer as a voltage-sensing mechanism, providing a more robust response to a voltage change than the previous generations of the voltage sensitive dyes. We used VoltageFluor dye VF2.1.Cl to record oscillatory changes in membrane potential in mouse pancreatic slices using confocal fluorescence imaging. With this method, electrical activity of many (>50) cells could be recorded simultaneously. Glucose responding cells showed a stimulus-dependent depolarization that was followed by a sustained oscillatory behavior. Waves of depolarizations were periodically spreading over the plane of an islet. The wave propagation was similar in its speed as the propagation of calcium waves in pancreas tissue slices during the oscillatory phase reported previously (2). In contrast, the repolarizing phase in the electrical activity seems to be at least partially uncoupled with regard to the calcium activity. The repolarization spreading over the plane of an islet showed different spatio-temporal properties than the depolarization waves. Moreover, the pattern of the propagation of repolarization has not been predictable. To directly determine the relationship between the electrical and calcium waves at higher temporal resolution, we recorded both simultaneously, the calcium oscillations from the plane of islet and potential changes in a beta cell from the network. The former was recorded using OGB-1 using a CCD camera and latter with a patch pipette in whole-cell patch-clamp configuration. Electrical activity was best correlated to the calcium oscillation in the nearest group of cells, relative to the patch pipette.

PCB305

Adverse effects of leptin on sperm count and morphology in Sprague-Dawley rats are reversed between six to eight weeks of recovery

F.A. Almabhouh[1], H. Singh[1], K. Osman[2] and S. Fatimah[2]

[1]Faculty of Medicine, Universiti Teknologi MARA, Kuala Lumpur, Selangor, Malaysia and [2]Faculty of Allied Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Selangor, Malaysia

Hyperleptinaemia of obesity is increasingly linked to numerous cardiovascular diseases and infertility. Exogenous leptin administration has been shown to adversely effect sperm count and sperm morphology in normal adult rats (Nizam et al., 2010). It is, however, unknown if these effects are reversible upon discontinuation of leptin treatment. This study therefore examined the effect of 3, 6 and 8-week recovery period on sperm count and morphology in normal adult rats following six weeks of leptin treatment.

Twelve-week old male Sprague-Dawley rats were randomized into four leptin and four saline treated control groups with 6 rats in each group. Intra-peritoneal (i.p.) injections of leptin were given daily at a dose of 60 μg/kg body weight in 0.1 ml 0.9 % saline for 42 days. Controls received 0.1 ml of 0.9% saline. On day 43, one group of leptin treated rats and one group of age-matched saline treated control rats was euthanized for collection of epididymal sperm. The remaining three groups together with their age-matched saline treated controls were allowed to recover further for either 21, 42 or 56 days. Upon completion of the recovery period, animals were euthanized and the epididymis was removed and minced in 2 ml of normal saline. The suspension was then filtered through a nylon mesh and a small drop of the filtrate was placed in the center of the disc area of a Makler counting chamber and covered with a cover slip. The number of total and abnormal sperm in a strip of 10 squares was counted (x10 magnification). This represented the concentration in million per ml. Data were analyzed using ANOVA and presented as mean ± SEM.

* P<0.05; **p<0.01; *** p<0.001 compared to the respective age-matched control

Sperm count was significantly lower and the fraction of abnormal sperm was significantly higher in leptin treated rats on day 1 of recovery i.e. 42 days after leptin treatment. These differences were still evident at days 21 and 42 but not at day 56 of recovery.

It appears the adverse effects of 42 days of leptin treatment on sperm count and morphology are completely reversed within 56 days post-treatment in Sprague-Dawley rats suggesting that the effect of leptin on sperm count and morphology includes effects further upstream in the sperm cycle, which is about 58 days in the rat.

	Total sperm count (Million/ml)	Abnormal sperm (%)
Control Recovery day 1	9.9 ± 0.2	3.6± 0.3
Leptin Recovery day 1	6.1 ± 0.2**	10.9 ± 1.0 ***
Control Recovery day 21	10.1 ± 0.2	3.16 ± 0.29
Leptin Recovery day 21	7.5 ± 0.4***	7.8 ± 0.8***
Control Recovery day 42	10.4 ± 0.3	5.1 ± 0.07
Leptin Recovery day 42	9.6 ± 0.3*	6.4 ± 0.26**
Control Recovery day 56	10.5 ± 0.05	4.95 ± 0.11

Glucagon-like peptide-1 enhances glucokinase activity in pancreatic β-cells

D. Song, J. Park, J. Bae and S. Im

Physiology, Keimyung University School of Medicine, Daegu, Republic of Korea

Glucokinase (GK), which phosphorylates d-glucose, is a major glucose sensor in β-cells for glucose-stimulated insulin secretion (GSIS) and is a promising new drug target for type 2 diabetes (T2D). In T2D, pancreatic β-cells exhibit defective glucose sensitivity, which leads to impaired GSIS. Although glucagon-like peptide-1-(7–36)-amide (GLP-1) is known to enhance β-cell glucose sensitivity, the effect of GLP-1 on GK activity is still unknown. The present study demonstrated that GLP-1 pretreatment for 30 min significantly enhanced GK activity in a glucose-dependent manner, with a lower Michaelis-Menten constant (Km) but unchanged maximal velocity (Vmax). Thus, GLP-1 acutely enhanced cellular glucose uptake, mitochondrial membrane potential, and cellular ATP levels in response to glucose in rat INS-1 and native β-cells. This effect of GLP-1 occurred via its G protein-coupled receptor pathway in a cAMP-dependent but protein kinase A-independent manner with evidence of exchange protein activated by cAMP (Epac) involvement. Silencing Epac2, interacting molecule of the small G protein Rab3 (Rim2), or Ras-associated protein Rab3A (Rab3A) significantly blocked the effect of GLP-1. These results suggested that GLP-1 can further potentiate GSIS by enhancing GK activity through the signaling of Epac2 to Rim2 and Rab3A, which is the similar pathway for GLP-1 to potentiate Ca^{2+}-dependent insulin granule exocytosis. The present finding may also be an important mechanism of GLP-1 for recovery of GSIS in T2D.

Protein kinase C α downregulation and increased cAMP generation both enhance calcium-sensing receptor-mediated intracellular calcium mobilisation in HEK-293 cells

M. Bin Khayat[1], K.L. Campion[1], A.D. Conigrave[2] and D.T. Ward[1]

[1]Faculty of Life Sciences, University of Manchester, Manchester, UK and [2]University of Sydney, Sydney, NSW, Australia

Extracellular Ca^{2+} homeostasis is maintained by the action of the Ca^{2+}-sensing receptor (CaR) on parathyroid hormone (PTH) secretion and renal Ca^{2+} reabsorption. CaR contains several protein kinase C (PKC) consensus sequences of which one, CaR^{T888}, is the key site responsible for PKC-mediated inhibition of CaR-elicited Ca^{2+}_i mobilisation *in vitro* and PTH secretion *in vivo*. However, we have not yet identified the PKC isotype responsible for CaR^{T888} phosphorylation nor determined whether CaR signalling can be modulated by cAMP given the fundamental regulatory roles of these second messengers in PTH secretion.

Therefore, siRNAs were used to knockdown specific PKC isoforms in turn, in CaR-transfected HEK-293 cells (CaR-HEK) with the effect on Ca^{2+}_i mobilisation then determined in Fura2-loaded cells by epifluorescence microscopy. Experimental buffer contained (mM) 20 HEPES (pH 7.4), 125 NaCl, 4 KCl, 0.5 $CaCl_2$, 0.5 $MgCl_2$ and 5.5 glucose. Following the siRNA-induced knockdown of PKCα, the EC_{50} of the CaR for Ca^{2+}_o was significantly lowered (3.2 ± 0.1 mM PKCα siRNA vs. 3.9 ± 0.2 mM siRNA control transfection; P<0.001, n=9) indicating that PKCα contributes to the inhibition of CaR-induced Ca^{2+}_i mobilisation. In contrast, no significant effect on CaR responsiveness to Ca^{2+}_o was observed following transfection with siRNAs against PKCs β, δ, ε or θ. In addition, PKCα knockdown lowered the threshold for Ca^{2+}_o-induced CaR activation whereby 1.8 mM Ca^{2+}_o elicited Ca^{2+}_i mobilisation in CaR-HEKs transfected with siRNA for PKCα but not with control siRNA (P<0.01; n=6). Intriguingly, this suggests that PKCα may even be active before the CaR elicits detectable Ca^{2+}_i mobilisation. Indeed, a similar effect was seen using the PKC inhibitor GF109203X (1μM) which permitted significant responses to 2mM Ca^{2+}_o that were not observed in the inhibitor's absence (P<0.05, n=7).

Next, following 2.5mM Ca^{2+}_o–induced CaR stimulation, cotreatment with either forskolin (10μM; adenylate cyclase activator), IBMX (75μM; 3-isobutyl-1-methylxanthine, phosphodiesterase inhibitor) or isoprenaline (100nM; β-adrenoceptor agonist) significantly enhanced the resulting Ca^{2+}_i mobilisation. In contrast, the inactive analogue 1,9 dideoxyforskolin (10μM) was without effect. Indeed forskolin (10μM) also reduced the agonist concentration threshold for CaR activation whereby 1.8mM Ca^{2+}_o elicited Ca^{2+}_i mobilisation in the presence of forskolin but not in its absence (P<0.001, n=9).

Together these data demonstrate that in CaR-HEK cells, PKCα inhibits CaR-induced Ca^{2+}_i mobilisation including at sub-threshold agonist concentrations. In contrast, cAMP lowers the threshold for CaR-induced Ca^{2+}_i mobilisation demonstrating the potential of the CaR to provide integration of multiple intracellular signals in Ca^{2+}_o homeostasis.

Litter size manipulation alters hormones plasma concentration and vascular reactivity

A.S. Mecawi[1], P.B. Marangon[1], N.A. Gonzaga[2], P. Passaglia[2], C.R. Tirapelli[2], L.L. Elias[1] and J. Antunes-Rodrigues[1]

[1]Department of Physiology, FMRP-USP, Ribeirão Preto, São Paulo, Brazil and [2]EERP-USP, Ribeirão Preto, São Paulo, Brazil

Litter size manipulation results in body weight gain alterations, such phenotype lingers until the adulthood. Several studies have demonstrated changes in hormonal profile, cardiovascular function and hydromineral homeostasis. Using the model of reduction or enhance of the litter size, the current work aimed to investigate the alterations in plasma angiotensin I and II, atrial natriuretic peptide (ANP), vasopressin and oxyitocin concentration on weaning (21st day) and adulthood (60th day) and vascular reaction of thoracic aorta to phenylephrine,

acetylcholine and sodium nitroprusside on adulthood. The litters were divided into 3 groups: Normal Litter (NL, 10 pups), Small Litter (SL, 3 pups) and Large Litter (LL, 16 pups). The reduction and enhance of the litter size, led to an increase and decrease of the weight gaining in SL (~25%) and LL (~19%) groups, respectively, at the weaning (21st day) till adulthood (60th day). Plasma angiotensin I and II levels were higher in both SL (~40%) and LL (~120%) groups in relation to the NL at the weaning, without differences on adulthood. We also observed a significant rise in the plasma vasopressin (~20%) and oxycitocin (~50%) in LL group on adulthood, without significant differences on weaning. We did not found significant differences on plasma ANP concentration on weaning, but on adulthood we observed an increase in plasma ANP in the SL and decrease in LL group (both ~20%). It was also observed a reduction (~10%) of endothelium-dependent vasodilation induced by acetylcholine in the SL group compared to control. No significant differences were observed in vasomotor responses to phenylephrine and sodium nitropruciato. Our results show that the litter size manipulation can program not only the weight gain, but also plasma hormones related to cardiovascular control and hydromineral balance and endothelium-dependent vascular reactivity.

Effects of leptin, TNF alpha, IL-1 and insulin on intracellular calcium concentration and pH in human articular chondrocytes from healthy and osteoarthritic cartilage

J.C. Sánchez and D.F. López-Zapata

Faculty of Health Sciences, Universidad Tecnológica de Pereira, Pereira, Risaralda, Colombia

Chondrocytes are the only cells in articular cartilage and are responsible for extracellular matrix metabolism, which confers its characteristic ability to withstand compression and distribute load (1). Osteoarthritis is characterized by an abnormal matrix metabolism which leads to a dysfunction of articular cartilage; this disease is associated with obesity, associated to an increase in leptin, TNF alpha, IL-1 and insulin. Chondrocyte intracellular calcium concentration (ICC) and pH (IpH) regulate matrix metabolism (2). In the present study, the effects of these substances on ICC and IpH, in human articular chondrocytes freshly isolated from healthy and osteoarthritic cartilage, were determined. Cells were isolated from knee or hip load-bearing car-tilage that was obtained from patients undergoing orthopedic surgery. All patients signed an informed consent form. Cells were isolated using a standard method (3).
ICC and IpH were measured by fluorescence employing Fura-2 and BCECF-loaded cells respectively, previous a standard calibration for each dye. The measurements were made in human chondrocytes from healthy cartilage (HCHC) and osteoarthritic cartilage (HCOC). Initial ICC was 88±14 nM in HCHC (n=38) and 79±12 nM in HCOC (n=36), with no significant differences between them. In HCHC, insulin, TNF alpha and IL-1 increased significantly ICC immediately after the application of each agent to 382±34 nM (n=12), 551±32 nM (n=8) and 604±44 nM (n=8) respectively ($p<0.05$ in all cases when compared with control); there were also significant differences between ICC increase induced by TNF alpha and IL-1 when compared with the ICC increase induced by insulin. In HCOC the effects of insulin, TNF alpha and IL-1 on ICC were in the same trend, but they were significantly lower: 211±21 nM (n=9), 243±32 nM (n=9) and 216±24 nM (n=8) respectively, without any significant differences. In both cells, leptin had no significant effect on ICC: 84±21 nM in HCHC (n=10) and 70±26 nM in HCOC (n=10).
On the other hand, initial IpH was 6.94±0.21 in HCHC (n=26) and 6.32±0.12 in HCOC (n=26), with a significant difference between these two data ($p<0.05$); only IL-1 was able to decrease IpH to 6.21±0.16 (n=8) and 6.02±0.09 (n=8) respectively; in both cases the differences were significant ($p<0.05$). Insulin, TNF alpha and leptin had no effect in both groups of cells.
In summary, these findings may help to understand the association between obesity and osteoarthritis because leptin, TNF alpha, IL-1 and insulin are all increased in obesity as a consequence of a metabolic misbalance; the effects of them on chondrocyte calcium and pH homeostasis can affect matrix metabolism and hence cartilage function, which can lead to osteoarthritis.

PCB311

Microarray Analysis of the retina in growth hormone transgenic mice

S. Harvey[1], B.T. Martin[1], E.O. List[3], J.J. Kopchick[3] and Y. Sauve[1,2]

[1]Physiology, University of Alberta, Edmonton, AB, Canada, [2]Ophthalmology, University of Alberta, Edmonton, AB, Canada and [3]Edison Biotechnology Institute, Ohio University, Athens, OH, USA

Purpose: Previous work in our lab using the electroretinogram has functionally characterized the bovine growth hormone expressing (bGH) mouse as having depressed oscillatory potentials (OPs) in comparison to wild-type (WT) littermates (1). A microarray analysis of the retina was therefore performed to identify candidate genes contributing to this phenotype.
Methods: Total RNA was extracted from the retinas of 6 WT and 6 bGH mice by BioServe (Beltsville, MD). The expression level of 29,922 gene transcripts was measured using the Phalanx Biotech OneArray (Palo Alto, CA). Hierarchical clustering and functional gene-set analysis was performed on the resulting data to compare the retina of WT and bGH mice.
Results: Gene-sets associated with Angiogenesis revealed 13 member genes in the retinas of bGH mice that had significant alterations ($P<0.05$) in their expression patterns in comparison with WT mice. Similarly, 52 genes associated with Apoptosis were altered, as were 8 genes associated with Diabetes, 12 with Neurotransmission, 10 with Neurotrophins, and 5 with the Janus-kinase (JAK) signaling pathways.
In the Angiogenesis gene set for bGH mice, vascular endothelial growth factor (VEGF) receptor 2 precursor expression was increased to 134% of WT levels, while VEGF-A precursor was increased to 123% of WT levels. Pro-apoptotic transcripts of

death-inducer obliterator 1 were reduced to 71% of WT levels. Transcripts for 6-phosphofructo-2-kinase/fructose- 2,6-biphosphatase 3, an enzyme important for glycolysis with involvement in diabetes, was upregulated to 146% of WT levels. There were significant changes to members of neurotransmission and neurotropic gene sets, including ATP-sensitive inward rectifier potassium channel 12 (118%), somatostatin receptor type 1 (91%), and insulin-like growth factor-binding protein 6 precursor (79%). Lastly, in the JAK pathway, suppressor of cytokine signaling 2 was upregulated to 154% of WT levels.

Conclusion: Mice overexpressing growth hormone show a defect in the ERG analogous to that seen in diabetic retinopathy and retinopathy of prematurity. The results of this study indicate that the defect in these mice may be caused by alterations in vascular function (Vegfa, Kdr), altered cell survival in development (Bnip1, etc.) or changes in several genes linked to diabetes (Mapk8, PFkfb3). The changes in neurotransmission-linked gene expression may be directly responsible for the changes seen in ERG. In particular, genes of the Agxt family are linked to glycine metabolism in retinal amacrine cells, which are likely cellular mediators of the OPs. Changes in the Janus-kinase pathway reflect the heightened GH signaling (Socs2). These changes in gene expression occurred independently of gross morphological changes in the retina, as no significant differences were seen in cell counts or retinal zonation.

PCB314

Duodenal I-cells contain CB1 receptor mRNA transcript that is upregulated by energy restriction

A. Sykaras, C. Demenis, R. Case, J. McLaughlin and C.P. Smith

University of Manchester, Manchester, UK

Gut-to-brain signalling has a pivotal role in the regulation of food intake and energy balance. Vagal afferent neurons (VANs) integrate a wide range of signals from the proximal intestine to stimulate or inhibit appetite. Gut hormones and intestinal endocannabinoids (eCBs) are key peptides that act on the vagus nerve and transmit signals to the brain, responding to the food digestion or food deprivation. Enteroendocrine (EE) cells sense nutrients and release gut hormones that regulate food digestion and appetite. I-cells are a subtype of EE cells, primarily localized in duodenum, that secrete the classic satiety hormone cholecystokinin (CCK), mainly in response to fat. Post-prandially, CCK suppresses appetite via vagal CCK-1 receptors and also down-regulates the expression of the orexigenic-signalling associated cannabinoid receptor CB1 in VANs, to inhibit food intake. CB1 receptor is up-regulated during fasting, when CCK levels are low and intestinal eCBs levels are increased, to promote stimulation of appetite. Intestinal eCBs levels can also selectively increase after a fatty meal, a response that is dependent on the orosensory properties of the meal. Elevated eCBs levels further induce fat intake by activating CB1 receptor. Although it is accepted that CB1 receptor is expressed in VANs, it remains unknown if it is expressed in the duodenal epithelium.

The aim of our study was to investigate if CB1 receptor is expressed in the duodenal mucosa and specifically in I-cells. We used the (Cck-EGFP)BJ203 transgenic mouse model to isolate I-cells by using fluorescence activated cell sorting (FACS). 5000-10000 I-cells were isolated by FACS in each experiment. Semi-quantitative RT-PCR analysis of total unamplified RNA prepared from sorted I-cells (eGFP+ cells) and equal number of non I-cells (eGFP- cells) revealed that I-cells are highly enriched in CB1 receptor mRNA transcript in comparison with non I-cells (epithelial cells). RT-PCR analysis was repeated on amplified RNA/cDNA samples from I-cells and non I-cells confirming that CB1 receptor mRNA transcript is specifically expressed in I-cells and cannot be detected in non I-cells. We then examined if the CB1 receptor mRNA levels are regulated by energy intake. We compared CB1 receptor mRNA levels using duodenal mixed cell populations from 3 different groups of mice (fed ad libitum, fasted for 16 hours and fasted for 16 hours/re-fed for 5 hours). Semi-quantitative RT-PCR indicated that CB1 mRNA is upregulated during fasting. Re-feeding of fasted mice down-regulates the expression of CB1 mRNA transcript.

Our results suggest that I-cells contain mRNA transcript encoding CB1 receptor and that its expression is upregulated during energy restriction, similarly with VANs. The presence of CB1 mRNA transcript in I-cells may suggest that eCBs directly inhibit CCK release to promote stimulation of food intake.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB315

Effects of ofloxacin residues on health biomarkers in chicken

M.I. Arshad, S.L. Butt, Z.U. Rahman and F. Asad

Physiology and Pharmacology, University of Agriculture, Faisalabad, Punjab, Pakistan

Now a days quinolones are frequently used antibiotics at poultry farms but their residual effects by oxidative damage to body of chicken have not been addressed. Therefore, we aimed to investigate the effect of antibiotic residues of ofloxacin on total antioxidants, oxidants, paraoxonase, arylesterase and catalase activities. Five weeks old broiler birds were treated with ofloxacin @ 10 mg/kg b.wt/day for 5 consecutive days through drinking water. Six birds were killed for each time interval for the detection of antibiotic residue in muscles and liver by HPLC with fluorescent detection. Experiment was conducted according to the institutional ethics committee. Health biomarkers including paraoxonase, arylesterase and catalase were analyzed by their respective reference methods and concentrations were measured by photometric method from serum, muscles and liver. Ofloxacin did show a residual effect on day 3 which turned into traces in muscles at the end of study. Oxidant status did increase on day 1 after ofloxacin therapy and level remained high throughout experimental period that may lead to deterioration of broiler meat. Ofloxacin did decrease the muscle arylesterase but did not put significant effect on serum arylesterase. Muscle catalase and serum paraoxonase were significantly decreased by ofloxacin at day 1 of the experiment. However, after 4 days of wash out period for drug, the antioxidants status was improved without any significance. In conclusion our results did show that residues of ofloxacin have deteriorative effects on meat quality by increasing the oxidant level in the muscles and serum.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB316

Effect of ciprofloxacin residues on the quality of meat and eggs in layer chicks

Z.U. Rahman, F. Asad and S.L. Butt

Physiology and Pharmacology, University of Agriculture, Faisalabad, Punjab, Pakistan

The extensive use of ciprofloxacin in poultry feed and to treat diseased birds by veterinarians may cause drug residue problems in eggs and meat of chicken. The effect of drug residues on the meat quality and withdrawal period of ciprofloxacin was investigated in experimentally treated birds with ciprofloxacin @ 10 mg/kg b.wt/day for 5 consecutive days. Samples of serum, muscle and eggs were collected, screened and quantified for ciprofloxacin by HPLC with fluorescent detection. Total antioxidant capacity (TAC) and total oxidant status (TOS) was measured and correlated with the presence of residues in meat. Experiment was conducted according to the institutional ethics committee. A significant decrease in antioxidants capacity and increase in oxidant status in muscles was found that may indicate deterioration of chicken meat quality. The mean concentrations of ciprofloxacin were calculated in collected samples from chicken and Analysis of variance and Duncan multiple range test was applied. Significant concentration of ciprofloxacin drug residues was present in serum, muscle, liver and kidney at day 1 of treatment, on different days of experiment and after the slaughter. Serum and muscles antioxidant capacity decreased while total oxidant status increased significantly. As birds were given wash out time after 5 days of treatment, serum TOS was low and little rise in TAC was observed in serum and muscles. Muscle samples positive for ciprofloxacin residues were cooked by two different methods (electric oven and microwave) to see the effect of on residual concentration was measured again. Ciprofloxacin concentration in muscles decreased but did not reach to a significant level after cooking. In conclusion, ciprofloxacin residue did change the TAC and TOS of muscles and indicate the presence of residue in meat, eggs and serum.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB317

Deteriorative effects of norfloxacin residues on quality of broiler meat

S.L. Butt, Z.U. Rahman and F. Asad

Physiology and Pharmacology, University of Agriculture, Faisalabad, Punjab, Pakistan

In current poultry production systems use of antibiotic is going be inevitable for efficient meat production and among the antimicrobial agents quinolones are proved to be efficient in curing various bacterial diseases of poultry. However, the residual effects of norfloxacin (one of the quinolones) in meat of broiler birds have not been largely addressed. Therefore, we aimed to investigate the effect of norfloxacin residues on the quality of broiler meat by measuring the oxidant status and antioxidant capacity. Five weeks old broiler birds were experimentally administered with norfloxacin (10 mg/kg b.wt/day) for 5 consecutive days through drinking water. Six birds were killed for each time interval to detect the norfloxacin residues by HPLC with fluorescent detection as well as oxidant and antioxidant capacity of serum and muscles was measured by photometric method. Animal experimentation was conducted according to the institutional ethics committee. Maximum drug residues were present in serum and muscles on day 1 of norfloxacin treatment. Norfloxacin did decrease the antioxidant capacity in serum and muscles of medicated chicken that may lead to deterioration of broiler meat The reactive oxygen species (ROS) production (oxidative capacity) increased in serum and muscles at day 1 of norfloxacin treatment in broiler birds. However, after 4 days of wash out period for drug, the antioxidants status was improved without any significance.. In conclusion our results did show that residues of norfloxacin have deteriorative effects on meat quality of chicken.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Correlated responses to a multidirectional artificial selection in the bank vole: Changes in organ size

P. Koteja[1], K. Baliga-Klimczyk[1], K.M. Chrzascik[1], G. Dheyongera[1], M. Konczal[1], U. Maiti[1], P. Orlowska[2], A. Rudolf[1], C. Stawski[1] and E.T. Sadowska[1]

[1]Institute of Environmental Sciences, Jagiellonian University, Krakow, Poland and [2]Institute of Zoology, Jagiellonian University, Krakow, Poland

A central question in evolutionary physiology is how complex physiological adaptations evolve in response to natural selection operating on performance traits hypothetically associated with Darwinian fitness. Selection experiments provide a powerful yet underutilized approach to that question [1,2]. We established an artificial selection experiment with lines of bank voles Myodes glareolus selected for high swim-induced aerobic metabolism (A), the ability to maintain body mass on a low-quality herbivorous diet (H), intensity of predatory behaviour towards crickets (P), and unselected control lines (C) (with four replicate lines in each of the categories [3]). In generation 13, voles from the selected lines achieved 48% higher maximum rate of metabolism, lost 38% less mass in the 3-day test with low-quality diet (at the age of 32-35 days), and attacked crickets 5 times more frequently than voles from control lines. Here we report correlated responses in whole body and internal organs mass, measured in 15-18 voles per line (both sexes, mean age 76 days). The animals were euthanized by an overdose of anaesthetic (isoflurane) and dissected. Organs were weighed to the nearest 0.001g. Although the selection was performed on mass-independent traits (residuals from regression), body mass was higher in H than in C lines (Mixed cross-nested linear model, adjusted least square means±SE; C: 22.5±0.57, A: 22.8±0.58, H: 25.9±0.56, P: 20.8±0.58g; effect of selection $p<0.001$). Apparently, selection for the capability to maintain energy balance during a period of undernourishment in juveniles resulted in evolution of increased body size in adults. As expected, mass of heart and gasterocniemus leg muscles were increased in A lines (Heart C: 0.117±0.004, A: 0.143±0.004, H: 0.117±0.004, P: 0.127±0.004g, $p=0.001$; Muscles C: 0.166±0.005, A:0.190±0.005, H:0.159±0.005,

P:0.177±0.005, p=0.003). Because our earlier results showed an increased level of basal metabolism and food consumption in A lines [4,5], we also expected an increased mass of organs related to whole-body metabolism, and the results confirmed the expectation (Liver: C:1.20±0.03, A:1.31±0.03, H:1.19±0.03, P:1.27±0.03g; p=0.02; Kidneys: C: 0.29±0.01, A: 0.34±0.01, H: 0.29±0.01, P: 0.32±0.01g, p=0.003; Small intestine: C: 1.07±0.02, A: 1.18±0.02, H: 1.15±0.02, P: 1.16±0.02g, p=0.030; similar pattern was also found for stomach and caecum). As we expected, brain mass increased in P lines, but surprisingly it was also significantly increased in A lines (Total brain mass C: 0.522±0.006, A: 0.557±0.006, H: 0.531±0.006, P: 0.552±0.006g, p=0.006; similar pattern was found for cerebrum and cerebellum analysed separately). The selected lines of voles will provide a unique model to investigate lower-level histological, biochemical and molecular factors underlining evolution of the organismal performance traits.

The postprandial thermal and metabolic responses (the specific dynamic action) are physiological traits phylogenetically conserved among vertebrates (refs. 1, 2). Their behavioral counterpart is a sequence of drinking, maintenance and sleep-like behaviors (known as the Behavioral Satiety Sequence, BSS) that have been thoroughly described in rodents, and allowed for refined evaluation of potential appetite suppressants (refs. 3, 4). However, BSS presence and attributes have not been systematically studied in non-mammalian species. Here, we describe the BSS in pigeons (*Columba livia*, adults, 340-400 g bw, N=6,) after 1) a palatable seed mixture (SM) offered to free-feeding (FF-SM) animals; 2) re-feeding after a 24-h food-deprivation (24FD), 3) brief (1-hour) removal of food and water, followed by palatable food presentation (the "seed mixture-induced BSS" or SM-BSS test). Behaviors were examined by continuous recording during 2 h after the meal. A set of graphic representations and indexes related to the temporal structure and the sequential relationships between these behaviors (latency for the 1st occurrence, time-to-peak (TTP) of each behavior, inter-peak interval (IPI) and the first intersection (ItS) between feeding curves and those of other BSS-typical behaviors). These indexes were used to describe changes in the SM-BSS evoked by retesting (3 times, 7-days apart), by gender, by different degrees of food preload (0, 33, 66 or 100 % of their mean intake in 3 preceding tests), by removing water during the test or by changing the palatability of the food offered (Regular chow vs. SM food vs. quinine-adulterated SM. Fasting- and SM-induced feeding were followed by a temporally similar sequence of increased bouts of drinking, then preening and then sleep, which can be integrally observed within 90 min after food presentation. The latency, TTP, IPI and ItS indexes were able to detect, describe and quantitatively assess BSS the temporal and sequential parameters of the BSS. The SM-BSS test indexes were not affected by retesting, by gender or by the absence of water during the test. Despite of significant differences in food intake, the temporal and sequential indexes of the BSS in SM-BSS test, in 24FD animals, after different preloads or foods of varying palatability were similar, suggesting that BSS is triggered by preabsortive signals (all food eaten is still in the crop 90 min after the test start), but its sequential and temporal patterns are not modulated by the meal size. These results diverge from those observed in rodents and primates, indicating that, beyond general behavioral similarities, BSS may be directed by distinct central mechanisms in birds and mammals.

Continuous and intermittent training protocols improve expression of proteins involved in muscle metabolism of induced-obese rats

P.M. Seraphim[1], B.B. Brandao[1], L.M. Souza[1], B.N. Trombetta[1], M.S. Teixeira[3], C.L. Santos[2] and S. Bordin[2]

[1]Physical Therapy, FCT-UNESP - Universidade Estadual Paulista, Presidente Prudente, Sao Paulo/ Presidente Prudente, Brazil, [2]Physiology and Biophysics, ICB- Institute of Biomedical Sciences, Sao Paulo, SP, Brazil and [3]Physics, Chemistry and Biology, FCT - UNESP- Universidade Estadual Paulista, Presidente Prudente, SP, Brazil

Obesity is associated to reduction of glucose transporter 4 (GLUT4) and/or impaired insulin signaling pathway in skeletal muscle(1). Muscle contraction culminates in 5' AMP-activated protein kinase (AMPK) activation and GLUT4 translocation(2). Training stimulates peroxisome proliferator-activated recep-

tor-γ coactivator (PGC1α) transcription in muscle which is involved in GLUT4 regulation(3). We aimed to evaluate the effects of continuous or intermittent training on AMPK (coded by Prkaa2), PGC1α (Ppargc1a gene) and GLUT4 (Slc2a4 gene) expression in muscle of diet-induced obese rats. Sixty male Wistar rats aged 90 days were divided: sedentary control (SC), continuous exercise control (CEC), intermittent exercise control (IEC), sedentary obese (SO), continuous exercise obese (CEO), intermittent exercise obese (IEO). All animals received standard chow and obese also received high fat diet during 16 weeks (wk). Insulin tolerance test and the double effort test were performed after 8 wk of diet and at the end of 8 wk of training using blood collected from the tail distal end. The CEC and CEO groups trained for 30 min at 90% of anaerobic threshold, 3x/wk, 8 wk. The IEC and IEO performed 11 efforts of 2 min, 1 min of interval, 3x/wk, 8 wk, over the delta zero to 120% of the critical load. Rats were anesthetized with Pentobarbital sodium 40mg/kg, ip, for removal of gastrocnemius muscle. RT-PCR and Western blotting were performed for mRNA and protein analysis. The experimental protocol was approved by the Ethics Committee for Animal Research (#74/2009). ANOVA was used for comparison among means with post-hoc (Tukey) if necessary, considering $p<0.05$. Obese presented similar gain of weight after 8 wk of diet (23%,$p<0.05$), which was softened after training (CEC-31%, EIC-28%,$p<0.01$vsSC; CEO-54%, IEO-44%,$p<0.001$vsSO).Obese presented reduced insulin sensitivity (SC=2.3+/-0.23; SO=1.8+/-0.2%/min,$p<0.05$), but both protocols reverted this condition (CEO=2.8+-0.7;IEO=2.4+-0.4%/min,$p<0.05$vsSO). Prkaa2 mRNA was increased with exercise (CEC=70%,EIC=72%,$p<0.01$vsSC;COE=75%, EIO=59%,$p<0.05$vsSO), AMPKα2 protein content was increased in exercised controls (CEC=47%,IEC=51%,$p<0.05$vsSC). pAMPKα2 was reduced in SO (39%,$p<0.05$vsSC), and increased after training (CEO=264%,IEO=299%,$p<0.01$vsSO). Both protocols were efficient to increase Ppargc1a mRNA expression (CEC=62%,IEC=126%,$p<0.05$vsSC; CEO=104%, IEO=152%,$p<0.05$vsSO). Continuous exercise provoked an increase (53%) in Slc2a4 expression in obese ($p<0.05$), Intermittent training improved control (55%,$p<0.05$). Eight weeks of both training protocols were able to soften the gain body mass, improve the insulin sensitivity and increase aerobic capacity, promoting increase of the protein expression involved in muscle metabolism.

Inflammatory responses to high-intensity intermittent training in diet-induced obese rats

P.M. Seraphim[1], R.J. Moreira[1], A. Panveloski-Costa[1] and M.S. Teixeira[2]

[1]Physical Therapy, FCT-UNESP - Universidade Estadual Paulista, Presidente Prudente, Sao Paulo/ Presidente Prudente, Brazil and [2]Physics, Chemistry and Biology, FCT - UNESP- Universidade Estadual Paulista, Presidente Prudente, Sao Paulo, Brazil

Adipose tissue is a source of inflammatory cytokines, such as TNF-α, characterizing a chronic low-grade inflammatory state (1). Lifestyle behavioral interventions, as physical activity, may have clinically significant benefits for improving inflammation (2). We aimed to investigate inflammatory responses in muscle after intermittent training of high intensity squat jump type in Wistar obese-induced rats. Forty adults male Wistar rats of 2 months-old were divided into: sedentary control (SC), exercise control (EC), sedentary obese (SO), exercise obese (EO). Control groups were fed with standard chow and obese received a cafeteria diet+standard chow ad libitum. The training protocol was performed following the adapted model of force from Tamaki et al. (3). It consisted on 3x a week, interposed by 24h among sessions, 3 series of 12 repetitions of 60s of interval among series with a strength load equivalent to 50% of the body weight (BW) during 6 weeks. An insulin tolerance test (ITT) was performed with venous blood collected from tail distal end for glicemia determinaton after ip injection of regular human insulin (0.5 IU/kg BW). The sacrifice was performed for removal of soleus muscle under anesthesia (Ketamine 80mg/kg,Xylazine 5mg/kg,ip). RT-PCR was performed for evaluation of Tnf and Il10 mRNA levels. ANOVA one-way was used for comparison among means with post-hoc (Tukey) if necessary, considering $p<0.05$. The experimental protocol was approved by the Ethics Committee for Animal Research (#15/2009). Obese (SO=538+/-19.6, EO=494.6+/-14; $p<0.01$vsSC,EC) presented a final weight significantly higher than controls (SC=415+/-18, EC=393+/-14) and significant increase in fat mass (around 49% in SO, $p<0.001$ vs SC; 42% in EO group $p<0.01$vsEC). ITT showed a reduction in insulin sensitivity in obese, however reversed by training (kITT expressed as %/min: SC=5.76+/-0,36;EC=6.63+/-0.45;SO=3.60+/-0.62*#; EO=7.07+/-0.47&;*$p<0.05$vsSC;#$p<0.01$vsEC, &$p<0.001$vsSO). The diet increased fat mass (SC=10.6+/-0.91,SO=20.83+/-0.17x0.001g/g BW, *$p<0.001$), and Tnf RNAm levels in obese group (SC=100.5+/-5.3, OS=133+/-7.9 AU, $p<0.001$). The training caused a 27%-reduction ($p<0.01$vsSO) in fat mass, and 39%-reduction in Tnf mRNA level (EO=80.7+/-6.2, $p<0.05$vsSO). The cafeteria diet positively modulated, while the training reduced Il10 levels mRNA (SC=100.6+/-4.2&, SO=210.4+/-10, EC=42.8+/-9.5&#, EO=153.9+/-13.7*, *$p<0.05$vsOS, &$p<0.001$vsSO, #$p<0.01$vsEO). We can conclude that the cafeteria diet was detrimental to insulin sensitivity in rats, and effective in body weight gain and increase of inflammatory cytokine TNFα levels. On the other hand, high-intensity intermittent training was effective in reversing this situation. Surprisingly, high-intensity intermittent training worsened, but the diet per se increased IL10 gene expression.

Irisin, a proteolytic derivative of muscle integral membrane protein FNDC5 is released into the bloodstream after endurance exercise in mice and humans. The gene is regulated by PGC-1α to activate thermogenic programs in white adipose tissue. We wanted to test the hypothesis if FNDC5 and irisin are link to exercise type and duration and if these are age-dependent.

Methods: Middle-aged, non-diabetic and non-athlete men performed a 1-hour low-intensity (50% VOmax) aerobic exercise (AE) with bicycle ergometer (n=17), 21-weeks of endurance exercise (EE, n=9) and a combined endurance and resistance exercise (EE+RE, n=9), and in age matched non-exercised controls (Con, n=2). Vastus lateralis biopsies and blood samples were taken at 3-hours post-exercise. Furthermore, skeletal muscle mRNA fold changes of PGC1α and FNDC5 are investigated after 1-hour and 48-hours of single resistance exercise bout (5 × 10 RM leg press) in (a) young (n=10) and (b) old (n=11) men. FNDC5 mRNA was quantified using Taqman primers by Real-Time quantitative PCR System. PGC1α and GAPDH were quantified using in-house designed primers, iQ SYBR supermix and CFX96 Real-time PCR Detection System. Relative expression levels for FNDC5 and PGC-1α were calculated with the deltaCt method and normalized to the expression of GAPDH. Serum irisin levels were measured from serum samples using a commercial EIA kit.

Results: In non-diabetic and non-athlete middle-aged men no significant changes were observed in skeletal muscle PGC-1α, FNDC5 and serum irisin after 1-hour low-intensity aerobic exercise, 21-week endurance training or 21-week endurance training combined with resistance exercise (RE) training, whereas a single RE bout increased significantly FNDC5 mRNA by 1.4-fold post-RE in young, but not in old previously untrained men. Moreover, while the increase in PGC-1α mRNA at 1-hour post-RE in old men was significant, no significant changes in FNDC5 were detected. Apart from the single RE-bout, large intra and inter-individual variations in PGC-1α, FNDC5 and serum irisin in response to endurance exercise and RE training were observed. Importantly, changes in skeletal muscle PGC-1α gene expression were not consistently accompanied by corresponding changes in FNDC5. Our findings indicate that 1) for the most part, exercise does not increase FNDC5 expression in skeletal muscle; 2) factor(s) other than PGC-1α may be involved in the regulation of FNDC5 expression.

In conclusion, the large intra and inter-individual variation in FNDC5 and irisin in response to different types of exercise indicate that exercise does not seem to increase FNDC5 in skeletal muscle or circulating irisin levels. However, the increase in a subset of young individuals in acute RE warrants further studies to determine whether the effects of exercise on FNDC5 and irisin are collection time, exercise type, protocol, intensity and age-dependent.

Celastrus paninculatus enhances endurance activity by improving angiogenesis, mitochondrial biogenesis, glucose and lactate transport and protect muscle cells against t-BHP induced oxidative and apoptotic damage

H.K. Kandikattu

Biochemistry and Nanosciences, Defence Food Research Laboratory, Mysore, India

Regular exercise and balanced diet are the effective strategies to maintain healthy life style. Moderate exercise improves muscle metabolism, cardiovascular function and mitochondrial biogenesis by fatty acid utilization, enhancing mitochondrial metabolic rate and proliferation. Intense exercise can cause increased free radical production in the skeletal muscle and myocardium and forms muscle fatigue by increasing lactic acid content leading to muscle acidosis. Herbal extract supplementation has been suggested as an alternate therapy to treat fatigue induced stress. In the present study, we evaluated the anti-fatigue activity of Celastrus paniculatus seed extract (CPSE) in swimming endurance model of male BALB/C mice (25±2g). The work is an attempt of obtaining some clues to help elucidate the energy sensing, mitochondrial metabolism, angiogenesis, lactate and glucose transport mechanisms under swimming alone as well as in combination with 50mg/kg body weight CPSE administration by gavage. Here, we observed that CPSE supplementation enhances the swimming endurance by 2.5 folds. In order to understand the molecular mechanisms of exercise endurance activity we measured the exercise responsive skeletal metabolic regulators such as silent information regulator-1 (SIRT-1), peroxisome proliferator-activated receptor gamma coactivator-1α (PGC-1α), AMP-activated protein kinase (AMPK) and lactate transporters monocarboxylic acid transporters-1 (MCT-1) and 4 (MCT-4), glucose transporter-4 (Glut-4), angiogenesis enhancer vascular endothelial growth factor (VEGF) and glycolysis regulator pyruvate dehydrogenase kinase-4 (PDK-4) and oxidative stress biomarkers superoxide dismutase-1 (SOD-1), catalase (CAT) and heat shock protein-70 (HSP-70). CPSE supplementation potentiated the expression of metabolic regulators. Further we used t-butyl hydroperoxide (t-BHP) induced C2C12 mice muscle cell model which mimics the reactive oxygen species (ROS) mediated fatigue stress to illustrate the underlying antioxidant and anti-apoptotic defense mechanism mediated by CPSE. Our observed results demonstrates that pre-treatment of C2C12 muscle cells with CPSE (50μg/ml) for 2h before 24h treatment with t-BHP protects cell damage by regulation of ROS formation by restoring the antioxidant enzyme/proteins SOD, CAT and HSP-70 levels. The extract also prevents t-BHP induced

apoptosis by restoring the mitochondrial membrane potential (MMP) and inhibition of DNA damage. These results demonstrate that CPSE supplementation might be a valuable therapeutic approach in regulation of endurance activity as well as prevention of oxidative and apoptotic damage of cells.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Body mass index impact on in vivo skin's physiology

L. Tavares[1], O.R. Santos[1], L. Palma[1], M.A. Roberto[4], M.J. Bujan[3] and L.M. Rodrigues[1,2]

[1]CBiOS, U Lusofona Fac Health Sc & Technol, Lisboa, Portugal, [2]Pharmacol Sc Departm, U Lisboa Fac Pharmacy, Lisboa, Portugal, [3]UAH, U Alcala Fac Medicine, Madrid, Spain and [4]PRS, St Joseph Hospital -CHLC, Lisboa, Portugal

Changes in skin physiology resulting from overweight appears to be associated to significant modifications in skin hydration, repair mechanisms and biomechanical behavior, but this subject is still poorly documented. The aim of this work is to evaluate the impact of the BMI on normal skin indicators. Our sample involved 89 female volunteers, 20 - 46 (32+7) years old, no relevant pathologies except overweight, obesity and morbid obesity. The study respected the Declaration of Helsinki and subsequent ethical guidelines. Volunteer's weight and height were obtained by anthropometric measurements and the BMI calculated. The sample was divided in four groups according to the WHO classification - Normal (group I), Overweight (group II), Obese(group III) and Morbid (group IV). One single measurement (noninvasive methods, under standard and controlled conditions) was performed, involving measurements on skin hydration, barrier function and biomechanical behavior, in three different anatomical sites: face (zygomatic and forehead), breast and abdomen. Descriptive and comparative statistics were applied (SPSS vs 20.0) and a 95%.significance level adopted. TEWL, Hydration and mechanical descriptors follow a U-shape or a J-shape relationship regarding the BMI as described for other risk biomarkers for cardiovascular disease. An increase in TEWL and a decrease on skin hydration is noted in all anatomic areas when normal subjects are compared with morbid obese. Regarding biomechanical descriptors, significant reductions are detected in all anatomic areas, especially in abdomen, specially involving morbid obesity. Overweight definitely affects skin's function and appearance. These hydration and biomechanical descriptors seems to be interesting biomarkers of the process and eventually correlate with the signs and symptoms that characterize these patient's (most frequent) complaints.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB325

Hydration and biomechanical biomarkers are useful to identify the impact of overweight in skin's physiology

L. Tavares[1], L. Palma[1], O.R. Santos[1], M.A. Roberto[3], M.J. Bujan[4] and L.M. Rodrigues[1,2]

[1]CBiOS, U Lusofona Fac Health Sc & Technol, Lisboa, Portugal, [2]Pharmacol Sc Dep, U Lisboa Fac Pharmacy, Lisboa, Portugal, [3]PRS, St Joseph Hosp - CHLC, Lisboa, Portugal and [4]UAH, U Alcala Fac Medicine, Madrid, Spain

Overweight and obesity have a huge impact on skin pathophysiology. Various related skin disorders seem to involve significant changes in skin hydration and biomechanical characteristics. However related biomarkers are difficult to obtain and to understand, considering skin's intraindividual's variability . This study aims to identify functional biomarkers to describe related changes in skin physiology. The study involved 89 female volunteers, between 19 and 46 (32±7) years old, without any pathologies besides overweight and obesity. All procedures observed the Declaration of Helsinki and subsequent ethical guidelines. Individuals were characterized according with their BMI following the WHO definitions, and cutaneous variables. These, obtained by noninvasive methods, under standard and controlled conditions included skin's epidermal hydration (corneometry), barrier function (TEWL) and several biomechanical descriptors. Z-scores were obtained to designed overall descriptors for hydration and biomechanics respectively. Since some of the indicators were distributed in a reverse scale (the higher the absolute value, the worse the performance of skin) the z-score of these variables became their symmetrical. The global indicators (for each anatomic region) were calculated using the arithmetic mean between these altered partial indicators. Statistical analysis was performed using SPSS version 20.0 and a significance level of 95% adopted.

Data revealed a direct relationship between hydration and biomechanical markers in different anatomical regions. Paradoxally, this is reversed with morbid obesity where an inverse association between skin hydration and biomechanical markers is consistently detected. In any case these relations follow the tendency of isolated descriptors. No matter the tendency, no significant correlation was found in the breast area. This strategy proved to be useful to design global indicators of these functional variables by anatomical area, allowing a fast and clearer view on skin's functional condition.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB326

Central effects of exenatide, a glucagon-like peptide-1 receptor agonist, on human brain activation

S. McKie[1], L. Wasse[2], T. Coulson[3], C. Bryant[2] and J. McLaughlin[2]

[1]Neuroscience and Psychiatry Unit, University of Manchester, Manchester, UK, [2]Gastrointestinal Centre, University of Manchester, Manchester, UK and [3]Salford Royal NHS Foundation Trust, Manchester, UK

Understanding the anorectic effects of native glucagon-like peptide-1 (GLP-1) is challenging because it is rapidly inactivated by the enzyme dipeptidyl peptidase (DPP4) (1). GLP-1

receptors are located throughout the body including the brain and vagal afferent neurones. Exenatide is a long acting GLP-1 receptor agonist which, like GLP-1, reduces food intake, decreases body weight and delays gastric emptying (2), but crucially is resistant to the effects of DPP4. Exenatide may activate central pathways that mediate satiety, however research in humans is lacking. Changes in the blood oxygen level dependent (BOLD) signal measured during functional magnetic resonance imaging (fMRI) can be used as a surrogate correlate of changes in neural activity (3). To examine brain activation in humans after exenatide administration, 15 healthy adult volunteers received a subcutaneous injection of either 5μg exenatide or a placebo in a randomised cross over fashion during 70 minutes of fMRI (3T Philips scanner). For each volunteer, the difference in the mean % BOLD signal change from baseline between exenatide and placebo was extracted from 10 regions of interest covering the brainstem and hypothalamus. The extracted data were analysed in 5 minute blocks using T-tests. Due to excessive movement during scans, 2 volunteers were excluded from analysis. Bilateral increases in BOLD signal in the lower hypothalamus were evident 45 min after exenatide injection ($P<0.05$). The extent and time course of this increase is shown in Figure 1. In the bilateral midbrain there were trends for an increase in BOLD signal after 45 mins ($P<0.075$). This pattern of BOLD signal change was also observed in the right upper hypothalamus and pons. Conversely, BOLD signal was significantly decreased in the left upper hypothalamus 40 mins after exenatide injection ($P<0.05$); a similar trend was evident in the left pons and medulla. The overall pattern is that key appetite regulatory brain regions were progressively activated 45 min after exenatide administration. This suggests the anorectic effects of exenatide in humans may be mediated via activation of central GLP-1 receptors, either directly or via vagal inputs, rather than by a direct effect on delayed gastric emptying of meals since this study was undertaken in a fasting condition.

PCB327

Effect of sequential oral and gastrointestinal stimulation on brain BOLD responses to glucose

C. Bryant[1], L. Wasse[1], S. McKie[2] and J. McLaughlin[1]

[1]Gastrointestinal Centre, Institute of Inflammation and Repair, University of Manchester, Manchester, UK and [2]Neuroscience and Psychiatry Unit, Institute of brain behaviour and mental health, University of Manchester, Manchester, UK

Human brainstem and hypothalamic responses to nutritional stimuli have been characterised in vivo using physiological functional magnetic resonance imaging (phys-fMRI)(1,2). This permits detailed comparison of spatiotemporal responses to different nutrient stimuli. One important discrepancy between human studies in this area is the method of nutrient administration used (intragastric versus oral). In reality, oral taste sequentially precedes gastrointestinal chemosensation and it is likely there is an interaction between the two sensory phases, which may occur within the CNS. Therefore, using fMRI, the purpose of the study was twofold: first, to establish the effects of oral and sequential gastrointestinal, "sweetness" on brain activation and second, to investigate whether oral sweet taste affects the gut to brain signal. 15 healthy fasted subjects were scanned in a single blind, randomised control trial involving 4 visits. Brain activation responses were mapped following a test solution of either glucose or artificial saliva (oral control) delivered into the mouth. Subjects were asked to hold the solution in the mouth and swallow on cue. Subjects then received an intragastric (IG) bolus of either glucose or saline (IG control). Data were analysed using Statistical Parametric Mapping (SPM8). First level analysis was performed on each subject for each study condition by splitting the scans into 26 consecutive 1 min time bins (one minute prior to and 25 following the IG infusion) at 5 minutes with Blood Oxygen Level Dependent (BOLD) signal averaged across the bin. The BOLD signal in each time bin was compared with the baseline average. A second level random effects ANOVA was used to investigate the effect that oral taste had on the glucose-induced intragastric BOLD signal. There was a significant ($qFDR<0.05$) interaction between oral taste and gastric infusion in several areas including the hypothalamus, pons and midbrain. Further analysis showed that this interaction was driven by abolition of the glucose-induced BOLD signal after an oral taste of glucose in most brain regions. This abolition was not observed following the artificial saliva condition. A representative time course is shown in figure 1. These findings suggest that pre-stimulation of sweet taste receptors in the mouth abolishes the reduction in BOLD signal previously seen in response to glucose infused directly into the gut lumen. The exact mechanism and physiological significance of this are not known, but sensory inputs transmitted from the oral cavity may directly modulate the gut-to-brain signals activated from the gut lumen by ingested nutrients.

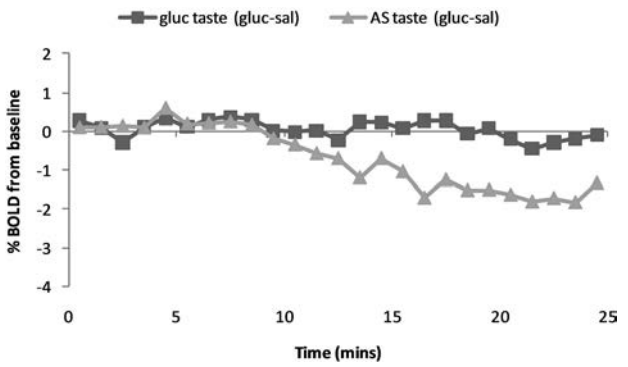

Figure 1. The average cluster time course per minute for oral glucose and artificial saliva during and after an to IG infusion in the hypothalamus region (right).

Differential effects of intragastric glucose and fructose on human brain activation, a physiological functional magnetic resonance imaging study

L. Wasse[1], C. Bryant[1], S. McKie[2] and J. McLaughlin[1]

[1]Gastrointestinal Centre, University of Manchester, Manchester, UK and [2]Neuroscience and Psychiatry Unit, University of Manchester, Manchester, UK

Using physiological magnetic resonance imaging (physMRI), we previously characterised the spatiotemporal brain responses to intragastric lipid. Significant increases in the blood oxygen level dependent (BOLD) signal were observed in brain areas including the brain stem and hypothalamus (1,2). We recently showed that unlike lipid, intragastric glucose decreases BOLD signal in these brain areas (unpublished data); a finding that persists regardless of administration route, i.e. oral or intravenous. However, the doses of glucose used have been high (1M). The effect of lower, nutritionally relevant doses of intragastric glucose on brain activation remains to be explored. Furthermore it is unknown whether fructose, which is chemically similar to glucose but unlike glucose is not used by the brain as a primary energy source, affects brain activation similarly to glucose. To examine this, 8 healthy human volunteers completed 4 trial visits in randomised order. Participants attended after an overnight fast, had a naso-gastric tube inserted and underwent 30 minutes of physMRI acquisition (3.0T Philips scanner). After a 5 min baseline period, participants received 250 mL of test 'drink' (0.25M glucose, 0.5M glucose, 0.5M fructose or a saline control) into the stomach. Data were analysed using the p-block method with 2 min time-bins. Two one-way repeated measures ANOVAs were used to investigate regions within the brainstem and hypothalamus that showed significant differences at qFDR<0.05 for glucose 0.25M vs glucose 0.5M and for glucose 0.5M vs fructose 0.5M. There was a significant difference between 0.5M glucose and 0.5M fructose observed in the hypothalamus (P<0.05; Figure 1). The BOLD responses were similar until approximately 8 min. They diverged thereafter, with a decrease in BOLD evident with 0.5M glucose but a progressive increase following fructose. In the hypothalamus and pons, BOLD signal was decreased after 0.5M glucose but not after 0.25M glucose. The results demonstrate a dose-response effect to glucose. However, despite glucose and fructose being chemically similar, administration of a 0.5M dose of glucose or fructose elicits a divergent BOLD response in the hypothalamus. The precise mechanism is unknown but neurons within this region may display sugar selectivity and only respond to glucose in this way as the brain's primary fuel. Furthermore, fructose does not elicit the same glycaemic and neuroendocrine responses as glucose, so differential changes in blood glucose and insulin could partly explain the different response seen. Similarly, a lower dose of glucose may be too low to exert any metabolic effect on glucose sensing neurons within the brain compared with 0.5M glucose, and thus explain the absence of a reduction in BOLD signal after a 0.25M glucose dose.

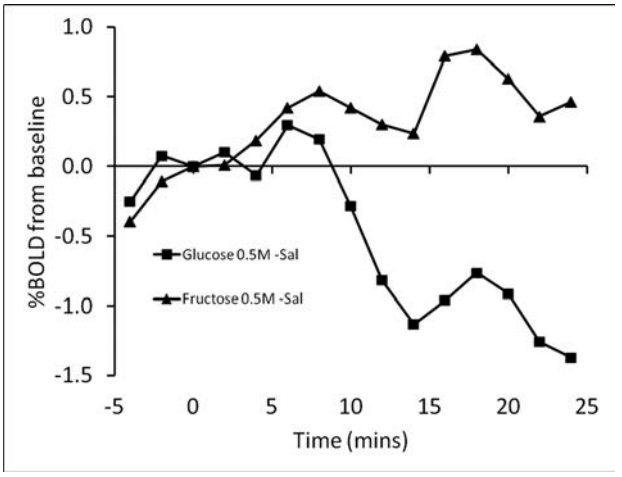

Figure 1. Time course of % BOLD signal change in the hypothalamus after 0.5M glucose and 0.5M fructose

PCB331

Role of the intermediate-conductance Ca^{2+}-activated K^+ channel, $K_{Ca}3.1$ in $CD4^+$ T-lymphocytes of mesenteric lymph node of mice inflammatory bowel disease model

S. Ohya[1,2], Y. Fukuyo[2], M. Matsui[2], H. Yamamura[2], R. Shibaoka[1], H. Niguma[1], M. Fujii[1] and Y. Imaizumi[2]

[1]Pharmacology, Kyoto Pharmaceutical University, Kyoto, Japan and [2]Molecular & Cellular Pharmacology, Nagoya City University, Nagoya, Japan

Dextran sodium sulfate (DSS)-induced rodent colitis models are widely used as a model system for examining IBD (Inflammatory Bowel Disease) pathogenesis including ulcerative colitis and Crohn's disease. Genome expression profile analysis during the development of DSS-induced IBD model showed correlation with IBD patient data. The intermediate-conductance Ca^{2+}-activated K,sup>+ $^{channel, K}_{Ca}$3.1 plays an important role for the modification of Ca^{2+} signaling through the control

of the membrane potential in T-lymphocytes, and $K_{Ca}3.1$ can be a potential target for therapeutic strategies of IBD (Di *et al.*, 2010; Simms *et al.*, 2010). However, pathophysiological impact of $K_{Ca}3.1$ on the immune dysfunction in mucosal lymphoid tissue of IBD model animals remains to be determined. Here, the involvement of $K_{Ca}3.1$ in the enlargement of mesenteric lymph node (MLN) on the pathogenesis of mice IBD model was investigated. Mice IBD model was prepared by exposing male C57BL/6 mice to 5 % dextran sulfate sodium (DSS) for 7 days. All animal experiments were carried out in accordance with the guiding principles for the care and use of laboratory animals in Kyoto Pharmaceutical University and Nagoya City University. Inflammation-induced changes in $K_{Ca}3.1$ activity, the expressions of $K_{Ca}3.1$ and its regulators, and the cell-cycle distribution in MLN $CD4^+$ T-lymphocytes were monitored by real-time PCR, Western blot, voltage-sensitive dye imaging, and flow cytometry analyses. Concomitantly with the up-regulation of $K_{Ca}3.1a$ and nucleoside diphosphate kinase B (NDPK-B), the increase in $K_{Ca}3.1$ activity was observed in MLN $CD4^+$ T-lymphocytes of DSS-induced IBD model. Pharmacological blockade of $K_{Ca}3.1$ produced 1) the significant decrease in disease severities in IBD model, and MLN enlargement, compared with the control mice (n=17), 2) the restoration of the expressions of $K_{Ca}3.1a$, NDPK-B, and Th1 cytokines in MLN $CD4^+$ T-lymphocytes of IBD model (n=4-6), 3) the arrest of both G_1/S and G_2/M transitions during cell-cycle progression in MLN $CD4^+$ T-lymphocytes of IBD model (n=8), and 4) the inhibition of interleukin-6 (IL-6) production in the inflamed tissues (n=4). In addition, tripartite motif containing protein 27 (TRIM27), which suppresses the $K_{Ca}3.1$ activity through the polyubiquitination of PI3K-C2β, was significantly increased in MLN $CD4^+$ T-lymphocytes of IBD model (n=6), suggesting that the up-regulation of TRIM-27 may be a compensatory mechanism in $CD4^+$ T-lymphocyte activation in IBD patients. These suggest that the increase in $K_{Ca}3.1$ activity through the up-regulation of $K_{Ca}3.1a$/NDPK-B complex may be involved in the pathogenesis of IBD via the enhancement of MLN $CD4^+$ T-lymphocyte proliferation. Pharmacological blockade of $K_{Ca}3.1$ may decrease the risk of IBD development.

Acute effect of dietary and skin TRPM8 ion channel stimulation on human thermoregulation and metabolism

A. Valente[1], A. Jamurtas[2], Y. Koutedakis[2] and A. Flouris[3]

[1]FAME laboratory, University of Thessaly, Trikala, Greece, [2]University of Thessaly, Trikala, Greece and [3]FAME Laboratory, Centre for Research and Technology Hellas, Trikala, Greece

Transient receptor potential melastatin 8 (TRPM8) is the receptor for cold sensation and is located on the cell membrane of brown adipocytes (1) and sensory neurons on the skin (2), and can be activated by both cold and L-menthol (3). Indeed, both skin (4, 5) and dietary (1) L-menthol treatments increase brown adipose tissue activity and metabolism in mice, leading to reduced body weight. However, the effects of these treatments in humans remain incompletely understood. The aim of this study was to examine the effect of dietary and skin TRPM8 stimulation on metabolism and thermoregulation in humans. After obtaining University of Thessaly ethical approval, nine healthy male volunteers were randomly distributed into either L-menthol skin (ST; n=4) and dietary (DT; n=5) treatment groups. Participants in both groups were treated with 10 mg/kg L-menthol (ST: gel; DT: capsule) and placebo (ST: water; DT: lactose capsule) in a random order on two different days. Fasted participants remained seated in a 24-25°C and 40-50% relative humidity environment. Core temperature (Tc), heat storage (S), metabolic rate (M), and mean skin temperature (Tsk) were measured at baseline, immediately following each treatment, and every hour thereafter for 7 hours. Each assessment lasted 15 min. The placebo condition data were subtracted from the L-menthol condition data to eliminate the effect of diurnal variation. Kruskal–Wallis one-way ANOVA was used to assess the effect of each treatment on all variables showing a change across time for both ST and DT (Figure 1; $p<0.05$). Post hoc Mann-Whitney U tests showed that ST reduced Tsk within 2 hours and increased S, M, and Tc within 4 hours ($p<0.05$). A similar, albeit weaker, effect was observed following DT ($p<0.05$). Between-treatments comparisons showed that ST produced a strong vasoconstriction [evident by a greater reduction in Tsk ($p<0.05$)] that resulted in a greater increase in S, M, and Tc ($p<0.05$). It is concluded that TRPM8 stimulation via L-menthol ST and DT result in cutaneous vasoconstriction and increased metabolic heat production. Moreover, the effects produced by ST appear to be stronger, as compared to those of DT.

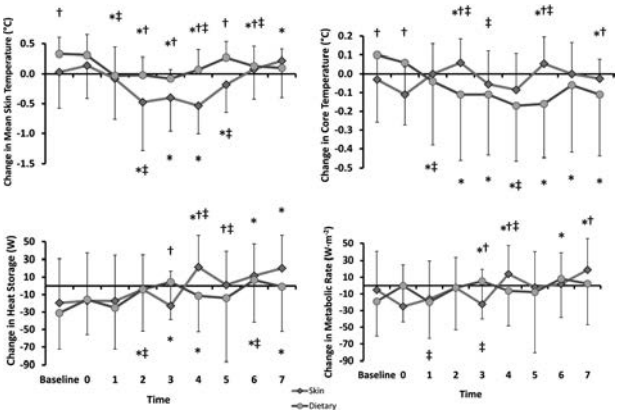

Figure 1. Median±SD change (L-menthol condition minus placebo condition) in mean skin temperature, core temperature, heat storage, and metabolic rate in the skin and dietary treatment groups. Symbols are placed at the respective end of the SD bars: * = difference from baseline for the same treatment; ‡ = difference from the previous time-point for the same treatment; † = difference between treatments for the same time-point.

Attenuation of unloading-induced rat soleus atrophy with the heat shock protein inducer 17-(Allylamino)-17-Demethoxygeldanamycin

T.L. Nemirovskaya[1] and Y.N. Lomonosova[2]

[1]Faculty of Basic Medicine, Lomonosov Moscow State University, Moscow, Russian Federation and [2]Institute for Bio-Medical Problems RAS, Moscow, Russian Federation

Heat-shock proteins (HSPs) are synthesized in great amounts in skeletal muscle, but HSP90 and HSP70 levels dramatically drop by 70–75% under muscle unloading in parallel with muscle atrophy. Probably, that inability to produce HSPs has an important effect on muscle atrophy during unloading. We assumed that under muscle unloading, HSP90 function, which leads to HSP70 synthesis preclusion, might be changed. We have tested the hypothesis that the HSP90 inducer 17-(allylamino)-17-demethoxygel-danamycin (17-AAG) can prevent HSP70 decrease and attenuate atrophy of unloaded soleus due to modulation of HSP90 function. 17-AAG, which specifically binds to the HSP90 ATP-binding site and disrupts its ATP-dependent function, is known to activate HSP90 nonspecifically by the activation of heat-shock factor, thereby causing the activation of the heat-shock or stress-response pathways. During unloading, we administered HSP90 inducer 17-AAG to disrupt ATP-dependent function and to increase the HSP amounts. The aim of the study was to analyze the involvement of HSP 90 into the anabolic and catabolic signalling alterations under conditions of muscle unloading. Male Wistar rats were divided into control (C, n=7), 3-day hindlimb unloading (HS, n=7), and 3-dayHS with HSP90 inducer administration, 17-AAG (60 mg/kg, HS+17-AAG, n=8). The experiment was carried out in accordance with the rules of biomedical ethics (protocol 264, March 5, 2011) certied by the Russian Academy of Sciences Committee on Bioethics. The HS model was used to employ a tail-traction method of noninvasive tail-casting procedure (without anesthesia), as described previously (Morey, E. R.,1979). The rats were sacrificed by intraperitoneal nembutal overdose (75 mg/kg). The relative weight of soleus muscle to body weight (soleus/BW (mg/g)) in HS group was less than those of the C and HS+17-AAG groups ($p<0,05$). We revealed HSP90, HSP70 mRNA decrease in HS (but not in HS+17-AAG) group vs. C ($p<0,05$). The unloading resulted in significant of μ-calpain and conjugated ubiquitin (Ub) increasing (proteins as well as mRNA levels) vs. C group whereas 17-AAG administration prevented these alterations (studied by SDS-PAGE and rt-PCR). pFOXO3 protein was decreased only in HS group vs. C, but not in HS+17-AAG. Content of E3-lygases (MuRF-1, MAFbx) mRNA was increased in both suspended groups. We found equal amounts of pAkt in control and HS+17-AAG groups (in parallel to pFOXO3 levels), but pAkt levels in the HS group were diminished. Modulation of HSP90 function by 17-AAG treatment lends support to the suggestion that anabolic signaling and phosphorylation of the FOXO3 transcription factor are controlled by Akt. Soleus atrophy attenuation in the HS+17-AAG group was not associated with phosphorylation of p70S6k, because its level was equal in all three groups of rats. In summary, 17-AAG administration (enhancing HSP90 expression) under HS conditions attenuated soleus atrophy and prevented HSPs mRNA drop, maintained p-Akt and p-FOXO 3 content at the control level. Moreover, the prevention of ubiquitination and μ-calpain expression were increased in the HS+17-AAG-treatment group.

An explanation of motility dysfunction of gut due to arsenicosis via neurotransmitter pathway regulation and oxidative stress

M. Ghosh and G. Paul

Department of Physiology, University of Kalyani, Kalyani, West Bengal, India

Arsenic contaminated groundwater consumption is the main route of human exposure for arsenicosis. We set out to illustrate the as yet poorly understood cellular mechanisms resulting in altered motility of small gut ensuing severe gastrointestinal dysfunctions related to arsenicosis. The current study was designed in two parts- A. Charles foster rats (male, 100 ± 17g, n=7) were exposed orally to 10 mg/kg body wt/day sodium arsenite for 5, 10 and 20 days and B. in vitro organ-bath studies were conducted on intestine with a combination of different neurotransmitters and arsenite (As+3) applied postmortem. Rats were humanely killed by cervical dislocation following institutional guidelines foregoing anesthesia due to the nature of the experiment. Chronic As+3 treatment resulted in reduced bound calcium deposition (1), consistent with the finding of significantly enhanced contraction of the gut (vide Fig 1), achieved with isotonic transducer (IT-2245) coupled to RMS-Polyrite D. The peak contraction was reached on the 10th day of treatment. Set B results proved, the effect of As+3 on smooth muscle contraction was upstream of calcium release where it acted as a partial antagonist to atropine and exerted synergistic effect with acetylcholine. This was supported by the As+3 induced decrease of acetylcholine esterase activity (2) found under Set A. Set B results further showed that As+3 inhibited the relaxant effect of exogenous nitric oxide and breached the cholinergic blockade completely when coupled with a soluble guanylyl cyclase (sGC) blocker. Evidence under Set A attested to As+3 induced downregulation of nitric oxide synthase leading support to the final conclusion that on the early days of chronic treatment As+3 induced facilitation of intestinal motility by stimulating muscarinic and suppressing sGC receptor. Set A results further showed a decrease in motility increment after 20 days of constant As+3 treatment, supported by histopathological evidence of progressive degeneration and gross architectural damage of the muscle layer of intestine. This was substantiated by studies on oxidative stress indices which showed that As+3 depleted protein thiol levels (3), increased lipid peroxidation (4), and severely depleted reduced glutathione (5) which may explain the decrease of gut motility due to tissue damage after prolonged exposure of 20 days (vide Table 1 for set A results).

Table 1. Effect of chronic arsenite treatment on cell biochemistry

Experiments were performed under set A and the final results are expressed as mean ± SEM, n=7, p< 0.05, *p< 0.05 vs control (T Test) in the table.

Molecular mechanisms involved in the suppression of atrophy-related genes induced by β2-adrenergic stimulation in denervated mouse skeletal muscles

D. Lustrino[1], W.A. Silveira[1], D.A. Gonçalves[1], N.M. Zanon[1], I.C. Kettelhut[2] and L.C. Navegantes[1]

[1]Physiology, University of São Paulo, Ribeirão Preto, São Paulo, Brazil and [2]Biochemistry and Immunology, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

β-adrenergic signaling pathway represents a novel therapeutic target for skeletal muscle wasting and weakness due to its role in the mechanisms controlling protein metabolism. However, the intracellular pathways that elicit these responses are far from being completely understood. In turn, this study was performed to shed light on the molecular mechanisms induced by chronic treatment with clenbuterol, a selective β2-agonist, in denervated muscles.

For this, C57/BL6 male mice (~30g) were previously anesthetized and submitted to

motor denervation (DEN) by unilateral sciatic nerve section. In the same day, the treatment with saline or clenbuterol (CB, 3mg/kg/day; s.c.) was started (n=5/group). After 3, 7, 14 and 21 days, tibialis anterior (TA) muscles were harvested to examine mRNA levels of atrophy-related genes (MuRF1, Atrogin-1 and cathepsin L) and Sik1, a CREB-target gene, by RT-qPCR, phospho-PKA substrates by western blot, and cAMP levels by ELISA. All experiments were approved by local Ethics Committee (044/2012). Comparisons were made by using Student's t test or two-way ANOVA followed by Bonferroni test ($p<0.05$).

DEN induced loss of muscle mass at 7th day (13%) that was prevented by CB. At 3rd day, CB increased muscle cAMP (857.12 ± 30.68 vs. 709.48 ±22.66 fmol/mg muscle in DEN treated with saline) and reduced the mRNA levels of MuRF1 (151% vs. 553% in DEN treated with saline), Atrogin-1 (-27% vs. 243%) and cathepsin L (129% vs. 208%). A similar profile was obtained to protein content. At 7th day, the expression of Ub-ligases (MuRF1 and Atrogin-1) were normalized in both groups, and DEN by itself increased the content of muscle cAMP (25%), phospho-PKA substrates (~2.2-fold), and Sik1 mRNA expression (~5.2 fold).

The data show that the chronic treatment with CB in vivo suppresses the DEN-induced up-regulation of genes involved in muscle atrophy (atrogin-1, MuRF1, and cathepsin L) and suggest that these effects may be mediated by cAMP/PKA/CREB signaling. Additionally, it seems that this signaling pathway integrates a fine-tuning adaptative mechanism responsible for preventing excessive muscle loss in the progression of DEN.

Using ^{31}P NMR spectroscopy to investigate the effects of iron deficiency on murine skeletal muscle metabolism and function during exercise

M. Curtis[1], L.E. Cochlin[1], M.A. Cole[2], D.P. O'Neill[1], M.S. Dodd[1], D.J. Tyler[1], K. Clarke[1] and P.A. Robbins[1]

[1]Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, UK and [2]University of Nottingham Medical School, University of Nottingham, Nottingham, UK

Physical work or exercise capacity has been widely reported as being impaired by iron deficiency. Previous, separate, studies using diet-induced iron deficient rats have shown decreased work rate capacity, diminished contractile force generation and an impairment of energetics during exercise, when compared to rats on normal chow. The aim of this project is to develop a technique that allows for the simultaneous assessment of force production, fatigue resistance and metabolic function of murine gastrocnemius muscle during exercise. To address this, a method of *in vivo* gastrocnemius muscle stimulation was established. A bespoke Perspex cradle was designed and manufactured for the hindlimb preparation. In this technique, mice are anaesthetised using 2 % isoflurane in oxygen (2 l/min), the ischiatic nerve is isolated surgically and electrodes are placed distal to the tibial nerve branch. The knee and ankle joints are immobilised, the calcaneal tendon is attached to a force transducer, via a suture thread, before a ^{31}P saddle-shaped coil is placed over the muscle. The cradle is then placed into the 7 Tesla magnet and images of cross-sectional area (CSA) of the gastrocnemius muscle are obtained using the ^{1}H volume coil. The measurement of CSA of the muscle allows the comparison of force produced between muscles of different sizes. A stimulation protocol consisting of a train

of eight pulses of 100 μs at 30 Hz, followed by a rest period of 1.25 seconds, is repeated over a 10 minute period. During this exercise period, and the subsequent 20 minute recovery period, a ^{31}P spectrum is acquired every 100 seconds. Reductions of contractile force in excess of 50 % are exhibited over the 10 minute exercise period, and increases in inorganic phosphate (Pi) and decreases in phosphocreatine (PCr) are acquired by ^{31}P NMR spectroscopy (Figure 1). This technique will facilitate the simultaneous assessment of skeletal muscle function and metabolism, including fatigue resistance, in both diet-induced and genetic mouse models of iron deficiency, in the presence or absence of ferric carboxymaltose.

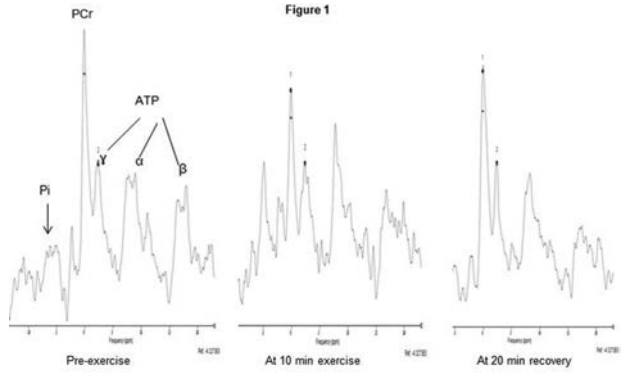

Figure 1: ^{31}P spectra acquired before exercise, after 10 minutes of exercise and at 20 minutes of recovery. The spectra are scaled to the height of the γ-ATP peak and the x-axis shows frequency in parts per million.

PCB340

Obesogenic diet alters feto-placental phenotype

A. Sferruzzi-Perri, O.R. Vaughan, M. Haro, B. Musial, M. Constancia and A.L. Fowden

University of Cambridge, Centre for Trophoblast Research, Cambridge, UK

In developed societies, diets high in sugar & fat (HSHF) are commonly eaten by women of reproductive age & contribute to the increasing rates of maternal obesity & excessive weight gain during pregnancy. In mice, offspring of mothers fed an obesogenic HSHF diet during pregnancy develop cardiovascular & metabolic dysfunction as adults, even when their birthweight was normal [1]. However, little is known about the mechanisms operating in utero which might account for the detrimental postnatal effects. This study tested the hypothesis that an obesogenic diet alters growth & function of the placenta, responsible for nutrient transfer to the fetus. We examined the effect of feeding pregnant mice an obesogenic HSHF diet on placental growth & nutrient transport in relation to fetal growth & placental expression of imprinted genes & signalling pathways known to regulate growth & metabolism.
Methods: C57BL6 female mice were fed a control diet (11%fat, 3%sugar) or an obesogenic HSHF diet (30%fat, 36%sugar) during pregnancy. On day (D) 16 or 19, placental transport of 14C-methyl aminoisobutyric acid (MeAIB) & 3H-methyl D-glucose (MeG) was measured in vivo. Placental expression of Slc38a1, Slc38a2, Slc38a4, Slc2a1, Slc2a3, Igf2, H19, Dlk1, Igf2r, Zac1, Snrpn, Grb10, Phlda2, Gtl2, Peg11, Peg3, Cdkn1c genes was quantified by Real Time PCR. Expression of proteins involved in phosphoinositol 3-kinase (PI3K) & mitogen activated protein kinase (MAPK) signalling was determined by Western blotting. Dietary differences were determined by ANOVA & linear mixed model repeated measures as required & significant if $P<0.05$.
Results: HSHF diet reduced fetal weight in parallel with placental weight at D16 ($P<0.001$, Table). By D19, placental weight remained less in HSHF dams ($P<0.001$), whereas the weight of fetuses had normalised (Table). This change in fetal growth trajectory was associated with enhanced placental glucose & amino acid transfer & upregulated Slc2a3 & Slc38a2 nutrient transporter genes on D16 (Fig 1&2, $P<0.03$). In the HSHF placenta there was also increased expression of imprinted genes on D16 (Igf2, Dlk1, Snrpn, Grb10 & H19, $P<0.005$, Fig 2) & PI3K & MAPK signalling proteins on D16 & D19 (PI3K p110α, pAkt, pGsk3 & pMAPK, $P<0.04$).
Conclusion: Placental transport adapts to an obesogenic HSHF diet through local changes in signalling pathways & imprinted genes involved in growth & metabolism. These adaptations help meet the fetal drive for growth even though placental growth is compromised by a HSHF diet. However by altering the provision of specific nutrients, dietary-induced changes in placental phenotype have an important role in tissue programming with implications for the adult health of infants of women eating obesogenic diets

HSHF diet & feto-placental growth

	Control diet (D16)	HSHF diet (D16)	Control diet (D16)	HSHF diet (D19)
Fetal weight (mg)	435±13	395±5*	1195±15	1166±16
Placental weight (mg)	106.0±2.5	94.0±2.4*	88.4±2.1	81.0±2.1*

PCB342

Signalling from fetus to mother; role of the Delta-like homologue 1

M. Charalambous[1,2], M.A. Cleaton[2] and A.C. Ferguson-Smith[2]

[1]Endocrinology, Queen Mary University of London, London, UK and [2]Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK

Whilst epidemiological studies robustly support the relationship between compromised maternal energy homeostasis and poor fetal and postnatal outcome, very little is known about the genetic pathways which control maternal energy allocation to the offspring. In turn, how maternal nutrient partitioning influences the growth and proportionality of the organism is not well understood. Furthermore, bi-directional communication between mother and fetus underlie these events and deciphering the molecular signals involved using genetic tools is now feasible and timely.

Late gestation in mammals is accompanied by multiple adaptations of maternal energy homeostasis that are thought to divert maternal resources towards the supply of glucose for the rapidly-growing fetus. These adaptations include peripheral insulin resistance and a reduction in hepatic lipogenesis (1). During pregnancy there is considerable remodelling of the anterior pituitary which causes an increase in somatolactotrophic cells (2). In addition, the syncytiotrophoblast cells of the placenta secrete placental lactogen and a pregnancy-specific version of growth hormone (GH) (2). Since GH and its family members are known to cause insulin resistance and inhibit hepatic lipogenesis (1, 3), increased activity of the pituitary-placental sommatolactotrophic axis may modulate maternal adaptations in late pregnancy.

The product of the imprinted Delta-like homologue 1, DLK1, is an endocrine signalling molecule that reaches a high concentration in maternal serum during late pregnancy (4). We have recently discovered that that the conceptus is the source of this molecule. DLK1 may be a novel endocrine signal from fetus to mother. Our studies with genetically-modified mice show that endocrine DLK1 acts to inhibit hepatic lipogenesis (5 and in preparation).

Our working hypothesis is that DLK1 produced by the conceptus alters the activity of the pituitary-placental somatolactotrophic axis, thus modulating important metabolic changes in maternal resource allocation during pregnancy. Understanding the function of DLK1 in pregnancy has potential clinical value since failures of growth and timely development occur when maternal resource allocation is disrupted. Moreover, maternal serum DLK1 could be a non-invasive biomarker for complications of pregnancy, and/or genetic variation in Dlk1 sequences in mother or fetus may be indicative of poor pregnancy outcome.

Periconceptional alcohol exposure impacts on placental structure and gene expression

E.M. Gardebjer, J. Cuffe and K. Moritz

School of biomedical sciences, The university of queensland, Brisbane, QLD, Australia

Perturbations during the periconceptional (PC) period are important determinants of a healthy pregnancy and offspring health. This period however is prior to maternal recognition of pregnancy when alcohol consumption is often a common social practice. Alcohol during pregnancy is known to impair the normal development of many organs and systems including the placenta. It is not known however whether alcohol consumption prior to implantation can impact on post implantation placental outcomes.

This study aimed to examine if there were changes in the late gestation placenta (E20), of fetuses exposed to moderate levels of ethanol (EtOH) prior to implantation.

Sprague-Dawley rats were exposed to a control liquid diet or one containing EtOH (12.5%, n=12/group) during the PC period (from embryonic day (E)-4 to E4). On E20, pregnant dams were deeply anesthetized with ketamine:xylazine (50:50) to ensure blood flow to fetuses and placentas during collection. Placentas from male and female fetuses were either fixed (whole) or frozen (as labyrinth and junctional zone separately). Dry weights of the placental components were derived by oven drying. Cross sectional areas of the labyrinth and junctional zone was determined following haemotoxylin/eosin staining. Relative mRNA expression of glucose transporters (GLUT1, GLUT3) and insulin like growth factors (IGF1 and IGF2) was examined via real-time PCR.

Maternal plasma alcohol concentration reached an average maximum of 0.17%. There was no difference between groups in calorie intake but fetuses were growth restricted ($p<0.05$). Placental dry weight was significantly increased in EtOH-exposed fetuses ($p=0.01$) when normalized to body weight. This was due to an absolute ($p=0.002$) and normalized ($p<0.0001$) increase in weight of the junctional zone only. This was supported by an increase in the cross sectional area of the junctional zone in PC-EtOH exposed placentas ($p=0.03$) whilst the cross sectional area of the labyrinth zone was significantly smaller ($p=0.03$). While gene expression studies for GLUT1 and GLUT3 showed no difference in the labyrinth zone, GLUT3 was expressed at higher levels in the junctional zone of the placenta from PC-EtOH exposed females ($p=0.03$). IGF1 relative gene expression was reduced in the labyrinth of PC-EtOH exposed placentas ($p=0.005$) whereas the expression of IGF2 was unaffected. In contrast, whilst IGF2 expression was upregulated in the junctional zone ($p=0.05$), there was no difference observed for IGF1 expression in this zone.

This study demonstrates that PC-EtOH significantly alters expression of key placental nutrient transporters and growth factors which are important for fetal growth and development. Moreover it also showed that exposure to EtOH prior to implantation alters the structure of the placenta and therefore potentially the future health of the offspring.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB344

Exogenous corticosterone administration increases materno-fetal glucose transport in the mouse in late pregnancy

O.R. Vaughan, H.M. Fisher, A.N. Sferruzzi-Perri and A.L. Fowden

Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK, UK

Introduction
Fetal glucose supply is a key determinant of growth in utero. Deficient or excess glucose availability is associated with fetal growth restriction and macrosomia, respectively. Glucocorticoid stress hormones influence blood glucose availability by antagonizing the action of insulin, in the non-pregnant animal. Furthermore, they reduce fetal growth and alter placental nutrient transporter expression [1]. This study aimed to determine whether maternal glucocorticoid treatment affects hepatic release and placental transport of glucose in the pregnant mouse in vivo.
Methods
All procedures were conducted in accordance with the Animals (Scientific Procedures) Act 1986. C57BL6/J mice (n=20) were treated with corticosterone (CORT, 76 μg/g/day in drinking water) between day (D) 11 and D16 of pregnancy (term = D21). This procedure is established to raise circulating corticosterone to stressed levels [1]. On D16 or D19, materno-fetal clearance of 3H-methyl-D-glucose (MeG) was measured under anaesthesia (fentanyl-fluanisone:midazolam in water, 1:1:2) [2] then the dam was euthanized and samples of maternal plasma, liver and placenta were collected. Expression of the insulin-insensitive Slc2a1 and Slc2a3 glucose transporter genes was determined in placentae by qPCR. Hepatic glycogen content was determined by enzymatic conversion to glucose using amyloglucosidase. Glucose and plasma insulin concentrations were analysed by automated glucometer and ELISA, respectively. Data were analysed separately at D16 and D19 by Student's t test and significance determined at the level P<0.05. Results are mean±SEM.
Results
Compared to untreated (UT) controls (n=51), CORT reduced placental weight on D16 and fetal weight on both D16 and D19. Maternal plasma insulin concentration was higher in CORT treated than UT dams on D16 (UT, 1.1±0.3 ng/ml, n=7; CORT 40.1±5.3 ng/ml, n=7; P<0.05) but not D19 (UT, 2.6±1.2 ng/ml, n=12; CORT, 2.0±0.7 ng/ml, n=12; P>0.05). However, neither hepatic glycogen content nor blood glucose concentration differed between UT and CORT dams at either gestational age (P>0.05). On D16, CORT increased placental expression of Slc2a1 and Slc2a3 (n=6 per group) but did not affect materno-fetal MeG clearance (UT, n=64 fetuses; CORT, n=25 fetuses) (Figure). Contrastingly, although placental Slc2 expression no longer differed from UT animals at D19, materno-fetal MeG clearance was increased by 26% in CORT treated dams (UT, n=41 fetuses; CORT, n=22 fetuses) (Figure).
Discussion
When maternal glucocorticoid concentrations are raised through stress, illness or exogenous administration, fetal glucose supply may be increased due to changes in placental transport, even if maternal metabolism is unaffected. Ultimately, this may alter fetal growth trajectory and increase neonatal morbidity and metabolic disease risk in the offspring.

PCB345

Hypoxia, placental phenotype and fetal growth in mice

J.S. Higgins, O.R. Vaughan, A.L. Fowden and A.N. Sferruzzi-Perri

Department of Physiology, Development and Neuroscience, Cambridge University, Cambridge, UK

Introduction: During normal pregnancy, the placenta supplies the fetus with sufficient oxygen (O2) and nutrients to match its demands for growth. The placenta is responsive to environmental cues and is capable of adapting its capacity for substrate transfer to favour fetal growth during adverse conditions, like undernutrition(1). However, relatively little is known about adaptation of placental function to hypoxia; a major cause of fetal growth restriction (FGR)(2,3) and pregnancy complications at high altitude(4,5). Thus, this study aimed to determine the effect of hypoxia on placental transport and fetal growth.
Methods: C57BL/6 female mice were time-mated and exposed to either 13% or 10% atmospheric O2 (13% H and 10% H, respectively) from day (D)14-D19 of pregnancy (term=D20). As exposure to hypoxia reduced maternal food intake, dams in 21% O2 fed ad libitum (ad lib) or pair-fed to the intake of hypoxic mice (13% PF and 10% PF) were used as controls. On D19, placental transport of 14C-methyl aminoisobutyric acid (MeAIB) was assessed in vivo and related to fetal growth. Litter means were analysed using ANOVAs with Bonferroni Post-hoc tests, unless stated otherwise.
Results: Maternal body weight was significantly reduced by 13% and 10% hypoxia compared to ad lib controls (Table 1). Fetuses of 10% H, but not 13% H, mice weighed significantly less than fetuses from ad lib mice (Table 1). Fetuses of 10% PF mice also weighed significantly less than those from ad lib mice but more than 10% H pups (Table 1). Placental weight did not differ significantly between groups although placental efficiency, measured as the ratio of fetal to placental weight, was significantly reduced in 10% H mice compared to all other groups (Table 1). Placental transport of MeAIB tended to be lower in all hypoxic and pair fed groups but was only significantly reduced in 10% H compared to ad lib mice (Figure 1).
Conclusions: In late pregnancy, placental efficiency and fetal growth were maintained in response to 13% O2, despite reduced maternal food intake and body weight. At the more severe insult of 10% O2, placental efficiency and transport were both compromised in association with reduced fetal weight. The data indicate that there is a threshold between 13% and 10% maternal inspired O2, at which the placenta can no longer

support normal fetal growth during hypoxia. They also suggest that, at 10% O2, it is the combined effect of hypoxia and undernutrition which determines maternal nutrient allocation to the fetus, via changes in placenta nutrient transfer capacity. This has implications for the mechanisms of FGR in pregnancies complicated by hypoxaemia.

Table 1: Values are mean ± SEM. On each row, significant differences between values is indicated by a different letter ($p<0.05$ or less). *Ad lib* (n=12), 13% PF (n=8), 13% H (n=9), 10% PF (n=15), 10% H (n=11)

The role of peroxisome proliferator-activated receptor gamma co-activator 1-alpha in pregnancy

A.C. Delany[1], F.P. McCarthy[3], S.K. Walsh[2] and L.C. Kenny[3]

[1]Physiology, University College Cork, Cork, Ireland, [2]The Robert Gordon University, Aberdeen, Scotland, UK and [3]Obstetrics and Gynaecology, Anu Research Centre, University College Cork, Cork, Ireland

Background: Peroxisome proliferator-activated receptor gamma co-activator 1-alpha (PGC-1α) is a transcriptional co-activator that drives mitochondrial biogenesis and other metabolic programs in many tissues, including the heart. PGC-1α is a powerful regulator of angiogenesis, a process of fundamental importance to the development of a healthy placenta in normal pregnancy. The angiogenic function of PGC-1α has been previously described in the heart where it has been shown to regulate angiogenesis. Its function and expression in the placenta is unknown. It may be the key link between placental development and the imbalance of key angiogenic factors observed in the pregnancy specific condition of pre-eclampsia.

Hypothesis: PGC-1α is expressed in the human placenta and in pathophysiological conditions, such as pre-eclampsia, the expression of PGC-1α is reduced.

Methods: Human placental samples were obtained from normal healthy pregnant women (n=4) for processing and analysed by means of immunohistochemistry using Calbiochem Anti PGC-1α, C-Terminal (777-797) rabbit polyclonal antibody. In addition, protein expression of PGC-1α was examined in placental tissue from normal pregnant rats (n=6) and those with surgically reduced uteroplacental perfusion (reduced uterine perfusion pressure (RUPP) model) (n=4).

Results: Positive staining for PGC-1α was noted in both human and rat placental samples with varying degrees of expression when compared with PBS treated controls. Expression was most prominent in the endothelial cells surrounding the vessels, the trophoblasts, syncytiotrophoblasts and vascular endothelial cells with scattered staining in the maternal decidua and stroma. Furthermore, RUPP placental tissue indicated lower levels of positive staining for PGC-1α when compared with normal and sham rats.

Conclusion: This study indicates that the transcriptional co-activator PGC-1α is expressed in the both human and rat placental tissue and is strongly localised to endothelial cells. Furthermore, our data may implicate PGC-1α in the pathogenesis of complications of pregnancy such as pre-eclampsia, but further investigation is needed to confirm this. Future studies could suggest the use of PGC-1α as a future pharmacological target for the treatment of complicated pregnancies.

High fat/high cholesterol diet induces TLRs-associated pulmonary inflammation in C57BL/6J mice

S. Wang[1,2], T. Zhu[2], T. Chen[1,2], L. Zhang[1,2] and X. Lian[1,2]

[1]Center for lipid research, Chongqing Medical University, Chongqing, China and [2]Department of Nutrition and Food Hygiene, Chongqing Medical University, Chongqing, China

Pulmonary inflammation were reported in several lipid metabolism related gene knock out mice. However, the effects of high fat/high cholesterol diet induced dyslipidemia on the homeostasis of wild C57BL/6J mice lung were poorly understood. 6-8 week-old male C57BL/6J mice were randomly divided into two groups and received either regular diet (RD) containing 10%kcal fat or high fat/high cholesterol diet (HCD) with 40%kcal fat, 1.25% cholesterol and 0.5% sodium cholate respectively. After 16 weeks feeding, mice were anaesthetised with pentobarbital (50mg/ kg, i.p.), and then euthanized by exsan-

guination from heart. Measured by autobiochemistry analyzer, Serum lipids results showed that hypercholesterolemia was induced in 16 weeks HCD fed C57BL/6J mice (Serum total cholesterol: 5.14±0.37 vs. 3.74±0.23 mmol/L, p<0.05, n=3; Serum low density lipoprotein: 3.35±0.41 vs. 0.46±0.06 mmol/L, p<0.01, n=3; HCD group vs. RD group). Values are means ± S.E.M, compared by student's t test. Oil red O staining demonstrated that pulmonary lipid accumulation was progressively exacerbated in HCD fed C57BL/6J mice. Hematoxylin and eosin (H&E) and immunohistochemistry studies showed distinctive signs of pulmonary inflammation including macrophage accumulation, lymphocyte infiltration and elevated levels of proinflammatory cytokines like MCP1. (Bronchoalveolar lavage fluid MCP levels HCD group vs. RD group: 110.83±0.79 vs. 81.78±3.69 pg/ml, p<0.01, n=3). Consistently, real-time quantitative PCR and western blotting results showed the mRNA and protein expressions of TLR2 and TLR4 were significantly up-regulated. (mRNA levels of TLR2 and TLR4 in the lungs of HCD group mice were elevated 8.13±0.39 and 3.78±0.23 folds respectively, compared to RD group mice. p<0.05, n=3). Meanwhile, the translocation of NFkappaB into nucleus was activated in high fat/high cholesterol diet fed mice lung. Our findings suggested that high fat/high cholesterol diet could promote lipid accumulation and inflammation in the lung of C57BL/6J mice, which may partly due to the activation of TLRs/NFkappaB pathway triggered by disturbance of lipid metabolism in the lung.

Investigating cholesterol homeostasis with a two-compartment mathematical model: Towards tailored prevention and treatment of high cholesterol

O. Hrydziuszko[1,2], K. Kubica[1], A. Wrona[1] and J. Balbus[3]

[1]Institute of Biomedical Engineering and Instrumentation, Wroclaw University of Technology, Wroclaw, Poland, [2]Department of Biosciences and Nutrition, Karolinska Institutet, Huddinge, Sweden and [3]Institute of Mathematics and Computer Science, Wroclaw University of Technology, Wroclaw, Poland

Background:
High blood cholesterol level has been long known as a classic coronary risk factor. It is suspected to cause third of ischaemic heart diseases which adds up to 2.6 millions of deaths each year (World Health Organization). However the underlying mechanisms causing cardiovascular diseases in respect to serum cholesterol levels, uptake of cholesterol from the dietary sources and exercises remain not fully understood, and if anything, rather ambiguous (Gold, Grover et al. 1992; Steinberg 2004).
Aim:
The primary aim of our work is advance our understanding of cholesterol homeostasis, including the transport of cholesterol in the circulatory system. This in turn, could lead to advancing prevention and treatment of high cholesterol, reducing the risk of developing cardiovascular diseases.
Materials & Methods:
The current knowledge on the transport of cholesterol in the circulatory system can be summarized by a set of enzymatic reactions including for instance cholesterol synthesis, cholesterol transport in different types of lipoproteins (chylomicrons, very-low-density intermediate-density, low-density and high density lipoproteins) or the interactions between them cells, tissues and organs. To study the behaviour of cholesterol homeostasis the current knowledge was summarized in the diagram capturing all known (literature reported and validated) cholesterol-related relationships and the diagram was reduced to a two-compartment mathematical model. The model encompasses a set of biochemical enzymatic reactions, with a single equation representing one process (e.g. cholesterol synthesis) and based on the Michaelis-Menten kinetics.
Results & Significance:
Our relative simple model enables modelling the cholesterol homeostasis under normal physiological conditions (serum cholesterol levels within the recommended boundaries) as well as set of pathological states. These, among others, include disorders linked to the disturbances in the creation of LDL and HDL lipoproteins or uptake of LDL lipoproteins by the LDL receptors. The significance of the up and running model of cholesterol homeostasis becomes clearer with the models parameters being adjusted on the individual patient basis and allowing, among others, prediction of the short and long-term impact of the cholesterol lowering drugs or diet modification.

PCB349

Pharmacological enhancement of postprandial macro and microvascular blood flow does not enhance the anabolic responses to nutrition in skeletal muscle of young men

B. Phillips[1,2], P. Atherton[1], K. Varadhan[2], M. Limb[1], M. Rennie[1], K. Smith[1] and J. Williams[1,3]

[1]School of Graduate Entry Medicine and Health, University of Nottingham, Derby, UK, [2]School of Biomedical Sciences, University of Nottingham, Nottingham, UK and [3]Anaesthetic Department, Royal Derby Hospital, Derby, UK

Background: Perfusion of the skeletal muscle microvasculature in response to nutrition is thought to be central for muscle mass maintenance (via protein anabolism) and whole-body glucose homeostasis (glucose disposal), both of which can be compromised in a variety of diseases including diabetes, cancer cachexia, COPD and in ageing muscle.
Objective: We set out to define whether enhancing muscle microvascular blood flow (MBF) could influence muscle protein turnover under postabsorptive and postprandial conditions in young men.
Design: We recruited 10 young (23.2±2.1 y) men in whom we measured bulk [femoral arterial] leg blood flow (LBF), muscle microvascular blood flow (MBF) and muscle protein synthesis (MPS) under postabsorptive (12 h fasted) and post-

prandial conditions (I.V glamin (prime: 34 mg.kg^{-1}, constant infusion: 102 mg.kg.hr^{-1}); dextrose to sustain blood glucose between 7-7.5 mmol.l^{-1}). In addition, we infused a pharmacological vasodilator (methacholine) into the artery of one leg to permit bilateral comparison of the effects of nutrition alone or nutrition coupled to pharmacological vasodilation. We measured LBF [femoral artery] by Doppler ultrasound and muscle MBF by contrast-enhanced ultrasound (CEUS) using Definity™ perflutren contrast agent infused at a rate of 1.2 ml.min^{-1} (1.5 ml in 18.5 ml 0.9 % saline). After 9 min to allow attainment of steady state concentrations, Definity™ microbubbles were destroyed by high mechanical index ultrasound and refilling of the microvascular space (MBF) was imaged during 4 consecutive 45 s recordings. Data was analysed using Q-lab quantification software. Rates of MPS and net leucine balance were measured using [1, 2-$^{13}C_2$] leucine tracer coupled to gas-chromatographic/ combustion mass-spectrometric techniques.
Results: We observed increases in LBF (0.51±0.02 vs. 0.57±0.04 l.min^{-1}, P<0.05), MBF (+25±10%, P<0.05), MPS (0.04±0.004 vs. 0.08±0.001 %.h^{-1}, P<0.05) and positive leucine net balance in the postprandial condition (-9.72±4.76 vs. 40.31±12.27 nmol.min.100g lean leg mass^{-1}, P<0.01). However, despite methacholine infusions augmenting nutrition-mediated increases in LBF (0.57±0.04 vs. 1.15±0.08 l.min^{-1}, P<0.05) and MBV (+79±30%, P<0.05) this provided no enhancement of MPS (0.08±0.01 vs. 0.07±0.01 %.h^{-1}) or leucine net balance (40.31±12.27 vs. 57.0±13.66 nmol.min.100g lean leg mass^{-1}).
Conclusion: We conclude that pharmacological enhancement of LBF and MBV above that of nutrition does not further augment muscle protein metabolism. This indicates that muscle nutritive blood flow is not a limiting factor for muscle protein metabolism, at least in young men.

Reproductive parameters and oxidative status of male Sprague Dawley rats treated with low and high salt diet

B.O. Iranloye, G.O. Oludare, N.A. Esume and L.C. Ekeh

Physiology, College of Medicine, University of Lagos, Lagos, Lagos, Nigeria

Diet and nutrition is a crucial part of reproductive health. Deficiency of minerals and micronutrients has been reported to impair the process of spermatogenesis (1) Salt has been used by women on their husbands to increase their libido (2). The present study was designed to determine the effect of low salt diet and high salt diet on sperm parameters, oxidative status and reproductive hormone levels of male rats. Eighteen healthy Sprague Dawley male rats weighing between 120- 130g were used. The rats were divided into three groups of six rats each. Group I: (control) received 0.3% salt diet, Group II: low salt (received 0.14% salt diet), and group III: high salt (received 8% salt diet). All animals were treated for six (6) weeks after which they were sacrificed by cervical dislocation. Sperm analysis was done on sample derived from the cauda epididymis by conventional methods. Sperm motility was done and expressed as percentage (3). The reduced glutathione (GSH) content of the testis and epididymis homogenate were determined using the method of Van Dooran (4). Malondialdehyde (MDA) was determined based on its interaction with thiobarbituric acid (TBA).The activity of the superoxide dismutase (SOD) enzyme in the testis homogenate was determined according to the method described by Sun and Zigman(5). Serum samples were also collected and an enzyme linked immunoassay (EIA) system was employed to determine testosterone, follicle stimulating hormone (FSH) and luteinizing hormone (LH) levels. Values are means ± S.E.M., compared by ANOVA. This study reports a decreased sperm count in the low salt diet rats (44.06 ± 1.3) and increased sperm count in the high salt diet treated rats (59.6±2.3) Vs control (51.45 ± 2.2). Both low salt and high salt diet treated rats had a significant increase in percentage abnormal sperm cells when compared with control values at P< 0.05 (12.6 ± 1.2, 9.9 ± 1.3 respectively Vs 5.46 ± 0.8) The level of MDA significantly increased while GSH significantly decrease in the epididymis of both low and high salt treated diet (P< 0.05). Also a significant decrease in the activities of SOD and CAT in both the testes and the epididymis were observed in both treated groups. The increased MDA levels in the epididymis and decrease in antioxidant status in both salt diets indicates the presence of oxidative stress thus both low and high salt diet might play a negative role in male rats reproduction/fertility.

Table 1: LH, FSH and Testosterone levels in control, Low and High Salt treated Rats

PARAMETERS	CONTROL	LOW SALT	HIGH SALT
FSH(miu/L)	7.27.2 ± 0.21	7.25 ± 0.22	10.9 ± 0.57*
LH (miu/L)	9.55 ± 0.25	9.35 ± 0.62	6.28 ± 0.38*
Testosterone (nmol/L)	9.9 ± 0.62	12.1 ± 0.45	18.7 ± 2.9 *

Values are expressed as Mean + SEM, n = 6, *P<0.05 compared with control group.

Gene polymorhisms of water and glycerol channels aquaporin 7 and 9 in obese and/or diabetic patients

O. Palabiyik[1,2], L. Ozturk[1], T. Sipahi[2] and S. Guldiken[3]

[1]Physiology, Trakya University Faculty of Medicine, Edirne, Turkey, [2]Biophysics, Trakya University Faculty of Medicine, Edirne, Turkey and [3]Endocrinology, Trakya University Faculty of Medicine, Edirne, Turkey

The alterations that may occur during glycerol transport between adipose tissue and liver can play an important role in the development of diabetes or obesity (1,2). In this study, polymorphisms of aquaporin 7 that provides glycerol release from adipose tissue and aquaporin 9 that provides glycerol entry into liver were investigated. After ethical approval, three groups were created by participants who signed the informed consent form. Group 1, the individuals with normal weight and no diabetes (n=49; M/W, 18/31; mean age, 36±10 year), Group 2, the individuals with obesity and no diabetes (n=60; M/W, 29/31; mean age, 47±10 year) and Group 3, the individuals with type 2 diabetes mellitus and obesity (n=89, M/W

venous blood samples. Polymorphisms of aquaporin 7 in 2 locations (V59L "rs: 4008659" and A953G "rs:2989924") and aquaporin 9 in 2 locations (C43T "rs:77284866" and T279A" rs:1867380") were studied. The rate of aquaporin 7 and aquaporin 9 polymorphisms were similar among the study groups. Statistical analysis showed that the levels of insulin and glycerol were significantly different (The mean insulin values 7.21±0.94, 13.71±2.20 and 18.21±2.32; the mean glycerol values 0.68±0.04, 0.79±0.05 and 0.97±0.05 in Group 1, 2 and 3, respectively, $p<0.001$ for both). Considering the polymorphisms of A953G and T276A, plasma glycerol and insulin levels were similar in subjects with different genotypes. These results suggested that polymorphisms of aquaporin 7 and aquaporin 9 were not associated with presence of obesity and/or diabetes.

PCB351a

The effects of Syzygium aromaticum-derived maslinic acid on blood glucose, blood pressure and kidney function of streptozotocin-induced diabetic rats

B.N. Mkhwanazi[1], F.R. Van Heerden[2] and C.T. Musabayane[1]

[1]Human Physiology, University of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa and [2]Chemistry, University of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa

The triterpene, maslinic acid (MA) lowers the blood glucose of adrenaline-induced diabetic mice and partial diabetic mice1. However, the anti-diabetic effects of MA in type 1 diabetes are unclear. Accordingly, we investigated the effects of MA on blood glucose levels streptozotocin (STZ)-induced diabetic rats, an experimental model for type 1 diabetes mellitus along with its influence on renal function and blood pressure; the major complications of diabetes. Oral glucose tolerance tests were conducted in separate groups of non-diabetic and STZ-treated diabetic rats given glucose load (0.86 g.kg-1, p. o.) after 18-h fast, followed by various MA doses (20, 40 and 80 mg kg-1, p.o.). Sub-chronic effects of MA on mean arterial blood pressure (MAP) and renal function were evaluated in conscious diabetic rats administered with MA twice every third day for five weeks. Sub-chronic effects of MA on blood glucose, mean arterial blood pressure (MAP) and renal function were evaluated in rats treated twice every third day for five weeks. Rats treated with deionized water (3 ml/kg, p.o.) and the standard hypoglycaemic drug metformin, 500 mg/ kg, p. o.) acted as untreated and treated positive controls, respectively.The effects of MA on proximal tubular Na+ handling were monitored in non-diabetic rats fed standard rodent chow supplemented with lithium chloride (12 mmol kg-1 dry weight) for 48 h prior to experimentation in order to raise plasma lithium to measurable concentrations without affecting renal Na+ or water excretion2. The animals were anaesthetized and the right jugular vein was cannulated to allow intravenous infusion of 0.077M NaCl. The urinary bladder was also cannulated via an incision in the lower abdomen. After a 3½ h equilibration period, urine samples were taken every 30 min over the 4h post-equilibration period of 1h control, 1h 30 min treatment and 1h 30 min recovery periods; blood samples were taken once per hour for the measurement of electrolyte and clearance marker concentrations. Li+ clearance is widely to assess proximal tubular function of the mammalian kidney3. Glomerular filtration rate (GFR) was assessed by creatinine clearance. Statistical comparison of the differences between the control means and experimental groups was performed with GraphPad InStat Software (version 4.00, GraphPad Software, San Diego, California, USA), using one-way analysis of variance (ANOVA), followed by Tukey-Kramer multiple comparison test. MA induced dose-independent hypoglycaemic responses in STZ-induced diabetic rats. Hepatic glycogen concentrations in STZ-induced diabetic rats were depleted at the end of the 5-week experimental period by comparison with non-diabetic rats. Sub-chronic MA treatment of STZ-induced diabetic rats with MA or metformin restored the hepatic glycogen concentrations to near normalcy. Acute MA infusion increased the fractional excretion of sodium (FENa) and lithium (FELi) in the absence of significant changes in GFR. STZ-induced rats exhibited marked weekly decreases in urinary Na+ excretion and elevated plasma creatinine concentration at the end of 5 weeks with concomitant reduction in GFR. MA treatment attenuated these changes and additionally reduced MAP indicating that maslinic acid might constitute a novel therapeutic strategy which can complement existing modern anti-diabetic medications.

Rab35 regulates pseudopodia extension of breast cancer cells in response to extracellular matrix

Y. Zhu

Nanjing Medical University, Nanjing, China

Pseudopodia extension in directional movement remains poorly defined in breast cancer cells. We showed that the modified Boyden chamber assay could be used for pseudopodia extension and isolation from migrating breast cancer cells in response to ECM (collagen type I). Rab35, enriched in pseudopodia of breast cancer cells, promoted pseudopodia extension in response to ECM. Dominant negative Rab35 mutant or Rab35 shRNA significantly decreased ECM-induced pseudopodia extension. Rab35 was strongly associated with fascin in MDA-MB-231 and MCF-7 cells. Rab35 mRNAs were significantly enriched in pseudopodia of breast cancer cells in response to ECM stimuli. Blocking microtubule assembly by microtubule-depolymerizing agent nocodazole significantly

retarded the asymmetries of Rab35 transcripts in pseudopodia. These findings may shed new light into the mechanism of breast cancer migration.

Role of a jumonji histone demethylase in osteoclast differentiation

S. Kim[1], H. Kim[1], J. Park[1,2] and Y. Chun[1,3]

[1]Department of Biomedical Sciences, Seoul, Republic of Korea, [2]Ischemic/Hypoxic Disease Institute, Seoul, Republic of Korea and [3]Department of Physiology, Seoul National University College of Medicine, Seoul, Republic of Korea

Osteoclasts are bone-resorbing multinucleated cells that differentiate from monocyte/macrophage-lineage precursors. Bone destruction and osteoporosis are attributed to increased and activated osteoclasts. Osteoclast differentiation is a complicated process governed by diverse classes of regulators. In particular, nuclear factor–activated T cells c1 (NFATc1) plays a key role in osteoclast differentiation in response to RANKL. Yet, the regulatory mechanism of the NFATc1 gene has not been uncovered so far. A growing body of evidence has demonstrated that histone methylation and demethylation are responsible for epigenetic regulation during stem cell differentiation. Therefore, we tested the possible involvement of a jumonji histone demethylase in the epigenetic regulation of NFATc1 during osteoclast differentiation. We generated transgenic (TG) mice overexpressing the jumonji demethylase and checked the structures of their long bones using microCT. Consequently, bone volume/tissue volume (BV/TV), trabecular number (Tb.N) and trabecular separation (Tb.Sp) were reduced in 4 month-old TG mice, whereas trabecular thickness (Tb.Th), body weight and tibia/femur length were not. Moreover, we found ex vivo that macrophages from the TG bone marrow have a higher potential for differentiation toward osteoclasts than those of wild type. We also identified that the jumonji histone demethylase associates with NFATc1 in macrophages stimulated by RANKL. These findings suggest that the jumonji histone demethylase potentiates bone resorption by promoting osteoclast differentiation, and imply that the inhibition of this enzyme could be a novel strategy for preventing inflammatory bone destruction or osteoporosis.

Coronary vasodilator effect of flavonoid quercetin

A. Monori-Kiss, E. Monos and G.L. Nádasy

Semmelweis University, Institution of Human Physiology and Clinical Experimental Research, Budapest, Hungary

Introduction
Fruits and vegetables contain several types of polyphenols, among them quercetin and its glycosylated products being physiologically important ones. Previous studies have demonstrated their direct vasodilatory capacity on larger arteries. Vasoactive actions on small resistance arteries, however, are still poorly defined.
Methods
Hearts from male Wistar rats (350-400g) were removed in pentobarbital anaesthesia (50 mg/kg, i.p.), and intramural coronary arterioles were prepared. Segments were cannulated at both ends and immersed in normal Krebs-Ringer solution in a glass-bottomed tissue bath of a pressure angiometer. The bath was thermostated and the solution was bubbled with a mixture of 20% O2, 5% CO2 and 75%N2.Inner and outer diameters were measured videomicroscopically at 50 mmHg intraluminal pressure in Krebs-Ringer solution (spontaneous tone) and with 100nM quercetin added. To test the effect of endogenous vasoactive prostanoids indomethacine (10μM) was applied. L-nitro-methil-arginine (100μM) was added to test a potential endothelial effect. Relaxed diameters were measured in calcium-free solution. Smaller arterioles (inner diameter in Krebs-Ringer solution at 50mmHg 103±9μm, n=7) and greater arterioles (201±11μm, n=9) were separately evaluated.
Results
In accordance with previous observations, spontaneous tone of the two groups were substantially different (25.6±3.4 % vs. 13.5±1.7 %, $p<0.05$). Quercetin significantly reduced the tone in both groups (46.7±9.9% and 45.7±9.1%). Indomethacine significantly increased the tone of quercetin treated, relaxed vessels by 44.7±9.9% and 45.3±14.5%. Further, addition of l-nitro-methil-arginine still induced significant relaxation

(18.9±8.4% and 27.8±8.2%, p<0.05). Statistical test was one-way ANOVA.

Conclusion

A physiologically relevant concentration of the flavonoid quercetin significantly decreases the spontaneous tone of intramural coronary arterioles. A substantial part of this vasorelaxation effect is connected to production of vasodilatory endogenous prostanoids while an endothelial NO-mediated mechanism seems to be negligible. These observations suggest the possibility that quercetin appearing in blood plasma from the food induces the operation of a coronary vasodilatory mechanism whose effectiveness is commeasurable with that of the known endothelial actions.

PCB357

Blood temperature influences erythrocyte ATP release and muscle blood flow in human limbs

K.K. Kalsi, S.T. Chiesa, S.J. Trangmar and J. González-Alonso

Centre for Sports Medicine and Human Performance, Brunel University, London, UK

Human limb muscle and skin perfusion alters with changes in tissue temperature evoked by heating or cooling and these processes may involve temperature sensitive regulatory mechanisms. We have previously shown that passive heating and exercise increase limb tissue blood flow in humans in association with the increases in muscle temperature and plasma adenosine 5'-triphosphate concentration [ATP] (1,2). Reduced haemoglobin O_2 saturation is thought to be the main stimulus for erythrocyte ATP release in the muscle microcirculation (3,4). Recent evidence, however, suggests that temperature is another potent stimulus. Here we tested the hypothesis that the release of the vasodilator mediator ATP from human erythrocytes is sensitive to physiological reductions and increases in blood temperature independently of oxygenation induced ATP release in the human forearm circulation. To accomplish this aim, we measured forearm blood flow (FBF; Doppler ultrasound), deep venous blood temperature (T_b), retrograde venous plasma [ATP], blood gas parameters and calculated forearm vascular conductance (FVC) in the experimental and the control contralateral forearm in 7 males (19 ± 2 years) during 1 hour of passive heating using a water perfused cuff and 1 hour of passive cooling using ice with 1 hour of rest in between. All data are mean ± SEM and were compared with ANOVA and Pearson correlation (SPSS). With heating T_b increased from 34.0 ± 0.5 to 36.8 ± 0.1°C (p<0.05) while with cooling T_b decreased from 34.4 ± 0.4 to 29.1 ± 0.7°C (p<0.05). Plasma [ATP] doubled with heating from 0.21 ± 0.03 to 0.43 ± 0.05 μmol.l^{-1} (p<0.05) but did not change with cooling remaining at 0.23 ± 0.03 μmol.l^{-1} similar to values in the control forearm. FBF progressively and significantly increased with heating from 124 ± 11 to 418 ± 10 ml.min^{-1} (p<0.05) and decreased with cooling from 121 ± 11 to 90 ± 14 ml.min^{-1} (p<0.05). Similar significant responses were observed with FVC, indicating that flow changes with heating and cooling were due to vasodilatation and vasoconstriction, respectively. In contrast, control forearm values for T_b, [ATP], FBF and FVC were unchanged throughout the study. During heating and cooling, FBF and FVC were exponentially correlated to T_b (R^2 = 0.86 and 0.87, respectively; p<0.01) and [ATP] (both R^2= 0.85; p<0.01). Contrary to the reported involvement of the O_2 saturation pathway, plasma [ATP] remained unchanged during cooling despite decreasing O_2 saturation from 62 ± 4 to 35 ± 4% (p<0.05) but increased with heating when O_2 saturation was elevated from 59 ± 6 to 82 ± 4% (p<0.05). These findings suggest that ATP from erythrocytes may be an important mechanism regulating human limb muscle and skin perfusion in conditions that alter blood and tissue temperature. Furthermore, it seems that temperature works through a distinct pathway to that sensitive to blood oxygenation.

PCB358

The NLRP3 inflammasome: link to interleukin-1β production in the human placenta

E. Maneta, D. Hay and R.N. Khan

Academic Division of Obstetrics & Gynaecology, University of Nottingham, Derby, UK

Introduction: Within the last ten years, DAMPs (Damage or Danger Associated Molecular Patterns) have been shown to activate a novel intracellular structure termed the inflammasome (1). Of the four types of inflammasomes that have been discovered, the NLRP3 (cryopyrin) inflammasome is linked to the production of interleukin-1β implicated in the onset of preterm labour. Activation of the NLRP3 inflammasome is complex requiring two 'hits' eventually triggering caspase-1 and release of IL-β, reliant, in part, on the purinergic receptor, P2X7 receptor. The hypothesis tested is that the NLRP3 inflammasome is expressed and functional in leukocytes isolated from the villous tissue of the placenta and cord blood.

Methods: Placentae and blood samples were obtained with ethical approval and informed consent from pregnant women at term. Leukocytes were purified from placentae, cord and peripheral blood using Ficoll-Hypaque isolation. Immunofluorescence was used to detect the presence of the NLRP protein. IL-1β production was measured by ELISA in the presence of antagonists of the P2X7 receptor and caspase-1, a key molecule of the NLRP3 inflammasome complex. IL-1β production ± drugs was compared using one-way ANOVA for n samples.

Results: NLRP3 (cryopyrin) protein was constitutively expressed in peripheral (n=5) and placental (n=8) leukocytes while expression in cord blood leukocytes (n=5) required priming with

lipopolysaccharide. IL-1β release was significantly greater (P <0.05) in villous leukocytes (n=8) compared with cord blood leukocytes (n=8) and enhanced further in placental leukocytes of labouring (P<.05; n=6) compared with nonlabouring women (n=7). Production of IL-1 β was significantly inhibited (P<0.05) following preincubation with the caspase-1 inhibitor, YVAD-CHO (n=6) and a selective P2X7 antagonist (n=6) while progesterone (100 nM) treatment reduced this response (P<0.05; n=6).

Conclusion: The human placental NLRP3 inflammasome is an important intracellular component mediating the release of IL-1β during pregnancy. Increased production of IL-1β and basal expression of NLRP3 in placental and peripheral leukocytes compared with those of cord blood suggest that the maternally-derived signals have a key role in inflammation during pregnancy.

miRNA-223 regulates platelet function by targeting β1 integrin and factor XIII-A

A. Elgheznawy, V. Randriamboavonjy and I. Fleming

Institute for Vascular Signalling, Frankfurt am Main, Germany

microRNA (miRNA) regulate protein expression levels either by degrading mRNA or repressing translation. Circulating miRNAs have been proposed as biomarkers for different diseases. One particular miRNA i.e. miR-223, is abundant in platelets and markedly downregulated in plasma from patients with diabetes or at a high risk of myocardial infarction. The aim of this study was to determine whether miR-223 is only a biomarker or whether changes in miR-223 also affect platelet function. Two models of miR-223 deletion in platelets were used; miR-223 knockout mice (miR-223 -/-) and platelets from diabetic patients. Values are means ± S.E.M., compared either by ANOVA or the Student t test.Platelets from miR-223-/- mice demonstrated an enhanced platelet aggregation in response to either thrombin (n=8) or collagen (n=22) compared to platelets from wild-type littermates (C57BL/6). Moreover, platelets from miR-223-/- mice developed large aggregates when added to different extracellular matrices such as collagen, fibronectin, and laminin and demonstrated a delayed clot retraction. Platelets from diabetic patients also formed large aggregates (339.8 μm2 ± 60 for diabetic patients vs. 78.46 μm2 ± 40.4 for healthy donors, p<0.05) and showed delayed clot retraction when compared to healthy donors. In miR-223-/- mice, the bleeding time was markedly shorter (419.7 sec ± 67.36 miR-223-/-, vs. 1177 sec ± 101.3 wild-type, p<0.001) and a significantly larger thrombus was developed after FeCl3-induced carotid artery injury than in wild-type mice (p<0.001, n=6). Furthermore, FACS analysis of whole blood showed an enhanced platelet-leukocyte aggregate (0.13 % ± 0.01 miR-223-/-, vs. 0.07% ± 0.008 wild-type, p<0.01) in miR-223-/- mice compared to wild-type. To identify proteins regulated by miR-223 we compared the proteome of miR-223-/- and wild-type platelets using 2D-differential in-gel electrophoresis. Validation of proteins identified by the proteomic analysis confirmed that miR-223-/- platelets expressed higher levels of kindlin-3, β1 integrin, α2 integrin and factor XIII-A (n=13) than wild-type platelets. The same changes in protein expression were also detected in platelets from diabetic patients (n=5). The α2β1 integrin antagonist; rhodocetin (5μg/ml, 5 min), prevented the changes in aggregate formation of platelets from miR-223-/- and diabetic patients. Additionally, factor XIII-A inhibition normalized the clot retraction process. In conclusion, our data indicate that miR-223 plays an important role in the regulation of platelet function through targeting integrin signaling and factor XIII-A expression and activity.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Vasoactive agonists causes changes in vascular smooth muscle cell stiffness and induces stiffness oscillations and remodeling of cytoskeletal architecture

Z. Hong[1], Z. Sun[1], Z. Li[1], J. Trzeciakowski[2] and G.A. Meininger[1,3]

[1]Dalton Cardiovascular Research Center, University of Missouri, Columbia, MO, USA, [2]Department of Systems Biology, Texas A&M University, College Station, TX, USA and [3]Department of Medical Pharmacology and Physiology, University of Missouri, Columbia, MO, USA

We have reported that vasoactive agonists induce coordinated changes in stiffness and integrin-mediated cell adhesion in vascular smooth muscle cells (VSMCs), i.e., vasoconstrictors cause coordinated increases in VSMCs stiffness and adhesion and vasodilators cause opposite results[1]. In these studies a temporal analysis was performed to examine the dynamic effects of vasoactive agonists on VSMCs stiffness and cortical cytoskeletal structure. Atomic force microscopy (AFM) was used to perform real-time measurements of cell stiffness using a nanoindentation protocol (0.1 Hz). Data were analyzed by spectral analysis (Eigen decomposition) and[2]. VSMC stiffness was found to exhibit temporal oscillations with three distinct frequency components at 0.001/1.0, 0.004/0.4, and 0.07/0.3 Hz/kPa frequency/amplitude, respectively. Following treatment with angiotensin II (ANG II, 10^{-6}M), amplitude of the oscillations increased significantly (+100%), whereas adenosine (ADO, 10^{-4}M), a vasodilator, reduced oscillation amplitudes (-30%). To examine whether ANG II and ADO also altered cortical cytoskeletal structure as part of their action, the VSMC membrane topography of the sub-membranous actin cytoskeleton (100-300 nm depth) was acquired by contact mode imaging with AFM. Height and deflection signals from the topographical images were analyzed (Matlab) to compare the cortical actin fiber distribution and orientation before and after treatment with ANG II or ADO (20 min). These data show that ANG II increased the parallel alignment, density and thickness of cortical stress fibers, consistent with a rapid remodeling process involving increased actin polymerization. By comparison, ADO decreased stress fiber alignment, density and thickness of the stress fibers, consistent with disassembly of actin stress fibers. These findings demonstrate that vasoactive agonists dynamically alter temporal behavior and cytoskeletal structure of the VSMCs. These events appear to play an important role in the contractile behavior of VSMCs to vasoactive agonists.

<Purpose> Efficacy of peppermint or its major component menthol on gut function is generally known. Menthol shows its cooling effect via TRPM8, which can be activated by cold stimulation (lower than 25-28°C). Here, we examined the effect of menthol (M) and synthesized menthol derivative (MD, donated by Takasago International Corporation) on smooth muscle contraction induced by acetylcholine (ACh) using isolated intestine of mice, and action mechanism was investigated with relation to TRP channel activity.
<Methods> Animal experiments were approved by the animal care and use committee at Chiba Institute of Science and Maebashi Institute of Technology. After euthanasia of mice (ddy, male, over 6 weeks ages) by deep anesthesia, intestines were isolated and divided into 5 different positions, that is, jejunum, upper part of ileum, lower part of ileum, colon, and rectum. After intestinal fragment was set in the Magnus tube kept at 37°C, intestinal motility was monitored by tension meter and recorded on chart recorder. M/MD were dissolved in DMSO and applied against the intestine at 100 μM (MD) or 200 μM (M) as a final concentration. Amplitude of contraction by ACh with DMSO was shown as 100% (control), and those with M or MD were relatively shown.
<Results & Discussion> M/MD inhibited ACh-induced intestinal contractions concentration-dependently. MD showed stronger inhibition than M at the same concentration. Inhibitory effects of M/MD were different from intestinal positions, that is, remarkable inhibition could be observed at jejunum and upper part of ileum. At all intestinal positions except jejunum, inhibitory effects of M/MD on ACh-induced contractions became weak at low temperature (23°C). At this temperature, it is thought that TRPM8 has been already activated. So, these results suggested that TRPM8 might involve in inhibitory effects of M/MD and distribution of TRPM8 might be different from intestinal positions. In order to clarify involvement of TRPM8 on inhibitory effects of M/MD, non-specific TRP channel inhibitor 'ruthenium red' or non-specific TRP channel antagonist 'capsazepine' was used. In spite of inhibitory condition of TRP channel (maybe TRPM8 too) by applying these reagents (final concentration was 10 μM), inhibitory effects of M on the ACh-induced contractions could be still observed. As ruthenium red and capsazepine are not specific against TRPM8, these reagents may action to other existed TRP channels in intestinal tissues and action of M may appear indirectly. It was reported TRPM8 was expressed at mucosa but not at muscle on small intestine (1), and the presence of TRPM8 in the gut has not yet been established clearly (2). These results and reports suggest that M may act at other sites in intestine in addition to TRPM8.

Platelets activate hepatic endothelium and provide P-Selectin as a bridge for leukocyte recruitment

P.F. Lalor, J. Herbert, R. Bicknell and D.H. Adams

Centre for Liver Research, University of Birmingham, Birmingham, West Midlands, UK

Platelets drive liver injury in murine models of viral hepatitis(1) and promote liver regeneration through the release of serotonin(2). Despite their emerging role in inflammatory liver disease little is known about the mechanisms by which platelets bind to the hepatic vasculature. We used human explanted tissue specimens and peripheral blood to investigate the mechanisms and consequences of platelet binding. Human hepatic sinusoidal endothelial cell (HSEC) adhesion receptor expression was determined by analysis of public SAGE expression data. We then used a combination of modified Stamper Woodruff adhesion assays and flow-based endothelial adhesion assays with cultured HSEC and human platelets and leucocyte populations, along with histochemical analysis of human explanted liver specimens and NF-KB activity assays. 1,5353 genes with differentially expressed in HSEC (FDR q-value <=0.05 with posterior probability of >= 0.8) compared to endothelium from kidney, breast, lung and aorta and of these 864 were enriched in HSEC. Expression of sinusoidal endothelial phenotypic indicators(3) CD32b (FCGR2B), LYVE-1, CLEVER-1 (STAB1) and mannose receptor was increased in HSEC, which had reduced expression of VWF, αv integrin and CD31. Exogenous platelets bound avidly to hepatic vessels in normal and chronically injured human liver tissue, and became activated on the diseased tissue. Adhesion was integrin dependent (>60% decrease 100ug/ml RGD peptide, p<0.001, n=3 livers) inhibited by blocking platelet CD41, and supported by binding to immobilised fibrinogen on the tissue endothelium (>50% decrease 100ug/ml Fb-binding peptide, P<0.05, n=3 livers). Flow based adhesion assays confirmed that binding of platelets to HSEC under flow was significantly inhibited by antibody raised against Gp1b (29±18% of control), Fb-peptide(53.5±20%),αIIb integrin(36.7±7.2%) and αv integrin(36.2±4.7%, P<0.05 for all, n=4 HSEC isolates). Binding of platelets resulted in activation of endothelial NF-KB, and a significant increase in secretion of CXCL8 (2600±300pg/ml vs 300±290pg/ml control, n=3 HSEC isolates p<0.001) and CCL2 (900±150pg/ml vs 260±175pg/ml control) by HSEC. Importantly platelet attachment to HSEC increased binding of neutrophils and lymphocytes under flow, and adhesion was inhibited using a P-Selectin inhibitor. In conclusion, we have demonstrated that resting platelets can adhere to human HSEC using the integrins αIIbβ3 and αVβ3 under physiological shear stress. Our findings explain how platelets bind to hepatic vessels and suggest that such interactions promotes immune cell recruitment by triggering chemokine secretion and providing an adhesive substrate for circulating leukocytes.

Local perfusion conditions influence the epidermal "barrier" function in the lower limb

H. Silva[1,2], H. Ferreira[4], L. Tavares[1], J. Bujan[3] and L.M. Rodrigues[1,2]

[1]CBiOS, U Lusofona Fac Health Sc & Technol, Lisboa, Portugal, [2]Pharmacol Sc Departm, U LIsboa School of Pharmacy, Lisboa, Portugal, [3]U Alcalá School of Medicine, Madrid, Spain and [4]IBEB, U LIsboa Faculty Sciences, Lisboa, Portugal

The study of the relationships between transcutaneous variables, especially microcirculatory flow by Laser Doppler Flowmetry (LDF), transcutaneous gas pressures (tcpO2 and tcpCO2) and transepidermal water loss (TEWL) has provided new directions to better understand local circulatory physiology. The objective is to explore how changes in local perfusion in the lower limb affect the epidermal "barrier" function. A group of fourteen young adult males (24.9 ± 0.6 years old), was selected after informed consent. All procedures complied with the ethical standards for human research by the Declaration of Helsinki and subsequent amendments. Two protocols were designed involving postural change maneuvers (protocol I – elevation of the leg 90° relative to the body axis while sitting; protocol II - supine with elevation of the leg 30°) and one protocol consisting of an occlusion test with application of suprasystolic pressure through a tourniquet-cuff (protocol III). Studied variables in distal locations of the lower limb involved microcirculatory blood flow by LDF (PeriFlux PF5000, PF5010 System, Perimed, Sweden), tcpO2 by transcutaneous gasimetry (Periflux PF5000, PF5040 System, Perimed, Sweden) and TEWL (Tewameter TM300, CK electronics, Germany). All variables were assessed before, during and after these maneuvers. Descriptive and nonparametric statistics were applied and a 95% confidence level was adopted.In Protocol I there was a statistically significant increase in the values of LDF and TEWL and an equally significant decrease in tcpO2 during the elevation of the lower limb. When the lower limb returned to the starting position values returned to baseline. In Protocol II there was a statistically significant decrease of LDF values, TEWL and tcpO2 during the elevation of the lower limb. The values returned to baseline when the lower limb returned to the starting position. In Protocol III there was a statistically significant decrease in the values of LDF and tcpO2 during the occlusion, accompanied by a significant increase of TEWL values, both of which returned to baseline when the tourniquet was removed. The present data confirms previously published results, suggesting that by modifying local perfusion conditions one may influence the epidermal skin "barrier".

Tocolytic Effects of *Talinum Paniculatum* Leaf Extract in Female Virgin Rats

C. Thanamool and S. Kupittayanant

Physiology, Suranaree University of Technology, Muang, Nakhon Ratchasima, Thailand

Talinum paniculatum (*T. paniculatum*) has long been used in Thai herbal recipes because of its various therapeutic properties such as improving vitality or treatment of type-2 diabetes, inflammatory skin problems, gastrointestinal disturbance and general weakness (Shimoda et al, 2001; Pak et al, 2005). *T. paniculatum* is also believed to be beneficial for female reproductive system by inducing lactation and restoring uterine functions after post-partum period (Manuhara et al, 2012). Although, the plant has been reported to influence the female reproductive system, but there is no scientific data regarding to clarify the effects on the uterus to support its therapeutic relevance. Therefore, the purpose of this study was to investigate the effects of *T. paniculatum* leaf extract on uterine contractility and its possible mechanism(s) on adult female virgin rats. In this study, animal cares, environmental conditions, and uses followed the guidelines of Laboratory Animal Resources, National Research Council of Thailand. The procedures of the experiment were approved by the Institutional Animal Care and Use Committee, Suranaree University of Technology, Nakhon Ratchasima, Thailand. The rats (200-250 g) were humanly euthanized by CO_2 asphyxia and uteri were removed. Isometric force was measured in strips of longitudinal myometrium (1-2 mm x 0.5 mm x 10 mm) in organ baths containing physiological Krebs' solution maintained at 37 °C, pH 7.4. The effects of *T. paniculatum* leaf extract at certain concentration level (IC_{50}; 1.67 mg/mL) on spontaneous contraction and agonist-induced contraction such as high KCl (40 mM) solution, Bay K8644 (1 μM), and oxytocin (10 nM) were observed. All values were analyzed by Paired student *t*-test. A probability level less than 5% ($P<0.05$) was considered statistically significant. The results showed that spontaneous uterine contractile activity was found to be dose-dependently inhibited by the extract ($n = 5$). In addition, the extract significantly inhibited the contraction induced by high KCl solution ($P<0.01$) ($n = 5$). In Bay K8644 and oxytocin studies, the extract significantly relaxed the uterus in a time-dependent manner ($P<0.05$) ($n = 5$). Interestingly, the extract could potentially inhibit oxytocin-induced contraction in the absence of external Ca^{2+} ($n = 7$). Taken together, the data implied that *T. paniculatum* produces tocolytic effects on both spontaneous and agonist-induced contractions. The possible mechanisms may be due to the blockade of Ca^{2+} influx via L-type Ca^{2+} channel and Ca^{2+} efflux from internal store.

PCB367

Modulation of urinary bladder muscle contractility and mucosal ATP release by inhibition of intracellular protein phosphatases

J. Clayton, D. Kitney, T. Hague, A. Talstaya, C. Fry and R.I. Jabr

Biochemistry and Physiology, University of surrey, Surrey, UK

Overactive bladder (OAB) is accompanied by abnormal muscle contraction and increased ATP release from the mucosa. An important common factor is an increase of intracellular Ca^{2+}, which in turn activates a central intracellular signalling pathway triggered by the Ca^{2+}-calmodulin-dependent protein phosphatase, calcineurin (Cn). An increase of Cn activity is associated with the development of an overactive bladder phenotype, that may represent a direct action or the secondary activation of other phosphatases such as PP1 and PP2A. The role of these phosphatases may be examined by the use of inhibitors such as cyclosporin (CsA for Cn) or okadaic acid (for PP1/PP2A). To date, the physiological role of Cn-dependent pathways in bladder contractions is unclear. The objectives of this study were: 1) to examine the effects of CsA or okadaic acid on spontaneous and carbachol-evoked, as well as nerve-mediated contractions and 2) the effect of CsA on mucosal-mediated ATP release upon muscle stretch.
Muscle strips were dissected from rabbit urinary bladders, and superfused with normal Tyrode's solution in horizontal organ baths. Isometric contractions were measured from preparations with the mucosa attached or denuded. Contractions were evoked in the absence and presence of CsA by either exposure to the muscarinic receptor agonist, carbachol or electrical field stimulation (20Hz). ATP release from mucosa-intact preparations after a rapid stretch (20% resting length) was measured from superfusate samples using a luciferin–luciferase assay. All data are mean±S.D., differences between data sets were tested with Student's t-test and the null hypothesis rejected at $p<0.05$.
Spontaneous contractions were suppressed by CsA at 1, 5 and 10 μM and also by 0.1 μM okadaic acid (CsA 36.2±12.2 % control; n=6; okadaic acid 40.2±23.1% control; n=4; $p<0.01$). Contractures evoked by 0.1 μM carbachol were unaffected by 1μM CsA but significantly attenuated at 5 and 10 μM (74.8±5.9 and 75.9±4.3% control respectively; n=5; $p<0.05$). Okadaic acid also reduced carbachol contractions (73.6± 11.8 % control; n=4; $p<0.05$). CsA also attenuated contractions from denuded strips evoked by electrical field stimulation, but only to 95±4% control, n=4, $p<0.05$). Finally, CsA reduced stretch-evoked ATP release from mucosa-intact preparations (73.8±4.4 % control; n=10, $p<0.05$).
Inhibition of intracellular phosphatase activity supressed both spontaneous and carbachol-induced contractions, but had a relatively small effect on nerve-mediated contractions: the effect of CsA was more potent on spontaneous activity. CsA also attenuated stretch-induced ATP release, which is a regulator of spontaneous activity. The data suggest that intracellular phosphatases are key regulators of several steps in the pathways that generate contraction in bladder smooth muscle.

Observation and analysis of an ultrafast calcium wave in cultured vascular smooth muscle cells

J.C. Quijano, J. Bény and J. Meister

École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland

Communication between vascular smooth muscle cells (SMCs) allows control of arterial contraction and blood flow. The contractile state of the SMCs is regulated by cytosolic Ca2+ concentration and propagates as Ca2+ waves over a significant distance along the vessel. In this work, we studied an intercellular ultrafast Ca2+ wave observed in cultured A7r5 cell line and in primary cultured SMCs (pSMC) from mesenteric arteries obtained from male Wistar rats (250-350g) that were anesthetized with isoflurane (4%) and then decapitated in agreement with the Care of Animals (edited by the Swiss Academy of Medical Sciences and the Helvetic Society of Natural Sciences). Cells were aligned along networks obtained by photolithography technique. Using this microtechnique and a fast acquisition rate (330 Hz) allowed us to analyze fast intracellular Ca2+ fluorescence responses in different parts along the network after mechanical or KCl stimulation in one of the aligned cells. In addition, we have recorded and analyzed membrane potential variations in cells away from the mechanical stimulation site. Values are means ± S.E.M., compared by Student's t-test on paired data. For both types of vascular SMCs, mechanical stimulation evoked an intercellular ultrafast Ca2+ wave with the same velocity (VpSMC=13.9±4.2mm/s, npSMC=10; VA7r5=16.3±3.9mm/s, nA7r5=16; $p<0.01$). Local KCl stimulation also induced an ultrafast Ca2+ wave that had the same magnitude for both SMCs (VpSMC=15.0±2.9mm/s, npSMC=7; VA7r5=14.5±2.7mm/s, nA7r5=9; $p<0.01$). The rate of increasing cytosolic Ca2+ along the network, decreased with distance from the stimulation site for both cases. Experiments performed in the presence of the gap junction uncoupler Palmitoleic acid (PA) (50μM) or in the presence of L-type voltage operated Ca2+ channel (VOCC) inhibitor Nifedipine (Nif)(10μM) suppressed the ultrafast Ca2+ wave propagation in all cases (npSMC,Nif=5; nA7r5,Nif=7; npSMC,PA=3; nA7r5,PA=5), inferring the crucial role of the electrical coupling through gap junctions and the importance of Ca2+ entry through the VOCCs for the ultrafast Ca2+ wave intercellular propagation. On the other hand, mechanical stimulation induced a membrane depolarization that propagated and decayed exponentially with distance. Both types of SMCs present different space constants (λpSMC=0.67mm, λA7r5=0.92mm). Our results suggest that in cultured vascular SMCs, an electrotonic spread of membrane depolarization drives the Ca2+ entry from the external media which can be modeled as an ultrafast Ca2+ wave. This ultrafast Ca2+ wave may triggers the Ca2+ release from intracellular stores that drives observed slower Ca2+ waves.

Lysosome-sarcoplasmic reticulum junctions: A trigger zone for calcium waves in vascular smooth muscle

N. Fameli[1], C. van Breemen[1] and A. Evans[2]

[1]Department of Anesthesiology, Pharmacology & Therapeutics, University of British Columbia, Vancouver, BC, Canada and [2]Centre for Integrative Physiology, University of Edinburgh, Edinburgh, UK

We investigate a hypothesis for the generation of nicotinic acid adenine dinucleotide phosphate (NAADP)-mediated Ca^{2+} waves in the vascular smooth muscle of the pulmonary artery. Agonist-stimulated waves of elevated cytoplasmic calcium concentration regulate blood vessel tone and vasomotion in vascular smooth muscle. In rat pulmonary artery smooth muscle cells, the calcium mobilizing messenger NAADP appears to trigger bursts of Ca^{2+} release from lysosomal Ca^{2+} stores by activating the Two Pore Segment Channel subtype 2 (TPC2). It is suggested that these Ca^{2+} transients initiate a propagating wave by Ca^{2+}-induced Ca^{2+} release from the sarcoplasmic reticulum (SR) via ryanodine receptors (RyRs). Deconvolution and confocal microscopy observations, including immunofluorescence, indicate that lysosome clusters may selectively couple to RyR subtype 3 (RyR3) in regions
where lysosomes and proximal SR are separated by a narrow space possibly < 100 nm and beyond the resolution of light microscopy. These results naturally lead to the hypothesis that lysosome-SR (L-SR) junctions may form a cytoplasmic trigger zone for the observed Ca^{2+} bursts and subsequent cell-wide Ca^{2+} waves. The present study combines prior optical microscopy observations with a thorough ultrastructural characterization of the L-SR junctions in rat pulmonary artery smooth muscle as input data for a quantitative model of the L-SR junction to test the above hypothesis. With this model, we simulate the Ca^{2+} bursts that may be generated in the L-SR junctions
to determine whether or not these bursts give rise to a sufficient increase in junctional [Ca^{2+}] to breach the threshold for RyR3 activation by CICR and thus initiation of a propagating Ca^{2+} wave.

We are grateful to Garnet Martens and the University of British Columbia Bioimaging Facility for their guidance in electron microscopy imaging, to David Walker for his insightful help with ultrastructure identification, to Tom Bartol for his continual assistance with MCell, and to Arash Tehrani for helping with image analysis. This work was supported by Grant No. CIHR MOP-84309 from the Canadian Institute of Health Research and by the British Heart Foundation Project Grants PG/03/065 and PG/10/95/28657.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Microsurgical extrahepatic cholestasis decreases vasoconstrictor response to phenylephrine in rat mesenteric resistance arteries

J. Blanco-Rivero[1,2], L. Caracuel[1,2], E. Sastre[1,2], I. Prieto[2,3], C. Nieto[4], M. Aller[5], J. Arias[5] and G. Balfagón[1,2]

[1]Fisiología, Universidad Autónoma de MAdrid, Madrid, Spain, [2]Instituto de Investigación Sanitaria IdIPAZ, Madrid, Spain, [3]Hospital Universitario La Paz, Madrid, Spain, [4]Servicio de Cirugía General, Complejo Hospitalario de Toledo, Toledo, Spain and [5]Cirugía, Universidad Complutense de Madrid, Madrid, Spain

Introduction: Obstructive cholestasis is clinically characterized clinically by jaundice, discolored urine, pale stools, pruritus, liver cirrhosis and portal hypertension, causing a high rate of morbidity and mortality in human clinical area. Microsurgical extrahepatic cholestasis (MHC) is the most commonly used model to study obstructive cholestasis since it presents with a systemic inflammatory response syndrome, characterized by hyperdynamic circulation, peripheral sympathetic hyperactivity and multiorgan dysfunction. The aim of the present study was to analyse the possible alterations on vascular function produced by microsurgical extrahepatic cholestasis.
Methods: Cholestasis induction was made under anaesthesia (ketamine/xylacine) by a surgical operation based on the ligation of the common bile duct and the 4 bile ducts and then the cut of them. Contraction to phenylephrine (Phe) was measured in MRA from SO (sham-operated) and MHC (maintained for 7-8 weeks) rats. Participation of nitric oxide (NO) and thromboxane A2 (TxA2) in this response was determined, as well as the vasomotor responses to exogenous NO and TXA2.
Results: MHC decreased vasoconstrictor response to Phe in MRA from MHC rats. Preincubation with NO synthesis inhibitor L-NAME increased the Phe-induced contraction in a similar extent in both groups. Preincubation with the COX-1/2 or COX-2 inhibitor (indomethacin and NS-398, respectively), decreased the Phe-induced contraction only in SO animals. TXA2 synthesis inhibitor (furegrelate) also decreased Phe contraction only in SO animals. Vasomotor responses to DEA-NO (NO donor) or U-46619 (TXA2 analog) were not modified by MHC.
Conclusion: MHC decreases Phe-induced vasoconstriction in MRA. This decrease is due to a decrease on contractile prostanoid participation in this response, probably through a decrease on TXA2 release, while the participation of NO on this modification is ruled out.

This study was performed by grants of Ministerio de Ciencia e Innovación (SAF2009-10374, SAF2012-38530) and Fundación Mapfre.

PCB371

Calcium activated chloride channels have critical functional effects on intracellular calcium and spontaneous contractions in human and rat myometrium

K. Noble and S. Wray

University of Liverpool, Liverpool, UK

The potential for calcium-activated chloride channels (CaCCs) as drug targets has led to the recent development of novel specific small molecule inhibitors of them [1]. These drugs are also enabling a much improved pharmacological dissection of the role of CaCCs within tissues.

Myometrial contractions need to be regulated for successful pregnancy and parturition. Our previous electrophysiological studies showed CaCCs in 30% of isolated myometrial cells in pregnant rats [2]. The aims of this study are thus to use these new inhibitors of CaCCs to determine the functional effects of CaCCs on human and rat myometrium and characterise the effect of CaCCs inhibition on Ca signaling.

Strips of myometrium (4 x 1mm) were dissected from biopsies taken from term, pre-labour elective caesarean sections in women and labouring (LR) or term pregnant (TPR) rats. Contractility was measured on strips under isometric conditions in HEPES buffered physiological salt solution at 37^0C and in some experiments simultaneous measurements of intracellular Ca^{2+} ($[Ca^{2+}]_i$) and force were made on strips previously loaded with Indo -1.

The CaCC inhibitor (CaCCinh-A01) and TMEM16A inhibitor (T16Ainh-A01) were both used at 30μM for 10–20 min based on preliminary dose response experiments. Data are mean ± S.E.M. and changes in baseline $[Ca^{2+}]_i$ are normalised to the amplitude of control phasic transients (100%).

Control spontaneous phasic contractions were established for 30 – 60 min. CaCCinh-A01 completely inhibited spontaneous contractions in all myometrial strips (human, n=5; LR, n=2 and TPR n=3. In contrast T16Ainh-A01 had no effect on spontaneous activity in any preparation.

In rats during control contractions, spontaneous phasic Ca transients (Ca entry through voltage-gated Ca channels; VOCCs) were recorded and basal Ca remained stable. The CaCCinh-A01 induced an immediate and profound decrease in basal $[Ca^{2+}]_i$ before cessation of spontaneous Ca and force transients. After 10 min basal $[Ca^{2+}]_i$ had decreased by 52 ±2%, n=4. CaCC inhibition has been shown to hyperpolarise smooth muscle [3] which might inhibit Ca entry through VOCCs and thus decrease basal Ca. Experiments were therefore repeated in nifedipine (an inhibitor of VOCCs). Nifedipine (1μM) inhibited spontaneous Ca and force transients and decreased basal $[Ca^{2+}]_i$ by 15%. However CaCCinh-A01 further decreased basal $Ca^{2+}]_i$ by 40% (preliminary data, n=2) suggesting that a significant component of CaCC activity on $[Ca^{2+}]_i$ is independent of VOCC entry.

These data suggest that there is a critical and constitutive role for CaCCs, but not the specific TMEM16A channel, in the myometrium in maintaining basal $[Ca^{2+}]_i$ and spontaneous activity. Further work using confocal microscopy will help elucidate the precise role of CaCCs on local and global intracellular calcium.

Overactive bladder mediated by accelerated Ca^{2+} influx mode of Na^+/Ca^{2+} exchanger in smooth muscle

H. Yamamura[1], W.C. Cole[2], S. Kita[3], S. Hotta[1], H. Murata[1], Y. Suzuki[1], S. Ohya[1,4], T. Iwamoto[3] and Y. Imaizumi[1]

[1]Department of Molecular and Cellular Pharmacology, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan, [2]Smooth Muscle Research Group, Department of Physiology and Pharmacology, Faculty of Medicine, University of Calgary, Calgary, AB, Canada, [3]Department of Pharmacology, Faculty of Medicine, Fukuoka University, Fukuoka, Japan and [4]Department of Pharmacology, Kyoto Pharmaceutical University, Kyoto, Japan

The Na^+/Ca^{2+} exchangers (NCXs) are expressed in a variety of cell types and participate in the regulation of cytosolic Ca^{2+} mobilization. In mammals, three NCX isoforms (NCX1, NCX2, and NCX3) have been identified as products of the SLC8 gene family. Among alternative splicing variants of NCX1, NCX1.3 and NCX1.7 are the predominant isoforms expressed in smooth muscle tissues. NCX is thought to be a key molecule in the regulation of cytosolic Ca^{2+} dynamics in smooth muscles. The relative importance of the two Ca^{2+} transport modes of NCX activity leading to Ca^{2+} efflux (forward mode) and Ca^{2+} influx (reverse mode) in smooth muscle, however, remain unclear. Unexpectedly, spontaneous contractions of urinary bladder smooth muscle were enhanced in transgenic mice overexpressing NCX1.3 ($NCX1.3^{tg/tg}$ mice) compared to wild-type (WT) mice. For this reason, the present study was undertaken to elucidate the contribution of Ca^{2+} influx via reverse mode NCX activity to the control of membrane electrical excitability, cytosolic Ca^{2+} mobilization in urinary bladder myocytes, urinary bladder smooth muscle contractility, and urinary bladder function. All experiments were approved by the Ethics Committee of the Nagoya City University and were conducted in accordance with the Guide for the Care and Use of Laboratory Animals of the Japanese Pharmacological Society. The enhanced spontaneous contractions of urinary bladder smooth muscle from $NCX1.3^{tg/tg}$ mice were attenuated by KB-R7943 or SN-6. Whole-cell outward NCX current sensitive to KB-R7943 or Ni^{2+} was readily detected in urinary bladder smooth muscle cells from $NCX1.3^{tg/tg}$ mice, but not in WT mice. The half duration of spontaneous transient outward currents (STOCs) in myocytes of $NCX1.3^{tg/tg}$ mice were significantly larger than those of WT mice. Spontaneous Ca^{2+} transients (Ca^{2+} sparks) in myocytes of $NCX1.3^{tg/tg}$ mice were larger and frequently resulted in propagating events and global elevations in cytosolic Ca^{2+} concentration (Ca^{2+} waves). Significantly, $NCX1.3^{tg/tg}$ mice exhibited a pattern of more frequent urination of smaller volumes and this phenotype was reversed by oral administration of KB-R7943. On the other hand, KB-R7943 did not improve it in KB-R7943-insensitive $NCX1.3^{tg/tg}$ ($G833C\text{-}NCX1.3^{tg/tg}$) mice. We conclude that NCX1.3 overexpression is associated with abnormal urination owing to enhanced Ca^{2+} influx via reverse mode NCX leading to prolonged, propagating spontaneous Ca^{2+} release events and a potentiation of spontaneous contraction in urinary bladder smooth muscles. These findings suggest the possibility that NCX is a candidate molecular target for overactive bladder (OAB) therapy.

α1 modulation of spontaneous activity in prostate tissue from men with benign prostatic hyperplasia (BPH) or prostate enlargement

B. Chakrabarty[1], M. Frydenberg[2], N. Lawrentschuk[3], G. Risbridger[2] and B. Exintaris[1]

[1]Drug Discovery Biology, Monash Institute of Pharmaceutical Sciences, Melbourne, VIC, Australia, [2]Anatomy And Developmental Biology, Monash University, Melbourne, VIC, Australia and [3]Department Of Surgery, Austin Health, University of Melbourne, Melbourne, VIC, Australia

Introduction and objective
There are dual reasons for the emergence of BPH: an increase in smooth muscle tone as well as an increase in the size and growth of the prostate gland. Smooth muscle tone is treated using α1 adrenoreceptor antagonists to reduce urethral obstruction by relaxing contractile tissue of the prostate gland and perhaps the urethral muscle as well. However, relatively little is known about smooth muscle function in this organ and the mechanism and effectiveness of α adrenergic drugs and how they directly regulate contractility prostate gland smooth muscle itself, is equivocal. Hence the aim of the current study was to investigate the direct effect of clinically used α1 adrenoreceptor antagonists on prostate contractility in specimens from males with BPH, or prostate enlargement.
Methods
Transition zone tissue (10mm X 15mm) from the prostate gland was obtained from consenting patients undergoing radical prostatectomy. These patients are diagnosed with BPH (volume >70cc and pathology) and have low to moderate grade prostate cancer; they will have had radical prostatectomy to surgically treat both conditions. TZ tissue was placed into ice-cold RPMI medium supplemented with 5% fetal calf serum and antibiotics (penicillin at 300 units/ml, streptomycin at 300 μg/ml and amphotericin at 1 μg/ml). Contractile recordings were made from prostatic preparations (3mm X 10mm) using standard tension recording techniques as we have previously described.
Results
All specimens contracted spontaneously at a frequency of 2.2 +/- 0.4 contractions per minute; the duration of each contraction was >12 seconds (n=18). The basal tension was 4.4 +/- 0.4 mN and the amplitude (normalised for tissue weight) was 0.20 +/- 0.03 N/g. Epidemiological data show that the incidence of BPH is age related and rises in men as they become older. Preliminary data show an age related change in men from 50 to >60 yo such that there is an increase in amplitude (from 0.13 +/- 0.05 N/g to 0.21 +/- 0.03 N/g) and frequency (from 1.4 +/- 0.2 min-1 to 2.5 +/- 0.6 min-1) of the spontaneous smooth muscle contractions with age. Tamsulosin (0.3nM) and prazosin (1.0μM) failed to completely block spontaneous contractility in the TZ of the human prostate gland but appeared to reduce the amplitude of the spontaneous contractions to ~70 % of control (both n=4; p<0.05 Student's paired t test). In addition, there appeared to be variation in the response by individual patients.
Conclusion
The results in human tissues fully substantiate our work with guinea-pig tissues and consistently provide explanation for the aetiology of the increase in smooth muscle tone observed in patients with BPH. The variability in the response to α1 adrenoreceptor antagonists foreshadows the need to consider individual vs group responses to current pharmacotherapy.

Enhanced Ca^{2+}-sensing receptor function in idiopathic pulmonary arterial hypertension

A. Yamamura[1,2], Q. Guo[1], H. Yamamura[1,3], A.M. Zimnicka[1], N.M. Pohl[1], K.A. Smith[1], R.A. Fernandez[1], A. Zeifman[1], A. Makino[1], H. Dong[4] and J.X. Yuan[1]

[1]Department of Medicine, University of Illinois at Chicago, Chicago, IL, USA, [2]Kinjo Gakuin University School of Pharmacy, Nagoya, Japan, [3]Nagoya City University Graduate School of Pharmaceutical Sciences, Nagoya, Japan and [4]Department of Medicine, University of California, San Diego, La Jolla, CA, USA

Idiopathic pulmonary arterial hypertension (IPAH) is a rare, progressive, and fatal disease that predominantly affects women. The pathogenic mechanisms involved in the pulmonary vascular abnormalities (eg, arterial remodeling and sustained vasoconstriction) in IPAH patients remain unclear. A rise in cytosolic Ca^{2+} concentration ($[Ca^{2+}]_{cyt}$) in pulmonary arterial smooth muscle cells (PASMCs) is an important stimulus for pulmonary vasoconstriction and PASMC migration and proliferation (which subsequently cause pulmonary vascular wall thickening leading to the increase in pulmonary vascular resistance). Increased resting $[Ca^{2+}]_{cyt}$ and enhanced Ca^{2+} influx have been implicated in PASMCs from patients with IPAH. We examined whether the extracellular Ca^{2+}-sensing receptor (CaSR), a unique G protein-coupled receptor (GPCR), is involved in the enhanced Ca^{2+} influx and proliferation in IPAH-PASMCs and whether blockade of CaSR inhibits experimental pulmonary hypertension. Approval to use the human lung tissues and cells was granted by the Institutional Review Board of University of Illinois at Chicago and all experiments were approved by the Ethics/Animal Care Committee of University of Illinois at Chicago. In normal PASMCs superfused with Ca^{2+}-free solution, addition of 2.2 mmol/L Ca^{2+} to the perfusate had little effect on $[Ca^{2+}]_{cyt}$. In IPAH-PASMCs, however, restoration of extracellular Ca^{2+} induced a significant increase in $[Ca^{2+}]_{cyt}$. Extracellular application of spermine also markedly raised $[Ca^{2+}]_{cyt}$ in IPAH-PASMCs but not in normal PASMCs. The calcimimetic R568 enhanced, whereas the calcilytic NPS2143 attenuated, the extracellular Ca^{2+}-induced $[Ca^{2+}]_{cyt}$ rise in IPAH-PASMCs. Furthermore, the protein expression level of CaSR in IPAH-PASMCs was greater than in normal PASMCs; knockdown of CaSR in IPAH-PASMCs with siRNA attenuated the extracellular Ca^{2+}-mediated $[Ca^{2+}]_{cyt}$ increase and inhibited IPAH-PASMC proliferation. Using animal models of pulmonary hypertension, our data showed that CaSR expression and function were both enhanced in PASMCs, whereas intraperitoneal injection of the calcilytic NPS2143 prevented the development of pulmonary hypertension and right ventricular hypertrophy in rats injected with monocrotaline and mice exposed to hypoxia. In conclusion, the extracellular Ca^{2+}-induced increase in $[Ca^{2+}]_{cyt}$ due to upregulated CaSR is a novel pathogenic mechanism contributing to the augmented Ca^{2+} influx and excessive PASMC proliferation in patients and animals with pul-

monary arterial hypertension. Targeting CaSR in PASMCs may help develop novel therapeutic approach for pulmonary hypertension.

PCB375

TMEM16A currents in urethra smooth muscle

E. Bradley, T. Webb, M.A. Hollywood, K.D. Thornbury, N.G. McHale and G.P. Sergeant

Smooth Muscle Research Centre, Dundalk Institute of Technology, Dundalk, Ireland

Urethral smooth muscle generates spontaneous electrical slow waves that are thought to underpin contraction of this tissue (Hashitani et al., 1996). Several studies suggest that this activity is initiated by activation of Ca^{2+}-activated Cl^- channels (CACCs) in specialised pacemaker cells known as interstitial cells of Cajal (ICC, Sergeant et al., 2000). However, the exact contribution of CACCs to myogenic tone in the urethra has not yet been ascertained, in part, because their molecular identity has not been determined in this tissue. The purpose of the present investigation was to determine if the novel Ca^{2+}-activated Cl^- channel, TMEM16A encoded CACCs in rabbit urethral smooth muscle (RUSM). The patch clamp technique was used to record Ca^{2+}-activated Cl^- currents (I_{ClCa}) in freshly isolated ICC from the rabbit urethra and stably expressed TMEM16A currents in HEK 293 cells. In addition, tension recordings were made from strips of RUSM using a WPI Myobath system. All experiments were approved by the Dundalk Institute of Technology animal care and use committee. Data are presented as mean ± SEM.

Current-voltage relationships were obtained from HEK cells stably expressing human TMEM16A, cloned from the testes. These currents were inhibited by the novel TMEM16A inhibitor, T_{inh}A01 (10 μM) across the voltage range and in 5 cells T_{inh}A01 reduced the mean current evoked by a step to +100 mV from 1.27 ± 0.23 to 0.3 ± 0.06 nA ($p<0.05$, paired t test). Similarly, T_{inh}A01 (30 μM) reduced the peak I_{ClCa} evoked by a step to +50 mV in native ICC from a mean of 797 ± 200 pA to 253 ± 69 pA (n=5, $p<0.05$, paired t test). Urethral ICC develop spontaneous transient inward currents (STICs) when voltage clamped at -60 mV (Sergeant et al., 2000). The amplitude of these events were also inhibited by T_{inh}A01, from a mean of -647 ± 152 pA under control conditions to -30 ± 25 pA in the presence of the drug (n=6, $p<0.05$, paired t test).

Next we investigated the effect of T_{inh}A01 on contractions of RUSM evoked by electrical field stimulation at frequencies of 2, 4 and 8Hz (pulse width 0.3 ms, nominal amplitude 20 V). T_{inh}A01 significantly reduced the peak contraction evoked during 4Hz stimulation from a mean value of 2 ± 0.4 mN under control conditions to 0.4 ± 0.1 mN in its presence (n=9, $p<0.05$). In addition, T_{inh}A01 also decreased spontaneous myogenic tone in strips of RUSM by 0.4 ± 0.07 mN. Finally, contractions of RUSM evoked by exogenous application of phenylephrine (1 μM) were inhibited by T_{inh}A01 from a mean value of 8.9 ± 1.9 to 7 ± 1.4 mN (n=8, $p<0.05$). Taken together these data suggest that TMEM16A channels contribute to I_{ClCa} in urethral ICC and that these channels are crucially involved in the generation and modulation of urethral tone.

PCB376

Oxytocin reduces the tocolytic effect of magnesium sulphate in human myometrium

S. Arrowsmith[1], H. Wood[1], J. Neilson[2] and S. Wray[1]

[1]Department of Cellular and Molecular Physiology, University of Liverpool, Liverpool, UK and [2]Department of Women's and Children's Health, University of Liverpool, Liverpool, UK

Magnesium sulphate (Mg) *in vitro* directly relaxes smooth muscle including myometrium. It is thought to compete with Ca thus, inhibit L-type Ca channel entry and contractility. Currently, the clinical evidence for using Mg as a tocolytic agent, such as for threatened preterm labour, is questionable: A Cochrane systematic review concluded that Mg for tocolysis *in vivo* is ineffective(1). We investigated whether the presence of the hormone oxytocin, which also effects calcium signalling dynamics, alters the tocolytic capability of Mg on human myometrium *in vitro* and if the effect (if any) could be reversed with the oxytocin antagonist, atosiban.

Methods: Isometric tension recordings were performed on strips of myometrium (1x5x2mm) obtained from 10 pregnant women undergoing pre-labour Caesarean section (with consent and ethical approval). Paired strips from the same woman were superfused with physiological saline and the effect of increasing [Mg] from 1.2mM (control) to 12mM in the presence and absence of oxytocin (0.5nM) was compared by calculating the mean effective concentration causing 50% reduction in force amplitude of contraction (EC50). In a subset of experiments (n=4), the effect of increasing [Mg] in the presence of Atosiban (10^{-7}M) on oxytocin-induced contractions was compared to Mg alone.

Results: Elevated [Mg] produced a significant, dose-dependent inhibition of phasic, spontaneous myometrial contractions: EC50 2mM, complete inhibition achieved at 3.4mM. In contrast, application of oxytocin significantly increased the [Mg] required to affect contractions, such that at 2mM Mg there was little reduction in force amplitude (98.5% of control). The EC50 was 10mM and full abolition of activity in all but 2 cases was achieved at 12mM (i.e.10 times greater than [Mg] in control solution). The addition of Atosiban reduced the [Mg] at which oxytocin-induced contractions were inhibited, from 12mM to 6mM.

Conclusion: *In vitro*, Mg at therapeutic doses (<2.5mM) significantly reduces spontaneous contractility of the myometrium however, the effect of Mg is significantly reduced in the presence of oxytocin; it is only effective at suprapharmacological concentrations. We suggest that the changed hormonal milieu in pregnancy, specifically towards oxytocin, underlies the poor tocolytic ability of Mg *in vivo*. Preliminary data suggest atosi-

ban may reduce the EC50 for Mg and raises the question of whether, clinically, oxytocin antagonists should be used in combination with Mg for uterine tocolysis.

PCB377

Role of BDNF-TrkB signaling in neuromuscular junction remodeling

G. Sieck, L. Ermilov, D. Sieck, W. Zhan and C. Mantilla

Mayo Clinic, Rochester, MN, USA

Our working hypothesis is that synaptic remodeling at the neuromuscular junction is an active process that ensures proper matching between presynaptic activity and postsynaptic response under varying conditions. In this study we specifically hypothesize that this synaptic remodeling requires TrkB signaling at the presynaptic terminal. TrkB signaling requires the presence of the full length receptor (TrkB.FL) and is dependent on phosphorylation and activation of a tyrosine kinase. Using laser capture microdissection coupled with quantitative RT-PCR and protein analyses, we found that TrkB.FL is present only in phrenic motoneurons, but not in diaphragm muscle fibers. Using a specific siRNA we knocked down TrkB expression in phrenic motoneurons and found impairment of neuromuscular transmission that was associated with altered presynaptic remodeling. Using mice expressing knockin alleles that allow selective inhibition (via 1NMPP1 treatment) of Trk kinase activity (TrKBF616A) we also demonstrated impaired neuromuscular transmission and altered presynaptic remodeling. In both cases, the impairment in presynaptic remodeling involved apparent retraction of axon terminals with accumulation of neurofilament. These changes in presynaptic terminals occurred in the absence of any alterations in muscle structure or contractile function. Using a-bungarotoxin to identify postsynaptic cholinergic receptors, there was no apparent change in end-plate area or cholinergic receptor density after 2 weeks. However, previously we did observe changes in postsynaptic ultrastructure including reduced gutter depth and branching complexity which may be attributed to presynaptic effects. Together, these results support the role of endogenous TrkB signaling in neuromuscular junction remodeling.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB378

Effects of 8-Br-cAMP and forskolin on spontaneous activity in isolated rabbit corpus cavernosusm myocytes

C. McCloskey, G.P. Sergeant, M.A. Hollywood, N.G. McHale and K.D. Thornbury

Smooth MuscleResearch Centre, Dundalk Institute of Technology, Dundalk, Co Louth, Ireland

When corpus cavernosum smooth muscle cells (CCSMC) relax, the corporal sinuses fill with blood causing penile erection. Thus knowledge of the mechanisms that cause corpus cavernosum relaxation is essential for understanding and treating erectile dysfunction. Although NO/cGMP is the main inhibitory pathway involved in penile erection, when the NO receptor is knocked out other pathways can compensate (Groneberg et al. 2013). One possibility is that cAMP production, in response to agonist such as adenosine, VIP or PGE1 may mediate relaxation. However, the effects of cAMP on CCSMC have not been adequately characterised. The aim of this study, therefore, was to characterise the effects of cAMP on spontaneous Ca2+-activated Cl- currents, spontaneous depolarisations and Ca2+ events in isolated CCSMC. All of the experiments were approved by DkIT Animal Care Committee. Male New Zealand white rabbits were euthanized with pentobarbitone (iv) and their corpora cavernosum removed. CCSMC were isolated with collagenase and perfused with physiological saline at 37oC. Their electrical events were studied using the patch clamp technique, and their intracellular Ca2+ events were recorded by loading them with Fluo-4AM (500 nM) and imaging with an EMCCD camera attached to a spinning disk confocal microscope.

When CCSMC were voltage clamped at -60 mV, they developed regular spontaneous transient inward currents (STICs), mediated by Cl- channels. 8-Br-cAMP (1 mM) reduced their amplitude from 193± 33pA to 62±39 pA (n=5, P<0.05) and frequency from 20.4 ±6.6/min to 6.4±3.0/min (P<0.05). Forskolin (1 μM) also decreased the frequency from 41.0 ± 13.6 to 14 ± 5.0/min (P<0.05, n=5), but increased amplitude from 323±102 pA to 613±153 pA (P<0.05). When held in current clamp mode, the cells developed regular spontaneous transient depolarisations (STDs). There were reduced in frequency both by 8-Br-cAMP (from 26.4±8.2/min to 11.6±6.1/min, n=5, P<0.05) and forskolin (from 42.4±10.8/min to 12.0±6.1/min, n=5, P<0.05), but both drugs increased the mean duration at half maximum amplitude (8-Br-cAMP from 140±60 ms to 309±136 ms, n=5, P<0.05; forskolin from 340±111 ms to 557±95, n=4, p<0.05).

CCSMC also developed robust global intracellular Ca2+ events that extended along the entire length of the cell. These were also inhibited by 8-Br-cAMP, which reduced their frequency from 15.6±2.9/min to 2.7±1.2/min, (n=5, p<0.05) and reduced basal Ca2+ (F/F0) from 1 to 0.70±0.04 (P<0.05, Wilcoxon). Similarly, forskolin decreased frequency from 19.8±3.4/min to 6.0±1.5/min (n=6, P<0.05) and basal Ca2+ from 1 to 0.66±0.04 (n= 6, P<0.05).

These results suggest that cAMP may reduce tone in CCSMC by inhibiting spontaneous pacemaker activity. This is similar to the action of NO/cGMP described previously (Sergeant et al. 2009).

PCB379

Angiotensin 1- 7 inhibits angiotensin II –induced calcium signal in pulmonary arterial smooth muscle cells

O.A. Ogunbayo, H. Yang and M.A. Evans

Centre for Integrative Physiology, University of Edinburgh, UK, Edinburgh, UK

Angiotensin (Ang) II, a vasoactive peptide and one of the main components of the rennin-angiotensin system (RAS), plays a very significant role in regulating blood pressure and may drive in part, the progression of pulmonary arterial hypertension (1). PAH is caused by functional and structural modifications in the pulmonary vasculature, resulting in increased resistance. This remodeling is accompanied by endothelial dysfunction, smooth muscle cell activation and recruitment of circulating progenitor cells (2). PAH contributes to the development of cardiovascular complications and despite advances in antihypertensive drug therapy, uncontrolled hypertension is still prevalent globally (3). Ang 1- 7, an ACE2 (Angiotensin Converting Enzyme 2)-derived metabolite of Ang II exerts cardioprotective effects and is regarded as a potential antagonist of Ang II (1, 4).
Using methods described previously (5), we assessed the mechanism of Ang II–induced Ca2+ signalling in acutely isolated rat pulmonary arterial smooth muscle cells (PASMCs) and the effect of Ang 1-7 on these responses. Extracellular application of 3μM Ang II evoked a robust Ca2+ transient in acutely isolated rat PASMCs, the Fura-2 fluorescence ratio (F340/F380) increasing from 0.44±0.01 to 1.19±0.05 (n=67). Ang II-evoked Ca2+ transients were abolished by the AT1R blocker Losartan (10μM; F340/F380 ratio increasing from 0.68±0.05 to 0.81±0.08 (n=9)), but remained unaffected by the AT2R blocker PD123319 (50μM; F340/F380 ratio increasing from 0.55±0.04 to 1.36± 0.06 (n=9)). Surprisingly, although Ang 1-7 (3μM) had little effect on intracellular calcium in its own right, it significantly attenuated Ang II-evoked Ca2+ transients; Ang II increasing the F340/F380 ratio from 0.46±0.04 to 0.72±0.07 (n=23) in the presence of Ang1-7.
We conclude that Ang II induces Ca2+ signals in rat PASMCs by activating AT1Rs and thus induces voltage-gated Ca2+ influx via L-type Ca2+ channels and SR Ca2+ release via RyRs, and in a manner that is be opposed by Ang 1- 7.

Investigation of role of "funny" (If) current in spontaneous and agonist-stimulated contractions in isolated rat myometrium

A. Ayar[1], O. Gedikli[1], A. Kurt[1], R. Sahan[1] and M. Ozcan[2]

[1]Department of Physiogy, Faculty of Medicine, Karadeniz Technical University, Trabzon, Turkey and [2]Department of Biophysics, Faculty of Medicine, Firat University, Elazig, Turkey

Mechanisms underlying generation of spontaneous myometrial contractions are poorly understood. Although morphological evidence indicates existence of interstitial cell of Cajal-like cells in myometrium it remains unclear whether these cells are involved in uterine pacemaking. The "funny" (If) current (or funny channel or pacemaker current), originally described in sinoatrial node and Purkinje fibers, are currently investigated for their potential role(s) in smooth muscles with generation of spontaneous phasic activity. The aim of this study was to obtain pharmacological evidence for the possible role of funny ion channels in spontaneous and agonist - stimulated contractions in isolated rat myometrium using the pharmacological blocker ivabradine. Myometrial strips were removed from nonpregnant rats and placed in an organ bath containing physiological salt solution at 37°C and pH 7.4, constantly bubbled with 95% oxygen-5% carbon dioxide and isometric contractions were recorded. Effects of cumulative concentrations of ivabradine (1, 3 and 10 uM) on amplitude, area-under contractile curve and frequency of spontaneous and oxytocin-and prostaglandin F2 alpha-induced contractions were studied by 10-minutes intervals. Statistical analysis was performed using one –way ANOVA and post-hoc tests were performed with Tukey HSD. Ivabradine (at any cumulative concentration) did not have any significant effect on either contractile parameter (amplitude, AUC or frequency) of spontaneous (n=6) and agonist induced contractions stimulated by oxytocin (n=7) or prostaglandin F2alpha (n=7). Results from this in vitro study involving myometrial strips from nonpregnant rat indicates that, funny currents does not have any significant role(s) in spontaneous contractions and nor they involve in agonist-induced phasic contractions.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB381

Enhanced contractility in the rat diabetic bladder: correlation with cellular remodelling

L. Johnston, K.M. Monaghan, B. McDonnell and K. McCloskey

Queen's University Belfast, Belfast, UK

Diabetes is an increasingly prevalent condition worldwide and is associated with a range of comorbidities including bladder dysfunction (1). The diabetic bladder exhibits an overactive phenotype arising from neurogenic and myogenic mechanisms; moreover, changes in the cellular architecture of the bladder wall occur. The purpose of the present study was to

investigate cellular remodelling in the rat diabetic bladder and correlate with in vitro contractility.
Bladders were removed from Sprague-Dawley female rats – either non-injected controls or diabetics following a single injection of streptozotocin (in accordance with local ethical committee approval and with the UK Animal Procedures Act. Tissue strips were prepared as full thickness or detrusor layers (mucosal layer removed) and studied with in vitro myography. Tissues were also processed for immunohistochemistry. Data are presented as mean±SEM and analysed by ANOVA/Student's t-test.
Diabetic rats (N=8) had significantly lower body mass than non-injected controls (N=6; p<0.042) however; mean bladder /body mass ratio for diabetics (1.96±0.42, N=8) was significantly greater than controls (0.48±0.05, N=6; P=0.01) indicative of smooth muscle hypertrophy. This was confirmed by imaging protocols. Spontaneous activity in full thickness and detrusor strips from diabetic bladder was significantly greater than controls. Control contraction amplitude in full thickness strips was 0.12±0.03g, n=8, N=4) compared with diabetic strips 0.22±0.03g (n=12, N=6, p=0.017). Neurogenic contractions, evoked by electrical field stimulation in the same preparations, were of greater amplitude in diabetic strips across a range of frequencies in both full thickness and detrusor preparations. Contraction amplitude at 16Hz in full thickness control strips was 3.94±0.52g (n=8, N=4), smaller than in diabetic strips 5.96±0.43g (n=12, N=6, P<0.01). Carbachol-evoked contractions (1μM) were significantly greater in diabetic strips whether or not the mucosal layer was present. In full thickness control strips, carbachol-evoked amplitude was 1.49±0.29g (n=10, N=5, p<0.05) compared with 3.01±0.42g (n=12; N=6; p<0.05). Extensive networks of Interstitial Cells (IC), labelled with PDGFRα were distributed in the lamina propria and detrusor layer of control bladders. In diabetic bladders, PDGFRα+-IC were notably disrupted in the detrusor layer but were present in the in the lamina propria.
In conclusion, enhanced contractility in the diabetic bladder; spontaneous activity, neurogenic and agonist-evoked contractions occurs in the presence or absence of the mucosal layer. This altered contractility is correlated with smooth muscle hypertrophy and disruption of detrusor IC.

PCB382

Retention of caveolae morphology during physiological mechanosensitisation of resistance arteries

M. Sweeney, C. Nicholson and M.J. Taggart

Institute of Cellular Medicine, University of Newcastle, Newcastle upon Tyne, UK

Caveolae are Ω-shaped invaginations of the plasma membrane containing a variety of proteins that have been suggested to participate in the orchestration of many signal transduction events including that of mechanosensitisation. For example, it has recently been reported that cultured HeLa cells respond to hypo-osmotic swelling by rapid (5 mins) disassembly of caveolae and membrane 'flattening' (Sinha et al (2011)). Resistance artery smooth muscle cells have abundant caveolae (Tong et al (2009)) and are highly mechanosensitive. This myogenic reactivity is commonly evinced as an initial dilation to an elevation in intralumenal pressure followed by an active vasoconstrictive response to return the vessel towards its initial diameter. It is physiologically important in maintaining tissue blood flow and minimising pre-capillary blood pressure surges. The purpose of this study was to determine if the morphological appearance of caveolae in vascular smooth muscle cells of resistance arteries, *in situ*, were altered in response to physiological mechanical stress, i.e. an increase in intravascular pressure. Uterine artery segments dissected from 3 month old C57BL mice were mounted in a pressure myograph (physiological salt solution, 5%CO_2-air, 37°C) for continuous monitoring of diameter. Intravascular pressure was initially set at 60mmHg and arteries allowed to equilibrate for 60 mins (diameter=156.2(±15.3)μm, mean(±SEM), n=10) before being exposed to physiological mechanical stress by increasing the intravascular pressure to 120mmHg. This caused vasodilation with a peak of +0.19 (±0.04)-fold change in diameter from 60mmHg. Subsequent myogenic contraction constricted vessel diameters to less than that (-0.13 (±0.05)-fold change c.f. to 60mmHg) previously observed at 60mmHg. Arterial segments in three conditions (i) resting 60mmHg intravascular pressure, (ii) 120mmHg intravascular pressure at peak dilation, (iii) 120mmHg intravascular pressure with myogenic contraction, were fixed within 1-2 seconds and processed for electron microscopic examination of caveolae. In each condition 3-5 segments (two sections of each) were examined. Figure 1 shows one electron micrograph of vascular smooth muscle cells from each of the three conditions. In each, rows of caveolae could be observed along the length of the plasma membrane of the vascular smooth muscle cells. There was no evidence of flattening of the caveolae structure in any sections examined. These results indicate that the integrity of caveolae is retained in vascular smooth muscle cells exposed to an acute, physiological mechanical stress. In addition to data from non-vascular smooth muscle (Gabella and Blundell (1978)), these results suggest that caveolae morphology can be retained during physiological mechanosensitisation.

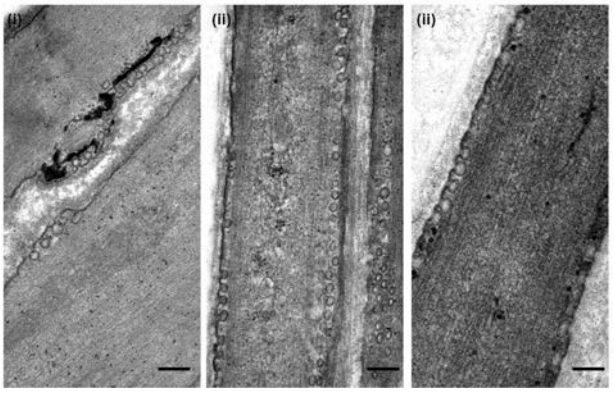

Figure 1. Electron micrographs showing caveolae in vascular smooth muscle cells in each condition. (i) 60mmHg resting, (ii) 120mmHg peak dilation, (iii) 120mmHg myogenic contraction. Black bar = 200nm.

PCB383

Interrelation between pyeloureteral and peribladder zones pacemaker activity

L. Simonyan and K. Kazaryan

Smooth muscle physiology, L.A.Orbeli Institute of Physiology, Yerevan, Armenia

The ureteral smooth muscle is characterized by a highly autonomous zone, acting as a pacemaker in pyeloureteral anastomosis. Stable slow automaticity promotes the subsequent emergence of spikes along with the ureter, which in turn provides the primary functional significance of the organ is peristaltic activity (1).
The ability of each ureteral individual cell to generate spontaneous electrical waves of excitation can assume about the existence of various rhythmogenic zones (2).
The subsequent identification of automatism also in the bordered area to the bladder pushes the task of studying the mechanisms of interaction between the two rhythmogenic regions in order to ensure functional activity of the whole ureter (3).
All experiments were carried out in situ on white "Albino" rats (300-350g, n=12) anesthetized by Nembutal (50-55mg/kg) intraperitoneally. The ureter was denervated by the section of the splanchnic and pelvic nerves roots. The spike activity was registrated with silver bipolar electrodes, the slow wave activity with silver monopolar ball electrodes by 8-channel EEG. Analysis of the results was carried out using modern packages Lab View software and Origine-8. All experiments were verified by the t-student test.
The histamine was used (Sigma-Aldrich, Germany). The drug was injected into the femoral vein (in 0.2 ml solution) in different concentrations: 10-6, 10-5 and 10-4 Mol/l (n=9).
Morpho-histochemical studies were performed by the orthophosphates detection method. This method allows tracking the smallest functional changes in cellular structures of the organ.
All procedures are performed according to "principles of laboratory animal care" (NIH publication 85-23 revised 1985). The killing was carried out with a lethal dose of anesthetic.
The automatism of perirenal zone is 22±2.05 and peribladder:11±0.67, n=13, $p<0.01$ under normal conditions in rat. The effect of disturbances of propagating spontaneous activity of pyeloureteral anastomosis to the bladder has been studied. The local cooling of the middle portion of ureter showed a small increase (up to 20-22%, n=10) of slow waves genesis of peribladder zone. Conduction disturbance between two ending zones of the rat ureter is also realized by the transection of ureter in its middle part. After a certain period of time in all cases, there was decrease in the frequency of primary pacemaker: 17±1.8 oscillations/min, $p<0.01$ and, respectively, passing the spikes. However, there is some increased frequency of slow waves in the junction of the ureter to the bladder (4). These data show the impact of the primary ureteral rhythmogenesis on the automatism of distal zone: excitatory propagating waves some reduce the genesis of distal autonomous waves.
Of all the variety of physiologically active compounds, changing the excitability of the membrane of ureteral smooth muscle tissue, the histamine causes a certain interest which is able not only to regulate spontaneous activity, but create slow pacemaker oscillations of membrane potential. Such regulation is associated with a high prevalence in the tissues of this organ with one hand H1-histamine receptors, and with another- the presence of mast cells capable of releasing histamine (5).
The subsequent injection of histamine into the femoral vein of the animal at a concentration of 10-4Mol/l leads to a sharp change of certain characteristics of both types of electrogenesis. The increasing rhythm as slow waves as well action potentials has been observed: 24.5±2.6 oscill/min (n=9) increase to 44.3±4.2 oscill/min, n=12, $p<0.01$. It is noted also the improving of conductivity and each spike that occurs on the base of a slow wave, as a rule, reaches the peribladder zone.
The regulatory role of histamine is expressed by activation of ureteral renal zone rhythmogenesis. It is also shown improvement in the conductivity of the propagating wave of excitation to the bladder, and the disturbed coordination of spike activity with slow waves in bordered area with bladder. Morphological analysis of the effect of histamine showed intense staining of cellular elements of the muscular layer in the area of kidney and bladder sections of ureter, which indicates a high functional status of these areas.
Slow-wave activity of peribladder area can be connected to the above-noted leadership role under the suppression of kidney automatism, or transection of the ureter. Lack of coordinated activity between the two ending zones of the ureter may indicate a backup role of peribladder pacemakers in norm. The peribladder area of the ureter, despite the relatively low-frequency of spontaneous activity in comparison with the basic renal pacemaker is characterized by polymodality and may provide a functional role of the ureter.

Characterisation of spontaneous activity in the human prostate gland

B. Chakrabarty[1], M. Frydenberg[4], N. Lawrentschuk[3], G. Risbridger[2] and B. Exintaris[1]

[1]Drug Discovery Biology, Monash Institute of Pharmaceutical Sciences, Melbourne, VIC, Australia, [2]Department of Anatomy and Developmental Biology, Monash University, Melbourne, VIC, Australia, [3]Department of Surgery, University of Melbourne, Melbourne, VIC, Australia and [4]Department of Surgery, Monash University, Melbourne, VIC, Australia

Introduction: Changes in spontaneous electrical activity promote an increase in prostatic tone and contractility in the guinea pig prostate gland (Dey et al., 2009). These contractions are likely to be regulating the resting smooth muscle tone of the prostate gland, a major component implicated in Benign Prostatic Hyperplasia (BPH); the most common neoplasm in men. BPH occurs in the transition zone (TZ), as opposed to the peripheral zone (PZ). However, the aetiology of BPH remains poorly understood, and the fundamental reason there is an increase in prostatic smooth muscle tone with age remains unknown. This study focuses on understanding the changes in basic physiology underlying the increase in prostatic tone with age, to ultimately identify a novel therapeutic target that targets the origins and underlying cellular mechanisms of spontaneous activity to potentially treat BPH. Our overall hypothesis is that age-related changes in the mechanisms regulating spontaneous activity of the prostate gland, significantly contribute to the pathogenesis of BPH. In this study, we characterised the spontaneous contractile activity in prostate specimens from 14 men.

Methods: TZ and PZ specimens were obtained from consenting patients undergoing a prostatectomy. Subsequent recordings were made from prostatic preparations (3mmx10mm) using conventional tension recording experiments (Dey et al., 2010).

Results: All specimens from the TZ displayed spontaneous contractions at 1.94±0.19 min^{-1}, with an average amplitude of 0.20±0.03 N g^{-1} (n=14). Spontaneous contractions were abolished in 71% of TZ preparations by an L-type Ca2+ channel blocker, 1μM nifedipine (n=7). Application of neurotransmission blockers, 1μM tetrodotoxin (n=5), 1μM guanethidine (n=4), and 1μM atropine (n=6), had no significant effects on frequency of spontaneous contractions in the TZ (Student's paired t-test, P>0.05). Spontaneous contractions in the PZ were significantly more frequent at 4.64±0.49 min^{-1}, in comparison to the frequency of spontaneous contractions at 2.09±0.41 min^{-1} in the TZ from the same patients (Student's paired t-test, P<0.05, n=5).

Conclusions: This study suggests that spontaneous contractions in the TZ may be myogenic in nature. Furthermore, mechanisms regulating spontaneous contractility may be zone-specific. This study provides novel insight into the basic physiology of the human prostate gland.

PCB386

Enhancement of BK channel activity in vascular smooth muscle (VSM) cells by cGMP-dependent protein kinase-induced phosphorylation of identified serine residues

B.D. Kyle, S. Hurst, P.S. Dhaliwal and A.P. Braun

Physiology and Pharmacology, University of Calgary, Calgary, AB, Canada

Background: VSM excitability is regulated by large conductance, calcium-activated K^+ (BK) channels. NO elevates VSM cytosolic cGMP levels, and activates the type I cGMP-dependent protein kinase (cGKI) to phosphorylate the BK channel at key residues. The nature and location of residues phosphorylated remain unresolved, along with their functional importance to the channel enhancement process.

Purpose: To identify key phosphorylatable residues underlying the NO/cGMP/cGKI-mediated BK channel enhancement in VSM and correlate their functional contribution with their phosphorylation status.

Procedures: Proximity ligation assay (PLA) was used to show BKα subunit and cGKI protein co-localization (spatial restriction <40 nm). *In vitro* phosphorylation of immune-purified wild type (WT, GenBank Acc# U09383) BK channel by cGKIα was characterized biochemically using radiolabeled γ^{32}ATP to identify phosphorylated residues using a combination of phosphoamino acid (AA) analysis and peptide mapping. Identified residues were individually replaced and mutant channels were transiently-transfected into A7r5 cells (Lipofectamine method), and studied under cell-attached patch clamp using 1s voltage ramps (-30mV to 200mV, 0mV holding potential).

Results: Freshly isolated rat cerebral VSM cells exhibited PLA fluorescence indicating BKα-cGKI association. Extensive association was also observed in A7r5 cells transiently-expressing BK channels. Non-transfected cells showed no measurable fluorescence.

Biochemical characterization of BK channels phosphorylated by purified cGKI *in vitro* revealed ^{32}P-labeled phosphoserine residues at "Arg/Lys-Arg/Lys/X-X-pSer" locations (where X is any AA). Using these criteria, 9 potential Ser residues were identified within the BKα subunit (see Figure 1). For each location, the critical Ser residue was mutated to Ala and mutant channels were expressed in A7r5 cells for functional analysis. Phosphorylation of WT BK channels by cGKI using γ^{32P}-ATP revealed a major ~120 kDa ^{32}P-labelled band corresponding to the BKα subunit. However, the ^{32}P-labeling intensity was clearly reduced in 3 mutant channels (25%, 50% and 60% reductions at Ser691, Ser873 and Sers1111-1113, respectively), indicating multiple phosphorylation sites.

Recordings from A7r5 cells expressing WT BK channels confirmed current enhancement to NO/cGMP/cGKI pathway stimulation (spermine-nonoate, 5 μM; db-cGMP, 100 μM). However, BK channels containing Ser to Ala substitutions at each of the 3 sites exhibiting low ^{32}P-labeling intensities exhibited no enhancement.

This study uncovers a definitive molecular mechanism explaining the BK channel enhancement following cGMP production *in situ*.

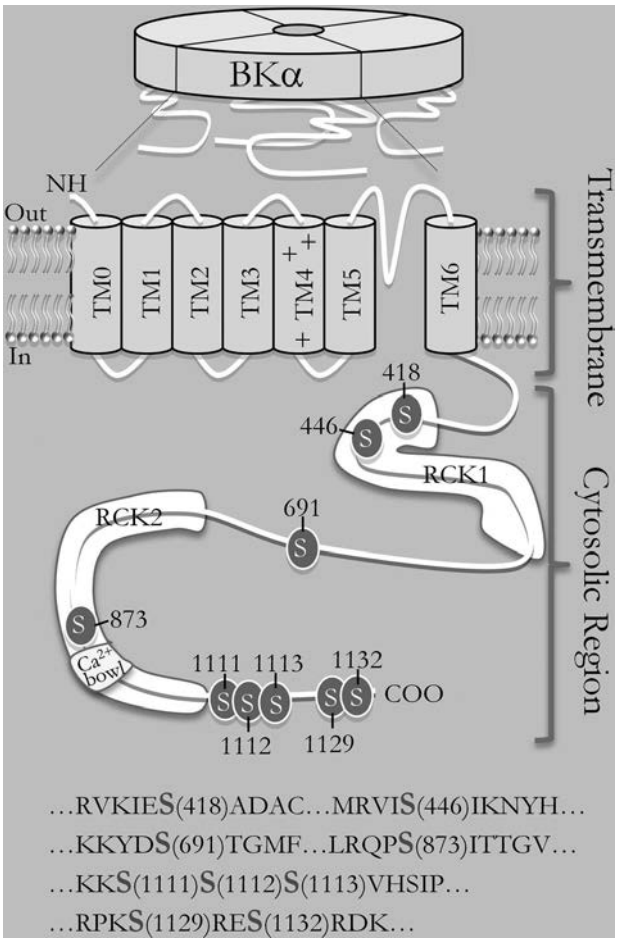

Figure 1 - BKα subunit Ser to Ala mutations; numbering reflects the predicted AA sequence of the BKα subunit cDNA, beginning with the N-terminal sequence MDALI...

Abnormal phosphorylation of myosin light chain phosphatase and myosin downstream of Rho-associated kinase contributes to the dysfunctional cerebral myogenic response of Goto-Kakizaki rats

K.S. Abd-Elrahman[1,2], E.J. Walsh[1,2], M.P. Walsh[1,3] and C.C. William[1,2]

[1]Smooth Muscle Research Group, University of Calgary, Calgary, AB, Canada, [2]Physiology and Pharmacology, University of Calgary, Calgary, AB, Canada and [3]Biochemistry and Molecular Biology, University of Calgary, Calgary, AB, Canada

The myogenic response of cerebral arteries is responsible for intravascular pressure-dependent control of blood flow to the brain1. This mechanism depends on cellular processes intrinsic to vascular smooth muscle cells (VSMCs) including: 1) Ca2+ influx, Ca2+- dependent activation of myosin light chain kinase, and phosphorylation of the 20 kDa regulatory light chains (LC20) of myosin, and 2) Rho-associated kinase (ROK)-dependent phosphorylation of the myosin targeting subunit (MYPT1) of myosin light chain phosphatase and suppression of the phosphatase activity2. Inappropriate regulation of these intrinsic mechanisms leading to dysfunctional control of cerebral arterial diameter may contribute to ischemic and hemorrhagic stroke in type 2 diabetes (T2D)3. Here, we used the Goto-Kakizaki (GK) rat model of T2D to determine if specific alterations in LC20 and MYPT1 phosphorylation contribute to dysfunctional control of cerebral arterial diameter. Rats were killed by halothane inhalation and exsanguination. Endothelium-denuded middle and posterior cerebral arteries of 8-10 and 18-20 week old GK and Wistar (WR) control rats were studied by pressure myography to detect pressure-dependent alterations in diameter (n=8), and by western blotting to quantify changes in LC20 and MYPT1 phosphorylation levels at 10, 60 and 120 mmHg (n=6)4. Values were expressed as mean±SEM and compared by ANOVA. Pressure-dependent increases in phospho-LC20 (from 26±0.5% to 38±1% and 49±1%; $p<0.05$) and phospho-MYPT1-T855 (from 1.0 to 2.0±0.15 and 2.8±0.18 normalized units; $p<0.05$) were detected at 10, 60 and 120 mmHg in vessels of 8-10 and 18-20 wks WR. Vessels of 8-10 wks GK had a compromised myogenic response, with enhanced constriction at low pressure and forced dilation at >100 mmHg, that progressed to a loss of myogenic tone in 18-20 wks GK. Phospho-MYPT1-T855 was elevated at 10 mmHg in 8-10 wks GK compared to WR (1.42±0.04-fold; $p<0.05$), and no increase was detected with pressure elevation to 60 or 120 mmHg (1.54±0.1 and 1.45±0.12). Phospho-LC20 was similarly elevated at 10 mmHg (35±1.8%) in 8-10 wks GK vessels, but no increase was detected on pressure elevation to 60 or 120 mmHg (40±1.9% and 37±2%, respectively). Phospho-LC20 and phospho-MYPT1-T855 levels of 18-20 wks GK and WR were not different at 10 mmHg, but a pressure-dependent increase in phosphorylation was not detected in GK. Inhibition of ROK with H1152 (0.5 μM) abolished the enhanced constriction at low pressure in 8-10 wks GK and suppressed the residual tone of vessels from 18-20 wks GK. Our findings suggest that a progressive dysfunctional control of ROK activity, and consequently inappropriate MYPT1 and LC20 phosphorylation, contribute to the abnormal myogenic response in cerebral resistance arteries of T2D GK rats.

PCB388

Alterations to spontaneous activity during mild, moderate and severe heating of isolated pig bladder preparations

D. Kitney, R.I. Jabr and C. Fry

Biochemistry and Physiology, University of surrey, Surrey, UK

Detrusor overactivity is a highly prevalent disorder severely affecting patient quality of life and is significantly associated with increased spontaneous activity in isolated bladder wall preparations. Therefore reducing spontaneous activity offers a means to relieve detrusor overactivity. Previously, we have shown that mild heating (42°C) of isolated bladder strips reversibly reduced spontaneous activity without tissue damage and we have tested the hypothesis that greater heating to 46°C (moderate) and 50°C (severe) exerts more profound reduction.

Pig bladders were obtained from a local abattoir and stored in cold Tyrode's solution (95%O_2:5%CO_2,4°C). The ventral wall was opened longitudinally and bladder wall preparations (10x20mm) were dissected and mounted in a horizontal trough superfused with Tyrode's (10ml/min). Isometric contractions were recorded at 37°C or during heating, generated by a heating coil placed directly above the superfusate surrounding the strip. Strips were exposed to either repeated 15 minute 50°C exposures or successive 42, 46 and 50°C with 30 minutes at 37°C between interventions. The amplitude, area under the curve (AUC) and frequency (*f*) of spontaneous contractions were measured for 10 minute periods at the end of control or heating periods. Time controls were done with no heating. Data are mean±S.D., the null hypothesis was rejected at $p<0.05$ using paired Student's *t*-tests.

Repeated exposure of severe heating increased the amplitude and AUC (156.1±95.2% and 148.5±110.9% of control, respectively; n=7). There was no recovery during return to 37°C but subsequent heat exposures further increased the amplitude and AUC. By contrast, mild heating to 42°C reduced both the amplitude and AUC to 41.5±20.7% and 43.2±29.2% of that at 37°C; n=3. Recovery to 37°C was incomplete after 30 minutes. Moderate heating to 46°C had no significant effect on either the amplitude or AUC but there was a significant increase during the recovery phase (119.8±15.5% and 118.9±24.4% of control, respectively; n=3). There was no effect on *f* during heating or upon return to 37°C.

These experiments show that the magnitude to which isolated bladder strips are heated have profoundly different effects on the magnitude of spontaneous contractions. Relatively mild heating to 42°C attenuated the amplitude of contractions, an effect that persisted for at least twice the duration of the heating interval itself. However, high heating (46 and 50°C) increased contraction amplitude, an effect that also persisted following the intervention. This implies that heating influences detrusor contractility by several mechanisms that are currently under investigation. Moreover, the design of heating paradigms to regulate spontaneous activity requires precise temperature ranges to be applied to the bladder.

PCB389

Inhibitory effect of visfatin and leptin on human and rat myometrial contractility

S. Mumtaz[1,2], S. AlSaif[1], S. Wray[1] and K. Noble[1]

[1]Cellular and Molecular Physiology, University of Liverpool, Liverpool, Merseyside, UK and [2]Physiology, Shifa College of Medicine, Islamabad, Federal Capital, Pakistan

Adipokines, active substances secreted from adipocytes influence metabolic functions. Their levels have been shown to alter in pregnancy and it has been suggested that their dysregulation could be associated with complications of pregnancy, including gestational diabetes. Visfatin, is a novel adipokine (originally known as pre-B cell colony-enhancing factor) with multiple functions including insulin mimetic effects, and it has been found to have altered plasma levels in obese women and during gestation. Leptin, one of the best characterised adipokines, has been reported to decrease contractility of the myometrium. We have therefore investigated the effect of visfatin on myometrial contractility and compared them to leptin. Myometrial strips from either term pregnant women having a caesarean section (with informed consent and ethical approval) or humanely killed rats were dissected, superfused with Krebs and the effects of visfatin (500pM- 25nM) or leptin (1nM-1μM) were studied. After establishment of regular contractions the tissue was incubated for control and test response at 37oC for 20mins. In pregnant human myometrium, visfatin at 1nM had little effect on contractility but compared with controls (100%), 10nM produced a significant (unpaired T Test) decrease in the 20 min integral of spontaneous (64±19%, n=13; P=0.02) and oxytocin-induced contractions (55.3± 9%, n=5; P=0.02), mean ± sem. Leptin at this concentration (10 nM) had no effect and at higher concentration of (1μM) produced a smaller inhibitory effect of (~ 80% controls, n=4) on contractions of rat and human myometrium. Preliminary data shows that the inhibitor FK-866 in the presence of visfatin in human myometrium attenuated the inhibitory effect of visfatin by ~ 60% (n=4). These data are the first to show that visfatin can inhibit myometrial contractility and that it may do so more potently than leptin. The visfatin inhibitor FK-866 reduces the inhibition of contraction by visfatin which suggests that visfatin is acting through the NAD-dependent pathway in myometrium. The data suggests that increased output of visfatin and leptin in obese pregnant women may impair uterine contractility resulting in an unplanned Cesarean delivery.

Prolonged elevation of cAMP enhances spontaneous contractility in human myometrium from pregnant women at term

P.F. Lai[1], R.M. Tribe[2] and M.R. Johnson[1]

[1]Department of Obstetrics & Gynaecology, Imperial College London, London, UK and [2]Women's Health Academic Centre, Kings College London, London, UK

Myometrial contractions in vitro can be inhibited by transient [cAMP] elevation. 48 h exposure to iloprost has been reported to enhance oxytocin-induced contractions in human tissue via increased [cAMP] and PKA activity (1). We have shown cAMP agonists enhance COX-2 expression in human myometrial cells via MAPK signalling cascade (2). The impact of prolonged exposure to cAMP agonists on human myometrial tissue spontaneous contractility has not been demonstrated, despite growing interest in the use of [cAMP]-elevating therapies to prevent preterm labour.

In the present study, human myometrial tissue samples were obtained (informed written consent) from women undergoing caesarean section (37-42 weeks, non-labour, TNL; n=88). Tissue strips were incubated in serum-free DMEM, under tension (5.9-7.9 mN) for 24 and 48 h with rolipram, forskolin, 8-bromo-cAMP, dibutyryl cAMP, 6-Bnz-cAMP and iloprost, plus vehicle controls (DMSO or H2O). Contractile activity was subsequently measured using an isometric organ bath. Mean integral tension (mean ± SEM) and related contraction parameters were analysed. Acute (1 h) exposure of myometrial tissue to cAMP agonists was also assessed. Statistical significance was tested using a Wilcoxon test.

Our experiments showed that pre-treatment (24 h) with 1 mM 8-bromo-cAMP, 1 μM rolipram or 10 μM rolipram resulted in 5.2, 3.4, and 2.8 -fold greater spontaneous contractile activity than vehicle control, respectively ($P<0.05$) (n=6). Pre-treatment (48 h) with 1 mM 8-bromo-cAMP or 1 μM forskolin also resulted in increased spontaneous contractile activity (19.1-fold and 3.7-fold respectively) versus vehicle control ($P<0.05$) (n=6). Oxytocin-induced contractions were enhanced following pre-treatment (24 h) with 1 mM dibutyryl cAMP (1.3-fold versus vehicle control, $P<0.05$) (n=6).

In conclusion, long-term [cAMP] elevation can increase the ability of myometrial tissue to spontaneously contract, as demonstrated with 8-bromo-cAMP and rolipram, without greatly affecting oxytocin-induced contractility. Hence there is a need for caution when considering the use of cAMP agonists as treatments for pre-term labour prevention due to the ability of prolonged [cAMP] elevation in promoting spontaneous contractions.

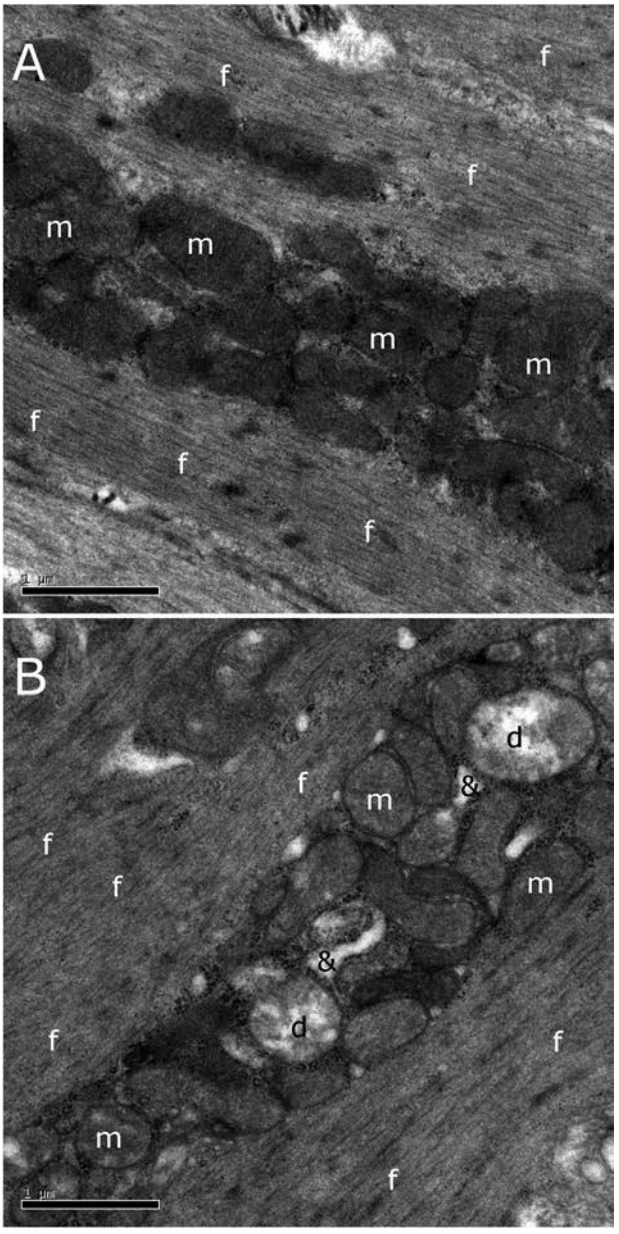
Intestine of dystrophic mice presents stretch resistance, muscle atrophy and impaired calcium-dependent contractility

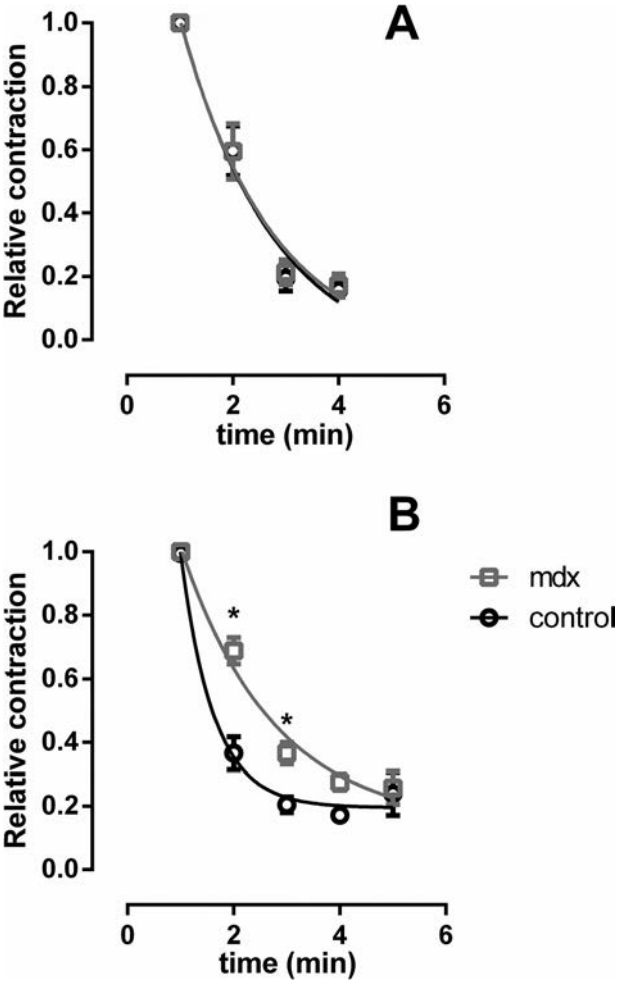
G.A. Alves[1], L.R. Silva[1], R.F. Ribeiro[1], E.F. Rosa[4,1], J. Aboulafia[1], E. Freymüller[3], C. Souccar[2] and V.L. Nouailhetas[1]

[1]Biophysics, Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Sao Paulo, Brazil, [2]Pharmacology, Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Sao Paulo, Brazil, [3]Centro de Microscopia Eletrônica, Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Sao Paulo, Brazil and [4]Centro Univesitário São Camilo, Sao Paulo, Sao Paulo, Brazil

The protein dystrophin is a component of the dystrophin-associated protein complex which links the contractile machinery to the plasma membrane to the extracellular matrix. The absence of dystrophin leads to a pathological condition known as the Duchenne muscular dystrophy (DMD), a disease characterized by a progressive skeletal muscle degeneration, disability, and early death. The mdx mice is the most common DMD animal model. Alterations in gastrointestinal tissues from DMD patients and mdx mice are scarcely described, and little understood. Using isolated tissue samples, explanted from mdx and control mice, we thus investigated the possible relationships between possible morphological and contractile properties impairments with alterations in the calcium handling due to the absence of the protein dystrophin in the mdx mice ileum. Absence of dystrophin caused 27% reduction in the longitudinal muscular layer thickness, accompanied by a partial damage to the mucosa layer (Chiu score of 2-4 by dystrophic animal in comparison with 0-2 score in control), and a partial damage to the mitochondria from the longitudinal muscular layer. Functionally, it was shown a higher resistance to basal tissue stretching (as the contractile response under 1 g-basal tension in mdx is maintained the same as under the optimal 0.5 g-basal tension in mdx mice. In control mice, the responses under 1 g-basal tension are already diminished) and impairment in the Emax (maximum effect) of both eletro- (mdx: 2.36 ± 0.09 g and control: 2.77 ± 0.13 g) and pharmacomechanical (mdx: 2.47 ± 0.09 g and control 2.95 ± 0.12 g) signaling associated with altered calcium influx (half-life time of 1.2 min in mdx mice compared to 0.4 in control stimulation with KCl successive stimuli), without any alteration in the sarcoplasmic reticulum calcium storage (maintenance of the caffeine-induced contraction, 1.12 ± 0.07 g in control and 0.98 ± 0.05 g in mdx mice), in the ileum isolated from the dystrophic animal as compared to control animals. It is thus concluded that intestine is sensitive to the dystrophic condition, as the protein dystrophin plays an important role in the preservation of both the micro and ultra structure of mice intestine, while exerting minor roles concerning both the intestinal contractile responsiveness and the SR calcium storage capacity and release in dystrophic mice.



Representative ultramicrographs from smooth muscle cells cytoplasm from ileum isolated from: control (A) and mdx (B) mice. Myofilaments (f), mitochondria (m); disorganized mitochondria (d), loose (thickened) endoplasmic reticulum (&). Scale bar: 1 μm.



Calcium exit evaluated by measuring contraction in response to repeated stimuli and washes using carbachol 30 μM (A) or KCl 80 mM (B). In (B), t1/2= 0.429 min in control and t1/2= 1.218 min in mdx. *: different from control group (two-way ANOVA, Bonferroni's post-test, P<0.05)

PCB393

Contrasting effects of gap junction blockers on contractility of rat urinary bladder strips

D.A. Bijos[1,2] and M.J. Drake[1,2]

[1]School of Clinical Sciences, University of Bristol, Bristol, UK and [2]Bristol Urological Institute, NHS North Bristol Trust, Bristol, UK

Gap junctions are present at the coupling of different cell types within the urinary bladder [1]. Detrusor, the smooth muscle of the bladder, displays contractile phasic activity (PA) during urine storage. This PA could be facilitated by cell-to-cell communication e.g. via gap junctions. Increased PA may result in pathologies. Hence, we characterize the effects of known gap junction blockers: isomers 18α- and 18β-glycyrrhetinic acid (18α-,18β-GA) and carbenoxolone (CBX) [2] on intact (including mucosa) and mucosa-denuded detrusor bladder tissue. Bladders were isolated from male Wistar rats (P19-24 days) killed by CO_2 under UK Schedule 1 regulations. Denuded and intact tissue strips (5-8mm long) were placed in superfusion tissue organ baths, maintained in oxygenated Krebs buffer at

37°C and tied to a tension transducer to a resting tension of 1g. In the absence of measureable spontaneous PA in intact strips and in all denuded strips, 1μM carbachol (CCh) was used to induce PA. Changes in the contractile force were measured (ADInstruments) throughout the control period, single dose drug exposure and a washout period, each 30min. 1,10 and 30μM 18β-GA; 30μM 18α-GA and 50μM CBX were used. The effect of a drug or drug vehicle on PA was investigated by measuring the amplitude (g per mg tissue) and frequency of PA (number of contractions during 5 min). Data show mean percentage change ± SEM from at least 7 strips from at least 6 animals (two-tailed paired t-test, $p<0.05$ was considered significant). Amplitude of bladder tissue CCh-induced PA decreased with increasing concentrations of the 18β-GA. In intact tissue 10μM 18β-GA decreased PA amplitude by 15.6 ± 4.7% ($p < 0.05$). Amplitude decreased by 33.3 ± 4.9% ($p < 0.001$) and 32.7 ± 3.4% ($p < 0.01$) with 30μM 18β-GA and 18α-GA, respectively. PA frequency increased by 20.1 ± 5.8% ($p < 0.01$) at 30μM 18β-GA. The effect of 18β-GA was stronger in denuded detrusor strips. 10μM 18β-GA decreased PA amplitude by 36.1 ± 2.0% ($p < 0.001$) and 30μM 18β-GA by 42.6 ± 9.1% ($p < 0.01$). At 30μM 18β-GA PA frequency increased by 51.2 ± 24.0% ($p < 0.05$). In contrast, 50μM CBX showed a trend of increasing PA amplitude in both denuded and intact strips, while simultaneously decreasing PA frequency. The frequency of contractions in intact strips decreased by 26.5 ± 6.1% ($p < 0.01$). Preliminary data on spontaneous, not CCh-induced PA suggest the effects of both drugs are less pronounced in unstimulated tissue. 18β-GA increased frequency and decreased amplitude of CCh-stimulated bladder tissue PA, with a stronger effect in denuded strips. CBX decreased PA frequency - a different observation to 18β-GA – and showed a trend in increasing PA amplitude - opposite to 18β-GA effect. This unexpected difference will be further characterized.

Time-dependent structural and functional changes in the spinal cord injured rat bladder

S.M. Gray[1], N. McKerr[1], B. Frias[2], C.D. Cruz[2], F. Cruz[2], G. McMurray[3] and K. McCloskey[1]

[1]Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, UK, [2]Faculty of Medicine of Porto, University of Porto, Porto, Portugal and [3]Neusentis, Pfizer limited, Cambridge, UK

Neurological insults including spinal cord injury (SCI) lead to disturbances in bladder function which include an acute areflexic phase followed by chronic bladder overactivity or underactivity. We previously investigated cellular changes in the SCI rat bladder, 5 weeks after injury and reported altered distribution of interstitial cells (IC), smooth muscle hypertrophy and patchy denervation (1). These changes were correlated with an underactive, hypercompliant phenotype (2). The purpose of the present study was to investigate structural and functional changes in the SCI rat bladder at selected time points after injury.

Female Sprague Dawley rats underwent spinal cord transection at T8/T9 in accordance with the European Commission Directive of 22 September 2010 (2010/63/EU). Animals underwent in vivo cystometry under anaesthesia by subcutaneous injection of urethrane (1.2g/kg) at selected time-points post-SCI before being humanely sacrificed. Bladders were removed and processed for histology, immunofluorescence and confocal imaging. Histological and immunofluorescence studies were carried out on 4 tissue samples from at least 3 animals. Cystometry demonstrated a loss of voiding and non-voiding contractions in acute SCI bladders at 2h (N=5) and 24h (N=4). Overactivity later developed and was characterised by an increased frequency of voiding contractions from 0.43±0.1min-1 (mean±SEM) in spinal-intact animals (N=5) to 1.4±0.64min-1 (N=3; $p<0.05$) at 4wk, and 1.84±0.33min-1 (N=3; $p<0.05$, Anova, post-hoc Dunnett's) at 8wk. Chronic SCI bladders also exhibited urinary retention/incomplete emptying. Initial loss of the urothelial layer in the acute phase was accompanied with inflammation throughout the bladder wall, which was repaired by 2wk. Notable smooth muscle hypertrophy occurred from 1wk. PDGFRα+-IC networks in the lamina propria were disrupted in the acute phase, but recovered in the later stages. PDGFRα+-IC in the detrusor were disrupted as early as 24h with marked loss of cellular morphology. This was correlated with partial denervation. In the chronic phase, the morphology of detrusor IC did not return to normal. Interestingly, α-smooth muscle actin+-myofibroblasts which were not present in controls, were detected in the bladder wall at 1wk and 2 wk post-SCI.

In conclusion, the acute SCI bladder is associated with loss of voiding and non-voiding contractions along with initial disruption of lamina propria PDGFRα+-IC networks. Cellular remodelling throughout the overactive chronic phase appears to restore lamina propria IC but the detrusor layer is typified with persistent hypertrophy, patchy denervation and disrupted IC.

In vivo irradiation negatively impacts neurogenic and agonist-evoked contractions in the mouse bladder

B. McDonnell, K. Butterworth, K. Prise and K. McCloskey

Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, UK

Patients undergoing radiotherapy for pelvic malignancies experience adverse effects on bladder function. The cellular basis of radiation-induced bladder dysfunction is incompletely understood and may represent pathologies in several cell types. We previously reported that ex vivo irradiation of guinea-pig bladder tissue attenuated spontaneous and neurogenic contractions (1). The purpose of the present study was to investigate the effect of in vivo pelvic irradiation on mouse bladder neurogenic and agonist-evoked contractions.

C57BL mice underwent pelvic irradiation in accordance with local ethics approval. Animals were sacrificed 1h or 1wk post-irradiation (UK Animal Procedures Act, Schedule 1). Full thickness and detrusor (mucosa removed) tissue strips were studied with in vitro myography and electrical field stimulation (EFS).

Neurogenic contractions, evoked by EFS in full thickness or detrusor strips (0.5Hz–16Hz) one-hour post-irradiation were not significantly different from controls (at 16Hz, 1.18±0.18g vs 1.38±0.15g; both data sets n=10; N=5; p=0.4). However, full-thickness bladder strips from animals one-week post-irradiation had smaller neurogenic contractions at all frequencies tested (n=10, N=5; at 16Hz, 1.18±0.18g in control vs 0.62±0.11g post-irradiation; p=0.012). This effect was not seen in detrusor strips (at 16Hz, 1.03±0.19g control vs 1.2±0.08g, p=0.44). Carbachol-evoked contractions were reduced in irradiated full thickness strips (0.89±0.12g in control vs 0.31±0.06g irradiated, n=10 N=5, p=0.0005) 1 week post-irradiation. Similarly, ATP-responses were reduced 1 week following irradiation (0.37±0.09g vs 0.12±0.02g, n=10; N=5, p=0.014). Interestingly, in detrusor strips, there was no difference in carbachol or ATP responses after irradiation (p=0.42 and p=0.40, respectively). Receptor-independent contractions evoked by high external K+ solution was also reduced in full thickness strips (n=10; N=5) one-week post-irradiation (1.02±0.11g vs 0.64±0.09g, p=0.018); an effect not seen in detrusor strips (n=10, N=5; p=0.78), indicating that the ability of the detrusor smooth muscle to contract was not affected by irradiation.

In summary, in vivo pelvic irradiation reduced neurogenic, agonist, and high external K+-evoked contractions in full thickness bladder strips, one week after irradiation. These differences were not found in detrusor strips, indicating that radiation may impact the cells of the mucosal layer.

PCB396

Simvastatin inhibits human myometrial contractility by mechanisms independent of cholesterol depletion and HMG-CoA reductase inhibition

V. Pang

Obstetrics & Gynaecology, University of Nottingham, Derby, UK

Knowledge of myometrial regulation is essential to understanding preterm labour. Cholesterol depleting agents have been reported to perturb the myometrial membrane microenvironment and therefore key ion channels (1), studies have also demonstrated the pleiotropic effects of such agents (2). Our hypothesis is that simvastatin decreases myometrial contractions via K+channel blockade and inhibition of its pleiotropic effects, including nitric oxide production and isoprenylated proteins. We aim to investigate effects of simvastatin on human myometrium.

Myometrial biopsies were collected with informed written consent from patients undergoing elective caesarean section (>37 weeks). Tissue was mounted for isometric tension recordings and effects of simvastatin (33 nM – 330 μM) on spontaneous contractility, in the absence and presence of SK channel blocker apamin (500 nM), BK channel blocker paxilline (1 μM), broad-acting K+ channel blocker TEA (5 mM), NOS inhibitor L-NAME (1.2 mM) and isoprenoid GGPP (30 μM) assessed. Cholesterol and protein were measured in untreated and treated myocytes, using Amplex red and bicinchoninic acid assays respectively. In all assay-based experiments, 15 mM methyl-β-cyclodextrin (MCD) was used as a comparative cholesterol-depleting agent. Data are presented as means + SEM and compared using ANOVA.

Simvastatin significantly decreased contractions until cessation at 330 μM ($p < 0.0001$, n=6) in contrast to MCD treatment which increased contractions ($p < 0.0001$, n=6). Selective inhibition of both SK ($p<0.05$, n=6), (IC50 = 2.56e-6 vs. 2.10e-7 M), BK ($p<0.01$, n=6), (IC50=4.41e-6 vs. 2.10e-7 M) and addition of both inhibitors ($p<0.001$, n=5), (IC50 = 1.68e-5 vs. 2.10e-7 M) produced a rightward shift of the concentration-response curve. Broad Inhibition of K+ channels with TEA elicited significant partial inhibition of simvastatin relaxation ($p<0.0001$, n=5), (IC50 = 1.84e-4 vs. 2.10e-7 M). Replenishment with GGPP had no effect on simvastatin -induced relaxation ($p>0.05$, n=6), however NOS inhibition was able to significantly inhibit simvastatin relaxation ($p<0.05$, n=4). Finally, only MCD treatment significantly decreased cholesterol concentration ($p<0.001$, n=5) while the total protein concentration was unchanged.

Data demonstrated evidence of K+ channel modulation by simvastatin. Absence of cellular cholesterol modulation and significant inhibition of simvastatin-induced relaxation by L-NAME, suggests an alternative mechanism of statin action, independent of HMG-CoA inhibition of novel cholesterol synthesis. Myometrial relaxation via simvastatin suggests that statins may have implications as tocolytic agents in the treatment of preterm labour, warranting further investigation into their mechanisms and therapeutic potential.

PCB397

Rapid dilatation induced by release of muscle compression

M. Turturici and S. Roatta

Neuroscience Dept, University of Turin, Turin, Italy

Several studies have shown that a rapid hyperaemia can be evoked by different stimuli such as short-lasting contractions, muscle compression, arterial occlusion and passive movement (Turturici et al. 2012, Kirby et al. 2007), suggesting that a rapid dilatation could be mediated by mechano-sensitive mechanisms responding to decreases in transmural pressure according to the Bayliss effect (Mohrman & Sparks 1974, Turturici et al. 2012). However the exact nature of the relevant mechanical stimulus is still unclear, given that these stimuli produce both a rapid decrease and rapid return of transmural pressure.

Aim of this study was to investigate the individual effects of these two events by analysing the hemodynamic responses to onset and release of muscle compression.
Hyperaemic responses to the external compression of Masseter muscle (MC) were recorded from the masseteric artery (n=8) of urethane-anaesthetized rabbits (1.2 g/kg, i.v.) (n=4) by means of ultrasound flowmetry.
Mechanical compressions of different duration (1, 10, 20, 50 and 100 s) were exerted by a cylindrical head (1.3 cm^2) pushed by a PC-driven servo-controlled motor (force= 0.9 N) resulting in a locally generated pressure of about 50 mmHg (Turturici et al. 2013).The relative amplitude of the hyperaemic responses was computed as (peak flow – baseline)*100/baseline.
MC did not substantially impair muscle blood flow. On the contrary, two different hyperaemic responses were detected both at the onset and release of MCs (with MC duration >= 10 s) of amplitude Po and Pr, respectively (see Fig. 1). None of these responses depended on MC duration p=(0,94). Po and Pr were not significantly different .Po=240±60% and Pr= 229±80% (averaged over all MC durations 10-100 s).
The 1-s lasting MC evoked a single hyperaemic response whose amplitude (394 ± 124 %) was of significantly higher than both Po and Pr.
In conclusion, rapid release of MC consistently evokes a rapid dilatation. MC does not stop blood flow to the muscle and the hyperaemia does not increase with MC duration, suggesting that metabolic mechanisms are not involved. It is suggested that the rapid dilatation underlying the hyperaemia can be mechanically-activated by both a rapid decrease and a rapid increase in transmural pressure of the musculo-vascular network. This particular manifestation of vascular mechanosensitivity is not explained by the classical myogenic response but is compatible with the dilatory effects reported by Smiesko et al (1971) in the isolated skeletal muscle.

PCB398

The role of TRPM8 channels in normal rat bladder function

M. King[1], O. Murray[2], S. Gray[2], L. Johnston[2], K. McKloskey[2] and C. Johnson[1]

[1]Biomedical Science Education, Queen's University, Belfast, UK and [2]Cntre for Cancer Research and Cell Biology, Queen's University,, Belfast, UK

Transient receptor potential melastatin 8 (TRPM8) channels are known to be present in rat and human bladder tissue (Stein et al., 2004). Recent studies in our lab (Johnson et al., 2009) have shown that this channel is present and functional in rat vascular smooth muscle. Therefore, this project aimed to examine the functional expression of TRPM8 channels in the bladder of normal rats using isometric contractile studies along with immunohistochemistry.
Bladders were taken from sacrificed male Sprague-Dawley rats (250-350g). Tissues were processed for histology and immunohistochemical staining. Bladder tissues labeled with anti-TRPM8 (N=4) showed positive staining in the urothelium, nerves and in cells with the morphological features of Interstitial Cells (IC) in the lamina propria and detrusor layers. Detrusor smooth muscle was not immunopositive for TRPM8 in contrast to DRGs which were used as positive controls. Isometric contraction studies were conducted in bladder strips pre-tensed to 1g with urothelium in tact or removed. TRPM8 agonist, menthol, (300μM in ethanol) failed to cause any contraction (N=4, n=16 where N=animals, n= preparations). Contraction (1.97±0.15 g; ave.±s.e, N=10, n=18) induced by carbachol (10 μM) was markedly relaxed on addition of menthol (72±5%, N=9, n=18, accounting for relaxation due ethanol alone; P<0.001, ANOVA, Tukey's post hoc test). However, when protocols were repeated in the presence of the L-type calcium channel blocker, nifedipine (10 μM) menthol-induced relaxation was vastly reduced (93 ±4 %, N=9, n=14, not significant). Results for these protocols were unaffected by removal of urothelium. Both WS-12 (10 μM, N=6, n=8) and icilin (10 μM in DMSO, N=3, n=12) failed to have contractile or relaxatory effects with urothelium in tact.
We conclude that in normal rat bladder, TRPM8 channels are not involved in contractile responses. This is consistent with the lack of TRPM8 staining in detrusor smooth muscle. The expression of TRPM8 in urothelium, nerves and IC may be related to sensory mechanisms in the bladder.

PCB399

Effects of chronic administration of virgin coconut oil on the cardiovascular profile in middle aged male rats

N.-. Thongsepee and C. Jansakul

Physiology, Prince of Songkla University, Hat-Yai, Songkhla, Thailand

Coconut oil has been used as a source of fatty acids since ancient times. However, its major chemical components are saturated fatty acids and these are now considered to be a health hazard, especially to the cardiovascular system. In this study we aimed to test for any harmful effects of feeding virgin coconut oil on the cardiovascular system of middle-aged rats. Tests included (1) blood sugar and lipid profiles, (2) basal blood pressure and heart rate, and (3) isolated blood vessel functions. The saturated fatty acid composition (%) of the virgin coconut oil (VCO, Thai pure coconut Co., Thailand) was: C8, 4.7; C10, 6.2; C12 (lauric acid), 51.9; C14, 18.2; C16, 6.9 and C18, 1.9. Middle-aged male rats (14-15 months old) were gavaged with 1 or 3 ml VCO /kg or distilled water (control), once a day for 6 weeks. Basal blood pressure and heart rate were measured from anesthetized rats (sodium pentobarbital, 60 mg/kg, i.p) via the right common carotid artery. Blood sugar and lipids profile were measured by enzymatic methods. The thoracic aorta was isolated from rats decapitated with a guillotine, then placed in oxygenated Krebs Heinseleit solution at 37oC (PSU-Ethic No.10/54) before performing a cumulative concentration response (C-R) curve to phenylephrine (Phe), acetylcholine (ACh) and glyceryl trinitrate (GTN). Data are expressed as a mean ± S.E.M. (6 rats/group/each experiment). Using the Student's paired t-test, a $p \leq 0.05$ between test and control was considered to be statistically significant. After 6 weeks of treatment with 1 or 3 ml of VCO/kg, there were no changes in serum glucose and lipid profiles, mean arterial blood pressure and heart rate when compared to the control group. There were no significant changes in vascular responses to Phe, ACh and GTN for the dosage of 1 ml/kg VCO. At a dosage of VCO of 3 ml/kg, the maximal contractile responses of the endothelium-intact thoracic aortic ring, with or without N-nitro-L-arginine (LNA, 300 μM)), a nitric oxide synthase inhibitor, to Phe was significantly lower than the one obtained from the control group. Also the vasodilatory response to ACh by the endothelium-intact aortic ring preconstricted with Phe (3 μM) was significantly higher than the control group. This effect disappeared when the blood vessels had been incubated with LNA or tetraethylammonium (1 mM) but not by glybenclamide (10 μM). The vasodilatation to GTN was not different from the control for the endothelium-intact thoracic aortic ring treated with LNA. These results indicate that consumption of the virgin coconut oil of 1-3 ml/kg/day had some beneficial effects on the cardiovascular system of the middle-aged male rats by increasing the release of nitric oxide from the vascular endothelium and opening of the Kca channels to cause a higher vasodilatation to ACh and to oppose the vasoconstriction produced Phe.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

Inhibitory mechanism of *T*-type Ca^{2+} channel inhibitor, mibefradil on voltage-dependent K^+ channels in coronary arterial smooth muscle cells

S. Na[2], D. Hong[1] and W. Park[1]

[1]Department of Physiology, Kangwon National University School of Medicine, Chuncheon, Gangwon-do, Republic of Korea and [2]Department of Obestetrics and Gynecology, Institute of Medical Sciences, Kangwon National University Hospital, Chuncheon, Gangwon-do, Republic of Korea

We investigated the effects of mibefradil, a *T*-type Ca^{2+} channel inhibitor, on voltage-dependent K^+ channels in smooth muscle cells from rabbit coronary arteries. Mibefradil inhibited the Kv current in a dose-dependent fashion with an apparent K_d of 1.17 ± 0.15 μM (n=5) . It accelerated the decay rate of Kv channel inactivation without altering the kinetics of current activation. The rate constants of association and dissociation for mibefradil were 2.23 ± 0.07 $\mu M^{-1}s^{-1}$ and 2.40 ± 0.42 s^{-1}, respectively (n=5). Mibefradil did not have a significant effect on the steady-state activation (n=5) and inactivation (n=6) curves. The recovery time constant from inactivation was decreased in the presence of mibefradil (n=5, $P<0.05$), and application of train pulses (1 or 2 Hz) caused a progressive increase in the mibefradil blockade (n=4, $P<0.05$), indicating that mibefradil-induced inhibition of Kv current is use-dependent. The inhibitory effect of mibefradil was not affected by extracellular Ca^{2+} free condition (n=5). Moreover, the absence of intracellular ATP did not change the blocking effect of mibefradil (n=4). From these results, we suggest that mibefradil directly inhibited the Kv current, independently of Ca^{2+} channel inhibition. ($P<0.05$ was regarded significant, and data analysis was done with student t-test.)

PCB401

Expression of smooth muscle-specific ion channels in TGF-β1-induced differentiation of human adipose-derived mesenchymal stem cells

Y. Son, D. Hong and W. Park

Department of Physiology, Kangwon National University School of Medicine, Chuncheon, Gangwon-do, Republic of Korea

Human adipose tissue-derived mesenchymal stem cells (hASCs) have the power to differentiate into various cell types including chondrocytes, osteocytes, adipocytes, neurons, cardiomyocytes, and smooth muscle cells. We characterized the functional expression of ion channels after TGF-β1-induced differentiation of hASCs, providing insights into the differentiation of vascular smooth muscle cells. The treatment of hASCs with TGF-β1 dramatically increased the contraction of a collagen-gel lattice and the expression levels of smooth muscle specific genes including α-smooth muscle actin, calponin, SM-MHC, smoothelin-B, myocardin, and h-caldesmon. We observed Ca^{2+} (n=5), big-conductance Ca^{2+}-activated K^+ (BK_{Ca},

n=4), and voltage-dependent K^+ (Kv, n=4) currents in TGF-β1-induced, differentiated hASCs and not in undifferentiated hASCs. The currents share the characteristics of vascular smooth muscle cells (SMCs). RT-PCR and western blotting revealed that the *L*-type (Cav1.2), *T*-type (Cav3.1, 3.2, and 3.3), known to be expressed in vascular SMCs, dramatically increased along with the Cavβ1 and Cavβ3 subtypes in TGF-β1-induced, differentiated hASCs ($P<0.05$, n=4). Although the expression-level changes of the β-subtype BKCa channels varied, the major α-subtype BK_{Ca} channel ($K_{Ca}1.1$) clearly increased in the TGF-β1-induced, differentiated hADSCs($P<0.05$, n=4). Most of the Kv subtypes; also known to be expressed in vascular SMCs, dramatically increased in the TGF-β1-induced, differentiated hASCs ($P<0.05$, n=3). Our results suggest that TGF-β1 induces the increased expression of vascular SMC-like ion channels and the differentiation of hASCs into contractile vascular SMCs. ($P<0.05$ was regarded significant, and data analysis was done with student *t*-test.)

PCB402

The effect of PI3 kinase inhibitor LY294002 on voltage-dependent K^+ channels in rabbit coronary arterial smooth muscle cells

D. Hong[1], S. Na[2], Y. Son[1] and W. Park[1]

[1]Department of Physiology, Kangwon National University School of Medicine, Chuncheon, Gangwon-do, Republic of Korea and [2]Department of Obstetrics and Gynecology, Institute of Medical Sciences, Kangwon National University Hospital, Chuncheon, Gangwon-do, Republic of Korea

We examined the effect of LY294002, a phosphatidylinositol 3-kinase (PI3K) inhibitor, on voltage-dependent K^+ (Kv) channels in smooth muscle cells from freshly isolated rabbit coronary arteries using the whole-cell patch clamp technique. The Kv current amplitude was inhibited by LY294002 in a dose-dependent manner, with a K_d value of 1.48 ± 0.20 μM (n=7). Without alteration of the kinetics of activation, LY294002 accelerated the decay rate of Kv channel inactivation. The rate constants of association and dissociation for LY294002 were 1.83 ± 0.01 $\mu M^{-1}s^{-1}$ and 2.59 ± 0.14 s^{-1}, respectively (n=6). Application of LY294002 had no significant impact on the steady-state activation (n=6) or inactivation (n=7) curves. In the presence of LY294002, the recovery time constant from inactivation was increased (n=7, $P<0.05$), and Kv channel inhibition increased under train pulses (1 or 2 Hz, n=6, $P<0.05$). This indicates that LY294002-induced Kv channel inhibition is use-dependent. Furthermore, pretreatment with another PI3K inhibitor, wortmannin (10 μM), did not affect the Kv current, and did not change the inhibitory effect of LY294002 (n=8). Based on these results, we suggest that LY294002 directly blocks Kv current irrespective of PI3K inhibition. ($P<0.05$ was regarded significant, and data analysis was done with student *t*-test.)

This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) (2010-0021126, 2011-0028573).

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB403

Decreased expression of ATP-sensitive K^+ channel in aortic smooth muscle during isoproterenol-induced left ventricular hypertrophy

Y. Son, D. Hong and W. Park

Department of Physiology, Kangwon National University School of Medicine, Chuncheon, Gangwon-do, Republic of Korea

We investigated the impairment of K_{ATP} channels in aortic smooth muscle cells (ASMCs) from hypertrophied rabbits. The amplitude of KATP channels induced by the K_{ATP} channel opener pinacidil was greater in ASMCs from control than from hypertrophied animals ($P<0.05$, n=6). In phenylephrine pre-constricted aortic rings, pinacidil induced relaxation in a dose-dependent manner. The dose-dependent curve was shifted to the right in the hypertrophied compared with the control model ($P<0.05$, n=4). Although the level of Kir6.2 subtype expression did not differ between ASMCs from the control and hypertrophied models (n=5), those of the Kir6.1 and SUR2B subtypes were decreased in the hypertrophied model ($P<0.05$, n=4). Application of the CGRP and forskolin induced a K_{ATP} current in both control and hypertrophied animals; however, the K_{ATP} current amplitude did not differ between the two groups (n=5). Furthermore, PKA expression was not altered (n=5). These results suggests that the decreased K_{ATP} current amplitude and K_{ATP} channel-induced vasorelaxation in the hypertrophied animals were attributable to the reduction in K_{ATP} channel expression, but not to changes in the intracellular signaling mechanism that activates the K_{ATP} current. ($P<0.05$ was regarded significant, and data analysis was done with student *t*-test.)

Physiological dynamics in the reversal of the Fåhraeus effect in the venous microcirculation of the human finger pulp

W.G. Murphy[1,2], S.M. Browne[2], R. Segurado[2], B. Gallagher[3], C. Murphy[3] and E. Tong[4]

[1]Health Service Executive, Dublin, Ireland, [2]University College Dublin, Dublin, Ireland, [3]Irish Blood Transfusion Service, Dublin, Ireland and [4]Department of Surgery, Our Lady's Children's Hospital, Dublin, Ireland

As blood flows from the arterioles into the capillaries the haemoglobin (Hb) concentration falls by approximately 50% to a level of 7 g/dL in the smallest capillaries due to a pro-

gressive increase in the relative amount of plasma in blood flowing through vessels < 300μ in diameter (the Fåhraeus effects). The effects reverse on the venous side of the capillaries - dynamical effects on this reversal process have not been described hitherto. Blood sampled from the human finger pulp comes predominantly from venules and small veins < 300μ and represents the physiological space where the Fåhraeus effects are reversed. The Hb content of blood from the finger pulp has been observed to vary in relation to the Hb content of venous blood in the same individuals with sex and venous Hb levels(1,2,3). We have now studied the relationship between venous and finger pulp Hb levels within individuals over time.

465 blood donors with hereditary haemochromatosis, 360 males and 105 females, underwent repeated 450 ml venesections at a single clinic over a 3 year period. The mean age at first venesection was 50 years (range 24 to 71 years) for men and 52 years (range 21 to 70 years) for women. Men had a mean of 6.3 venesections over the period of the study, range 1 – 26; females a mean of 4.88 venesections, range 1 - 28. The difference between finger pulp and venous Hb levels for each donation was plotted against the finger pulp Hb level for the entire cohort of donors and for each individual donor. For each 1g/dL change in finger pulp Hb level, the mean difference between venous and finger pulp levels changed by -0.694 g/dL (Figure 1a). This relationship is significantly different from zero ($p<0.001$), the value expected for a 1:1 relationship between the Hb levels in the venous and finger pulp vascular spaces. Correcting for donor-specific effects and time-correlation of Hb levels at each donation date, finger pulp Hb levels recovered on average 0.496 mg/dL/day, ($p<0.001$), while venous Hb levels recovered slower: 0.113 mg/dL/day on average ($p=0.019$). The rate of finger pulp Hb recovery between venesections was 4.39 times faster than venous Hb recovery ($t(4798)=2.743$, $p=0.006$). These rates were not affected by sex or season (Figure 1b).

These findings indicate that the Hb level of finger pulp blood affects the reversal of the Fåhraeus effects in blood flowing from smaller to larger vessels on the venous side of the circulation, consistent with vasodilation induced by deoxygenated red cells in the venous microvasculature. A sex difference has been observed before in the relative size of the gap between venous and finger pulp Hb levels per unit Hb level in venous blood (2,3); the net effect of the deoxyHb-associated effect may be to allow red cells in excess of resting requirements to be stored in a low pressure slow moving reserve on the venular side.

Lercanidipine and labedipinedilol-A play anti-inflammatory role through inhibition of lipopolysaccharide/interferon-γ-induced HMGB1 release and MMP-2, 9 activities in vascular smooth muscle cells

S. Liou, M. Shih and C. Chen

Department of Pharmacy, Chia-Nan University of Pharmacy and Science, Tainan, Taiwan, Tainan, Taiwan

Inflammation is an important molecular basis of atherosclerosis. Several reports have revealed that dihydropyridine calcium channel blockers (CCBs) exert anti-inflammatory effects on various vascular cells. The purpose of the present study was to evaluate anti-inflammatory effects and mechanisms of lercanidipine and labedipinedilol-A, new generation dihydropyridine CCBs, in rat vascular smooth muscle cells (VSMCs) exposed to lipopolysaccharide (LPS) and interferon-γ (IFN-γ). MTT, Griess reagent, RT-PCR, ELISA, gelatin zymography, immunocytochemistry and Western blotting were employed.

We found that lercanidipine and labedipinedilol-A attenuated production of NO, ROS and TNF-α from LPS/IFN-γ-stimulated VSMCs. In addition, they both diminished the LPS/IFN-γ-induced expression of iNOS protein and mRNA, with attenuation of HMGB1 cytosolic translocation and subsequent extracellular release. Furthermore, they down-regulated MMP-2/MMP-9 activities, whereas expression of tissue inhibitor of matrix metalloproteinase-1 (TIMP-1), an inhibitor of MMP-9, was up-regulated. Finally, we found that lercanidipine and labedipinedilol-A inhibited the nuclear translocation of NF-κB and suppressed the phosphorylation of JNK, p38 MAPK and Akt. Lercanidipine and labedipinedilol-A can exert their anti-inflammatory effects through suppression of NO, ROS and TNF-α through down-regulation of iNOS, MMP-2/MMP-9, and HMGB1, with inhibition of signaling transduction of MAPKs, Akt/IkB-α and NF-κB pathways. These findings implicate a valuable role of new generation dihydropyridine CCBs lercanidipine and labedipinedilol-A for the treatment of inflammatory vascular diseases.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB406

Effect of azelastine on cardiac action potential duration and hERG K^+ channel current

M. Park and H. Su

Department of Physiology, School of Medicine, Kangwon National University, Chuncheon, Gangwon-do, Republic of Korea

Azelastine is a second gengeration histamine H_1 receptor antagonist used as an anti-asthmatic and anti-allergic drug that can induce QT prolongation, which may lead to *torsades de pointes*. Since block of cardiac human *ether-a-go-go*-related gene (*hERG*) channels is one of leading causes of acquired long QT syndrome, we investigated the acute effects of azelastine on hERG channels to determine the electrophysiological basis for its proarrhythmic potential. Azelastine increased the action potential duration at 90% of repolarization (APD_{90}) in a concentration-dependent manner, with an IC_{50} of 1.08 μM when action potentials were elicited under current clamp in guinea pig ventricular myocytes. We examined the effects of azelastine on the hERG channels expressed in *Xenopus* oocytes and HEK293 cells using two-microelectrode voltage-clamp and patch-clamp techniques. Azelastine induced a concentration-dependent decrease of the current amplitude at the end of the voltage steps and hERG tail currents. The IC_{50} for the azelastine-induced block of the hERG currents in HEK293 cells at 36 °C was 11.43 μM at +20 mV, while the drug blocked L-type Ca^{2+} channel expressed in HEK293 cells with an IC_{50} of 26.21 μM. The S6 domain mutations, Y652A and F656A partially attenuated (Y652A) or abolished (F656A) the hERG current block. These results suggest that azelastine is a blocker of the hERG channels, providing a molecular mechanism for the arrhythmogenic side effects during the clinical administration of azelastine.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB407

Differential effects of environmental toxicants, PCB 126 and PCB 77, on cardiac electrophysiology

M. Park and S. Jo

Department of Physiology, School of Medicine, Kangwon National University, Chuncheon, Gangwon-do, Republic of Korea

Polychlorinated biphenyls (PCBs) have been known as serious persistent organic pollutants (POPs), causing developmental delays, motor dysfunction. We have investigated the effects of two PCB congeners, 3,3',4,4'-tetrachlorobiphenyl (PCB 77) and 3,3',4,4',5-pentachlorobiphenyl (PCB 126) on ECG, action potential, and the rapidly activating delayed rectifier K+ current (I_{Kr}) of guinea pigs' hearts, and hERG K^+ current expressed in *Xenopus* oocytes. PCB 126 shortened the corrected QT interval (QTc) of ECG and decreased the action potential duration at 90% (APD_{90}), and 50% of repolarization (APD_{50}) ($P < 0.05$) without changing the action potential duration at 20% (APD_{20}). PCB 77 decreased APD_{20} ($P < 0.05$) without affecting QTc, APD_{90}, and APD_{50}. The PCB 126 increased the I_{Kr} in guinea-pig ventricular myocytes held at 36°C and hERG K^+ current amplitude at the end of the voltage steps in voltage-dependent mode ($P < 0.05$), however, PCB 77 did not change the hERG K^+ current amplitude. The PCB 77 increased the diastolic Ca^{2+} and decreased Ca^{2+} transient amplitude ($P < 0.05$), however PCB 126 did not change. The results suggest that PCB 126 shortened the QTc and decreased the APD_{90} possibly by increasing I_{Kr}, while PCB 77 decreased the APD_{20} possibly by other modulation related with intracellular Ca^{2+}. The present data indicate that the environmental toxicants, PCBs, can acutely affect cardiac electrophysiology including ECG, action potential, intracellular Ca^{2+}, and channel activity, resulting in toxic effects on the cardiac function in view of the possible accumulation of the PCBs in human body.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB408

Novel approach to inhibition of neointimal hyperplasia in arteriovenous fistulae

R.W. Corbett[1], N. Demicheli[2], L. Grechy[2], F. Iori[2], J. Crane[1], N. Duncan[1], P. Vincent[2] and C.G. Caro[3]

[1]Imperial College Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, UK, [2]Department of Aeronautics, Imperial College London, London, UK and [3]Department of Bioengineering, Imperial College London, London, UK

Haemodialysis is a predominant modality for the treatment of end-stage renal failure, but is dependent on high quality access to the circulation to allow effective removal, treatment and return of blood through an extracorporeal circuit. The preferred method is via an established arteriovenous fistula, created surgically by anastomosing a patient's own artery and vein. This technique is, however, hampered by a high failure rate (up to 40% before first use) (1) caused by early neointimal hyperplasia, in the genesis of which haemodynamic factors appear to play an important role (2). Given the seeming importance of the local flow, including its physiological three-dimensionality (3), we have attempted to determine in model studies whether geometric modification at the anastomosis can reduce the burden of neointimal hyperplasia.

Perspex models of a vascular anastomosis were created with planar orientation of the vessels at a range of anastomotic angles. A further, otherwise identical set of models, was created with 'offset' junctions, novel non-planar anastomoses, which mimicked the geometry at the origin of arterial branches. Comparative observations were made under non-pulsatile (but otherwise physiological) flow conditions, using flow visualisation and computational fluid dynamics (CFD).
Similar results were observed in the flow visualisation and CFD work (see Figure). Flow separation occurred in both planar and offset (non-planar) models within both vessels. It is suggested that flow disturbance (including separation, wall shear abnormality and instability) occur in regions associated with neointimal hyperplasia development in humans and animal models.
Flow visualisation and CFD allowed complementary assessment of vascular anastomosis models. Preliminary results suggest that modification of anastomosis configuration can alter the peri-anastomotic and downstream flow fields. Planned observational studies in human patients will increase understanding of how current practice, and resulting flow patterns, correlate with clinical outcomes. Concurrent work, including with animal models, will allow examination of the hypothesis that these changes affect the burden of neointimal hyperplasia, possibly mediated through wall shear stress and/or mass transport mechanisms.

Perivascular adipose tissue inhibits thoracic aorta endothelial function through Cav-1-dependent inhibition of nitric oxide production

S. Chen[1], H. Lee[2], C. Tsao[3] and C. Wu[4]

[1]Nursing, Kang-Ning Junior College of Medical Care and Management, Taipei, Taiwan, [2]Graduate Institute of Life Sciences, National Defence Medical Centre, Taipei, Taiwan, [3]Anaesthesiology, Taipei Veterans General Hospital and National Yang-Ming University, Taipei, Taiwan and [4]Pharmacology, National Defence Medical Centre, Taipei, Taiwan

Perivascular adipose tissue (PVAT) has been proposed as a cause of atherosclerosis, recently. The location of PVAT is in association with the artery wall, which enables diffusion of adipokines (e.g. superoxide anion, angiotensin II, tumor necrosis factor-α, and adiponectin). The adipokines are capable of inducing endothelial dysfunction and enhancing vasoconstriction in rat thoracic aortas. Caveolin-1 (Cav-1), a structure protein of caveolae, is present in most of cells involved in the development of atherosclerosis. Cav-1 inhibits nitric oxide (NO) production by occupying the calcium/calmodulin binding site of endothelial NO synthase. The inhibition of NO production is a characteristic of endothelial dysfunction. In this study, adult male Wistar rats weighing 265 to 305 g were euthanatized by intravenous injection of overdose of sodium pentobarbital. The thoracic aortas were isolated, dissected without the PVAT, divided into endothelium-intact (+E) and endothelium-denuded (-E) groups, and mounted in organ bath containing a Krebs' solution bubbled with 95% O2 and 5% CO2 at 37 C. PVAT was incubated in Krebs' solution for 30 minutes and transferred to organ bath before the isometric tension studies. The remaining aortas were frozen for Western blotting. The dose-response curve of phenylephrine, acetylcholine, and sodium nitroprusside were performed to examine the vascular reactivity and endothelial function, respectively. We found that the unknown factor(s) released from PVAT increased Cav-1 protein expression and induced a vasocontractile effect via inhibition of endothelial NO production in rat thoracic aorta.

PKG signalling mediates perivascular adipose tissue function of up- and downstream of secreted adipokines via regulation of the expression and signalling of adiponectin

S. Withers, L. Simpson, M. Werner and A. Heagerty

University of Manchester, Manchester, UK

Objective: Perivascular adipose tissue (PVAT) has an anticontractile effect which is lost in obesity and the metabolic syndrome leading to hypertension associated cardiovascular complications (1). cGMP dependent protein kinase has been implicated in as a key molecule in regulating vascular tone (2), furthermore obesity the intake of a high fat diet is associated with a reduction in PKG expression (3). We investigated the role of cGMP dependent protein kinase (PKG) in PVAT function specifically in modulating adipokine release/signalling and whether activation of PKG is beneficial using an in vitro model of obesity.
Methods: Contractility of mesenteric arteries±PVAT from PKG+/+, PKG-/-, adiponectin-/- knockout and C57/Bl6J mice was investigated by wire myography. All procedures were performed in accord with current UK legislation. Vessels were studied under normoxia +/- DT-2 (PKG1α peptide selective inhibitor)

(125nM), hypoxia (95% N2/ 5%O2)± atrial natriuretic peptide (ANP) (5μM). Contractile responses to noradrenaline (NA) (1x10-5M to 3x10-9M) were calculated as a percentage of KCl (60mM) contraction, and expressed as mean±SEM. Expression of adiponectin was assessed by immunohistochemistry.
Results: Healthy PVAT had an anticontractile effect which was absent in PKG-/- mice and following pharmacological inhibition of PKG signalling (PVAT vs. no PVAT: PKG+/+: P<0.001 n=13; PKG-/-: P=0.052, n=13; DT-2: P=0.071, n=8). Solution transfer studies between preconstricted (3x10-8M NA) PKG+/+ (+PVAT) donor arteries to PKG-/- (-PVAT) recipient arteries and PKG-/- (+PVAT) donor arteries to PKG+/+ (-PVAT) recipient arteries were associated with a significantly impaired relaxation compared with PKG+/+ +PVAT to PKG+/+ -PVAT solution transfer (P=0.023 and P=0.043 respectively, n=13). Experimental hypoxia in PKG+/+ induced a loss of PVAT associated anticontractile effect which was prevented by ANP (PVAT+normoxia vs. PVAT+hypoxia: P=0.0157, n=10; PVAT+hypoxia vs. PVAT+hypoxia+ANP P=0.0093, n=8) No significant effects of hypoxia +/- ANP were observed in PKG-/- animals. Furthermore, the loss of anticontractile effect observed in adiponectin-/- mice was not affected by hypoxia and could not be rescued by ANP (no PVAT vs PVAT: P=0.1486, n=6; PVAT vs. PVAT+hypoxia: P=0.6507, n=6; PVAT+hypoxia vs. PVAT+hypoxia+ANP: P=0.1538, n=6). Immunohistochemical detection of adiponectin demonstrated reduced adiponectin following hypoxia, which was prevented when ANP was present.
Conclusions: Our data implicate PKG signalling in mediating PVAT function both up and down stream of secreted adipose tissue factor(s) through its role in mediating the expression and signalling of adiponectin. Investigations in obesity are necessary to confirm the role of PKG in PVAT dysfunction.

PCB411

Local cleavage of endothelial cell junctional adhesion molecule (JAM)-C by neutrophil elastase governs development of systemic inflammation

B. Colom[1], J.V. Bodkin[1], M.B. Voisin[1], D.A. Leinster[1], M. Aurrand-Lions[2], T. Chavakis[3], B.A. Imhof[4] and S. Nourshargh[1]

[1]Barts and The London School of Medicine, Queen Mary University of London, London, UK, [2]Institut Paoli-Calmettes, Marseille, France, Centre de Recherche en Cancérologie de Marseille, Marseille, France, [3]Dresden University of Technology, Dresden, Germany and [4]Centre Médical Universitaire, Geneva, Switzerland

JAM-C is a member of the Ig-superfamily that localizes to cell-cell contacts and is specifically enriched at tight junctions. Originally detected on endothelial cells (ECs), JAM-C has since been reported to be expressed on numerous other cell types such as spermatids, epithelial cells, smooth muscle cells, fibroblasts and Schwann cells. As such JAM-C has been associated with numerous biological functions but most notably it has been studied in the context of vascular and inflammatory responses[1]. Despite a growing interest in this complex molecule there remain many unanswered questions with respect to the expression and functions of JAM-C. In the present study we sought to investigate the expression and regulation of expression of EC JAM-C under inflammatory scenarios.
The expression of EC JAM-C was investigated in mouse ear skin and cremaster muscle by immunofluorescent staining and confocal microscopy using whole-mount tissues. With this approach JAM-C was found to be strongly expressed at junctions of ECs in capillaries and venules, but not arterioles. The venular expression of JAM-C was unaltered in ears stimulated with intradermal C5a (1μg), or the chemokines KC and MIP-2 (both at 500ng) but was significantly reduced in LTB4-stimulated tissues (300ng). The latter occurred in a dose and time-dependent manner with reduced expression of JAM-C being noted at 30 mins, peaking at 4 h and returning back to normal levels by 24 h post LTB4 administration. In addressing the mechanism of JAM-C cleavage, studies with neutrophil-depleted mice and neutrophil elastase (NE) KO mice demonstrated a role for neutrophil-derived NE in LTB4-induced loss of EC JAM-C. Local administration of LTB4 induced neutrophil reverse transmigration in mouse cremasteric venules (analysed by confocal intravital microscopy) and this was associated with lung inflammation. These results suggest that loss of local EC JAM-C can lead to disrupted modes of neutrophil transmigration which can in turn contribute to secondary organ inflammation[2].
Collectively, our data indicate that the expression and regulation of expression of EC JAM-C is vessel type and stimuli specific, respectively, and that JAM-C is shed from ECs after LTB4 stimulation in a neutrophil and NE dependent manner, a phenomenon that can contribute to turning a local inflammatory response to a systemic reaction.

PCB413

Potentiated vasoconstrictor responses in mesenteric arterioles in elevated extracellular glucose may be due in part to a reduction in receptor desensitisation

R. Jackson[2], N.W. Davies[2] and R.D. Rainbow[1]

[1]Cardiovascular Sciences, University of Leicester, Leicester, UK and [2]Cell Physiology and Pharmacology, University of Leicester, Leicester, UK, UK

Elevated extracellular glucose potentiates vasoconstrictor signalling in vascular smooth muscle. We have previously demonstrated that elevating bathing glucose from 5 to 20mM causes a marked increase in contractile responses, recorded using wire myography, to angiotensin II (ATII), UTP, U46619 in mesenteric(1), and U46619 in coronary arterioles that is PKC-dependent in mechanism(1,2). We hypothesised that 20mM glucose reduced receptor desensitisation in a PKC-dependent manner so providing a mechanism to explain the increased vasocon-

striction in elevated bathing glucose.Rat mesenteric arterioles (200-400μm in diameter) were mounted in a Mulvany-Halpern myograph (Danish Myo Technology, Aarhus, Denmark) and maintained at a constant temperature of 37°C. Arteries were held under a tension equivalent to 90% of the diameter of the vessel at a pressure of 100 mmHg in 1.8 mM Ca2+ recording solution containing 5 or 20mM glucose for 30 minutes prior to experimentation. The myograph chamber was continuously perfused throughout the recording. 60mM potassium was applied to cause a depolarisation-induced contraction and all data was normalised to the peak contraction. 100nM ATII was perfused for 45 seconds followed by 100 (approximate EC50 value), 300 (maximal) and then a second 100μM addition of UTP to measure desensitisation for 5 minutes each, with a 5 minute wash between applications. Finally, 100nM ATII was reapplied at the end of the recording. In 5mM glucose, the second submaximal UTP response was reduced to 54.2±5.3% (n=10) of the first response and was unaffected by inclusion of 20μM L-NAME to inhibit eNOS (61.6±3.9%, n=20). In 20mM glucose this desensitisation was reduced to 76.4±4.2% (82.4±6.5% with L-NAME, P<0.01 compared to 5mM glucose control for both with and without L-NAME, t-test). Similarly, ATII desensitisation was reduced by 20mM glucose (5.1±2.4% vs 34.6±8.6%, 5 and 20mM glucose respectively, 20 vessels in each concentration, P<0.01, t-test). Inhibition of PKCα and β with 300nM Gö6976 in 20mM glucose attenuated the reduction of desensitisation to the same level as in 5 mM glucose control (54.2±5.3%, 76.4±4.2%** to 48.4±3.3%, in 5mM, 20mM glucose and with Gö6976 respectively, **P<0.01, ANOVA with Bonferroni's post-hoc test), and reversed the ATII reduction in desensitisation (5.1±2.4%, 34.6±8.6% to 4.0±2.7% in 5mM, 20mM glucose and with Gö6976 respectively, **P<0.01, ANOVA with Bonferroni's post-hoc test). In this study we demonstrate that receptor desensitisation is markedly reduced by increasing bathing glucose from 5 to 20mM, but that this can be attenuated using conventional PKC inhibition. This data support our hypothesis that glucose-mediated PKC activation reduces receptor desensitisation and enhancing vasoconstrictor responses in elevated glucose.

PKCalpha and beta activation by elevated extracellular glucose cause a marked inhibition of Kv currents in mesenteric arterial smooth muscle

Outgrowth endothelial cell responses to hypoxia: role for BMP/SMAD signalling?

I. Ali, M. Hookham, T. Schmidt, N. Cantley, M.H. Wilson, A. Mullins, R. Medina, A.W. Stitt and D.P. Brazil

Centre for vision and vascular science, Queens University Belfast, Belfast, select a state, UK

Outgrowth endothelial cells (OECs) can induce de novo blood vessel formation in vivo. The vasculogenic ability of OECs is comprised in diabetes with much lower proliferative potential and reduced ability to respond to proangiogenic cytokines. This results in impaired vascular repair leading to ischaemia which is commonly observed in diabetic complications such as retinopathy due to decreased vascular supply. We replicated the low O2 environment of an ischemic retina by exposing OECs isolated from umbilical cords to 1% O2 and assessed their response at the molecular level. Together with their morphology, high proliferative potential and immunophenotypic expression profile, OEC identity was confirmed in accordance with the phenotype described in the literature. Exposing OECs to 1% O2 induced a state of hypoxia as we were able to detect HIF1α, 2α proteins which accumulate under low O2 conditions. OECs in 1% O2 exhibited an increase in filamentous actin staining, focal adhesion deposition and also enhanced migration indicating that OECs in hypoxia adapt a pro-migratory phenotype. Hypoxia also induced a state of stress-induced premature senescence. We observed a decrease in cell proliferation, changes in morphology and positive staining for β-gal a surrogate marker of cell senescence. There was also a decrease in expression of markers such as CD34, commonly associated with "stemness" after chronic exposure to hypoxia.
Molecular analysis identified that bone morphogenetic protein 4 (BMP4) and several Smad pathway associated genes were up-regulated under hypoxia. We therefore hypothesised that BMP4 and its Smad pathway associated genes are HIF dependent and may play a role in OEC function. We were unable to detect any significant BMP4 activity via ELISA or Western blot either in hypoxic or normoxic conditions. However acute exposure to hypoxia down regulated inhibitory Smad6 protein, which was recovered with MG132 treatment suggesting proteasome dependant degradation. Gremlin, a potent BMP4 inhibitor has been implicated as a proangiogenic cytokine in human umbilical vein endothelial cells. We are now assessing the role of gremlin in OEC function in normoxic and hypoxic conditions. These data taken together should enhance our knowledge of vascular stem cell function in ischaemic diseases.

Novel inhibitors of serine-rich protein kinase -1 prevent choroidal neovascularization in rodent models - a role for potential topical therapeutics in macular degeneration

M. Gammons[1], A.D. Dick[2], S.J. Harper[1] and D.O. Bates[1]

[1]Physiology and Pharmacology, University of Bristol, Bristol, UK and [2]Cellular and Molecular Medicine, University of Bristol, Bristol, UK

Exudative age related macular degeneration (wet AMD) is a leading cause of vision loss in the western world, and current therapy requires monthly injection into the eye of anti-vascular endothelial growth factor (VEGF) proteins. VEGF is generated as two isoform families by alternative splicing – pro-angiogenic and anti-angiogenic. Retinal pigmented epithelial (RPE) cells require serine-rich protein kinase-1 (SRPK1) to phosphorylate serine/arginine-rich splicing factor-1 (SRSF1) to induce alternative splicing that generates pro-angiogenic isoforms. We tested the hypothesis that SRPK1 selective inhibitors could

be generated that reduce pro-angiogenic isoforms, and that SRPK1 inhibitors could be administered topically to prevent choroidal neovascularisation.
Novel SR Phosphorylation Inhibitors, (SPHINXs) were tested for SRPK inhibition in vitro, pro-angiogenic VEGF production in RPE cells by PCR and ELISA, and for inhibition of choroidal neovascularisation induced by laser photocoagulation in mice and rats.
A novel disubstituted furan inhibitor, SPHINX, was selective for the SRPK family of kinases targeting SRPK1 with an IC50 <1μM (Hills model of regression; log (inhibitor) vs. response – variable slope) and reduced the expression of pro-angiogenic but not anti-angiogenic VEGF isoforms. Choroidal neovascularisation was significantly reduced in vivo by SPHINX (0.039±0.026mm2; n=5) and the known SRPK inhibitor SRPIN340 (0.038±0.008mm2; n=5), compared with vehicle controls (0.11±0.016mm2; p<0.05, One-way ANOVA, Bonferonni post hoc). Topical administration of SPHINX and SRPIN340 significantly inhibited CNV to 38.5±7.4% (n=5) and 53.6±8.5% (n=6) of control respectively (p<0.05, One-way ANOVA, Bonferonni post hoc). These results indicate that novel SRPK1 selective inhibitors could be potential novel topical (eye drop) therapeutics for wet AMD.

PCB418

Effect of perivascular adipose tissue and AMPK activation on vascular myocyte BK_{Ca} currents

Y. Dong, G. Edwards and A. Heagerty

Institute of Cardiovascular Sciences, University of Manchester, Manchester, UK

All peripheral arteries are surrounded by perivascular adipose tissue (PVAT) which, in health, releases several factors with vasodilator properties. Recent evidence suggests that one such factor acts by opening voltage-sensitive (Kv7) K^+ channels[1], although our recent experiments suggest that the K^+ channel-opener released is likely to be adiponectin and that it acts by opening large conductance Ca^{2+}-dependent K^+ channels (BK_{Ca})[2]. In many tissues, adiponectin receptors signal via the AMP-dependent protein kinase (AMPK). Opening of BK_{Ca} channels and enhanced activity of AMPK are both linked to smooth muscle relaxation[3,4,5]. The present study investigated the effect of adiponectin and AMPK activation on BK_{Ca} currents in single myocytes which were freshly-isolated (enzymatically) from male Sprague-Dawley rat mesenteric arteries. BK_{Ca} currents were recorded at room temperature using the whole-cell configuration of the patch-clamp technique.
Under the conditions employed (calculated intracellular calcium concentration of 0.2 μM), 500 ms steps from a holding potential of -10 mV to a series of test potentials ranging from -40 to 50 mV generated outward currents with an activation threshold of -20 mV which were inhibited by 0.1 μM iberiotoxin (a selective BK_{Ca} channel blocker). The AMPK activator A-769,662 (10 μM) significantly increased BK_{Ca} currents without modifying the activation threshold of the channel. The current induced by A-769,662 was reversibly inhibited by iberiotoxin (0.1 μM), but was insensitive to the (ATP-competitive) AMPK inhibitor dorsomorphin (2 μM). Furthermore, a less-selective AMPK activator, AICAR (1 mM), did not increase BK_{Ca} currents. Interestingly, the physiological saline solution which had bathed PVAT for 1 h (at 37°C) also increased an iberiotoxin-sensitive outward K^+ current. Neither the background nor the induced current was sensitive to inhibition by either XE-991 (30 μM; a selective blocker of Kv7 channels) or dorsomorphin (2 μM). When myocytes were perfused with adiponectin (0.5 μg/ml), the BK_{Ca} current was also enhanced.
Consistent with our previous findings[2], under the conditions of the present study only BK_{Ca} channels were activated by a PVAT-derived factor and both adiponectin and A-769,662 were able to mimic this effect. The simplest hypothesis is that PVAT releases adiponectin which acts via AMPK to activate BK_{Ca} channels. Nevertheless, we are unable to explain why activation of BK_{Ca} by A-769,662 (which at the concentration employed is considered to be selective for AMPK), was not mimicked by AICAR or inhibited by dorsomorphin, although this might reflect the mechanisms of action of the different drugs and work is currently in progress to investigate this further.

Normotension with enhanced body weight and fat deposition in mice deficient for *CYP17A1*

Z. Aherrahrou[1,4], K. Schmidt[2,4], R. Aherrahrou[1,4], H. Schunkert[3], J. Erdmann[1,4] and C. de Wit[2,4]

[1]Institut für Integrative und Experimentelle Genomik, Universität zu Lübeck, Lübeck, Germany, [2]Institut für Physiologie, Universität zu Lübeck, Lübeck, Germany, [3]Deutsches Herzzentrum München, Technische Universität München, München, Germany and [4]DZHK (German Centre for Cardiovascular Research), Partner site Hamburg/Kiel/Lübeck, Lübeck, Germany

CYP17A1 is an enzyme in metabolism of steroids exhibiting 17alpha hydroxylase and C17-20 lyase activity. It is required for the synthesis of testosterone, estrogens, and cortisol by converting pregnenolone and progesterone to intermediate products. Recently, *CYP17A1* gene was associated with coronary artery disease (CAD) and hypertension in genomewide association studies. A deficiency for this enzyme exists in humans and causes a rare form of congenital adrenal hyperplasia characterized by a dysfunctional sexual development in male patients, glucocorticoid lack, as well as a mineralocorti-

coid excess and according functional consequences (hypokalemia, hypertension). To investigate potential pathomechanisms that contribute to the development of CAD we generated Cyp17a1-deficient mice (Cyp17a1-/-) in the CardioGENE program. Breeding of heterozygous mice yielded offspring according to mendelian ratio. All Cyp17a1-/- littermates exhibited a female phenotype, but genotyping revealed that 55% of the offspring carried a Y-chromosome. Female Cyp17a1-/- mice had a higher body weight and increased subcutaneous as well as visceral fat deposits compared to female wild type littermates. Additionally, blood cholesterol levels were altered. Blood pressure and heart rate was measured in freely moving mice using telemetry. 24h mean arterial pressure (MAP) was similar in Cyp17a1-/- and wild type controls (~111 mmHg), whereas heart rate was slightly reduced in Cyp17a1-/- (591±5 vs. 620±12, *P*<0.05). In female wild type mice MAP was elevated at night (104±1 mmHg vs. 119±4 mmHg, day vs. night, *P*<0.01), as expected during enhanced activity. Similar findings were obtained in genotypic male (111±2 mmHg vs. 117±1 mmHg, *P*<0.05), but not in female Cyp17a1-/- mice (108±2 mmHg vs. 114±2 mmHg, *P*=0.08). Genotypic male Cyp17a1-/- (with female phenotype) had a significantly higher MAP than female wild type controls during day (111±2 vs. 104±1 mmHg, *P*<0.05). Serum potassium concentration was not different between genotypes. In a subgroup of mice voluntary running in a wheel was investigated, in which wild type mice ran up to 6 km/night. Interestingly, Cyp17a1-/- ran less distance (only 25%) but lost approximately 10% of their body weight during this period of 10 d, while weight did not decrease in wild type mice. We conclude that Cyp17a1 has a strong impact on body weight and fat deposition. Its role in blood pressure regulation is less obvious, which is also reflected by the normokalemia suggesting that aldosterone is not produced in excess as observed in humans. It remains to be determined whether the alterations in cholesterol levels enhance atherosclerosis and CAD in these mice or whether obesity itself is the only contributing factor.

Where applicable, the authors confirm that the experiments described here conform with The Physiological Society ethical requirements.

PCB420

Preferential Involvement of PPARβ/δ Versus IP in Mediating PAR-Stimulated Angiogenesis

C.E. Farrar[1], G. Kalindjian[1], J. Mason[3], J. Mitchell[2] and C.P. Wheeler-Jones[1]

[1]Comparative Biomedical Sciences, Royal Veterinary College, London, UK, [2]Cardiothoracic Pharmacology, Imperial College London, London, UK and [3]Imperial Centre for Translational & Experimental Medicine, Imperial College London, London, UK

The enzymatic products of cyclo-oxygenase (COX) activity regulate angiogenesis in vitro and in vivo, implicating altered COX expression and prostaglandin (PG) synthesis in the actions of pro-angiogenic mediators. We have previously shown that inhibition of induced COX-2 activity decreases endothelial cell (EC) tube formation in vitro and that this is rescued by exogenous iloprost (PGI2 analogue), suggesting an autocrine mode of action. PGI2 binds to the cell surface GPCR, IP, and to the ligand-activated nuclear receptor peroxisome proliferator activated receptor (PPAR) β/δ. Here, we have determined the relative contributions of PPARβ/δ and IP to EC function and angiogenesis. Iloprost, cicaprost (binds IP) and selective PPARβ/δ agonists (GW501516; L-165,041) increased neovascularisation in vivo (chick CAM assay; p<0.05 iloprost and cicaprost n=10-13, and p<0.001 PPARβ/δ n=17-26) and EC tubulogenesis on Matrigel in vitro (p<0.05 for all agonists; n=3). The PPARβ/δ antagonist GSK0660 abrogated iloprost- and PPARβ/δ agonist-induced tube formation. The angiogenic responses to thrombin and to protease-activated receptor agonist peptides (PAR2-AP and PAR4-AP) were attenuated by GSK0660 (p<0.01 for all agonists; n=3) and by PPARβ/δ siRNA but not by a specific IP antagonist, CAY10441. Immunoblotting studies showed that thrombin and PAR2-AP, but not PAR4-AP, enhance COX-2 expression and that this is reduced by antagonists of PPARβ/δ but not IP (n=3). EC exposure to thrombin or to PPARβ/δ agonists promoted acute activation of ERK, AMPK and Akt, as well as induction of COX-2 expression, all of which were inhibited by PPARβ/δ blockade (n=3). GSK0660 also reduced phosphorylation of Akt, AMPK and ERK in response to thrombin (n=3). These data implicate PPARβ/δ in the regulation of COX-2 induction by thrombin and PAR2-AP, and in the consequent tubulogenesis, and suggest that PPARβ/δ propagates the angiogenic response through an autocrine feedback loop. The observation that GSK0660 suppressed PAR4-AP-driven tube formation indicates that PPARβ/δ also regulates tubulogenesis through COX-2-independent mechanisms. Together, these studies provide evidence of a key role for PPARβ/δ in mediating agonist-induced angiogenesis.

Patterns of arterial wall permeability to plasma macromolecules change with age –a high-throughput confocal microscopy study

E. Bailey, E. Bazigou, P. Sowinski and P. Weinberg

Bioengineering, Imperial College London, London, UK

Elevated permeability of the arterial wall to circulating macromolecules is implicated in the development of atherosclerotic lesions. Lesions occur near branches, suggesting a role for haemodynamic wall shear stress, and in both human and rabbit aortas their distribution changes with age. To assess the relationship between lesion development and arterial wall permeability, we used a novel high-throughput technique employing tile-scanning confocal microscopy to systematically quantify macromolecule uptake around branch ostia in the rabbit aorta at different ages.

Rhodamine-labelled albumin was administered intravenously via the marginal ear vein to New Zealand white rabbits aged 2, 6 and >12 months (n>4 rabbits/group) and allowed to circulate for 10 minutes. Via the same route an anticoagulant (heparin), followed by an overdose of sodium pentobarbitone (0.8ml/kg) were given. The aorta was fixed post mortem under physiological pressure, excised and scanned en face using confocal microscopy. Tracer concentrations in the inner 10μm of the wall were mapped using MATLAB® and scaled to plasma tracer concentrations. Intensity data were statistically analysed using a nested ANOVA, and mass transfer coefficients were calculated.

In young rabbits, tracer uptake was greater downstream of intercostal branch ostia than upstream. This pattern significantly reversed with increasing age – by 6 months the majority of tracer uptake localised lateral to the branch mouth and by 12 months downstream regions showed the least uptake. (Downstream-upstream)/mean uptake values were signifi-

cantly different between 2 month versus both 6 month and >12 month animals (p<0.001). In young animals, the downstream mass transport coefficient was 1.5 times the upstream value (2.52±0.24x10-8cm/s vs 4.06±0.26x10-8cm/s). Mass transfer coefficients around the branch mouth averaged 3±0.3x10-8cm/s for all ages.
Our results demonstrate changes in permeability patterns that parallel the age-related patterns of lipid deposition seen in rabbit and human aortas, supporting a critical role for permeability in atherogenesis. Our new tile-scanning confocal method can easily image the whole aorta and provide permeability data to compare with shear stress data and lesion maps.

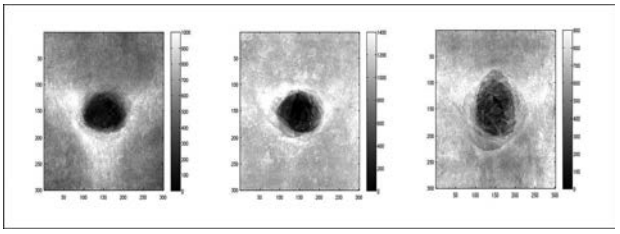

Figure 1. Maps of short-term macromolecule uptake around aortic branch ostia in rabbits of increasing age (left to right: 2 months, 6 months, >12 months). White areas indicate high uptake, Data represents the average of n>12 branches taken from a minimum of n=4 rabbits.

IR emissions from human hands: changes and recovery profiles following a reliable, quantifiable provocation challenge

D. Clegg and P. McCarthy

Clinical Technology and Diagnostic Research Unit (CT-DRU), University of Glamorgan, Pontypridd, UK

INTRODUCTION: Raynaud's disease (RD) is characterised by numb, white and often painful distal extremities[1]. Severity varies and it affects 10-20% of the UK population[2]. Infrared (IR) thermography has previously been used to measure the distal-dorsal difference (DDD) of RD sufferers[3]. The DDD is a parameter for quantifying temperature change between the nail bed and dorsal metacarpophalangeal (MCP) joint of the same digit; a difference of -1ºC or greater in a negative direction is considered clinically relevant[3]. Assessment has typically followed evoking of symptoms by cold water provocation at 0-10ºC from an ambient temperature of 20-24ºC[4,5]. We report here preliminary findings from a less noxious provocation challenge. AIM: The aim of the study was to assess the DDD of hands following a period of warmth provocation using IR thermography in order to determine sensitivity and clinical benefit. METHOD: 6 subjects (4 males, 2 females; age=24±3.6yrs) were recruited for the study. Of the 6 subjects, 2 had a history of primary RD. Following a 15 minute acclimatisation period in a room whose temperature was relatively constant (22ºC ± 1ºC), subjects placed their hands and proximal wrists under a temperature controlled incubator, with an air temperature of 30ºC for 2 minutes. IR images of the dorsal hands were taken at the following intervals: 5, 3 and 1 minute prior to a 2 minute provocation, then immediately following (0), 1, 3 and 5 minutes following the cessation of the provocation. For RD subjects only, additional images were taken at 7 and 9 minutes to allow consideration for any delays in recovery of the circulation which is usual in other forms of testing of RD sufferers[5]. IR images were assessed by measuring the DDD of the 2nd and 4th digits. Images were taken using a LAND FTIM vIR IR camera and analysis software LIPS mini V1.10.02. The DDD and means were calculated using IBM SPSS Statistics V19, figures produced by Microsoft Excel for Windows 2007. Ethical approval was granted by The Faculty of Health Science and Sport's Ethics Committee, University of Glamorgan, written informed consent was obtained.RESULTS Figure 1& 2 show comparisons between recovery profiles. Figure 1 – Recovery profiles for the R 2nd digit normal hands. Both the 2nd and 4th digits of both hands appeared similar in profile. Figure 2 - R 2nd digit recovery profiles for the 2 subjects with RD. CONCLUSIONS Although only a pilot study, results were encouraging as the recovery profiles of the RD sufferers was visibly different to the normals. The large difference in reaction between the 2 RD sufferers suggests that this test might be sensitive to cause of the disease, consistent with DDD assessment following cold provocation[3]. Subjects elicited clinically relevant changes consistent with those elicited following cold provocation.

Phenotypic characterisation and molecular changes induced by gestational diabetes mellitus on human umbilical endothelial cells: focus on the KDM2B/miR-101/ EZH2 pathway

I. Floris[1], G. Mangialardi[1], A. Posadino[2], G. Capobianco[3], P. Gianfranco[2] and C. Emanueli[1]

[1]Department of Vascular Pathology and Regeneration, Bristol Heart Institute, Bristol, UK, [2]Laboratory of Vascular Biology, Department of Biomedical Science, University of Sassari, Sassari, Italy and [3]Obstetrics and Gynaecology Clinic, University of Sassari, Sassari, Italy

Background and aims: Gestational diabetes mellitus (GDM) is characterised by maternal hyperglycaemia that is first recognised during pregnancy (1). GDM results in chronic foetal hyperglycaemia and hyperinsulinaemia (2), with consequent changes in foetal endothelial gene expression and endothelial cell (EC) function (3). We aim to determine whether exposure to a diabetic intrauterine environment alters human umbilical vein EC (HUVEC) function, with further investigation into microRNA (miR) expression and epigenetic pathways.
Methods: HUVECs were extracted from expecting mothers with and without GDM. We performed functional assays and focused miR and target gene analyses on extracted cell lineages. Finally, we also studied 'healthy' HUVECs that were grown in high glucose conditions.
Results: We observed a reduced capacity of closure on scratch assay, diminished capillary-like tube formation on Matrigel and decreased proliferation in response to foetal bovine serum (FBS), after a period of FBS-starvation, in the GDM-extracted lineages compared with the controls. On microRNA screening we found a tendency towards increased levels of miRs belonging to the miR-15 family. Specifically, miR-101 was significantly upregulated in the GDM-extracted lineages; hence we focused on this miR's molecular mechanisms in our target cell lineages. There was a strong positive correlation between miR-101 levels and apoptosis (Pearson r = 0.9, p value < 0.001). There was a decreased expression of Enhancer of Zester Homolog 2 (EZH2) in the GDM-extracted lineages. Confirming previous reports which have validated EZH2 as a target-gene of miR-101 in HUVECs (4), we found their expression levels were negatively correlated. EZH2 mRNA levels correlated positively with KDM2B and VEGF-A; conversely miR-101 levels correlated negatively with KDM2B. These data are in line with the described KDM2B/EZH2/miR-101/EZH2 axis (5).
Anti-miR-101 treatment in GDM cells resulted in upregulation of EZH2, decreased apoptosis and an improved angiogenic phenotype, restoring the endothelial tube formation to the level seen in control lineages. As expected, in vitro exposure of "healthy" HUVECs to high glucose significantly impaired cellular function. Moreover, we found a concomitant upregulation of miR-101, which is in agreement with high miR-101 levels in GDM HUVECs..
Conclusion: These data identify a signalling pathway that links hyperglycaemia to miR-101 and its target gene EZH2, suggesting new targets in the fields of gestational diabetes and EC dysfunction induced by hyperglycaemia in utero. We characterise a novel mechanism regulating hyperglycaemia-impaired angiogenesis, with the possibility of restoring the angiogenic capacity of GDM cells in vitro by blocking miR-101 and subsequently upregulating its target EZH2.

Modeling of drug kinetics and blood flow response dynamics during transdermal iontophoresis of metacholine and acetylcholine

F. Iredahl[1], J. Hackethal[1], V. Sadda[1], L. Ward[1], E. Tesselaar[1], S. Farnebo[1,2] and F. Sjöberg[1,2]

[1]Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden and [2]Department of Hand and Plastic Surgery, County Council of Östergötland, Linköping, Sweden

Transdermal iontophoresis can be used to noninvasively deliver vasoactive drugs into the skin by means of electric current pulses (1). A limitation of iontophoresis is that the delivered drug dose is unknown and the vascular response can only be measured in arbitrary units. Time-response modeling may give better insight in the physiology underlying the vascular drug responses (2).
Acetylcholine (ACh) causes endothelium-dependent vasodilatation after iontophoretic delivery in the skin, and is therefore widely used for measuring endothelial function. ACh is rapidly hydrolyzed by acetylcholinesterase (AChE). Metacholine (MCh) has similar actions as ACh but is hydrolyzed by AChE at a considerably slower rate (3).
In this study, we applied a mechanistic time-response model to the blood flow response to ACh and MCh delivered by iontophoresis in 21 healthy subjects. We measured skin blood flow using laser-Doppler flowmetry. We took into account the physical transport of drugs into the skin and the vascular response to these drugs. The kinetic part of the model consists of one-compartment, with a zero-order influx of drugs, a first order elimination and a lag time constant accounting for the delay between drug delivery and onset of response. The response dynamics are modeled using the Hill equation.
Then, we compared the response to an identical dose (12 mC) of ACh given using a single 10-min current pulse and five 2-minute current pulses with 1-minute intervals.
We found that ACh and MCh caused similar increases in blood flow, whereas the return to baseline perfusion after iontophoresis differed distinctly between drugs (Figure 1). Modeling revealed a mean (95% CI) elimination half-life of 9.0 min (8.0-10.3 min) for ACh and 71 min (41 - 247 min) for MCh. ACh delivered using a single current pulse resulted in stronger vasodilatation than with multiple shorter pulses (38.5 ± 31.7 vs. 30.7 ± 15.5 PU, p < 0.01, Figure 2).
These findings can be explained by the differences in drug kinetics in the skin, as ACh is rapidly hydrolyzed by AChE while MCh is not actively degraded. The sustained vasodilatation after iontophoresis of MCh suggests that washout of these drugs by skin blood flow is slow and that the return to baseline is mainly caused by active degradation.
In conclusion, modeling of drug kinetics and dynamics gives a better understanding for the physiological and pharmacological parameters during iontophoresis of vasoactive drugs and may improve iontophoresis as a non-invasive technique for assessment of vascular function.

Novel mapping of intercellular stresses in endothelial monolayers during contractile responses to hyperpermeability

E. Valent[1], C.C. Hardin[2], R. Krishnan[3], V.W. van Hinsbergh[1] and G.P. van Nieuw Amerongen[1]

[1]Physiology, VU University Medical Center, Amsterdam, Netherlands, [2]Div Pulmonology & Critical Care Med, Massachusetts Gen Hosp, Boston, MA, USA and [3]Center for Vascular Biology Research, Beth Israel Deaconess Medical Center, Boston, MA, USA

Clinical Relevance: The endothelial monolayer is a dynamic, single cell layer which forms a barrier to prevent blood fluids from leaking into the surrounding tissues. During inflammation, endothelial barrier disruption causes vascular leakage which contributes to disease severity in disorders such as sepsis, cancer, diabetes, and atherosclerosis. Despite this tremendous medical threat to the critically ill patients, specific therapy counteracting vascular leakage are lacking up to today.
Rationale: Hyperpermeability of the endothelial barrier is a significant pathogenic phenomenon and is associated with many life-threatening diseases. Previous studies have shown that contractile forces, generated by the endothelium itself, play an important role in the process of barrier dysfunction. With the use of traction force microscopy it is possible to study the developed acto-myosin dependant interaction via the focal adhesions to the cells substrate. However, a measurement of the situation at endothelial cell–cell junctions was not experimentally accessible. Here, we aim for the first time to elucidate the intercellular forces in an endothelial monolayer sheet and observe the developed stresses during thrombin receptor-mediated hyperpermeability.
Methods & Results: Endothial cell monolayer contractions were mapped by the novel described monolayer stress microscopy (1) in combination with previous published traction force microscopy of 4 kPa polyacrylamide gel substrates. (2) Displacements of the caroxylate-modified fluorescent microspheres (Invitrogen, Eugene, OR) incorporated in the gels, were converted into stress components and monolayer traction forces.
Conclusion: Novel intracellular stress mapping in endothelial monolayer was successful and displaced highly diverse stress maps which provides new information about vascular hyperpermeability responses.

Sex differences in the left ventricle ACE activity and ACE inhibition in Spontaneously hypertensive rats

P.L. Dalpiaz[1], A. Lamas[1], I. Caliman[1], L. Gusmão[1], P. Oliveira[1], G. Abreu[1], A. Carmona[1,2], M. Alves[1,2] and N. Bissoli[1]

[1]Physiological Sciences,, Federal University of Espírito Santo, vitoria, espirito santo, Brazil and [2]Biophysics Escola Paulista de Medicina, Unifesp, são paulo, são paulo, Brazil

Studies in humans and hypertension models have demonstrated the role of the RAS in the progression of ventricular dysfunction. The activation of the renin-angiotensin system (RAS) is essential for structural and functional remodeling of the heart. Additionally, it is recognized the role of sex hormones (SH) modulating the RAS. Therefore, we aimed to evaluate the influence of SH on the activity of angiotensin I-converting enzyme (ACE) and angiotensin 2-converting enzyme (ACE2) in male and female rats SHR and the influence of ACE inhibitor in the SRA local and plasma deficiency in HS. Materials and methods: Female (F) and male (M) SHR rats were divided into 8 experimental groups: sham+vehicle (SV), sham+enalapril (SE; 10 mg/kg body weight), castrated+vehicle (CV), and castrated+enalapril (CE). The treatments began 21 days after castration and lasted for 30 days. The ACE and ACE2 activity were measured by fluorimetry. Results: Male rats exhibited a higher values than the female rats in ACE ventricular activity (MSV: 8.47 ± 0.81 AFU, FSV: 5.78 ± 0.79 AFU) and ACE2 (MSV:0.1154 ± 0.017 AFU; FSV: 0.063 ± 0.006 AFU). Regarding ACE activity the castration reduced in males and did not change in female (MCV: 3.72 ± 0.46; FCV: 6.26 ± 0.31). Enalapril treatment both in Sham animals (MSE: 3.99 ± 0.50 and; FSE: 3.91 ± 0.21) as castrated (MCV: 1.94 ± 0.69; FCV: 2.42 ± 0.44) reduced the ACE activity and eliminated the differences between the sexes. In relation to ACE2 activity, in female, none of interventions promoted change in ACE 2 (FSV: 0.063 ± 0.006 AFU; FSE: 0.091 ± 0.010, FCV: 0.095 ± 0.009; FCE: 0.074 ± 0.013). In males the castration promoted reduction in ACE2 (MCV: 0.012 ± 0.003), the enalapril treatment was able to increase ACE2 activity in sham (MSE: 0.167 ± .018) and castrated (MCE: 0.058 ± 0.009) when compared with vehicle values. Conclusion: we observed sexual dimorphism in the plasma and left ventricle ACE activity and in the left ventricle ACE2 activity. Male showed higher activity these enzymes than females. Enalapril treatment reduces the ACE activity regardless of gender and increases ACE2 activity in male, but did not affect in female. The castration, in males, reduced ACE and ACE2, in both plasma and left ventricle depending effects hormones. The effect of enalapril on ACE activity appears to be hormones independent while on ACE2 activity in males appears to dependent on hormones.
